October 29, 1958

Washington 25, D. C.

Vol. 6, No. 53

ANNUAL SUPPLEMENT

Reported Incidence of Notifiable Diseases in the United States, 1957

This supplement contains final figures on the reported incidence of notifiable diseases for 1957. The data are compiled from annual reports supplied by State and Territorial departments of health.

Trends in incidence of the notifiable diseases for the last 10 years are shown in table 1; and the distribution of cases by month, usually by month of report, is shown in table 2. The age distribution for 7 diseases appears in table 3. Distribution of cases by States and outlying areas and the numbers of cases of certain diseases not requested to be regularly reported are shown in other tables.

The reported incidence of many notifiable diseases decreased in 1957 as compared with previous years. Those which showed substantial reduction compared with 1956 are brucellosis, diphtheria, encephalitis, hepatitis, malaria, poliomyelitis, psittacosis, trichinosis, tuberculosis, and typhoid fever. The reported cases of poliomyelitis according to type for the 3-year period 1955-57 are shown in figure 1.

The number of reported cases of infectious hepatitis has declined about 20 percent from the 1956 figure of 19,234 and about 70 percent from the 50,093 cases reported in the peak year 1954.

The total number of cases of psittacosis reported in 1957 was about half that in 1956. For several years there has been considerable fluctuation in numbers reported. The totals were relatively large in both 1954 and 1956, partly because of localized outbreaks among workers in poultry processing establishments. No large concentration of cases occurred in 1957.

A decline in the number of malaria cases occurred again in 1957. A few cases of indigenous or locally acquired malaria were found in California and in Oklahoma. However, the disease continues to occur almost exclusively in persons who have been exposed to infection endemic areas outside of the United States.

Diseases which showed little change in reported incidence were dysentery, rheumatic fever, tetanus, meningococcal infections, and venereal diseases.

Figure 1

REPORTED CASES OF ACUTE POLIOMYELITIS: UNITED STATES, 1955-57

Morbidity and Mortality Weekly Report

Substantial increases were reported for amebiasis, other types of meningitis, and streptococcal infections. There was a 36-percent increase in the number of cases of amebiasis reported in 1957 as compared with the number in the previous year. This may reflect the greater use of laboratory examinations for diagnosis rather than an actual increase in incidence.

Comparisons of the numbers of reported cases for each of 6 notifiable diseases for the years 1947, 1952, and 1957 are shown in figure 2.

Poliomyelitis

The number of cases of poliomyelitis reported in 1957 was 5,485 which was lower than the number reported for any year since 1942. That year the total was 4,167 cases. The provisional total derived from a summation of weekly reports received during 1957 was 5,894 of which 2,158 were reported as paralytic poliomyelitis, 2,802 as nonparalytic, and 934 unspecified as to type. The final figures for the year showed that 2,499 cases were classed as paralytic, 2,826 as nonparalytic, and 160 as unspecified. (See figure 1.) The larger number of paralytic cases in the final report seems to indicate that 341 cases previously reported as of unspecified type were found to be paralytic. It appears that only 24 cases were added to the number of nonparalytic cases and that a diagnosis of poliomyelitis could not be confirmed in 409 cases. The small remainder of 160 cases of unspecified poliomyelitis in the final figures undoubtedly is the result of greater activity in obtaining followup information and in use of laboratory tests for confirmation of diagnosis.

There were no extensive outbreaks of poliomyelitis in 1957. However, a localized epidemic occurred in an area of the District of Columbia where poor socioeconomic conditions prevailed. Most cases in this area had received no poliomyelitis vaccine, and the proportion of other persons in the area who had been vaccinated was lower than in most other sections of the city.

The age distribution of poliomyelitis showed 4 percent of all cases were in children under 1 year of age, 25 percent in the age group 1-4 years, and 23 percent in the group 5-9 years. Of the paralytic cases 7 percent were in the group under 1 year of age, 38 percent in the group 1-4 years, and 18 percent in the

group 5-9 years. The highest proportion of paralytic cases in any age group was in the group 1 year of age (297 cases). Of all cases in children 1 year of age, 79 percent were paralytic.

Diphtheria

The incidence of reported cases of diphtheria in 1957 continued its steady decline, begun in 1946. In 1957, 23 percent fewer cases were reported than in 1956. However, 12 States reported more cases in 1957 than in 1956, and the 3 geographic divisions along the Atlantic coast each showed higher incidence in 1957. Michigan reported an outbreak of more than 100 cases in December 1957, and Washington State reported 17 cases in July 1957. These outbreaks accounted for most of the cases reported from each of these States.

Fifty-five percent of the cases occurred in children under 10 years of age; few of these children were under 1 year of age. The number of cases in age groups 1-4 years and 5-9 years were about equal. Nineteen percent of the cases occurred in persons 20 years of age and over. This age distribution is similar to that for 1956.

Encephalitis

The number of cases of encephalitis reported in 1957 is about 20 percent less than reported in 1956, but about the same number as reported in 1955. Of the 2,135 cases in 1957, 144 were reported as arthropod-borne infections. This is considerably fewer than the 504 cases of arthropod-borne encephalitis reported in 1956. However, the types of encephalitis are not differentiated in all State reports. Only 2 cases of arthropod-borne encephalitis were reported east of the Mississippi River.

Venereal diseases

During 1957 there were 136,039 cases of syphilis in all stages reported in the United States. This is slightly more than reported in 1956, which was the first year since 1946 in which the number of syphilis cases exceeded the number reported the preceding year. One county in California reported more than 10,000 cases among migrant agricultural workers.

The number of cases of gonorrhoea is down about 5 percent from 1956 figures. This continues the decrease of about 5 percent shown between the 1955 and 1956 figures.
