COMPUTER MODELING OF DUST AND FORCES
FOR LONGWALL MINING SYSTEMS

By B. D. Hanson¹ and W. W. Roepke²

ABSTRACT

An interactive computer program has been developed by the Bureau of Mines which enables the user to identify the effect of cutting system changes on relative dust generation for longwall shearer drums. The program simultaneously evaluates machine and coal seam parameters, and those parameters which the user can control. The user can change one or more of these parameters at a time to determine their effect on relative dust generation, cutting forces, and/or cost. The program is written in the BASIC programming language. A complete program listing is included along with user instructions and sample outputs. This program is a more comprehensive version of the relative dustiness index (REDI) program described in Bureau Report of Investigations 8979.

INTRODUCTION

Since the enactment of the Federal Coal Mine Health and Safety Act of 1969, the Bureau of Mines has conducted an extensive research program on the control and reduction of respirable coal dust. Over the past 15 yr, research has been conducted in small-scale laboratory tests, in intermediate-sized prototype tests, and in full-scale in-mine demonstrations. The main objective of the work at the Bureau's Twin Cities (MN) Research Center has been the determination of the effect of controllable cutting system parameters on respirable dust generation. These controllable parameters include depth of cut, bit spacing, bit geometry, and operating conditions.

The body of data collected during this research provides a broad base of knowledge on the coal cutting phenomenon. The results are available to the industry in the form of a multitude of Bureau publications. There is so much information in so many places that individuals interested in reducing respirable dust generation at a specific mining operation will have difficulty finding their way through the available data to extract the specific information they need. The advent of the microcomputer and its universal availability provides a means of alleviating this problem.

This report presents a cutting system model (CSM) that incorporates the research results on the effects of various cutting system parameters on the generation of respirable coal dust. The CSM provides the user with a means to evaluate, on a relative basis, the effect of cutting system changes without the time or expense of actual equipment modification. The CSM is an advanced version of REDI (I).³ This new version incorporates preliminary models of multiple bit interaction and bit wear effects.

The CSM mathematically evaluates the effects of cutting system changes on primary respirable dust generation. A longwall respirable dust simulator developed by Haney (2) at the Mine Safety and Health Administration (MSHA) correlates the effects of secondary dust sources and primary dust generated by cutting action of the drum. The MSHA model requires personal dust exposure measurements and dust source measurements collected at the face to determine the contribution of each dust source to the worker's exposure. The MSHA program provides a qualitative list of recommended options to aid in correcting any compliance problems.

PROGRAM DESCRIPTION

The CSM program was developed to analyze the relative dust generated by a double-drum ranging arm shearer cutting in a coal seam containing rock band or middle man. Simpler situations, such as a single drum shearer, may also be analyzed. The program is menu driven, allowing the user to make parametric changes with a minimum of steps. It is written in BASIC and will run on an IBM personal computer (PC), or equivalent. The menus through which the program operates allow the user to change parameter values, calculate dust values, save modified data files, obtain printer copies of summary reports, lists of modifications, and a listing of the entire data file. Also, two "Help" menus provide online assistance to the user. The program performs the analysis using either a fixed number of bits, or will vary the number of bits based on the cut depth and a space-depth ratio specified by the user. A program listing is given in appendix A. The parameters used are defined in appendix B.

The logical flow of the program is shown in figure 1. An average cut depth will be calculated based on either a user specified advance rate, or, if none is supplied, the computer will calculate the advance rate from the maximum volume of cut coal that the drum can hold. Maximum volume is defined as

\[ V_o = (D_o^2 - D_i^2)W(\pi/4) - (V_iV_hV_tV_n), \]

where \( D_o \) = drum diameter,
\( D_i \) = inner drum diameter,
\( W \) = web width,
\( V_i \) = vane length,
\( V_h \) = vane height,
\( V_t \) = vane thickness,
and \( V_n \) = number of starts (vanes).

If the user has selected the fixed space-depth ratio mode for the analysis, the number of bits is calculated. The space to depth ratio (S-D) may be set to any value the operator chooses. The average cut depth will then be computed for each vertical strata (coal, rock, coal) through which the drum is cutting (fig. 2). This average cut depth is calculated based on the analysis of rotary cutting performed by Roepke (3). The equation used is

\[ \text{average depth} = \int \frac{W_2}{(W_2 - W_1)} D(W) \, dW, \]

where \( W_1 \) = angle at entry,
\( W_2 \) = angle at exit,
\( D(W) = R + A \cos(W) - (R^2 - A^2 \sin^2(W))^{1/2} \)
unless \( D(W) > D_{\text{max}} \) in which case \( D(W) = D_{\text{max}} \)

\[ R = \text{drum radius}, \]
\[ A = \text{advance per revolution}, \]
\[ D_{\text{max}} = \text{maximum cut depth due to bit interaction}, \]
and \( W \) = rotation angle about drum center.

Once the average cut depth is calculated, the cutting and normal forces will be computed. Both the cutting and normal forces have been shown to be linear functions of depth (3-4). The force equations are defined by a slope and intercept, which can be obtained from either laboratory cutting tests or from in situ measurements with the Bureau's in-seam tester (5). The effect of bit wear is incorporated by the application of multipliers to both the cutting and normal forces. For new bits (e.g., wear equal to 0 pct), the multiplier is 1. A wear effect with up to three different stages of wear can be used by the program. The wear effect values used in appendix C (parameters 39 to 60) are taken from laboratory wear research results (4).

The required drum torque and advancing thrust are then calculated from the cutting and normal forces, drum revolution per minute, drum diameter, and number of bits. If either the torque or thrust exceeds that which is available, the advance rate is reduced to 95 pct of the current value and the calculation procedure is repeated. This iterative process is continued until both the required torque and thrust are less than available. Airborne dust, production, and cost values are calculated for a summary report. The program then returns the user to the main menu.

Return to main menu

Figure 1.—Program flowchart.
The program is menu driven. The main menu, which controls all the program functions, is shown in figure 3. Selecting item 1 on this menu causes the program to recalculate the relative dust value using the procedures described in the previous section. Figure 4 shows an example of the summary report that is generated by the analysis. At this point the user is given the option of printing a hard copy of the report. The user will be returned to the main menu regardless of the choice made.

Changes in parameter values are accomplished by using item 2 on the main menu, which gives the user access to the parameter modification menu (fig. 5). The parameters used by the program are divided into the five categories listed in figure 5. Appendix B gives a list of parameter definitions and identifies the category in which the parameter appears. Figure 6 demonstrates how a parameter value (in this case, drum revolutions) would be changed. Item 3 on the main menu allows the user to specify the advance rate either in foot per minute or ton per shift. If an advance rate is not specified the program will automatically calculate the advance rate based on the maximum volume of coal that the drum can transport without excessive secondary dust generation caused by crushing and regrinding of the cut coal. If the user sets the advance rate higher than this maximum, the program will perform all the necessary calculations to determine forces, cost, and production. However, no relative dust value will be printed. Instead, the program will print a statement indicating that the drum is overloaded and causing excessive secondary dust generation. Selecting item 4 allows the analysis to be done using any fixed space-depth ratio set by the user. The number of bits will be determined from the calculated average cut depth and S-D ratio. If option 4 is not selected, the analysis will be performed using the number of bits specified in element 25 of the parameter list. Item 5 sets the wear condition of the bits. The value is entered as a percent of total bit life. Item 6 provides a data file utility that allows saving the current data file, inputting a new data file, or obtaining a hard copy of the entire data file. Item 7 provides online help messages to assist the user. Selecting this item causes another menu (fig. 6) to be printed. The first six items of the help index menu are identical to their counterparts on the main menu. Selecting the appropriate item from this menu will cause a help message covering the subject to be printed. The parameter modification menu also contains a help index, which covers the items in that menu.

Two aspects of the analysis are controlled by the parameter values. Setting the rock band top (data element 21) and the rock band bottom (data element 22) equal to

the same value eliminates the rock band from the calculations. Secondly, if the mining height (data element 24) and the drum diameter are the same, the program assumes there is only a single drum cutting.

The program has a built-in limit on the number of bits per vane. This limit is calculated from the bit block and drum dimensions. If the number of bit blocks reaches the physical limit for the space available, the program will continue the calculations fixing the number of bits at this maximum. Should the program reach the maximum number of bits, a message stating this fact will appear on the screen.

Figure 5.—Parameter modification menu.
In using the CSM to analyze drum designs it is important to realize the user may not have access to values for all the parameters used by the program. A number of the variables in the program were included in anticipation of program expansion and/or development of broader data bases to more fully support the program. Table 1 specifies which data elements must be known to analyze relative dust; forces and drum torque requirements; bit and power costs and production; and to evaluate the effect of bit wear. Appendix C lists a data file used in development of the program which can be used for default values.

Data elements 9 and 10 (available advancing thrust and available cutting torque) are used by the program to limit the maximum advance of the shearer. In determining the proper values to use, advancing thrust should reflect only the thrust available to advance the drum into the face. The force necessary to move the machine should not be included in data element 9. Also, the value for available cutting torque should reflect not only the cutting motor torque, but also the shearer's ability to react that torque load. The cutting motors may have the capability to generate more torque than the shearer can successfully react, resulting in the shearer climbing the face. The value used for data element 10 should take this into consideration. The equipment manufacturer should have this information.

Since the program was developed as a relative dust indicator, the default values for the first and second dust parameters and grindability should be adequate for most applications. The four slope-intercept pairs (data elements 35-38 and 48-51) needed for normal and cutting forces can be obtained by using the Bureau's in-seam-tester (5) or from laboratory tests. Data elements 39-47 and 52-60 are used to determine normal and cutting force as a function of wear condition. Ongoing Bureau bit wear testing on a number of different bit types will provide data that can be used to determine these data elements.

Data element 30, dust suppression, is included to allow a measured value to be used if the operator wishes to make the program site specific. Normally, it need not be changed by a user.

The interaction between the parameters is complex and the effect of changing any single parameter is dependent on the values of the others. The two variables that have the major influence on dust generation are the depth of cut and the number of bits on the drum. Increasing the depth of cut and/or reducing the number of bits will reduce the dust generated by the drum. While the number of bits is limited by only the bit block dimensions, the depth of cut may be limited by any of several variables. The depth of cut is determined by the advance rate, the drum revolution per minute, and the number of starts.

</table>

1Not used in current version of program.
The advance rate in turn may be limited by the volume of cut coal the drum can hold or by high cutting or normal forces. These high cutting and normal forces could result from the presence of a rock-band or by assuming highly worn bits. The total force on the drum is a function of the number of vane bits and gauge bits. The percent contribution of the vane and gauge bits to the dust make is given in the summary report (fig. 4) to aid the user in determining the best place from which to remove bits.

The dust values computed by the program are relative. A single value of 10.0, for example, has no meaning unless another number is generated by a change in some parameter(s). If the second number is lower than 10.0, then the change should result in lower dust generation and vice versa.

**VERIFICATION**

A comparison of relative dust values calculated by the CSM and in-mine results from a Bureau contract (6) was made. The drum specifications and operating conditions for the test drum are given in table 2. Table 3 shows the combinations of drum speed and bits per vane that were run, along with the average advance rate for each combination. The 7.5 bit per vane figure shown in these two tables occurs because as part of the test series every other bit on each vane was removed, leaving seven bits on one vane and eight on the other, thereby doubling the bit spacing on each vane. Since the CSM treats both vanes as being equal, 7.5 bits per vane was used. The values for inner drum diameter, vane thickness, and vane height were estimated since values were not given in reference 6. The value of 14 in for inner drum diameter was necessary to allow sufficient open volume in the drum to allow the 27.5 ft/min advance rate. This could have also been accomplished by specifying a lower swell factor and using a larger inner drum diameter. The results from the CSM analysis and the test results are shown in table 4 and figure 7. Both the test results and CSM analysis show an increase in dust generation as drum speed is increased and a drop in dust generation as the number of bits per vane was halved. The test result data show a higher rate of increase with drum speed than does the CSM analysis, while the drop in dust generation, due to removal of bits, was approximately the same order of magnitude.

Other reports on field tests were reviewed for use in evaluating the CSM. None of the field tests covered by these reports were conducted in a manner that allowed the results to be used to evaluate the CSM. The primary problem was that variables not modelled by the CSM, such as water spray systems, were simultaneously changed with the cutting system parameters. This effectively masks any changes in dust generation due to changes in the cutting system.

DISCUSSION

An interactive computer program has been developed which allows the user to evaluate, on a relative basis, the effect of cutting system changes on primary dust generation for double arm ranging shearsers. The program is written in BASIC for use on IBM compatible microcomputers. The program is menu driven and allows the user to systematically vary cutting system parameters either individually or collectively to determine their effect on dust generation.

Expensive and time consuming underground "cut and try" testing can be substantially reduced or eliminated by using the program to determine the range of cutting parameters that produces a minimum relative dust value. Those parameters which have the greatest effect on dust can be easily identified and given priority on any underground equipment changes to reduce dust generation.

HELP INDEX FOR PARAMETER MODIFICATION MENU

1 - MACHINE PARAMETERS
2 - SEAM PARAMETERS
3 - OPERATOR CONTROLLABLE PARAMETERS
4 - BIT NORMAL FORCE PARAMETERS
5 - CUTTING FORCE PARAMETERS
6 - RETURN TO PARAMETER MODIFICATION MENU

ENTER THE NUMBER OF THE MENU ITEM FOR WHICH YOU REQUIRE HELP:
1: INPUT HT
GOTO 4260, 4330, 4420, 4480, 4480, 4540

THE USER CAN CHANGE ANY OF THE 13 VARIABLES WHICH DESCRIBE THE SHEARER DRUM.
THE PROGRAM HAS NO INTERNAL ERROR CHECKING ROUTINES TO INSURE THAT THE DRUM DIMENSIONS ARE CONSISTENT WITH EACH OTHER (E.G., THE WEB WIDTH IS GREATER THAN"
THE VANE WIDTH ETC.)."

THE USER CAN CHANGE ANY OF 11 SEAM AND/OR COAL PROPERTY VARIABLES. THE ROCK BAND VALUES (TOP AND BOTTOM) ARE MEASURED FROM THE TOP OF THE-MINING HORIZON.
TWO ASPECTS OF PROGRAM FLOW ARE CONTROLLED BY VARIABLES IN THIS MENU. FIRST
SETTING THE ROCK BAND TOP EQUAL TO THE ROCK BOTTOM WILL CAUSE THE PROGRAM TO
CONSIDER CUTTING ONLY COAL. SECOND, IF THE SEAM HEIGHT IS EQUAL TO THE DRUM
DIAMETER THE PROGRAM WILL BASE THE CALCULATIONS ON ONE DRUM ONLY.

THE USER CAN CHANGE ANY OF 26 FORCE AND WEAR
CHARACTERISTICS OF THE BITS
4500 PRINT"BEING USED IN THE ANALYSIS. THE VALUES FOR FORCE AND WEAR
PARAMETERS MUST BE"
4510 PRINT"OBTAINED FROM IN SITU FORCE MEASUREMENTS AND FROM LAB WEAR
TESTS."
4520 PRINT "*******************************************************************************

<tr>
<td>5</td>
<td>Vane width</td>
<td>in</td>
<td>Width of vane section of drum.</td>
</tr>
<tr>
<td>6</td>
<td>Vane thickness</td>
<td>in</td>
<td>Thickness of vane measured perpendicular to vane.</td>
</tr>
<tr>
<td>7</td>
<td>Vane height</td>
<td>in</td>
<td>Height of vanes, inner drum diameter plus twice vane height should equal top vane diameter.</td>
</tr>
<tr>
<td>8</td>
<td>Drum vane wrap</td>
<td>deg</td>
<td>Wrap angle of drum.</td>
</tr>
<tr>
<td>9</td>
<td>Available advancing thrust</td>
<td>lb</td>
<td>Thrust available to advance shearer drum unto coal.</td>
</tr>
<tr>
<td>10</td>
<td>Available cutter torque</td>
<td>ft-lb</td>
<td>Cutterhead torque available to turn shearer drum.</td>
</tr>
<tr>
<td>11</td>
<td>Number of starts</td>
<td>N/Ap</td>
<td>Number of starts on the drum.</td>
</tr>
<tr>
<td>12</td>
<td>Number of gauge lines</td>
<td>N/Ap</td>
<td>Number of gauge lines on drum end ring.</td>
</tr>
<tr>
<td>13</td>
<td>Drum revolutions</td>
<td>rpm</td>
<td>Drum speed.</td>
</tr>
<tr>
<td>14</td>
<td>1st dust parameter</td>
<td>N/Ap</td>
<td>Intercept of linear dust versus cut depth equation.</td>
</tr>

<td>Breakout angle</td>
<td>deg</td>
<td>Measure of bit interaction, included angle of trench left by bit.</td>
</tr>
<tr>
<td>21</td>
<td>Rock band top</td>
<td>in</td>
<td>Distance from top of seam to top of rock band.</td>
</tr>
<tr>
<td>22</td>
<td>Rock band bottom</td>
<td>in</td>
<td>Distance from top of seam to bottom of the rock band; if set equal to rock band top program assumes there is no rock band.</td>
</tr>
<tr>
<td>23</td>
<td>Percent silica in rock band</td>
<td>pct</td>
<td>Percent silica in the rock band.</td>
</tr>
<tr>
<td>24</td>
<td>Mining height</td>
<td>in</td>
<td>Height of coal and rock being removed, if set equal to drum diameter the program will assume a single drum is being analyzed.</td>
</tr>
<tr>
<td>25</td>
<td>Bits per vane</td>
<td>N/Ap</td>
<td>Number of bits on each vane.</td>
</tr>
<tr>
<td>26</td>
<td>Bit block length</td>
<td>in</td>
<td>Length of vane bit blocks.</td>
</tr>
<tr>
<td>27</td>
<td>Bit block width</td>
<td>in</td>
<td>Width of vane bit blocks.</td>
</tr>
<tr>
<td>28</td>
<td>Number of gauge bits</td>
<td>N/Ap</td>
<td>Total gauge bits on end of drum.</td>
</tr>
<tr>
<td>29</td>
<td>Airflow</td>
<td>cfm</td>
<td>Av airflow at middle of face.</td>
</tr>
<tr>
<td>30</td>
<td>Dust suppression</td>
<td>pct</td>
<td>Percent reduction in total dust value due to secondary water suppression system.</td>
</tr>
<tr>
<td>31</td>
<td>Production time per shift</td>
<td>pct</td>
<td>Percent of shift spent cutting coal, based on an 8-hr shift.</td>
</tr>
<tr>
<td>32</td>
<td>Cost per bit</td>
<td>N/Ap</td>
<td>Cost of bit installed on drum.</td>
</tr>
<tr>
