

# HIV | SURVEILLANCE REPORT

SUPPLEMENTAL REPORT

**Monitoring Selected National HIV  
Prevention and Care Objectives  
by Using Surveillance Data  
United States and 6 Dependent Areas, 2019**

**Centers for Disease  
Control and Prevention**  
National Center for HIV/AIDS,  
Viral Hepatitis, STD, and  
TB Prevention

This issue of the *HIV Surveillance Supplemental Report* is published by the Division of HIV/AIDS Prevention (DHAP), National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, Centers for Disease Control and Prevention (CDC), U.S. Department of Health and Human Services, Atlanta, Georgia.

Data are presented for diagnoses of HIV infection reported to CDC through December 2020.

The *HIV Surveillance Supplemental Report* is not copyrighted and may be used and copied without permission. Citation of the source is, however, appreciated.

### **Publication credit**

Publication of this report was made possible by the contributions of the state and territorial health departments and the HIV surveillance programs that provided surveillance data to CDC.

This report was prepared by the following staff and contractors of the Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, CDC: Shacara Johnson Lyons, Zanetta Gant, Anna Satcher Johnson, Xiaohong Hu, Chenchen Yu, Chan Jin, J. Scott Cope, André F. Dailey, Baohua Wu, Jianmin Li, Muhling Chong, Shihua Wang, Norma Harris, Ya-lin Huang, Donna McCree, Krishna Kota, and Anne Peruski.

<b>Figures in the National Profile</b>	
1 Status of CD4 and viral load reporting, by area of residence as of December 2020—United States and dependent areas	10
2 Stage of disease at HIV diagnosis during 2019 among persons aged $\geq 13$ years—44 states and the District of Columbia	11
3 Stage of disease at HIV diagnosis during 2019 among persons aged $\geq 13$ years, by selected characteristics—44 states and the District of Columbia	12
4 Linkage to HIV medical care within 1 month of HIV diagnosis during 2019 among persons aged $\geq 13$ years, by area of residence—44 states and the District of Columbia	13
5 Linkage to HIV medical care within 1 month of HIV diagnosis during 2019 among persons aged $\geq 13$ years, by selected characteristics—44 states and the District of Columbia	14
6 Viral suppression within 6 months of HIV diagnosis during 2019 among persons aged $\geq 13$ years, by area of residence—44 states and the District of Columbia	15
7 Viral suppression within 6 months of HIV diagnosis during 2019 among persons aged $\geq 13$ years, by selected characteristics—44 states and the District of Columbia	16
8a Receipt of HIV medical care among persons aged $\geq 13$ years living with diagnosed HIV infection, by area of residence, 2019—44 states and the District of Columbia	17
8b Retention in HIV medical care among persons aged $\geq 13$ years living with diagnosed HIV infection, by area of residence, 2019—44 states and the District of Columbia	18
9 Viral suppression among persons aged $\geq 13$ years living with diagnosed HIV infection, by area of residence, 2019—44 states and the District of Columbia	19
10 Receipt of HIV medical care, retention in HIV medical care, and viral suppression among persons aged $\geq 13$ years living with diagnosed HIV infection, by gender, 2019—44 states and the District of Columbia	20
11 Receipt of HIV medical care, retention in HIV medical care, and viral suppression among persons aged $\geq 13$ years living with diagnosed HIV infection, by age, 2019—44 states and the District of Columbia	20
12 Receipt of HIV medical care, retention in HIV medical care, and viral suppression among persons aged $\geq 13$ years living with diagnosed HIV infection, by race/ethnicity, 2019—44 states and the District of Columbia	21
13 Receipt of HIV medical care, retention in HIV medical care, and viral suppression among persons aged $\geq 13$ years living with diagnosed HIV infection, by transmission category, 2019—44 states and the District of Columbia	22
14 Viral suppression among persons aged $\geq 13$ years living with diagnosed HIV infection, by selected characteristics, 2019—44 states and the District of Columbia	23
15 Prevalence-based HIV care continuum for persons aged $\geq 13$ years living with HIV infection (diagnosed or undiagnosed) at year-end 2019—United States	24
16 Prevalence-based HIV care continuum for persons aged $\geq 13$ years living with HIV infection (diagnosed or undiagnosed) at year-end 2019, by sex at birth—United States	24
17 Prevalence-based HIV care continuum for persons aged $\geq 13$ years living with HIV infection (diagnosed or undiagnosed) at year-end 2019, by age—United States	25
18 Prevalence-based HIV care continuum for persons aged $\geq 13$ years living with HIV infection (diagnosed or undiagnosed) at year-end 2019, by race/ethnicity—United States	25

19	Prevalence-based HIV care continuum for persons aged $\geq 13$ years living with HIV infection (diagnosed or undiagnosed) at year-end 2019, by transmission category—United States	26
20	Stage 3 (AIDS) at time of diagnosis of HIV infection among persons aged $\geq 13$ years, by year of diagnosis and population area of residence, 2015–2019—United States	27
21	Stage 3 (AIDS) at time of diagnosis of HIV infection among persons aged $\geq 13$ years, by area of residence, 2019—United States	28
22	Stage 3 (AIDS) at time of diagnosis of HIV infection among persons aged $\geq 13$ years, by selected characteristics, 2019—United States	29
23	Age-adjusted rates of death among persons aged $\geq 13$ years with diagnosed HIV infection, by year of death and area of residence, 2019—United States	30
24	Age-adjusted rates of death among persons aged $\geq 13$ years with diagnosed HIV infection ever classified as stage 3 (AIDS), by year of death and area of residence, 2019—United States	31
25	Survival for $>3$ years after a diagnosis of HIV infection during 2016, by selected characteristics—United States	32
26	PrEP coverage among persons aged $\geq 16$ years, by area of residence, 2019—United States and Puerto Rico	34
27	PrEP coverage among persons aged $\geq 16$ years, by selected characteristics, 2019—United States	35

## Figures in the Special Focus Profiles

### Section 1 Gay, Bisexual, and Other Men Who Have Sex With Men

28	Earlier and late stage of disease at HIV diagnosis during 2019 among men who have sex with men, by race/ethnicity—44 states and the District of Columbia	37
29	Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among men who have sex with men, by race/ethnicity—44 states and the District of Columbia	38
30	Receipt of HIV medical care, retention in HIV medical care, and viral suppression during 2019 among men who have sex with men, by race/ethnicity—44 states and the District of Columbia	39

### Section 2 Persons Who Inject Drugs

31	Earlier and late stage of disease at HIV diagnosis during 2019 among persons who inject drugs, by sex at birth and race/ethnicity—44 states and the District of Columbia	40
32	Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among persons who inject drugs, by sex at birth and race/ethnicity—44 states and the District of Columbia	40
33	Receipt of HIV medical care, retention in HIV medical care, and viral suppression during 2019 among persons who inject drugs, by sex at birth and race/ethnicity—44 states and the District of Columbia	40

### Section 3 Transgender Persons

34	Receipt of HIV medical care, retention in HIV medical care, and viral suppression during 2019 among transgender persons—44 states and the District of Columbia	40
----	--	----

### Section 4 Women

35	Earlier and late stage of disease at HIV diagnosis during 2019 among women, by race/ethnicity—44 states and the District of Columbia	43
36	Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among women, by race/ethnicity—44 states and the District of Columbia	43
37	Receipt of HIV medical care, retention in HIV medical care, and viral suppression during 2019 among women, by race/ethnicity—44 states and the District of Columbia	44

### Section 5 Persons with Perinatally Acquired HIV Infection

38	Perinatally acquired HIV infection, by year of birth and mother's race/ethnicity, 2015–2019—United States	45
39	Perinatally acquired HIV infection among persons born in the United States, by year of birth and mother's race/ethnicity, 2015–2019—United States	46

### Section 6 Young Persons

40	Earlier and late stage of disease at HIV diagnosis during 2019 among young persons, by race/ethnicity—44 states and the District of Columbia	47
41	Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among young persons, by race/ethnicity—44 states and the District of Columbia	48
42	Receipt of HIV medical care, retention in HIV medical care, and viral suppression during 2019 among young persons, by race/ethnicity—44 states and the District of Columbia	49
43	Status of linkage to HIV medical care within 1 month of HIV diagnosis during 2019 among persons aged $\geq 13$ years with diagnosed HIV infection, by selected characteristics—44 states and the District of Columbia	50
44	Status of viral suppression during 2019 among persons aged $\geq 13$ years with diagnosed HIV infection, by selected characteristics—44 states and District of Columbia	52

## Tables

1a	Stage of disease at time of HIV diagnosis during 2019 among persons aged $\geq 13$ years, by selected characteristics—44 states and the District of Columbia	69
----	--	----

1b	Stage of disease at time of HIV diagnosis during 2019 among persons aged $\geq 13$ years, by area of residence—44 states and the District of Columbia	70
1c	Stage of disease at time of HIV diagnosis during 2019 among persons aged $\geq 13$ years, by race/ethnicity and selected characteristics—44 states and the District of Columbia	71
1d	Stage of disease at time of HIV diagnosis during 2019 among males aged $\geq 13$ years with infection attributed to male-to-male sexual contact, by race/ethnicity and age at diagnosis—44 states and the District of Columbia	75
2a	Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among persons aged $\geq 13$ years, by selected characteristics—44 states and the District of Columbia	76
2b	Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among persons aged $\geq 13$ years, by area of residence—44 states and the District of Columbia	77
2c	Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among persons aged $\geq 13$ years, by race/ethnicity and selected characteristics—44 states and the District of Columbia	78
2d	Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among males aged $\geq 13$ years with infection attributed to male-to-male sexual contact, by race/ethnicity and age at diagnosis—44 states and the District of Columbia	82
3a	Receipt of HIV medical care among persons aged $\geq 13$ years with HIV infection diagnosed by year-end 2018 and alive at year-end 2019, by selected characteristics—44 states and the District of Columbia	83
3b	Receipt of HIV medical care among persons aged $\geq 13$ years with HIV infection diagnosed by year-end 2018 and alive at year-end 2019, by area of residence—44 states and the District of Columbia	84
3c	Receipt of HIV medical care and viral suppression among persons aged $\geq 13$ years with HIV infection diagnosed by year-end 2018 and alive at year-end 2019, by race/ethnicity and selected characteristics—44 states and the District of Columbia	85
3d	Receipt of HIV medical care and viral suppression during 2019 among males aged $\geq 13$ years with infection attributed to male-to-male sexual contact, by race/ethnicity and age group—44 states and the District of Columbia	89
4a	HIV viral suppression during 2019 among persons aged $\geq 13$ years with HIV infection diagnosed by year-end 2018 and alive at year-end 2019, by selected characteristics—44 states and the District of Columbia	90
4b	HIV viral suppression during 2019 among persons aged $\geq 13$ years with HIV infection diagnosed by year-end 2018 and alive at year-end 2019, by area of residence—44 states and the District of Columbia	91
5	Prevalence-based HIV care continuum for persons aged $\geq 13$ years living with HIV infection (diagnosed or undiagnosed) at year-end 2019, by selected characteristics—United States	92
6a	Stage 3 (AIDS) at time of HIV diagnosis among persons aged $\geq 13$ years, by year of diagnosis and selected characteristics, 2015–2019—United States	93
6b	Stage 3 (AIDS) at time of HIV diagnosis among persons aged $\geq 13$ years, by year of diagnosis and selected characteristics, 2015–2019—United States and 6 dependent areas	95
6c	Stage 3 (AIDS) at time of HIV diagnosis among persons aged $\geq 13$ years, by year of diagnosis and area of residence, 2015–2019—United States and 6 dependent areas	96
6d	Stage 3 (AIDS) at time of HIV diagnosis among persons aged $\geq 13$ years, by race/ethnicity and area of residence, 2019—United States	98
7a	Deaths of persons aged $\geq 13$ years with diagnosed HIV infection, by year of death and selected characteristics, 2015–2019—United States	99
7b	Deaths of persons aged $\geq 13$ years with diagnosed HIV infection, by year of death and selected characteristics, 2015–2019—United States and 6 dependent areas	100
7c	Deaths of persons aged $\geq 13$ years with diagnosed HIV infection, by year of death and area of residence, 2015–2019—United States and 6 dependent areas	101
7d	Deaths of persons aged $\geq 13$ years with diagnosed HIV infection ever classified as stage 3 (AIDS), by year of death and selected characteristics, 2015–2019—United States	106
7e	Deaths of persons aged $\geq 13$ years with diagnosed HIV infection ever classified as stage 3 (AIDS), by year of death and selected characteristics, 2015–2019—United States and 6 dependent areas	107
7f	Deaths of persons aged $\geq 13$ years with diagnosed HIV infection ever classified as stage 3 (AIDS), by year of death and area of residence, 2015–2019—United States and 6 dependent areas	108
8a	Persons surviving $>3$ years after a diagnosis of HIV infection during 2011–2016, by year of diagnosis and selected characteristics—United States	113
8b	Persons surviving $>3$ years after a diagnosis of HIV infection during 2011–2016, by year of diagnosis and selected characteristics—United States and 6 dependent areas	114
8c	Persons surviving $>3$ years after a diagnosis of HIV infection during 2011–2016, by year of diagnosis and area of residence—United States and 6 dependent areas	115
8d	Persons with HIV surviving $>3$ years after stage 3 (AIDS) classification during 2011–2016, by year of diagnosis and selected characteristics—United States	116
8e	Persons with HIV surviving $>3$ years after stage 3 (AIDS) classification during 2011–2016, by year of diagnosis and selected characteristics—United States and 6 dependent areas	117

8f	Persons with HIV surviving >3 years after stage 3 (AIDS) classification during 2011–2016, by year of diagnosis and area of residence—United States and 6 dependent areas	118
9a	Number of persons prescribed PrEP, number of persons with PrEP indications, and PrEP coverage in 2019 among persons aged ≥ 16 years, by selected characteristics—United States	119
9b	Number of persons prescribed PrEP, number of persons with PrEP indications, and PrEP coverage in 2019 among persons aged ≥ 16 years, by area of residence—United States and Puerto Rico	120
10a	Perinatally acquired HIV infection, by year of birth and mother’s race/ethnicity, 2015–2019—United States	121
10b	Perinatally acquired HIV infection among persons born in the United States, by year of birth and mother’s race/ethnicity, 2015–2019—United States	121
11	Monitoring Ending the HIV Epidemic (EHE) indicators by using data from the National HIV Surveillance System (NHSS) and other reporting systems	122
12	Status of CD4 and viral load reporting by HIV surveillance reporting area, as of December 2020—United States and 6 dependent areas	123

## Appendix: Tables for Ending the HIV Epidemic Phase I Jurisdictions

A1	Stage of disease at time of HIV diagnosis during 2019 among persons aged ≥13 years, by area of residence—Ending the HIV Epidemic Phase I jurisdictions	125
A2	Linkage to HIV medical care within 1 month and viral suppression within 6 months of HIV diagnosis during 2019 among persons aged ≥13 years, by area of residence—Ending the HIV Epidemic Phase I jurisdictions	126
A3	Receipt of HIV medical care among persons aged ≥13 years with infection diagnosed by year-end 2018 and alive at year-end 2019, by area of residence—Ending the HIV Epidemic Phase I jurisdictions	127
A4	HIV viral suppression during 2019 among persons aged ≥13 years with HIV infection diagnosed by year-end 2018 and alive at year-end 2019, by area of residence—Ending the HIV Epidemic Phase I jurisdictions	128
A5	Number of persons prescribed PrEP, number of persons with PrEP indications, and PrEP coverage in 2017 (recalculated), 2018 (updated), and 2019 among persons aged ≥ 16 years, by area of residence—Ending the HIV Epidemic Phase I jurisdictions	130

## Supplementary Tables

S1	Stage of disease at time of HIV diagnosis during 2017 among persons aged ≥13 years, by race/ethnicity and selected characteristics—41 states and the District of Columbia	132
S2	Stage of disease at time of HIV diagnosis during 2017 among males aged ≥13 years with infection attributed to male-to-male sexual contact, by race/ethnicity and age at diagnosis—41 states and the District of Columbia	136
S3	Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2017 among persons aged ≥13 years, by race/ethnicity and selected characteristics—41 states and the District of Columbia	137
S4	Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2017 among males aged ≥13 years with infection attributed to male-to-male sexual contact, by race/ethnicity and age at diagnosis—41 states and the District of Columbia	141
S5	Receipt of HIV medical care and viral suppression among persons aged ≥13 years with infection diagnosed by year-end 2016 and alive at year-end 2017, by race/ethnicity and selected characteristics—41 states and the District of Columbia	142
S6	Receipt of HIV medical care and viral suppression during 2017 among males aged ≥13 years with infection attributed to male-to-male sexual contact, by race/ethnicity and age group—41 states and the District of Columbia	146
S7a	Number of persons prescribed PrEP, number of persons with PrEP indications, and PrEP coverage in 2017 and 2018 among persons aged ≥ 16 years, by selected characteristics—United States	147
S7b	Number of persons prescribed PrEP, number of persons with PrEP indications, and PrEP coverage in 2017 and 2018 among persons aged ≥ 16 years, by area of residence—United States and Puerto Rico	148
S8a	Stage 3 (AIDS) at the time of diagnosis of HIV infection among adults aged ≥50 years, by year of diagnosis and selected characteristics, 2015–2019—United States	149
S8b	Stage 3 (AIDS) at the time of diagnosis of HIV infection among adults aged ≥50 years, by year of diagnosis and selected characteristics, 2015–2019—United States and 6 dependent areas	150
S9a	Stage 3 (AIDS) at the time of diagnosis of HIV infection among adults aged ≥50 years, by year of diagnosis, sex at birth, and selected characteristics, 2015–2019—United States	151
S9b	Stage 3 (AIDS) at the time of diagnosis of HIV infection among adults aged ≥50 years, by year of diagnosis, sex at birth, and selected characteristics, 2015–2019—United States and 6 dependent areas	152
S10a	Stage 3 (AIDS) at the time of diagnosis of HIV infection among adults aged ≥50 years, by year of diagnosis, age group, sex at birth, and selected characteristics, 2015–2019—United States	153
S10b	Stage 3 (AIDS) at the time of diagnosis of HIV infection among adults aged ≥50 years, by year of diagnosis, age group, sex at birth, and selected characteristics, 2015–2019—United States and 6 dependent areas	156

# Guide to Acronyms and Initialisms

ACS	American Community Survey
AGI	additional gender identity
AIDS	acquired immunodeficiency syndrome
ART	antiretroviral therapy
CD4	CD4+ T-lymphocyte count (cells/ $\mu$ L) or percentage
CDC	Centers for Disease Control and Prevention
EHE	Ending the HIV Epidemic in the U.S. initiative
FTM	female-to-male
HIV	human immunodeficiency virus
IDU	injection drug use
MMSC	male-to-male sexual contact
MMSC-IDU	male-to-male sexual contact <i>and</i> injection drug use
MSA	metropolitan statistical area
MSM	gay, bisexual, and other men who have sex with men
MTF	male-to-female
NHANES	National Health and Nutrition Examination Survey
NHSS	National HIV Surveillance System
NIR	no identified risk factor
OI	opportunistic illness
OMB	Office of Management and Budget
PrEP	preexposure prophylaxis
PWID	persons who inject drugs
VS	viral suppression
ZCTA	ZIP Code tabulation area

# Commentary

The Centers for Disease Control and Prevention (CDC) collects data to monitor progress toward achieving national goals and the objectives set forth in other federal directives, including the updated strategic plans of the Division of HIV/AIDS Prevention (DHAP) and for the United States [1–4]. This surveillance supplemental report complements the 2019 *HIV Surveillance Report* [5] and presents the results of focused analyses of National HIV Surveillance System (NHSS) [6] data to measure progress toward achieving national goals [1–3]. Data in this report are also used to assess Department of Health and Human Services (HHS) core indicators [7, 8] and to monitor progress toward the HIV-related national objectives in Healthy People 2030 and the National HIV Strategic Plan for the United States: A Roadmap to End the Epidemic 2021–2025 (NHSP), and the Ending the HIV Epidemic in the U.S. (EHE) initiative [9, 10].

## REPORT CHANGES

Recognizing the changing needs for data, CDC has transitioned this report to a new format that includes figures and tables, and includes data reported to CDC’s NHSS through December 31 of the prior year. The use of data reported to CDC through December 31, 2020 will allow for a 12-month reporting delay and assessment of trends through the most recent diagnosis, death, and prevalence year (2019). Death and prevalence trends through 2019 should be interpreted with caution.

New to this report are the following:

- This report is presented in a new, digital format that includes figures based on charts and maps from the former Selected National HIV Prevention and Care Outcomes slide set.
- Tables now display additional geographic stratifications (i.e., region and population area of residence).
- A Special Focus Profiles section was added to highlight 6 key populations: (1) Gay, Bisexual, and Other Men Who Have Sex With Men (MSM), (2) Persons Who Inject Drugs (PWID), (3) Transgender Persons, (4) Women, (5) Persons with Perinatally Acquired HIV Infection, and (6) Young Persons. This section also includes the following topics: 2019 status and disparities for linkage to care within 1 month of HIV diagnosis and for viral suppression by race/ethnicity, transmission category, and geography.
- Supplementary Tables S1–S7b display 2017 and 2018 data (where indicated) that have been updated. Stage of disease at time of diagnosis, linkage to HIV medical care, viral suppression within 6 months of diagnosis, receipt of HIV medical care, viral suppression, and preexposure prophylaxis (PrEP) coverage are included. Tables S8a–S10b on stage 3 (AIDS) classification at time of diagnosis of HIV infection for older adults were added.

# National Profile

The term *diagnosis of HIV infection* refers to a diagnosis of HIV infection regardless of the person's stage of disease (stage 0, 1, 2, 3 [AIDS], or unknown) at the time of diagnosis. The standard used for reporting trends in numbers, percentages, and rates is an increase or a decrease of 5% or more during the specified time frame (e.g., when comparing 2015 and 2019). The exceptions to this standard are where numbers were small (i.e., less than 12) and percentages or rates were based on small numbers. Please use caution when interpreting data on diagnosed HIV infection (see Technical Notes for additional information on Definitions and Data Specifications).

Data from jurisdictions that reported complete CD4 and viral load laboratory results to CDC were used for the analyses that require laboratory data (Tables 1a–4b). Data from the 50 states, the District of Columbia, and 6 U.S. dependent areas (where indicated) were used for analyses of stage 3 (AIDS) at the time of diagnosis of HIV infection (Tables 6a–6d), deaths and survival of persons with diagnosed HIV infection (Tables 7a–8f), and persons with diagnosed, perinatally acquired HIV infection (Tables 10a/b). For tables on PrEP (Tables 9a/b), the number of persons who have been prescribed PrEP, the estimated number with PrEP indications, and PrEP coverage are presented. For tables that include data by transmission category, the data were statistically adjusted to account for missing transmission category and are presented based on sex at birth. For a summary of indicators for EHE, see Table 11. For information and data among selected populations, see the special focus profiles and the 2019 status on linkage to care and viral suppression outcomes section.

Please read all titles and footnotes carefully to ensure a complete understanding of the displayed data. Please note that we highlight an important point with the magnifying glass icon in the text.

## Status of laboratory reporting

Monitoring stage of disease at time of diagnosis, linkage to HIV medical care, retention in HIV medical care, and viral suppression (on the basis of NHSS data) is dependent upon complete reporting of HIV-related laboratory results (including CD4+ T-lymphocyte [CD4] and viral load results) to HIV surveillance programs and CDC. Although most jurisdictions have regulations that require laboratories and providers to report at least a subset of CD4 and viral load test results to health departments, not all jurisdictions have mandatory reporting of all levels of CD4 and viral load (i.e., detectable and undetectable) results.

As of December 2020, 45 jurisdictions (44 states and the District of Columbia) had complete laboratory reporting for specimens collected from at least January 2018 through September 2020 (Figure 1).

**Figure 1. Status of CD4 and viral load reporting, by area of residence as of December 2020—United States and dependent areas**

*Note.* See Technical Notes for more information on areas with complete laboratory reporting.

The jurisdictions included in this report differ from those in previous reports. A jurisdiction’s data are included only if that jurisdiction met CDC’s criteria (see Technical Notes) for the collection and reporting of CD4 and viral load test results for all the data years examined. In comparison with the 2018 report, the 2019 report includes data from 3 additional states (Arizona, Arkansas, and Connecticut) that met the criteria.

## DIAGNOSIS-BASED HIV CARE CONTINUUM—OVERVIEW

The Diagnosis-based HIV Care Continuum describes each step of the continuum as a percentage of the number of people living with diagnosed HIV. The denominator is the number of persons aged  $\geq 13$  years living with diagnosed HIV infection at year-end 2019 (note: denominator for linkage to care and viral suppression within 6 months of diagnosis is limited to people with HIV diagnosed in a single year). The numerator is from the 45 jurisdictions with complete CD4 and viral load reporting. For more information on Definitions and Data Specifications, see Technical Notes.

Uses of the diagnosis-based continuum include monitoring the United States progress in comparison to national strategic plan, EHE, and UNAIDS 90-90-90 goals, monitoring disparities among subgroups of the population, and monitoring data at a local level to understand local progress and identify additional action steps to meet national level goals.

## Stage of disease at time of diagnosis of HIV infection

Among 33,795 persons with HIV infection diagnosed during 2019 in 45 jurisdictions with complete laboratory reporting, the stage of disease at time of diagnosis was classified as follows: stage 0 (7.9%), stage 1 (25.9%), stage 2 (30.7%), stage 3 (AIDS) (20.2%), and stage unknown (15.3%). A higher percentage of persons had HIV diagnosed at an earlier stage (stage 0, 1, or 2: 64.5%) than at the late stage (stage 3 [AIDS]: 20.2%) (Table 1a, Figure 2).

**Figure 2. Stage of disease at HIV diagnosis during 2019 among persons aged  $\geq 13$  years—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

The highest percentages for persons whose infection was diagnosed at an earlier stage (stage 0, 1, or 2) by selected characteristics (i.e., gender, age group, race/ethnicity, and transmission category) were for persons of additional gender identity (AGI) (23.5% [stage 0], 47.1% [stage 1], 23.5% [stage 2]), transgender female-to-male (FTM) persons (13.3% [stage 0], 37.8% [stage 1], 31.1% [stage 2]), persons aged 13–24 at time of diagnosis (11.2% [stage 0], 27.8% [stage 1], 36.2% [stage 2]), American Indian or Alaska Native persons (10.2% [stage 0], 29.6% [stage 1], 33.0% [stage 2]), males with infection attributed to male-to-male sexual contact *and* injection drug use (MMSC-IDU) (9.4% [stage 0], 33.4% [stage 1], 26.5% [stage 2]), and males with infection attributed to MMSC (8.9% [stage 0], 25.4% [stage 1], 32.2% [stage 2]) (Table 1a, Figure 3). The highest percentages for persons whose infection was diagnosed at a late stage (stage 3 [AIDS]) by selected characteristics were for females (20.5%), males (20.3%), persons aged  $\geq 45$  years at time of diagnosis (45–54 years: 31.3%,  $\geq 55$  years: 34.4%), Asian persons (24.6%), and males with infection attributed to heterosexual contact (32.5%) (Table 1a, Figure 3). Please use caution when interpreting data for persons of AGI, transgender FTM persons, American Indian or Alaska Native persons, and Native Hawaiian or other Pacific Islander persons: the numbers are small.

**Figure 3. Stage of disease at HIV diagnosis during 2019 among persons aged ≥13 years, by selected characteristics—44 states and the District of Columbia**

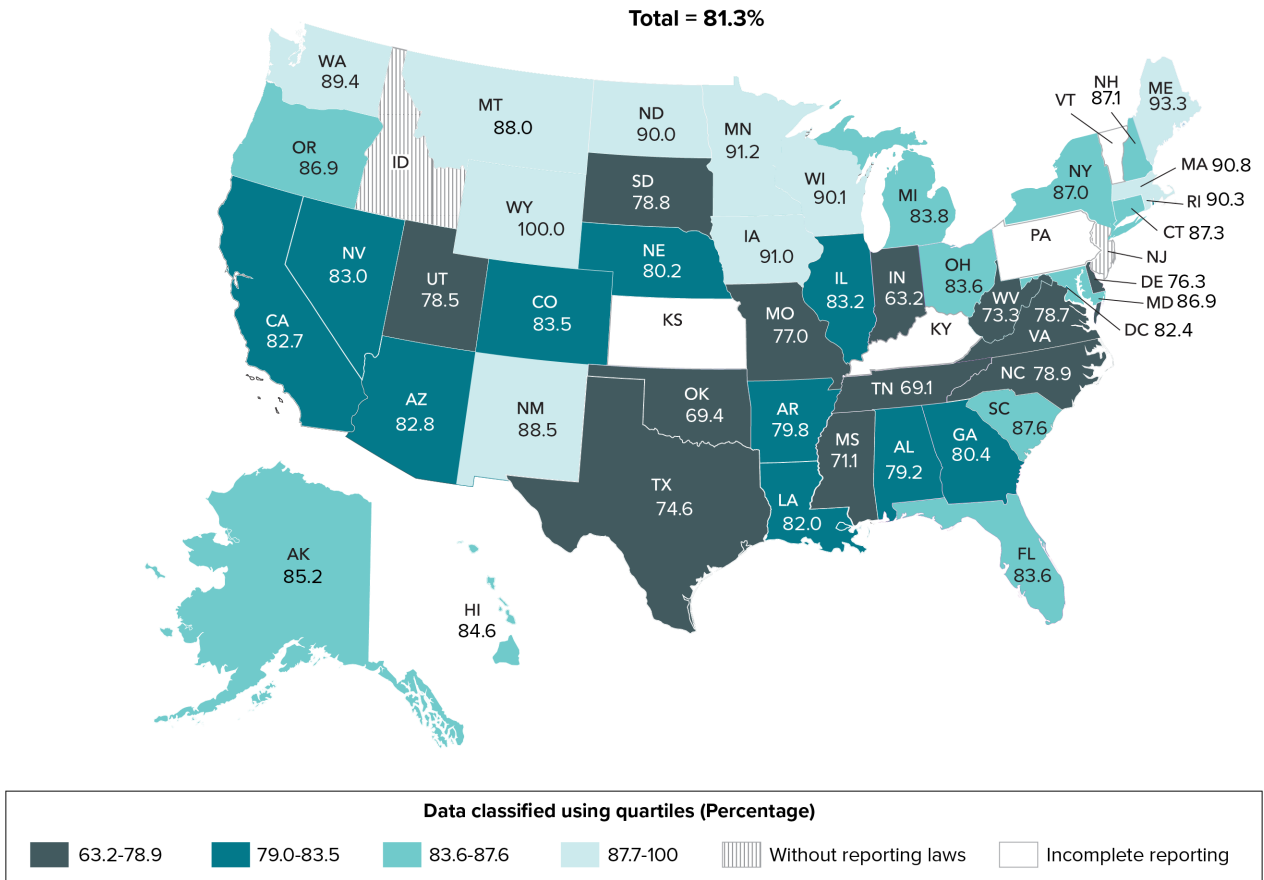

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

## Linkage to HIV medical care and viral suppression within 6 months after diagnosis of HIV infection

Among 33,795 persons with HIV infection diagnosed during 2019 in 45 jurisdictions with complete laboratory reporting, 81.3% were linked to HIV medical care ≤1 month after diagnosis (Table 2a). During 2019, 11 states (Iowa, Maine, Massachusetts, Minnesota, Montana, New Mexico, North Dakota, Rhode Island, Washington, Wisconsin, and Wyoming) in the top 25% had the highest percentages (≥87.7) of persons linked to HIV medical care within 1 month of diagnosis. Twelve states (Delaware, Indiana, Mississippi, Missouri, North Carolina, Oklahoma, South Dakota, Tennessee, Texas, Utah, Virginia, and West Virginia) in the lowest 25% had the lowest percentages (≤78.9) of persons linked to HIV medical care within 1 month of diagnosis (Table 2b, Figure 4).

**Figure 4. Linkage to HIV medical care within 1 month of HIV diagnosis during 2019 among persons aged ≥13 years, by area of residence—44 states and the District of Columbia**

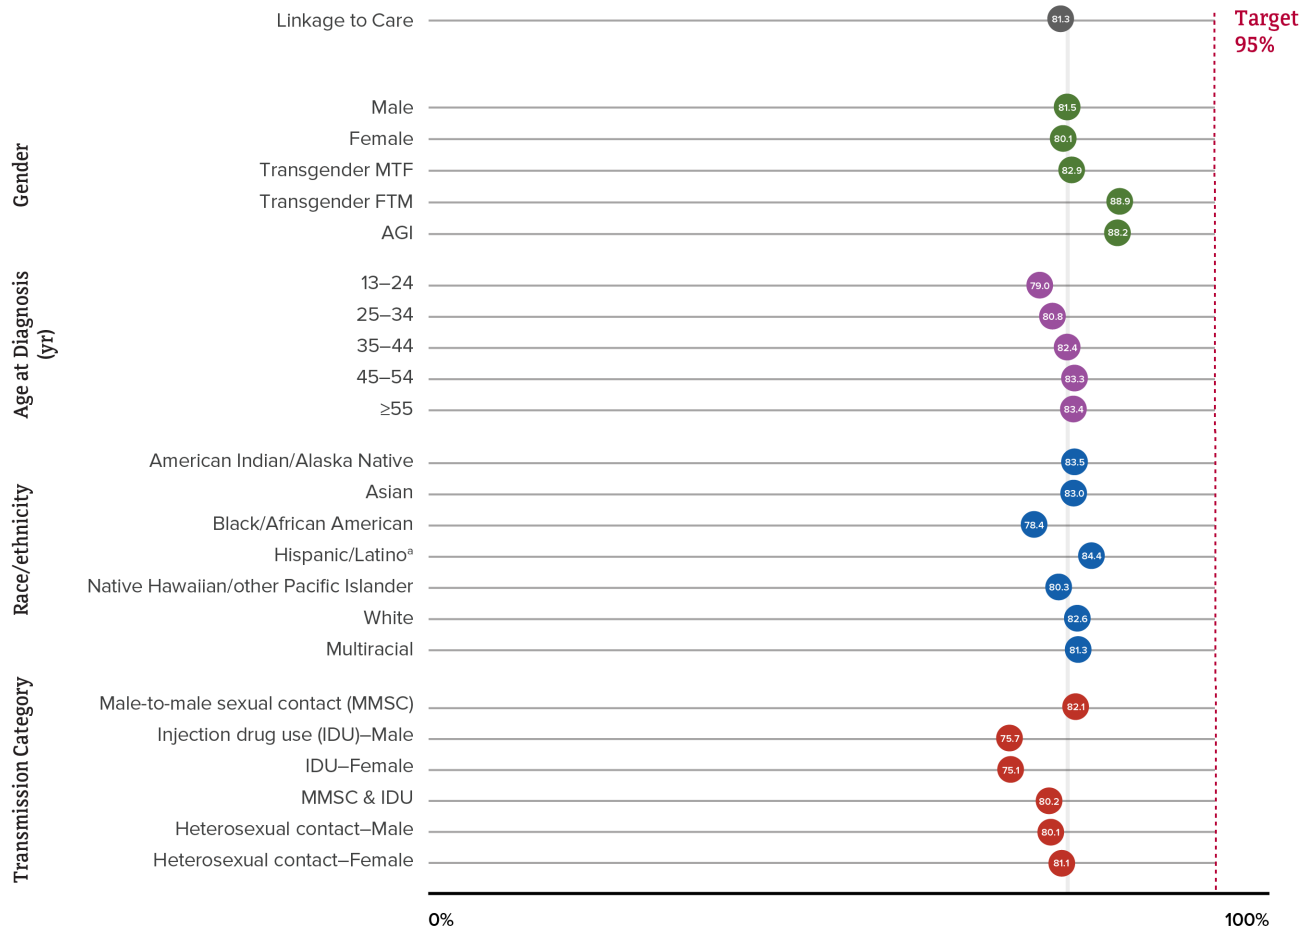

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

Although linkage to HIV medical care overall is below the EHE target of 95%, the highest percentages for persons linked to HIV medical care ≤1 month of diagnosis by selected characteristics (i.e., gender, age group, race/ethnicity, and transmission category) were for transgender FTM persons (88.9%), persons of AGI (88.2%), persons aged ≥45 years (45–54 years: 83.3%, ≥55 years: 83.4%), Hispanic or Latino persons (84.4%), and males with infection attributed to MMSC (82.1%). The lowest percentages for persons linked to HIV medical care were for females (80.1%), persons aged 13–24 years (79.0%), Black or African American persons (78.4%), and females with infection attributed to IDU (75.1%) (Table 2a, Figure 5). Please use caution when interpreting data for persons of AGI, transgender FTM persons, and Native Hawaiian or other Pacific Islander persons: the numbers are small.

A closer look at linkage to HIV medical care within 1 month of diagnosis reveals that among 33,795 persons with HIV infection diagnosed during 2019 in 45 jurisdictions with complete laboratory reporting, no demographic group or group with infection attributed to any of the transmission categories met the forthcoming EHE target of 95% (Figure 5).

**Figure 5. Linkage to HIV medical care within 1 month of HIV diagnosis during 2019 among persons aged ≥13 years, by selected characteristics—44 states and the District of Columbia**

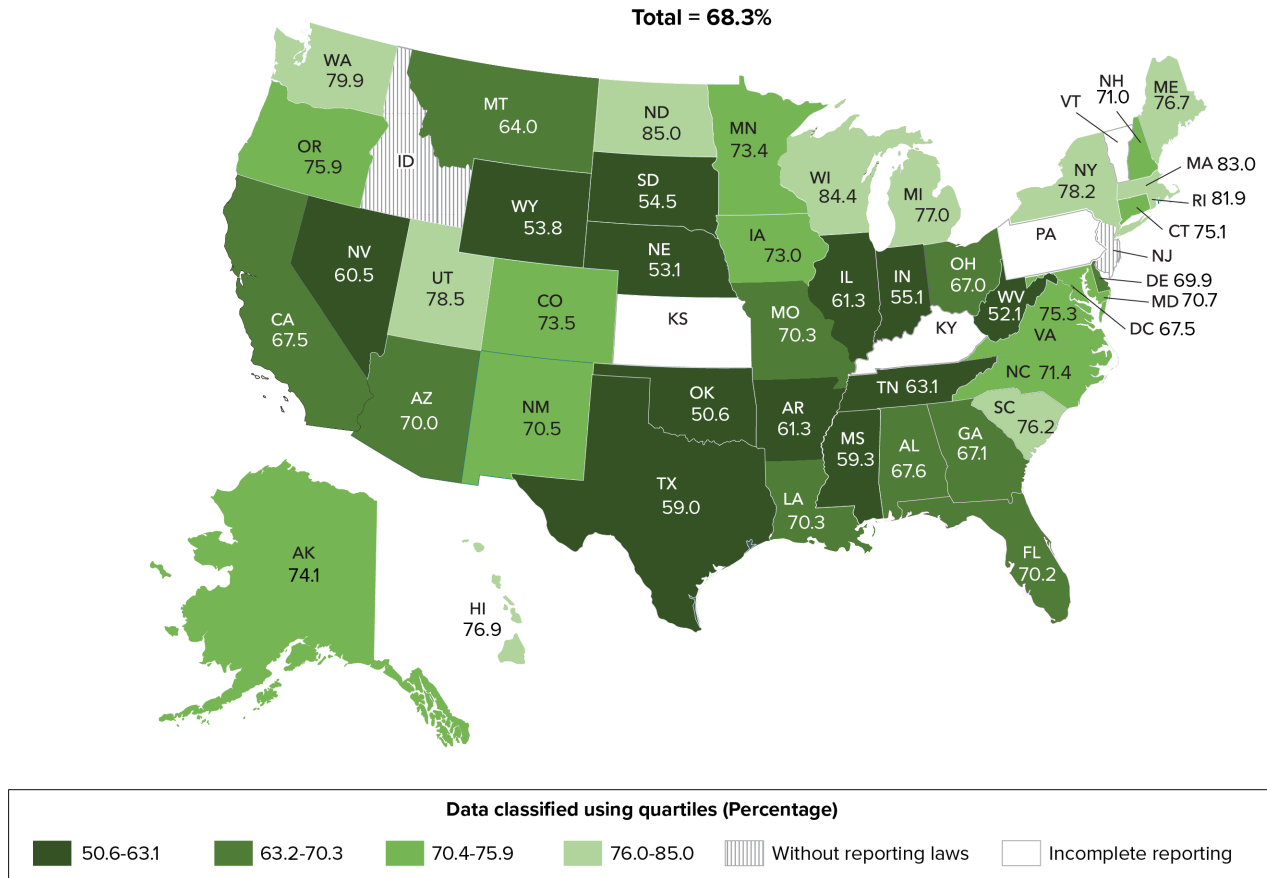

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

For any viral load test result received within 6 months of HIV diagnosis during 2019, viral load was suppressed in 68.3% of persons whose HIV infection was diagnosed during 2019 in the 45 jurisdictions (Table 2a). Eleven states (Hawaii, Maine, Massachusetts, Michigan, New York, North Dakota, Rhode Island, South Carolina, Utah, Washington, and Wisconsin) in the top 25% had the highest percentages ( $\geq 76.0$ ) of persons with viral suppression within 6 months of diagnosis in 2019. Twelve states (Arkansas, Illinois, Indiana, Mississippi, Nebraska, Nevada, Oklahoma, South Dakota, Tennessee, Texas, West Virginia, and Wyoming) in the lowest 25% had the lowest percentages ( $\leq 63.1$ ) of persons with viral suppression within 6 months of diagnosis in 2019 (Table 2b, Figure 6).

**Figure 6. Viral suppression within 6 months of HIV diagnosis during 2019 among persons aged ≥13 years, by area of residence—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

The highest percentages for persons whose viral load test result indicated viral suppression within 6 months of diagnosis in 2019 by selected characteristics (i.e., gender, age group, race/ethnicity, and transmission category) were for persons of AGI (88.2%), persons aged 45–54 years (69.0%), Asian persons (76.1%), females with infection attributed to heterosexual contact (69.9%), and males with infection attributed to MMSC (69.8%). The lowest percentages for persons that were virally suppressed within 6 months of HIV diagnosis in 2019 were for transgender male-to-female (MTF) persons (65.8%), persons aged 25–34 years and persons ≥55 years (67.9%), American Indian or Alaska Native persons (64.1%), and females with infection attributed to IDU (54.2%) (Table 2a, Figure 7). Please use caution when interpreting data for persons of AGI, transgender FTM persons, and Native Hawaiian or other Pacific Islander persons: the numbers are small.

**Figure 7. Viral suppression within 6 months of HIV diagnosis during 2019 among persons aged ≥13 years, by selected characteristics—44 states and the District of Columbia**

Note. See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

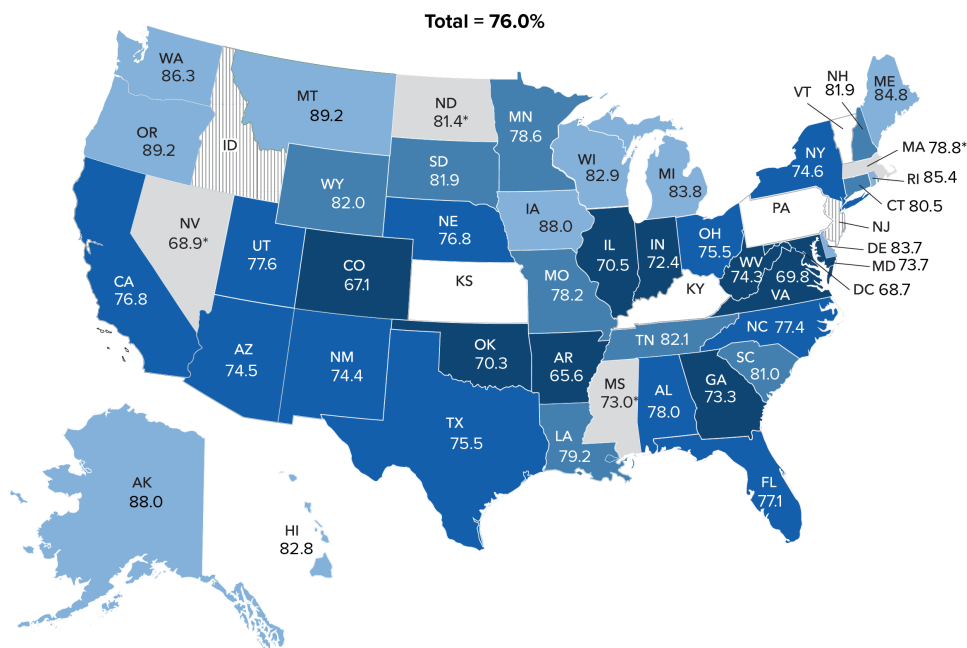

<sup>a</sup> Hispanic/Latino persons can be of any race.

## Receipt of HIV medical care, retention in HIV medical care, and viral suppression

During 2019 in 45 jurisdictions with complete laboratory reporting, 76.0% of 925,077 persons alive at year-end 2019 received any HIV medical care, and 57.8% of persons were retained in HIV medical care (Table 3a). Eleven states (Alaska, Delaware, Hawaii, Iowa, Maine, Michigan, Montana, Oregon, Rhode Island, Washington, and Wisconsin) in the top 25% had the highest percentages ( $\geq 82.2$ ) of persons who received any HIV medical care. Eleven states (Arkansas, Colorado, Georgia, Illinois, Indiana, Maryland, Mississippi, Nevada, Oklahoma, Virginia, and West Virginia) and the District of Columbia were in the lowest 25% and had the lowest percentages ( $\leq 74.3$ ) of persons who received any HIV medical care (Table 3b, Figure 8a). Eleven states (Florida, Iowa, Louisiana, Maine, Montana, New York, South Carolina, Tennessee, Washington, Wisconsin, and Wyoming) in the top 25% had the highest percentages ( $\geq 61.0$ ) of persons retained in HIV medical care. Eleven states (Arkansas, Colorado, Illinois, Indiana, Minnesota, Nebraska, Nevada, New Mexico, Ohio, Virginia, and West Virginia) and the District of Columbia were in the lowest 25% and had the lowest percentages ( $\leq 52.1$ ) of persons retained in HIV medical care (Table 3b, Figure 8b). Please note that due to incomplete reporting of deaths for the year 2019, data for Massachusetts, Mississippi, Nevada, and North Dakota should be interpreted with caution.

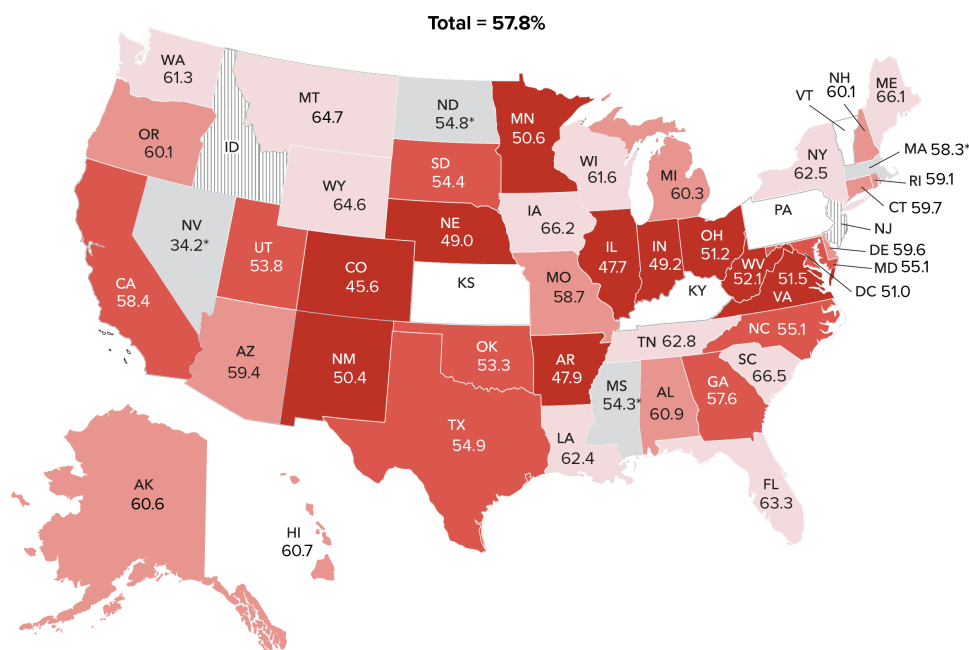

**Figures 8a. Receipt of HIV medical care among persons aged ≥13 years living with diagnosed HIV infection, by area of residence, 2019—44 states and the District of Columbia**

*Note.* Data for the year 2019 are preliminary and based on deaths reported to CDC as of December 2020. See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

**Figures 8b. Retention in HIV medical care among persons aged ≥13 years living with diagnosed HIV infection, by area of residence, 2019—44 states and the District of Columbia**

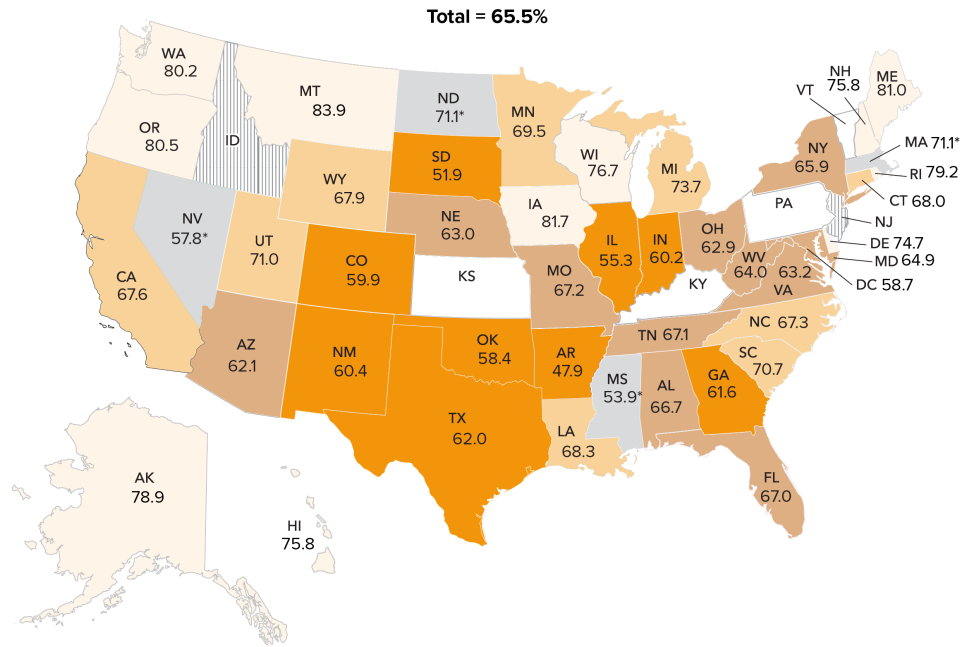

*Note.* Data for the year 2019 are preliminary and based on deaths reported to CDC as of December 2020. See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

During 2019, 76.0% of 925,077 persons had at least 1 CD4 or viral load test (i.e., received any HIV medical care in 2019), and 73.2% had at least 1 viral load test. At the most recent viral load test during 2019, viral load was suppressed in 86.2% of persons who received any HIV medical care (at least 1 CD4 or viral load test) in 2019 and 89.5% of persons with at least 1 viral load test (Table 4a).

Persons with suppressed viral load at the most recent viral load test represented 65.5% of the total number of persons with an HIV diagnosis by year-end 2018 and alive at year-end 2019 in the 45 jurisdictions (Table 4a). Eleven states (Alaska, Delaware, Hawaii, Iowa, Maine, Montana, New Hampshire, Oregon, Rhode Island, Washington, and Wisconsin) in the top 25% had the highest percentages (≥73.8) of persons with viral suppression at the most recent viral load test during 2019. Eleven states (Arkansas, Colorado, Georgia, Illinois, Indiana, Mississippi, Nevada, New Mexico, Oklahoma, South Dakota, and Texas) and the District of Columbia were in the lowest 25% and had the lowest percentages (≤62.0) of persons with viral suppression at the most recent viral load test during 2019 (Table 4b, Figure 9). Please note that due to incomplete reporting of deaths for the year 2019, data for Massachusetts, Mississippi, North Dakota, and Nevada should be interpreted with caution.

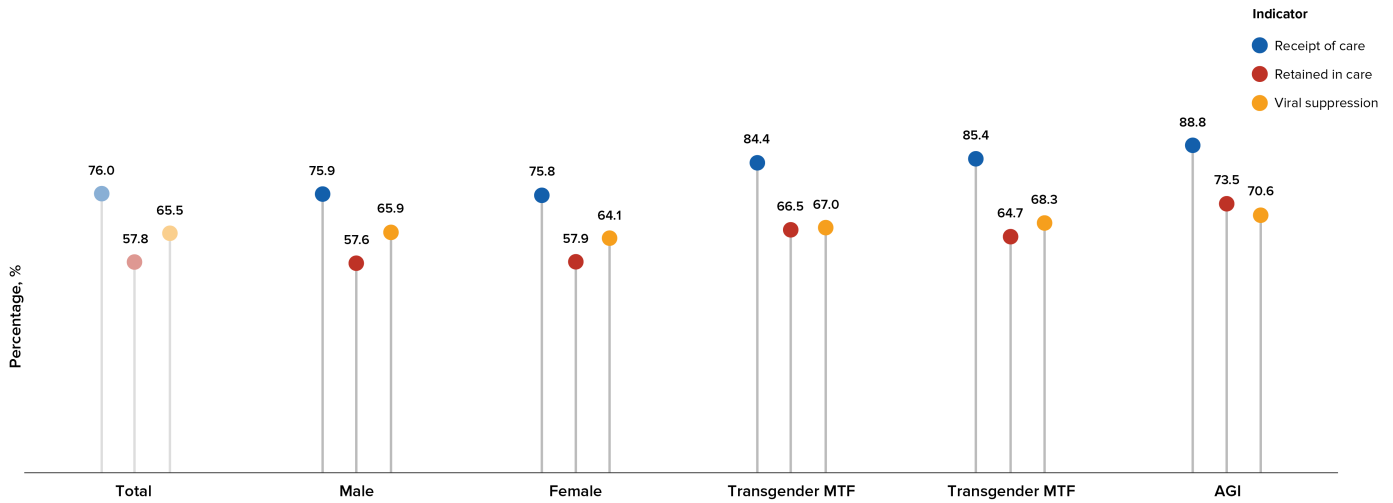

**Figure 9. Viral suppression among persons aged ≥13 years living with diagnosed HIV infection, by area of residence, 2019—44 states and the District of Columbia**

*Note.* Data for the year 2019 are preliminary and based on deaths reported to CDC as of December 2020. See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

The following percentages are for persons living with diagnosed HIV by year-end 2019 in the 45 jurisdictions with complete laboratory reporting who received any HIV medical care, were retained in HIV medical care, or had a most recent viral load test result in 2019 that indicated viral suppression. By gender, the highest percentage for persons who received any HIV medical care was for persons of AGI (88.8%) and the lowest percentage was for females (75.8%). The highest percentage for persons retained in HIV medical care was for persons of AGI (73.5%) and the lowest percentage was for males (57.6%). The highest percentage for persons who were virally suppressed at the most recent viral load test was for transgender FTM persons (70.6%) and the lowest percentage was for females (64.1%) (Tables 3a and 4a, Figure 10).

**Figure 10. Receipt of HIV medical care, retention in HIV medical care, and viral suppression among persons aged ≥13 years living with diagnosed HIV infection, by gender, 2019—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

By age, the highest percentage for persons who received any HIV medical care was for persons aged 13–24 years (80.0%) and the lowest percentage was for persons aged ≥55 years (74.8%). The highest percentage for persons retained in HIV medical care was for persons aged ≥55 years (59.5%) and the lowest percentage was for persons aged 35–44 years (55.5%). The highest percentage for persons who were virally suppressed at the most recent viral load test was for persons aged ≥55 years (67.3%) and the lowest percentage was for persons aged 25–34 years (62.6%) (Tables 3a and 4a, Figure 11).

**Figure 11. Receipt of HIV medical care, retention in HIV medical care, and viral suppression among persons aged ≥13 years living with diagnosed HIV infection, by age, 2019—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

By race/ethnicity, the highest percentage for persons who received any HIV medical care was for multiracial persons (86.3%) and the lowest percentages were for Native Hawaiian or other Pacific Islander (73.9%) and Black or African American persons (73.7%). The highest percentage for persons retained in HIV medical care was for multiracial persons (65.9%) and the lowest percentage was for Native Hawaiian or other Pacific Islander

persons (52.9%). The highest percentage for persons who were virally suppressed at the most recent viral load test was for multiracial persons (73.2%) and the lowest percentage was for Black or African American persons (60.8%) (Tables 3a and 4a, Figure 12).

**Figure 12. Receipt of HIV medical care, retention in HIV medical care, and viral suppression among persons aged ≥13 years living with diagnosed HIV infection, by race/ethnicity, 2019—44 states and the District of Columbia**

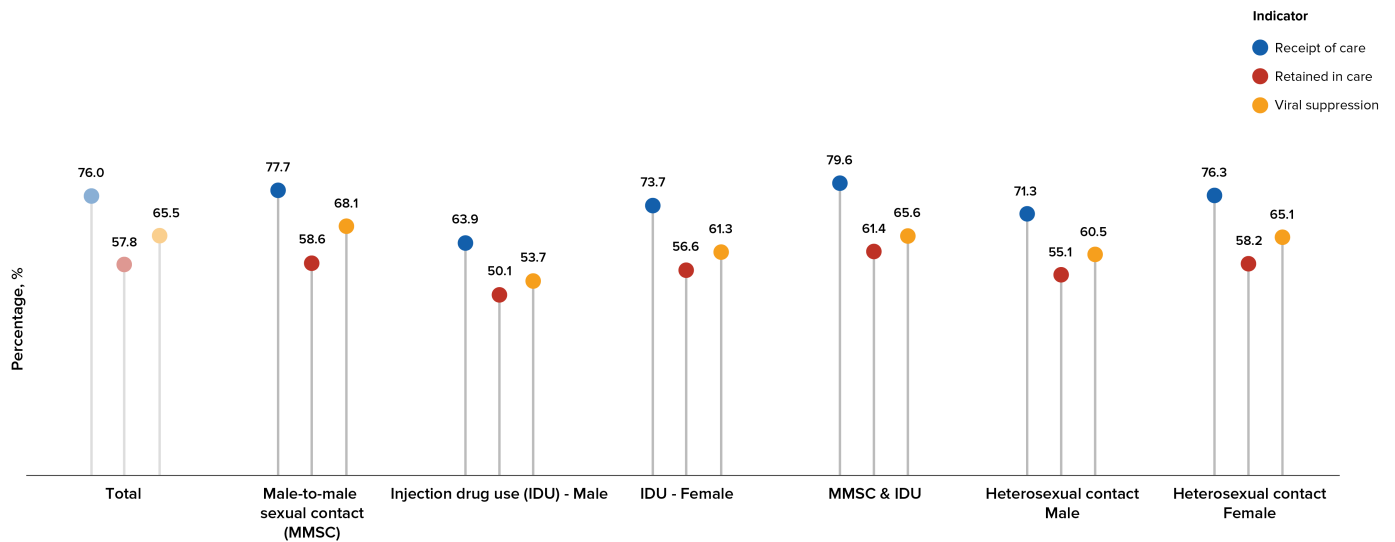

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Includes Asian/Pacific Islander legacy cases.

<sup>b</sup> Hispanic/Latino persons can be of any race.

By transmission category, the highest percentage for persons who received any HIV medical care was for males with infection attributed to MMSC-IDU (79.6%) and the lowest percentage was for males with infection attributed to IDU (63.9%). The highest percentage for persons retained in HIV medical care was for males with infection attributed to MMSC-IDU (61.4%) and the lowest percentage was for males with infection attributed to IDU (50.1%). The highest percentage for persons who were virally suppressed at the most recent viral load test was for males with infection attributed to MMSC (68.1%) and the lowest percentage was for males with infection attributed to IDU (53.7%) (Tables 3a and 4a, Figure 13).

**Figure 13. Receipt of HIV medical care, retention in HIV medical care, and viral suppression among persons aged  $\geq 13$  years living with diagnosed HIV infection, by transmission category, 2019—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

A closer look at viral suppression at the most recent viral load test reveals that among 925,077 persons aged  $\geq 13$  years living with diagnosed HIV infection at year-end 2019 in the 45 jurisdictions with complete laboratory reporting, no demographic group or group with infection attributed to any of the transmission categories met the forthcoming EHE target of 95% (Figure 14).

**Figure 14. Viral suppression among persons aged ≥13 years living with diagnosed HIV infection, by selected characteristics, 2019—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Includes Asian/Pacific Islander legacy cases.

<sup>b</sup> Hispanic/Latino persons can be of any race.

## PREVALENCE-BASED HIV CARE CONTINUUM—OVERVIEW

The Prevalence-based HIV Care Continuum describes each step of the continuum as a percentage of the total number of people living with HIV (diagnosed or undiagnosed). The denominator is the estimated number of persons aged ≥13 years living with diagnosed or undiagnosed HIV infection at year-end 2019 (calculated using the first CD4 test after HIV diagnosis and a CD4 depletion model indicating disease progression). The numerator is extrapolated from the 45 jurisdictions with complete CD4 and viral load reporting (apply the percentage from 45 jurisdictions to the total number of people living with diagnosed HIV in the United States). For more information on Definitions and Data Specifications, see Technical Notes.

Uses of the prevalence-based continuum include monitoring testing efforts in the United States and demonstrating the importance of diagnosing HIV infections to achieve viral suppression, monitoring how the United States is doing among all persons living with HIV, and comparing United States data to other countries who monitor the continuum among all persons living with HIV.

Among the estimated 1.2 million people living with HIV in the United States, 87% received a diagnosis, 66% received HIV medical care in 2019, 50% were retained in HIV medical care, and 57% were virally suppressed (Table 5, Figure 15).

**Figure 15. Prevalence-based HIV care continuum for persons aged  $\geq 13$  years living with HIV infection (diagnosed or undiagnosed) at year-end 2019—United States**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

Among persons living with HIV in the United States, a higher percentage of females received a diagnosis, received HIV medical care in 2019, were retained in HIV medical care, and were virally suppressed than males (Table 5, Figure 16).

**Figure 16. Prevalence-based HIV care continuum for persons aged  $\geq 13$  years living with HIV infection (diagnosed or undiagnosed) at year-end 2019, by sex at birth—United States**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

Among persons living with HIV in the United States, a higher percentage of persons aged  $\geq 55$  years received a diagnosis than other age groups, a higher percentage of persons aged  $\geq 45$  years received HIV medical care in 2019 than other age groups, a higher percentage of persons aged  $\geq 55$  years were retained in HIV medical care than other age groups, and a higher percentage of persons aged  $\geq 55$  years were virally suppressed than persons in other age groups. A lower percentage of persons aged 13–24 years received a diagnosis, received HIV medical care in 2019, were retained in HIV medical care, and were virally suppressed than other age groups (Table 5, Figure 17).

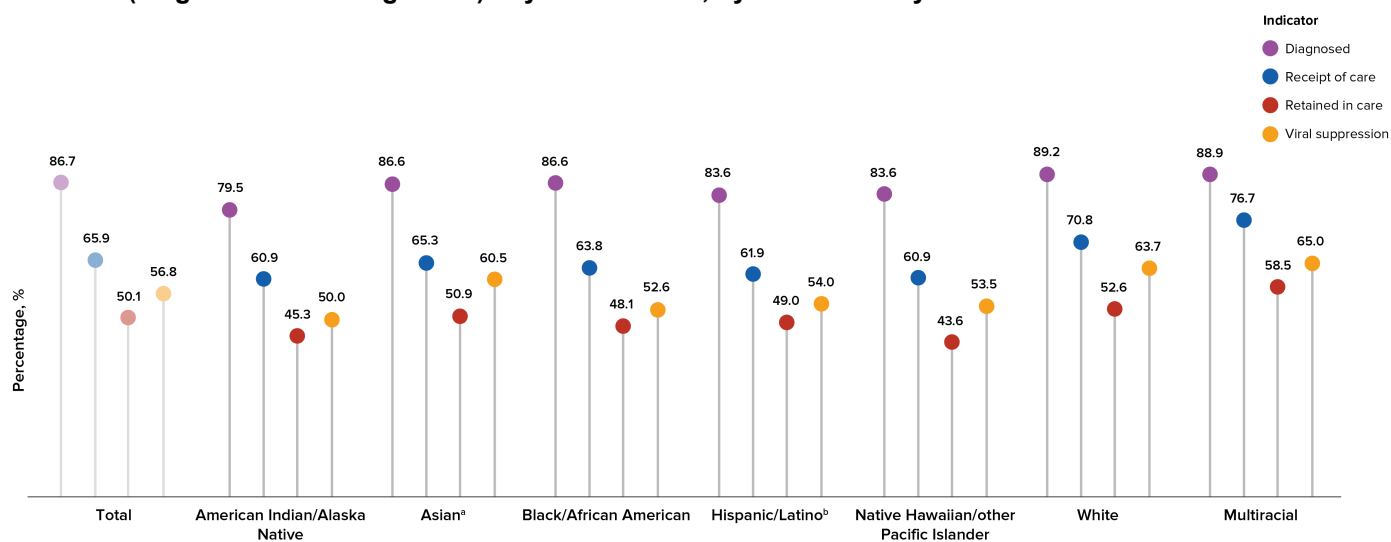

**Figure 17. Prevalence-based HIV care continuum for persons aged ≥13 years living with HIV infection (diagnosed or undiagnosed) at year-end 2019, by age—United States**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

Among persons living with HIV in the United States, higher percentages of White and multiracial persons received a diagnosis than other racial/ethnic groups, a higher percentage of multiracial persons received HIV medical care in 2019 than other racial/ethnic groups, a higher percentage of multiracial persons were retained in HIV medical care than other racial/ethnic groups, and higher percentages of multiracial and White persons were virally suppressed than other racial/ethnic groups. A lower percentage of American Indian/Alaska Native persons received a diagnosis, lower percentages of American Indian or Alaska Native and Native Hawaiian or other Pacific Islander persons received HIV medical care in 2019 than other racial/ethnic groups, lower percentages of Native Hawaiian or other Pacific Islander and American Indian or Alaska Native persons were retained in HIV medical care than other racial/ethnic groups, and a lower percentage of American Indian or Alaska Native persons were virally suppressed than other racial/ethnic groups (Table 5, Figure 18).

**Figure 18. Prevalence-based HIV care continuum for persons aged ≥13 years living with HIV infection (diagnosed or undiagnosed) at year-end 2019, by race/ethnicity—United States**

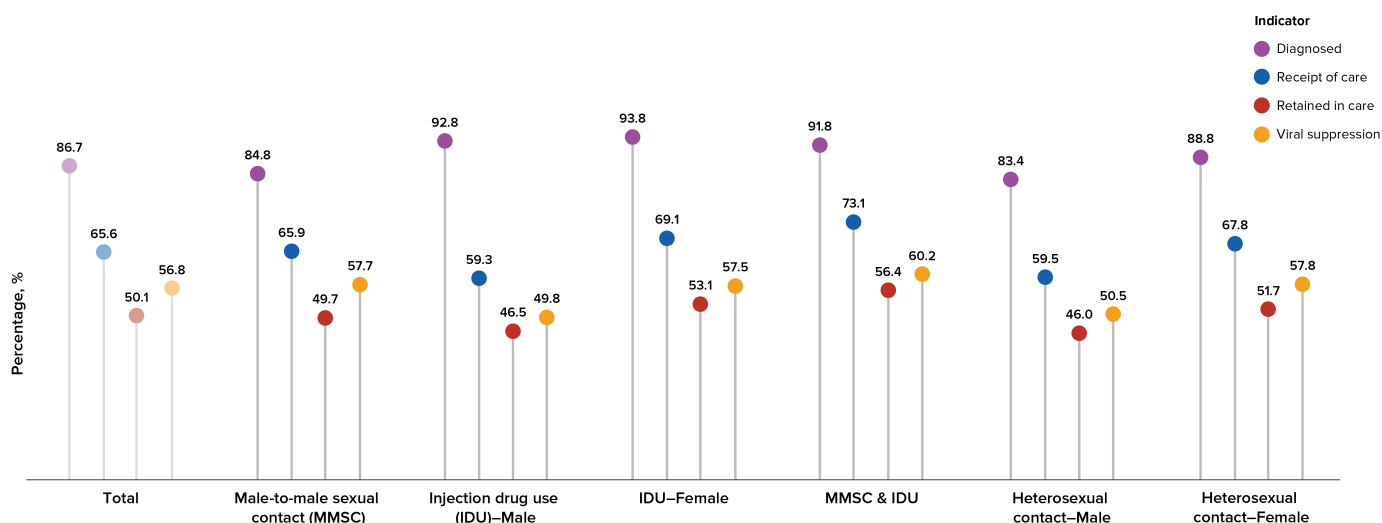

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Includes Asian/Pacific Islander legacy cases.

<sup>b</sup> Hispanic/Latino persons can be of any race.

Among persons living with HIV in the United States, a higher percentage of persons (females and males) with infection attributed to IDU received a diagnosis than persons with infection attributed to other transmission categories, a higher percentage of males with infection attributed to MMSC-IDU received HIV medical care in 2019 than persons with infection attributed to other transmission categories, a higher percentage of males with infection attributed to MMSC-IDU were retained in HIV medical care than persons with infection attributed to other transmission categories, and higher percentages of males with infection attributed to MMSC and females with infection attributed to heterosexual contact were virally suppressed than persons with infection attributed to other transmission categories. A lower percentage of males with infection attributed to heterosexual contact received a diagnosis than persons with infection attributed to other transmission categories, a lower percentage of males with infection attributed to heterosexual contact received HIV medical care in 2019 than persons with infection attributed to other transmission categories, lower percentages of males with infection attributed to heterosexual contact and males with infection attributed to IDU were retained in HIV medical care, and lower percentages of males with infection attributed to heterosexual contact and males with infection attributed to IDU were virally suppressed than persons with infection attributed to other transmission categories (Table 5, Figure 19).

**Figure 19. Prevalence-based HIV care continuum for persons aged ≥13 years living with HIV infection (diagnosed or undiagnosed) at year-end 2019, by transmission category—United States**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

## STAGE 3 (AIDS) AT TIME OF DIAGNOSIS OF HIV INFECTION, AND DEATH AND SURVIVAL AFTER DIAGNOSIS OF HIV INFECTION

Data from the 50 states, the District of Columbia, and 6 U.S. dependent areas (where indicated) were used for analyses of stage 3 (AIDS) at the time of diagnosis of HIV infection (even when not all CD4 values are reportable), and deaths and survival of persons with diagnosed HIV infection ≥13 years of age.

### Stage 3 (AIDS) classification at time of diagnosis of HIV infection

From 2015 through 2019, the percentage of stage 3 (AIDS) classifications or late-stage diagnoses varied among persons with an HIV diagnosis in each area of residence or subgroup in the United States (Table 6a). The percentage of stage 3 (AIDS) classifications decreased overall and in metropolitan and urban areas from 2015 through 2019 (Figure 20). The percentage of stage 3 (AIDS) classifications remained stable among persons liv-

ing in rural areas. In 2019, the highest percentage was 25.2% in rural areas, followed by 22.0% in urban and 19.8% in metropolitan areas.

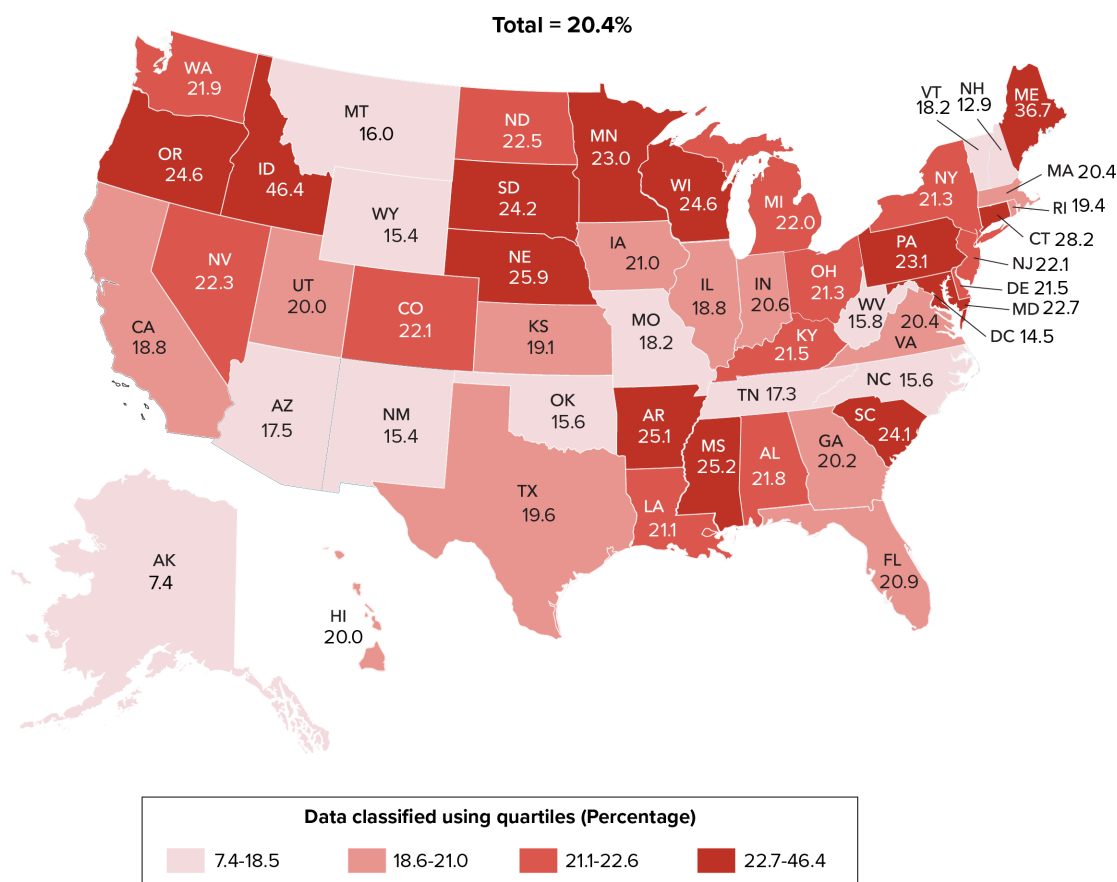

**Figure 20. Stage 3 (AIDS) at time of diagnosis of HIV infection among persons aged ≥13 years, by year of diagnosis and population area of residence, 2015–2019—United States**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

In the United States and 6 dependent areas, more than one in five persons (20.4%) received a late-stage diagnosis (stage 3, AIDS) among 36,740 persons with an HIV diagnosis during 2019. The percentages of a late-stage diagnosis were highest in the dependent areas (25.1%) and the Northeast (22.0%) compared to other regions (Table 6b). During 2019, 13 states (Arkansas, Connecticut, Idaho, Maine, Maryland, Minnesota, Mississippi, Nebraska, Oregon, Pennsylvania, South Carolina, South Dakota, and Wisconsin) in the highest 25% had the highest percentages ( $\geq 22.7$ ) of persons who received a late-stage diagnosis. Twelve states (Alaska, Arizona, Missouri, Montana, New Hampshire, New Mexico, North Carolina, Oklahoma, Tennessee, Vermont, West Virginia, and Wyoming) and the District of Columbia were in the lowest 25% and had the lowest percentages ( $\leq 18.5$ ) of persons who received a late-stage diagnosis (Table 6c, Figure 21).

**Figure 21. Stage 3 (AIDS) at time of diagnosis of HIV infection among persons aged ≥13 years, by area of residence, 2019—United States**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

In 2019, the highest percentages of a late-stage diagnosis in the United States and 6 dependent areas by selected characteristics (i.e., gender, age, race/ethnicity, and transmission category) were for females (20.7%), males (20.5%), persons aged ≥45 years at time of diagnosis (45–54 years: 31.9%; ≥55 years: 34.5%), Asian persons (24.9%), and males with infection attributed to heterosexual contact (33.4%) (Table 6a, Figure 22). Please use caution when interpreting data for persons of AGI, transgender FTM persons, and Native Hawaiian/other Pacific Islander persons: the numbers are small.

**Figure 22. Stage 3 (AIDS) at time of diagnosis of HIV infection among persons aged ≥13 years, by selected characteristics, 2019—United States**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

## DEATHS

Annual rates of death among adults and adolescents aged ≥13 years were calculated per 100,000 population and per 1,000 persons with diagnosed HIV infection or with infection ever classified as stage 3 (AIDS). Age-adjusted rates per 100,000 population and per 1,000 persons with diagnosed HIV infection or with infection ever classified as stage 3 (AIDS) were also calculated and are presented by area of residence.

### Deaths of persons with diagnosed HIV infection

From 2015 through 2019 in the United States and 6 dependent areas, the annual rate of deaths per 100,000 population and the annual rate per 1,000 persons with diagnosed HIV infection decreased (Table 7b). Trends in rates varied by area of residence at death (Table 7c). In 2019, the age-adjusted rates were 5.2 per 100,000 population and 12.1 per 1,000 persons with diagnosed HIV infection.

During 2019, 12 states (Alabama, Arkansas, Delaware, Iowa, Louisiana, Maine, Missouri, Ohio, Oklahoma, South Carolina, Tennessee, and West Virginia) in the highest 25% had the highest age-adjusted rates of death (≥14.0) per 1,000 persons with diagnosed HIV infection. Twelve states (Colorado, Idaho, Kansas, Massachusetts, Minnesota, Montana, Nevada, New Hampshire, North Dakota, South Dakota, Utah, and Vermont) and the District of Columbia were in the lowest 25% and had the lowest age-adjusted rates of death (≤9.9)

per 1,000 persons with diagnosed HIV infection (Table 7c, Figure 23). Please note that due to incomplete reporting of deaths for the year 2019, data for Kansas, Massachusetts, Mississippi, Nevada, North Dakota, and Vermont should be interpreted with caution.

**Figure 23. Age-adjusted rates of death among persons aged ≥13 years with diagnosed HIV infection, by year of death and area of residence, 2019—United States**

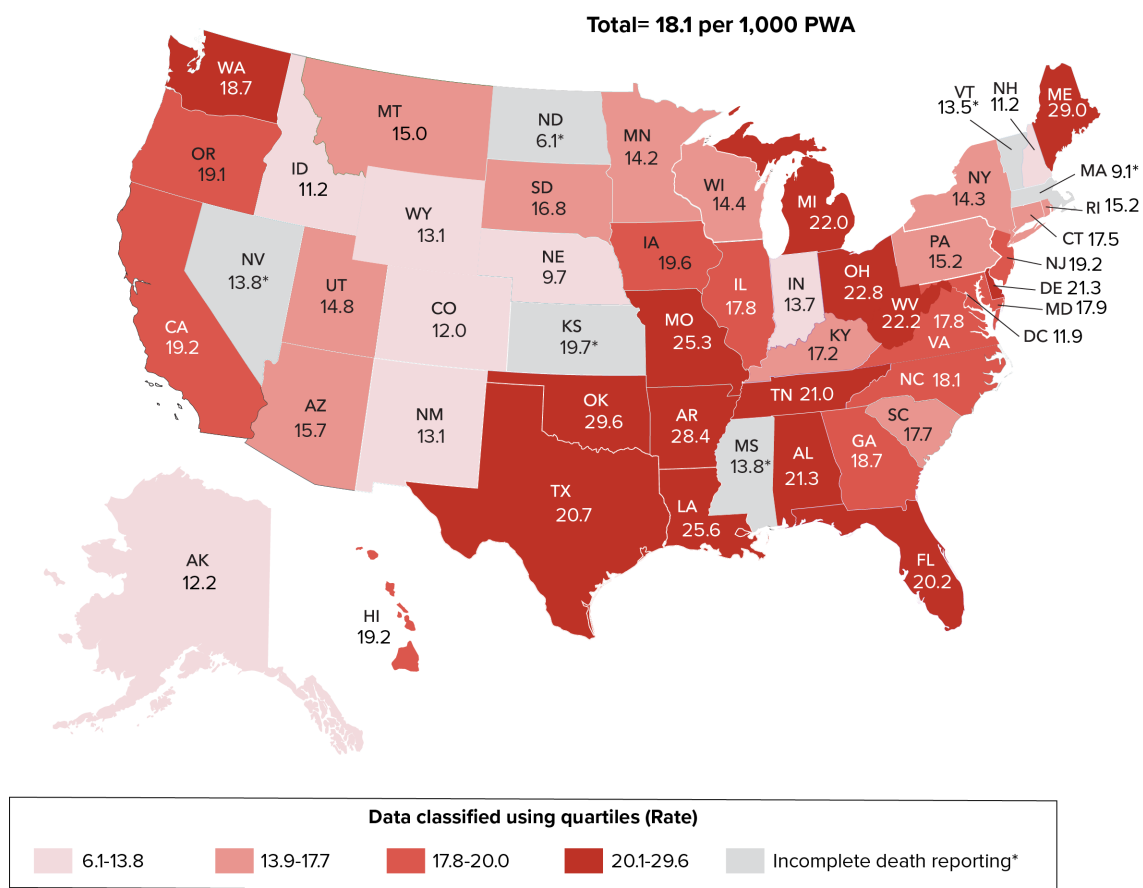

*Note.* Data for the year 2019 are preliminary and based on deaths reported to CDC as of December 2020. See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

### Deaths of persons with stage 3 (AIDS) classification

From 2015 through 2019 in the United States and 6 dependent areas, the annual rate of deaths per 100,000 population and the annual rate per 1,000 persons with stage 3 (AIDS) decreased (Table 7e). Trends in rates varied by area of residence at death (Table 7f). In 2019, the age-adjusted rates were 4.0 per 100,000 population and 18.1 per 1,000 persons with stage 3 (AIDS).

During 2019, 13 states (Alabama, Arkansas, Delaware, Florida, Louisiana, Maine, Michigan, Missouri, Ohio, Oklahoma, Tennessee, Texas, and West Virginia) in the highest 25% had the highest age-adjusted rates of deaths ( $\geq 20.8$ ) per 1,000 persons with diagnosed HIV infection ever classified as Stage 3 (AIDS). Twelve states (Alaska, Colorado, Idaho, Indiana, Massachusetts, Mississippi, Nebraska, New Hampshire, New Mexico, North Dakota, Vermont, and Wyoming) and the District of Columbia were in the lowest 25% and had the lowest age-adjusted rates of deaths ( $\leq 13.7$ ) per 1,000 persons with diagnosed HIV infection ever classified as Stage 3 (AIDS) (Table 7f, Figure 24). Please note that due to incomplete reporting of deaths for the year 2019, data for Kansas, Massachusetts, Mississippi, Nevada, North Dakota, and Vermont should be interpreted with caution.

**Figure 24. Age-adjusted rates of death among persons aged ≥13 years with diagnosed HIV infection ever classified as stage 3 (AIDS), by year of death and area of residence, 2019—United States**

*Note.* Data for the year 2019 are preliminary and based on deaths reported to CDC as of December 2020. See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

### Survival for >3 years after diagnosis of HIV infection

In the United States, survival for >3 years after a diagnosis of HIV infection was above 94% and remained stable for diagnoses that were made during 2011–2016 (Table 8a). The following percentages are for persons in the United States who survived >3 years after receiving a diagnosis in 2016 (Figure 25).

By gender, the highest percentage was for transgender MTF persons (96%), followed by males (95%) and females (94%). Percentages for transgender FTM persons and persons of AGI are not displayed because the number of cases were too small for the calculation of reliable survival estimates.

By age, the highest percentage was for persons aged 13–24 years (99%) and the lowest percentage was for persons aged ≥55 years (83%).

By race/ethnicity, the highest percentages were for Asian and Hispanic or Latino persons (96%), followed by American Indian or Alaska Native (95%), Black or African American (95%), multiracial (94%), and White persons (93%). Percentages for Native Hawaiian or other Pacific Islander persons are not displayed because the number of cases was too small for the calculation of reliable survival estimates.

By transmission category, the highest percentage was for males with infection attributed to MMSC (96%), followed by females with infection attributed to heterosexual contact (95%) and males with infection attributed to MMSC-IDU (94%). The lowest percentages were for males and females with infection attributed to IDU (86%, 89% respectively).

By area of residence, at least 93% of persons survived >3 years after diagnosis in all but 1 area (Table 8c).

**Figure 25. Survival for >3 years after a diagnosis of HIV infection during 2016, by selected characteristics—United States**

*Note.* Asterisk (\*) indicates sample too small (<600 diagnoses during the 6-year period) for the calculation of meaningful survival estimates. See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

Survival for >3 years after stage 3 (AIDS) classification was below 90% and remained stable over time (Table 8d). The following percentages are for persons who survived >3 years after receiving a stage 3 (AIDS) classification in 2016.

By gender, the highest percentage was for transgender MTF persons (92%). The lowest percentages were for males and females (86%). Percentages for transgender FTM persons and persons of AGI are not displayed because the number of cases were too small for the calculation of reliable survival estimates.

By age, the highest percentage was for persons aged 13–24 years (96%) and the lowest percentage was for persons aged ≥55 years (71%).

By race/ethnicity, the highest percentage was for Hispanic or Latino persons (90%), followed by Asian (89%), Black or African American (86%), and multiracial persons (84%). The lowest percentage was for White persons (82%). Data for American Indian or Alaska Native and Native Hawaiian or other Pacific Islander persons are not displayed because the numbers of cases were too small for the calculation of reliable survival estimates.

By transmission category, the highest percentage was for males with infection attributed to MMSC (88%), followed by females with infection attributed to heterosexual contact (87%), males with infection attributed to

MMSC-IDU (84%), and males with infection attributed to heterosexual contact (83%). The lowest percentages were for males and females with infection attributed to IDU (74%, 79% respectively).

By area of residence, at least 83% of persons survived >3 years after stage 3 (AIDS) classification in all but 1 area (Table 8f).

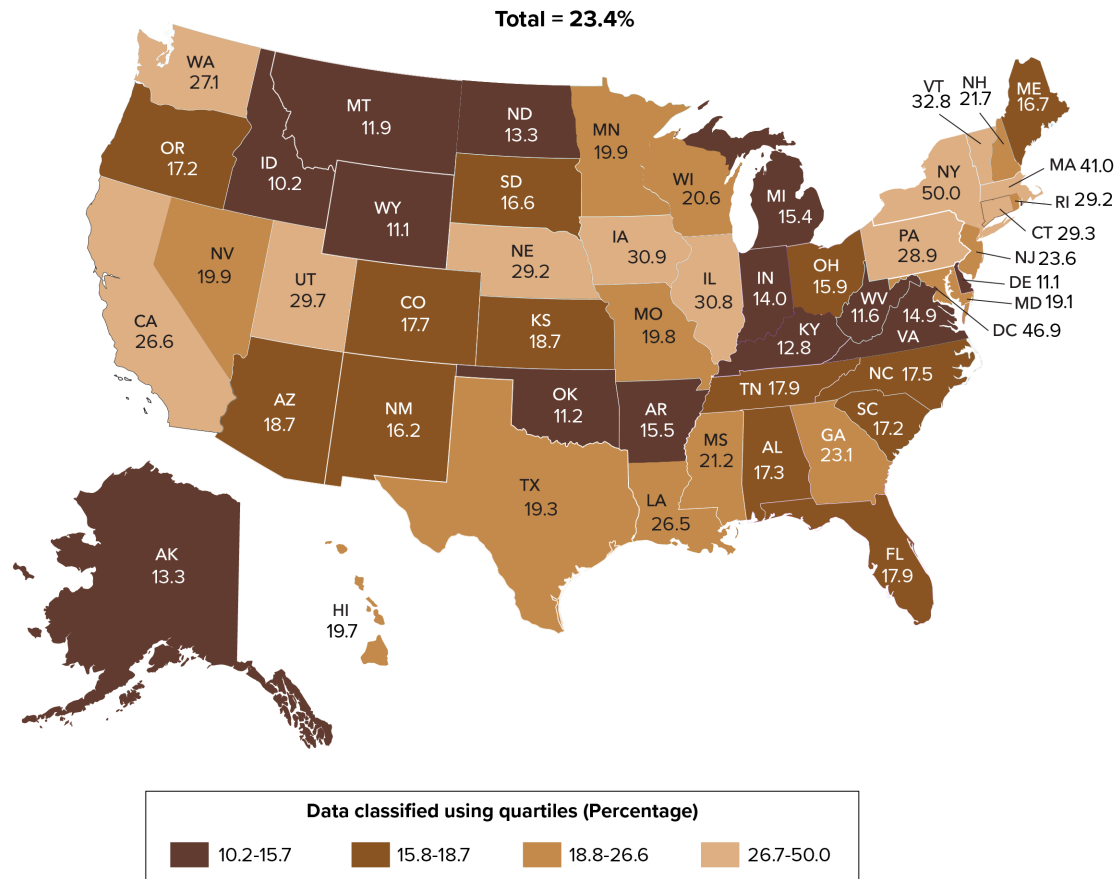

## **PREEXPOSURE PROPHYLAXIS (PREP) COVERAGE AND PERSONS PRESCRIBED PREP**

The number of persons classified as having been prescribed PrEP, the estimated number of persons with PrEP indications, and PrEP coverage in the United States were produced using data from several sources: the IQVIA Real-World Longitudinal Prescriptions database, NHSS, National Health and Nutrition Examination Survey (NHANES), and the U.S. Census American Community Survey (ACS). For more information, see Technical Notes.

By using the pharmacy and other national data sources, we estimated 1.2 million persons in the United States had indications for PrEP and 23.4% were prescribed PrEP in 2019 (Table 9a).

PrEP coverage varied by area of residence. Twelve states (California, Connecticut, Illinois, Iowa, Massachusetts, Nebraska, New York, Pennsylvania, Rhode Island, Utah, Vermont, and Washington) and the District of Columbia were in the top 25% and had the highest percentages ( $\geq 26.7\%$ ) of PrEP coverage. Thirteen states (Alaska, Arkansas, Delaware, Idaho, Indiana, Kentucky, Michigan, Montana, North Dakota, Oklahoma, Virginia, West Virginia, and Wyoming) in the lowest 25% had the lowest percentages ( $\leq 15.7\%$ ) of PrEP coverage (Table 9a, Figure 26).

**Figure 26. PrEP coverage among persons aged ≥16 years, by area of residence, 2019—United States and Puerto Rico**

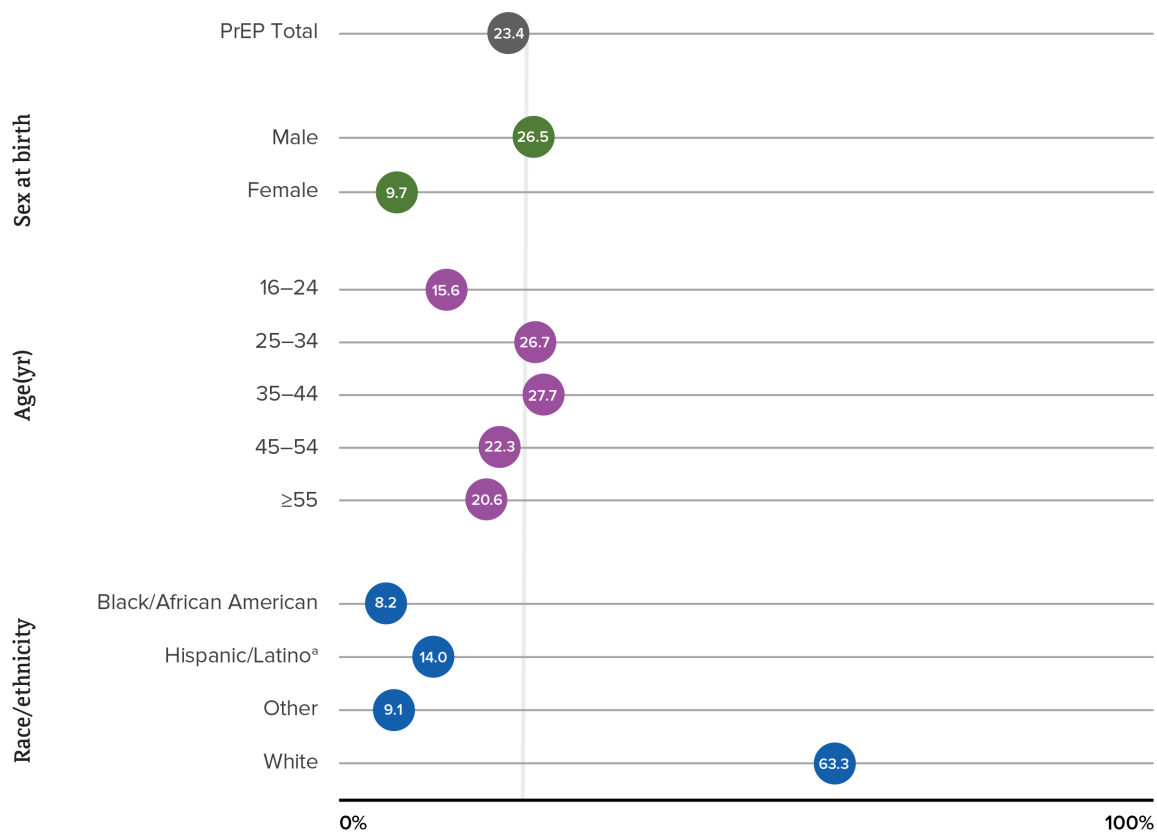

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

PrEP coverage was nearly three times as high among males (26.5%) as among females (9.7%). The highest percentages of PrEP coverage were for persons aged 25–44 years (25–34 years: 26.7%; 35–44 years: 27.7%). The lowest percentage was for persons aged 16–24 years (15.6%). In 2019, after adjusting for missing race/ethnicity, the highest percentage was for White persons (63.3%), followed by Hispanic or Latino (14.0%) and Black or African American persons (8.2%) (Figure 27).

**Figure 27. PrEP coverage among persons aged ≥16 years, by selected characteristics, 2019—United States**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

# Special Focus Profiles

The Special Focus Profiles highlight the distribution of the diagnosis-based HIV care outcomes and identify potential gaps in these outcomes among 6 populations of interest to HIV prevention programs in state and local health departments: (1) Gay, Bisexual, and Other Men Who Have Sex With Men (MSM), (2) Persons Who Inject Drugs (PWID), (3) Transgender Persons, (4) Women, (5) Persons with Perinatally Acquired HIV Infection, and (6) Young Persons [aged 13–24 years].

## GAY, BISEXUAL, AND OTHER MEN WHO HAVE SEX WITH MEN

Gay, bisexual, and other men who have sexual contact with men (MSM) are most affected by HIV in the United States. Stigma, homophobia, and discrimination make MSM of all races/ethnicities susceptible to multiple physical and mental health problems and can affect whether they seek and receive high-quality health services, including HIV testing, treatment, and other prevention services. In 2019, MSM accounted for 65.4% (24,084 MMSC not including persons with infection attributed to MMSC-IDU) of the 36,801 HIV diagnoses in the United States and 6 dependent areas. Many Black or African American and Hispanic or Latino MSM with HIV, particularly young MSM, are unaware of their HIV infection. Lack of awareness of HIV status among young MSM may be due to recent infection, not getting tested due to underestimation of personal risk or stigma (e.g., homophobia), or fewer opportunities to get tested. Persons who do not know they have HIV do not get medical care or receive treatment and can unknowingly infect others.

Among MSM with HIV infection diagnosed during 2019 in 45 jurisdictions with complete laboratory reporting, stage of disease at diagnosis varied with 66.5% of infections diagnosed at an earlier stage (stage 0, 1, or 2) and 18.7% classified as stage 3 (AIDS) at the time of diagnosis (Table 1a). Moreover, 82.1% of MSM were linked to HIV medical care within 1 month of diagnosis and 69.8% were virally suppressed within 6 months of diagnosis (Table 2a). Of 528,606 persons with infection attributed to MMSC living with diagnosed HIV in the 45 jurisdictions at year-end 2019, 77.7% received HIV medical care, 58.6% were retained in HIV medical care, and 68.1% were virally suppressed at the most recent viral load test (Tables 3a and 4a).

HIV care outcomes varied among MSM by race/ethnicity. For MSM of all racial/ethnic groups,  $\geq 63.2\%$  of infections were diagnosed at an earlier stage (Table 1c, Figure 28). Yet, Asian (23.4%), White (21.1%), and Hispanic or Latino MSM (19.7%) had  $\geq 20\%$  of infections classified as stage 3 (AIDS) at the time of diagnosis. Among Asian, White, and Hispanic or Latino MSM, infections classified as stage 3 (AIDS) increased with age at the time of diagnosis (Table 1d).

**Figure 28. Earlier and late stage of disease at HIV diagnosis during 2019 among men who have sex with men, by race/ethnicity—44 states and the District of Columbia**

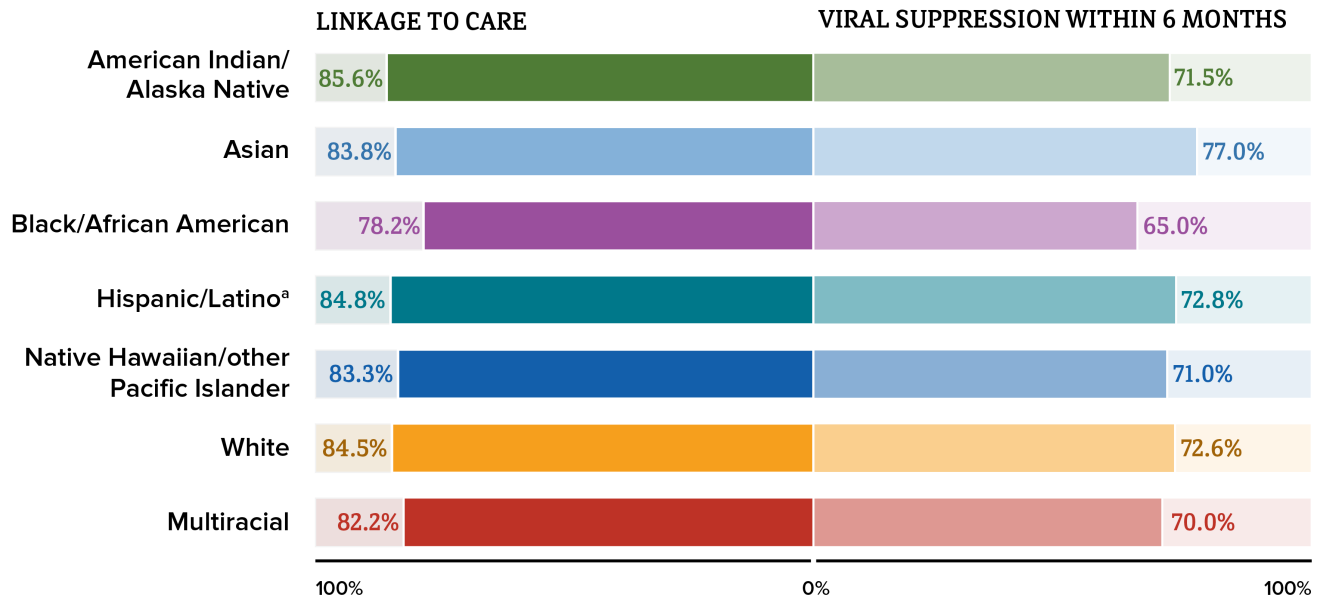

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

The highest percentage for MSM by race/ethnicity who were linked to care within 1 month of diagnosis was for American Indian or Alaska Native persons (85.6%) and the lowest percentage linked to care within 1 month of diagnosis was for Black or African American persons (78.2%) (Table 2c, Figure 29). Among Black or African American MSM, persons aged 13–34 years had the lowest percentages linked to care within 1 month of diagnosis (13–24 years: 77.4%, 25–34 years: 77.5%; Table 2d). The highest percentage for MSM by race/ethnicity who were virally suppressed within 6 months of diagnosis was for Asian persons (77.0%) and the lowest percentage for viral suppression within 6 months of diagnosis was for Black or African American persons (65.0%) (Table 2c, Figure 29). Among Black or African American MSM, persons aged 25–34 years and persons aged ≥55 years had the lowest percentages for viral suppression within 6 months of diagnosis (25–34 years: 63.8%, ≥55 years: 63.7%; Table 2d).

**Figure 29. Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among men who have sex with men, by race/ethnicity—44 states and the District of Columbia**

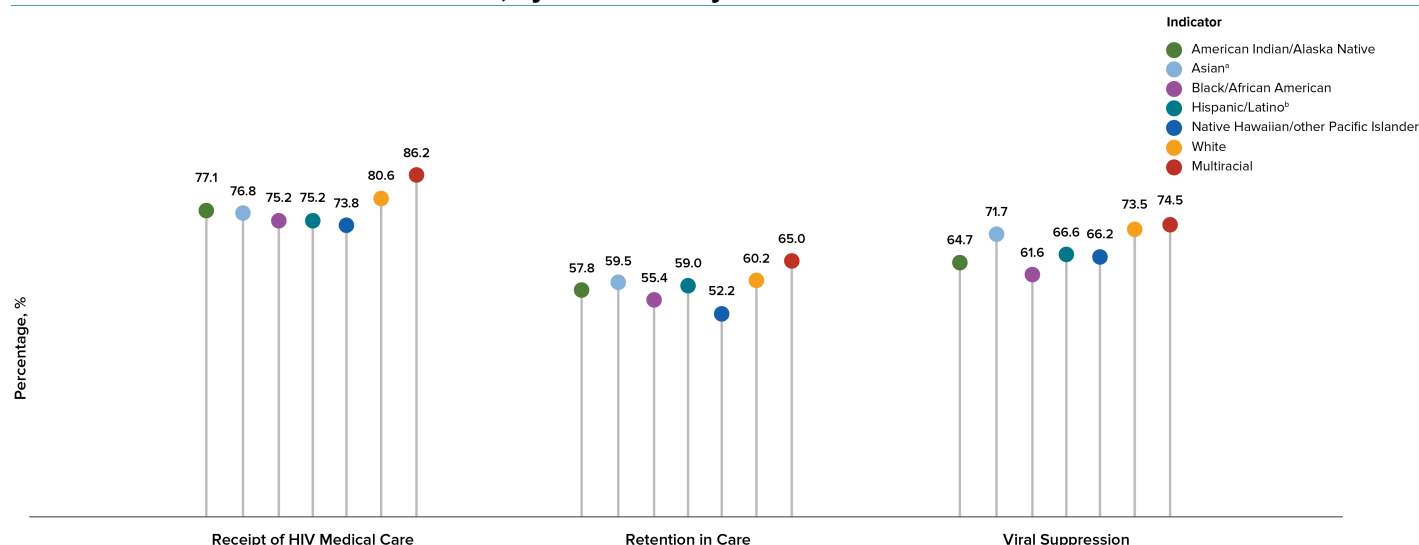

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

The highest percentage for MSM by race/ethnicity who received any HIV medical care was for multiracial persons (86.2%) and the lowest percentage was for Native Hawaiian or other Pacific Islander persons (73.8%) (Table 3c, Figure 30). Among Native Hawaiian or other Pacific Islander MSM, persons aged 13–24 years had the lowest percentage who received any HIV medical care (68.0%) (Table 3d). The highest percentage for MSM by race/ethnicity who were retained in HIV medical care was for multiracial persons (65.0%) and the lowest percentage was for Native Hawaiian or other Pacific Islander persons (52.2%). Among Native Hawaiian or other Pacific Islander MSM, persons aged 35–44 years had the lowest percentage retained in HIV medical care (47.5%) (Table 3d). The highest percentage for MSM by race/ethnicity who were virally suppressed at the most recent viral load test was for multiracial persons (74.5%) and the lowest percentage was for Black or African American persons (61.6%) (Table 3c, Figure 30). Among Black or African American MSM, persons aged 25–34 years had the lowest percentage for viral suppression (59.6%) (Table 3d).

**Figure 30. Receipt of HIV medical care, retention in HIV medical care, and viral suppression during 2019 among men who have sex with men, by race/ethnicity—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Includes Asian/Pacific Islander legacy cases.

<sup>b</sup> Hispanic/Latino persons can be of any race.

## PERSONS WHO INJECT DRUGS

Persons who inject drugs (PWID) can get HIV if they use and share needles, syringes, or other drug injection equipment (e.g., cookers) that someone with HIV has used. PWID account for about 1 in 15 HIV diagnoses in the United States. In recent years, the opioid (including prescription and synthetic opioids) and heroin crisis has led to increased numbers of PWID. HIV diagnoses among PWID have increased in the 50 states and District of Columbia. IDU in rural areas has created prevention challenges and placed new populations at risk for HIV.

Among PWID with HIV infection diagnosed during 2019 in 45 jurisdictions with complete laboratory reporting, stage of disease at diagnosis varied by selected characteristics. Overall, 58.2% of infections were diagnosed at an earlier stage (stage 0, 1, or 2) and 22.0% were classified as stage 3 (AIDS) at the time of diagnosis (Table 1a). Moreover, the percentage of PWID linked to care within 1 month of diagnosis was 75.4%, and 54.6% were virally suppressed within 6 months of diagnosis (Table 2a). Of 98,290 persons with infection attributed to injection drug use living with diagnosed HIV in the 45 jurisdictions at year-end 2019, 68.0% received HIV medical care, 52.9% were retained in HIV medical care, and 56.9% were virally suppressed at their most recent viral load test (Tables 3a and 4a).

HIV care outcomes varied among PWID by sex at birth and race/ethnicity. Among persons with infection attributed to IDU, by race/ethnicity, American Indian or Alaska Native males (70.8%) and White females (65.7%) had the highest percentages for persons who were diagnosed at an earlier stage and Asian males (39.5%) and African American females (54.0%) had the lowest percentages for persons who were diagnosed at an earlier stage at time of diagnosis (Figure 31). Among males with infection attributed to IDU, by race/ethnicity, all racial/ethnic groups (except American Indian or Alaska Native and Native Hawaiian or other Pacific Islander persons) had over 20% of infections classified as stage 3 (AIDS) at time of diagnosis. Among females with infection attributed to IDU, by race/ethnicity, Asian, Black or African American, and Hispanic or Latino persons had over 20% of infections classified as stage 3 (AIDS) at time of diagnosis (Table 1c, Figure 31).

**Figure 31. Earlier and late stage of disease at HIV diagnosis during 2019 among persons who inject drugs, by sex at birth and race/ethnicity—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

\* No cases were diagnosed among this group.

Among males with infection attributed to IDU, by sex at birth and race/ethnicity,  $\geq 73.7\%$  were linked to care within 1 month of diagnosis and  $\geq 41.0\%$  were virally suppressed within 6 months of diagnosis in 2019. Among females with infection attributed to IDU, by sex at birth and race/ethnicity,  $\geq 67.7\%$  were linked to care within 1 month of diagnosis and  $\geq 40.6\%$  were virally suppressed within 6 months of diagnosis in 2019 (Table 2c, Figure 32).

**Figure 32. Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among persons who inject drugs, by sex at birth and race/ethnicity—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

\* No cases were diagnosed among this group.

The highest percentages by sex at birth and race/ethnicity for PWID who received any HIV medical care were for multiracial persons (males: 86.3%, females: 88.0%) and the lowest percentages were for Hispanic or Latino males (58.9%) and Asian females (61.7%). The highest percentages by sex at birth and race/ethnicity for PWID who were retained in HIV medical care were for multiracial persons (males: 68.5%, females: 69.6%) and the

lowest percentages were for Hispanic or Latino males (48.6%) and Asian females (48.5%). The highest percentages by sex at birth and race/ethnicity for PWID who were virally suppressed at the most recent viral load test were for multiracial persons (males: 72.0%, females: 71.5%) and the lowest percentages were for Hispanic or Latino males (49.8%) and Native Hawaiian or other Pacific Islander females (53.7%) (Table 3c, Figure 33).

**Figure 33. Receipt of HIV medical care, retention in HIV medical care, and viral suppression during 2019 among persons who inject drugs, by sex at birth and race/ethnicity—44 states and the District of Columbia**

Note. See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Includes Asian/Pacific Islander legacy cases.

<sup>b</sup> Hispanic/Latino persons can be of any race.

## TRANSGENDER PERSONS AND PERSONS OF ADDITIONAL GENDER IDENTITY

*Transgender* is an umbrella term that is used to identify persons whose sex assigned at birth does not match current gender identity or expression. *Gender identity* refers to one’s internal understanding of one’s own gender, or the gender with which a person identifies. *Gender expression* is a term used to describe people’s outward presentation of their gender. Gender identity and sexual orientation are different facets of identity. Everyone has a gender identity and a sexual orientation, but a person’s gender does not determine a person’s sexual orientation. Transgender persons and persons of additional gender identity may identify as heterosexual, homosexual, bisexual, or none of the above. Transgender persons and persons of additional gender identity face numerous prevention challenges, including lack of public/provider knowledge about gender identity and transgender issues and social rejection and exclusion (e.g., transphobia or discrimination), and are underreported (e.g., gaps in reporting or limited data availability) or not well-represented in HIV prevention activities (e.g., PrEP and treatment interventions).

Among transgender persons and persons of additional gender identity with HIV infection diagnosed during 2019 in 45 jurisdictions with complete laboratory reporting, stage of disease at diagnosis varied by selected characteristics. Overall, 72.0% of infections were diagnosed at an earlier stage (stage 0, 1, or 2) and 13.6% were classified as stage 3 (AIDS) at the time of diagnosis (Table 1a). Moreover, 83.4% of transgender persons and persons of additional gender identity were linked to HIV medical care within 1 month of diagnosis and 67.2% were virally suppressed within 6 months of diagnosis in 2019 (Table 2a). Of 925,077 persons living with diagnosed HIV in the 45 jurisdictions with complete reporting of laboratory data at year-end 2019, 10,260 (1.1%) were

transgender persons (Table 3a). Of 10,260 transgender persons and persons of additional gender identity living with diagnosed HIV, 84.6% received HIV medical care, 66.6% were retained in HIV medical care, and 67.2% were virally suppressed at their most recent viral load test (Tables 3a and 4a, Figure 34). Please use caution when interpreting data for transgender persons, persons of additional gender identity, and their subpopulations: the numbers are small.

**Figure 34. Receipt of HIV medical care, retention in HIV medical care, and viral suppression during 2019 among transgender persons—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

## WOMEN

Though HIV diagnoses among women have declined in recent years, approximately 7,000 women received an HIV diagnosis in the United States and 6 dependent areas in 2019. One in nine women with HIV are unaware they have it. Because some women may be unaware of their partner's risk factors for HIV (such as injection drug use or having sex with men), they may not use condoms or medicines to prevent HIV.

Among women with HIV infection diagnosed during 2019 in 45 jurisdictions with complete laboratory reporting, stage of disease at diagnosis varied by selected characteristics. Overall, 63.3% of infections were diagnosed at an earlier stage (stage 0, 1, or 2) and 20.5% were classified as stage 3 (AIDS) at the time of diagnosis (Table 1a). Moreover, 80.1% of women were linked to care within 1 month of diagnosis and 67.5% were virally suppressed within 6 months of diagnosis (Table 2a). Of 212,405 women living with diagnosed HIV in the 45 jurisdictions with complete reporting of laboratory data at year-end 2019, 75.8% received HIV medical care, 57.9% were retained in care, and 64.1% were virally suppressed at their most recent viral load test (Tables 3a and 4a).

HIV care outcomes varied among women by race/ethnicity. For women of all racial/ethnic groups with diagnosed HIV,  $\geq 59.9\%$  of infections were diagnosed at an earlier stage. Yet, Asian (22.8%), Hispanic or Latino (22.3%), Native Hawaiian or other Pacific Islander (22.2%), and Black or African American females (21.0%) had  $>20\%$  of infections classified as stage 3 (AIDS) at the time of diagnosis (Table 1c, Figure 35).

**Figure 35. Earlier and late stage of disease at HIV diagnosis during 2019 among women, by race/ethnicity—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

The highest percentage for women by race/ethnicity who were linked to HIV medical care within 1 month of diagnosis was for American Indian or Alaska Native persons (84.1%) and the lowest percentage was for White persons (77.5%). The highest percentage for women by race/ethnicity who were virally suppressed within 6 months of diagnosis was for Asian persons (75.0%) and the lowest percentage was for American Indian or Alaska Native persons (52.3%) (Table 2c, Figure 36).

**Figure 36. Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among women, by race/ethnicity—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

The highest percentage for women by race/ethnicity who received any HIV medical care was for multiracial persons (86.0%) and the lowest percentage was for Native Hawaiian or other Pacific Islander persons (70.4%) (Figure 37). The highest percentage for women by race/ethnicity who were retained in HIV medical care was for multiracial persons (66.3%) and the lowest percentage was for Native Hawaiian or other Pacific Islander persons (49.6%). The highest percentage for women by race/ethnicity who were virally suppressed at the most recent viral load test was for multiracial persons (71.3%) and the lowest percentage was for American Indian or Alaska Native persons (59.3%).

**Figure 37. Receipt of HIV medical care, retention in HIV medical care, and viral suppression during 2019 among women, by race/ethnicity—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Includes Asian/Pacific Islander legacy cases.

<sup>b</sup> Hispanic/Latino persons can be of any race.

## PERSONS WITH PERINATALLY ACQUIRED HIV INFECTION

In order to make informed decisions about antiretroviral therapy to reduce perinatal transmission of HIV to infants, pregnant women should know their HIV infection status. In 1995, the first recommendations for HIV counseling and voluntary testing for pregnant women were published. In 2006, CDC released revised recommendations for HIV testing which specified that opt-out HIV screening should be included in the routine panel of prenatal screening tests for all pregnant women. Because of delays in the reporting of births and diagnoses of HIV infection attributed to perinatal exposure, the data presented provide minimum counts reported to the surveillance system. Please use caution when interpreting perinatally acquired HIV infection cases due to the dynamic nature of reporting. Additionally, numbers less than 12, and rates based on these numbers, should be interpreted with caution.

The overall annual rate of perinatally acquired HIV infections in the United States (regardless of place of birth) decreased from 1.6 per 100,000 live births in 2015 to 0.8 in 2019 (Table 10a). However, annual rates differed by race/ethnicity. Although the annual rate among Black or African American persons decreased from 6.8 in 2015 to 2.9 in 2019, the 2019 rate among Black or African American persons (2.9) was nearly 5 and 10 times the 2019 rates among Hispanic or Latino (0.6) and White persons (0.3) (Figure 38).

**Figure 38. Perinatally acquired HIV infection, by year of birth and mother's race/ethnicity, 2015–2019—United States**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications. Live-birth data reflect race/ethnicity of the infant's mother.

<sup>a</sup> Hispanic/Latino persons can be of any race.

Among infants born in the United States, the overall annual rate of perinatally acquired HIV infections decreased from 1.4 per 100,000 live births in 2015 to 0.8 in 2019 (Table 10b). However, annual rates differed by race/ethnicity. Although the annual rate among Black or African American persons decreased from 5.8 in 2015 to 2.9 in 2019, the 2019 rate among Black or African American persons (2.9) was nearly 5 and 10 times the 2019 rates among Hispanic or Latino (0.6) and White persons (0.3) (Figure 39).

**Figure 39. Perinatally acquired HIV infection among persons born in the United States, by year of birth and mother's race/ethnicity, 2015–2019—United States**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications. Live-birth data reflect race/ethnicity of the infant's mother.

<sup>a</sup> Hispanic/Latino persons can be of any race.

## YOUNG PERSONS

Young persons (persons aged 13–24 years) accounted for 20.8% of 36,801 diagnoses of HIV infection in 2019 in the United States and 6 dependent areas [1]. Young persons are the least likely of any age group to be aware of their HIV infection. Lack of awareness of HIV status may be due to recent infection or low rates of HIV testing. Persons who do not know they have HIV do not get medical care or receive treatment and can unknowingly infect others. In addition, young persons have higher rates of STDs and lower rates of condom use, greatly increasing the chance of getting or transmitting HIV. Addressing HIV among this group requires that they have access to the information and tools they need to make healthy decisions, reduce their risk, get treatment, and stay in care.

Among young persons with HIV infection diagnosed during 2019 in 45 jurisdictions with complete laboratory reporting, 75.2% of infections were diagnosed at an earlier stage (stage 0, 1, or 2) and 8.4% were classified as stage 3 (AIDS) at time of diagnosis (Table 1a). Moreover, 79.0% of young persons were linked to HIV medical care within 1 month of diagnosis and 68.2% were virally suppressed within 6 months of diagnosis (Table 2a). Of 29,533 young persons living with diagnosed HIV in the 45 jurisdictions at year-end 2019, 80.0% received HIV medical care, 58.7% were retained in HIV medical care, and 63.3% were virally suppressed at their most recent viral load test (Tables 3a and 4a).

Although HIV care outcomes varied among young persons by race/ethnicity,  $\geq 72.1\%$  of infections were diagnosed at an earlier stage for all racial/ethnic groups at time of diagnosis. Young Asian persons had the highest percentage of infections classified as stage 3 (AIDS) at time of diagnosis (11.7%), but no racial/ethnic group had  $>20\%$  of infections classified as stage 3 (AIDS) at the time of diagnosis (Table 1c, Figure 40).

**Figure 40. Earlier and late stage of disease at HIV diagnosis during 2019 among young persons, by race/ethnicity—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

The highest percentage for young persons by race/ethnicity who were linked to HIV medical care within 1 month of diagnosis was for American Indian or Alaska Native persons (87.0%) and the lowest percentage was for Black or African American persons (77.1%). The highest percentage for young persons by race/ethnicity who were virally suppressed within 6 months of diagnosis was for Native Hawaiian or other Pacific Islander persons (80.0%) and the lowest percentage was for Black or African American persons (65.7%) (Table 2c, Figure 41).

**Figure 41. Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among young persons, by race/ethnicity—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

The highest percentage for young persons by race/ethnicity who received any HIV medical care was for Asian persons (85.4%) and the lowest percentage was for Native Hawaiian or other Pacific Islander persons (71.0%). The highest percentage for young persons by race/ethnicity who were retained in HIV medical care was for Asian persons (67.9%) and the lowest percentage was for Native Hawaiian or other Pacific Islander persons (54.8%). The highest percentage for young persons by race/ethnicity who were virally suppressed at the most recent viral load test was for Asian persons (79.9%) and the lowest percentage was for Black or African American persons (58.6%) (Table 3c, Figure 42).

**Figure 42. Receipt of HIV medical care, retention in HIV medical care, and viral suppression during 2019 among young persons, by race/ethnicity—44 states and the District of Columbia**

<sup>a</sup> Includes Asian/Pacific Islander legacy cases.

<sup>b</sup> Hispanic/Latino persons can be of any race.

## 2019 STATUS AND DISPARITIES IN LINKAGE TO CARE WITHIN 1 MONTH OF HIV DIAGNOSIS AND VIRAL SUPPRESSION

Achieving equitable health in HIV-related outcomes can reduce new HIV infections and eliminate HIV-related disparities in the United States consistent with the goals of Healthy People 2030, NHSP, and the EHE initiative. This section presents the current status and HIV-related disparities for two favorable care outcomes, the percentage of persons with newly diagnosed HIV who were linked to care within 1 month of diagnosis and persons living with diagnosed HIV that were virally suppressed during 2019, prior to the start of national plans and initiatives.

To assess the status and measure HIV-related disparities for both outcomes, we explored the analytic approach used in Healthy People 2030 [9–12]. We assessed the status of the overall outcomes relative to the proposed national targets of 95% for linkage to care and viral suppression. We measured disparities for the two outcomes by selected characteristics (i.e., race/ethnicity, transmission category, and geographic area) and either chose the 95% outcome target or the group with the highest percentage for each outcome as our reference point. We measured the HIV-related disparities comparing the population groups with the highest and lowest percentage for that outcome to their respective targets and to each other using one absolute (i.e., maximal percentage difference) and/or two relative disparity measures (i.e., maximal percentage ratio and summary percentage ratio) to highlight opportunities for improvement. Maximal or absolute percentage difference is the difference between the group with the highest and lowest percentage for an outcome. Maximal percentage ratio is the ratio between the group with the highest and lowest percentage for an outcome. The summary percentage ratio is the ratio between the average of the percentages of all other groups [excluding the group with the highest percentage] and the group with the highest percentage for an outcome.

## 2019 Status and Disparities in Linkage to HIV Medical Care Within 1 Month of HIV Diagnosis

Our objective is to increase the percentage of persons linked to HIV medical care within 1 month of HIV diagnosis. In 2019, 81.3% of persons with an HIV diagnosis were linked to HIV medical care within 1 month of diagnosis (Table 2a). Linkage to HIV medical care was 13.7% from the 95% target (absolute percentage difference, 95.0%–81.3%) and 0.856 times the 95% target (81.3/95.0). The 2019 status for linkage to care varied by race/ethnicity, transmission category, and population area of residence (Figure 43).

**Figure 43. Status of linkage to HIV medical care within 1 month of HIV diagnosis during 2019 among persons aged ≥13 years with diagnosed HIV infection, by selected characteristics—44 states and the District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

By race/ethnicity, the highest linkage to care group percentage was for Hispanic or Latino persons (84.4%) and the lowest linkage to care group percentage was for Black or African American persons (78.4%) (Table 2a, Figure 43). Hispanic or Latino persons (highest linkage to care group) were the closest to the target (absolute percentage difference, 95.0%–84.4%=10.6%) and had a group percentage higher than the overall linkage to care outcome of 81.3%. Black or African American persons were the farthest from the target (absolute percentage difference, 95.0%–78.4%=16.6%) and had a group percentage lower than the overall linkage to care outcome. The percentages for Hispanic or Latino and Black or African American persons were 0.888 and 0.825 times the 95% target respectively ([Hispanic or Latino persons/target]: 84.4/95.0, [Black or African American persons/target]: 78.4/95.0; meeting the target equals 1).

The absolute percentage difference between the percentages for Hispanic or Latino persons (highest linkage to care group, 84.4%) and for Black or African American persons (lowest linkage to care group, 78.4%) was 6.0%. The percentage for Hispanic or Latino persons was 1.077 times the percentage for Black or African American persons (maximal percentage ratio, 84.4/78.4). The average percentage for all other racial/ethnic groups (excluding the percentage for Hispanic or Latino persons) was 81.5%. The absolute percentage difference between the percentage for Hispanic or Latino persons and the average percentage for all other racial/ethnic groups was 2.9% (84.4%–81.5%). The average percentage for all other racial/ethnic groups was 0.966 times the percentage for Hispanic or Latino persons (summary percentage ratio, 81.5/84.4).

By transmission category, the highest linkage to care group percentage was for males with infection attributed to MMSC (82.1%) and the lowest linkage to care group percentage was among females with infection attributed to IDU (75.1%) (Table 2a, Figure 43). Males with infection attributed to MMSC were the closest to the target (absolute percentage difference, 95.0%–82.1%=12.9%) and had a group percentage higher than the overall linkage to care outcome of 81.3%. Females with infection attributed to IDU were the farthest from the target (absolute percentage difference, 95.0%–75.1%=19.9%) and had a group percentage lower than the overall linkage to care outcome. The percentages for males with infection attributed to MMSC and females with infection attributed to IDU were 0.864 and 0.791 times the 95% target respectively ([males with infection attributed to MMSC/target]: 82.1/95.0; [females with infection attributed to IDU/target]: 75.1/95.0).

The absolute percentage difference between the percentages for males with infection attributed to MMSC (highest linkage to care group, 82.1%) and for females with infection attributed to IDU (lowest linkage to care group, 75.1%) was 7.0%. The percentage for males with infection attributed to MMSC was 1.093 times the percentage for females with infection attributed to IDU (maximal percentage ratio, 82.1/75.1). The average percentage for all other transmission categories (excluding the percentage for males with infection attributed to MMSC) was 78.4%. The absolute percentage difference between the percentage for males with infection attributed to MMSC and the average percentage for all other transmission categories was 3.7% (82.1%–78.4%). The average percentage for all other transmission categories was 0.955 times the percentage for males with infection attributed to MMSC (summary percentage ratio, 78.4/82.1).

By population area of residence, linkage to care was similar for all geographic areas (metropolitan: 81.8%, urban: 80.2%, rural: 80.1%). The highest linkage to care group percentage was for persons who resided in metropolitan areas (81.8%) and the lowest linkage to care group percentage was for persons who resided in rural areas (80.1%) (Table 2a, Figure 43). Persons who resided in metropolitan areas were the closest to the target (absolute percentage difference, 95.0%–81.8%=13.2%) and had a group percentage higher than the overall linkage to care outcome of 81.3%. Persons who resided in rural areas were the farthest from the target (absolute percentage difference, 95.0%–80.1%=14.9%) and had a group percentage lower than the overall linkage to care outcome. The percentages for persons who resided in metropolitan areas and in rural areas were 0.861 and 0.843 times the 95% target respectively ([metropolitan/target]: 81.8/95.0, [rural/target]: 80.1/95.0).

The absolute percentage difference between the percentages for persons who resided in metropolitan areas (highest linkage to care group, 81.8%) and for persons who resided in rural areas (lowest linkage to care group, 80.1%) was 1.7%. The percentage for persons who resided in metropolitan areas was 1.021 times the percentage for persons who resided in rural areas (maximal percentage ratio, 81.8/80.1). The average percentage for all other geographic areas (excluding the percentage for persons who resided in metropolitan areas) was 80.2%. The absolute percentage difference between the percentage for persons who resided in metropolitan areas and the average percentage for all other geographic areas was 1.6% (81.8%–80.2%). The average percentage for all other geographic areas was 0.980 times the percentage for persons who resided in metropolitan areas (summary percentage ratio, 80.2/81.8).

## 2019 Status and Disparities in Viral Suppression

Our objective is to increase the percentage of persons living with diagnosed HIV that were virally suppressed. During 2019, 65.5% of persons living with diagnosed HIV infection at year-end were virally suppressed at the most recent viral load test (Table 4a). Viral suppression was 29.5% from the 95% target (absolute percentage difference, 95.0%–65.5%) and was 0.689 times the 95% target (65.5/95.0). The 2019 status for viral suppression varied by race/ethnicity, transmission category, and population area of residence (Figure 44).

**Figure 44. Status of viral suppression during 2019 among persons aged ≥13 years with diagnosed HIV infection, by selected characteristics—44 states and District of Columbia**

*Note.* See Guide to Acronyms and Initialisms, Data Tables, and Technical Notes for more information on definitions and data specifications.

<sup>a</sup> Hispanic/Latino persons can be of any race.

By race/ethnicity, the highest viral suppression group percentage was for multiracial persons (73.2%) and the lowest viral suppression group percentage was for Black or African American persons (60.8%) (Table 4a, Figure 44). Multiracial persons were the closest to the target (absolute percentage difference, 95.0%–73.2%=21.8%) and had a group percentage higher than the overall viral suppression outcome of 65.5%. Black or African American persons were the farthest from the target (absolute percentage difference, 95.0%–60.8%=34.2%) and had a group percentage lower than the overall viral suppression outcome. The percentages for multiracial and Black or African American persons were 0.770 and 0.640 times the 95% target respectively ([multiracial persons/target]: 73.2/95.0, [Black or African American persons/target]: 60.8/95.0; meeting the target equals 1).

The absolute percentage difference between the percentages for multiracial persons (highest viral suppression [VS] group, 73.2%) and for Black or African American persons (lowest VS group, 60.8%) was 12.4%. The percentage for multiracial persons was 1.204 times the percentage for Black or African American persons (maximal percentage ratio, 73.2/60.8). The average percentage for all other racial/ethnic groups (excluding the

percentage for multiracial persons) was 65.8%. The absolute percentage difference between the percentage for multiracial persons and the average percentage for all other racial/ethnic groups was 7.4% (73.2%–65.8%). The average percentage for all other racial/ethnic groups was 0.899 times the percentage for multiracial persons (summary percentage ratio, 65.8/73.2).

By transmission category, the highest viral suppression group percentage was for males with infection attributed to MMSC (68.1%) and the lowest viral suppression group percentage was for males with infection attributed to IDU (53.7%) (Table 4a, Figure 44). Males with infection attributed to MMSC were the closest to the target (absolute percentage difference, 95.0%–68.1%=26.9%) and had a group percentage higher than the overall viral suppression outcome of 65.5%. Males with infection attributed to IDU were the farthest from the target (absolute percentage difference, 95.0%–53.7%=41.3%) and had a group percentage lower than the overall viral suppression outcome. The percentages for males with infection attributed to MMSC and males with infection attributed to IDU were 0.717 and 0.565 times the 95% target respectively ([males with infection attributed to MMSC/target]: 68.1/95.0, [males with infection attributed to IDU/target]: 53.7/95.0).

The absolute percentage difference between the percentages for males with infection attributed to MMSC (highest VS group, 68.1%) and for males with infection attributed to IDU (lowest VS group, 53.7%) was 14.4%. The percentage for males with infection attributed to MMSC was 1.268 times the percentage for males with infection attributed to IDU (maximal percentage ratio, 68.1/53.7). The average percentage for all other transmission categories (excluding the percentage for males with infection attributed to MMSC) was 61.2%. The absolute percentage difference between the percentage for males with infection attributed to MMSC and the average percentage for all other transmission categories was 6.9% (68.1%–61.2%). The average percentage for all other transmission categories was 0.899 times the percentage for males with infection attributed to MMSC (summary percentage ratio, 61.2/68.1).

By population area of residence, viral suppression was similar for all geographic areas (metropolitan: 65.6%, urban: 66.7%, rural: 64.8%). The highest viral suppression group percentage was for persons who resided in urban areas (66.7%) and the lowest viral suppression group percentage was for persons who resided in rural areas (64.8%) (Table 4a, Figure 44). Persons who resided in urban areas were the closest to the target (absolute percentage difference, 95.0%–66.7%=28.3%) and had a group percentage higher than the overall viral suppression outcome of 65.5%. Persons who resided in rural areas were the farthest from the target (absolute percentage difference, 95.0%–64.8%=30.2%) and had a group percentage lower than the overall viral suppression outcome. The percentages for persons who resided in urban areas and in rural areas were 0.702 and 0.682 times the 95% target respectively ([urban/target]: 66.7/95.0; [rural/target]: 64.8/95.0).

The absolute percentage difference between the percentages for persons who resided in urban and rural areas was 1.9% (66.7%–64.8%). The percentage for persons who resided in urban areas was 1.029 times the percentage for persons who resided in rural areas (maximal percentage ratio, 66.7/64.8). The average percentage for all other geographic areas (including the percentage for persons who resided in metropolitan and rural areas and excluding the percentage who resided in urban areas) was 65.2%. The absolute percentage difference between the percentages for persons who resided in urban and all other geographic areas was 1.5% (66.7%–65.2%). The average percentage for all other geographic areas was 0.978 times the percentage for persons who resided in urban areas (summary percentage ratio, 65.2/66.7).

# Technical Notes

## A. SURVEILLANCE OF HIV INFECTION OVERVIEW

This report includes data reported to CDC through December 31, 2020, from all 50 states, the District of Columbia, and 6 U.S. dependent areas (American Samoa, Guam, the Northern Mariana Islands, Puerto Rico, the Republic of Palau, and the U.S. Virgin Islands). After the removal of personally identifiable information, data were submitted to CDC.

Please use caution when interpreting data on diagnoses of HIV infection. HIV surveillance data on persons with diagnosed HIV infection may not be representative of all persons with HIV because not all infected persons have been (1) tested or (2) tested at a time when the infection could be detected and diagnosed. Also, some states offer anonymous HIV testing; the results of anonymous tests are not reported to the confidential name-based HIV registries of state and local health departments. Therefore, reports of confidential test results may not represent all persons who tested positive for HIV infection.

Please use caution when interpreting laboratory data for persons with diagnosed HIV infection. Laboratory data presented in this report are from 45 jurisdiction (44 states and the District of Columbia) that reported complete CD4+ T-lymphocyte (CD4) and viral load test results to CDC as of December 31, 2020. Data from these jurisdictions represent 89% of all persons aged  $\geq 13$  years living with diagnosed HIV infection at year-end 2019 in the United States and are therefore not representative of data on all persons living with diagnosed HIV infection in the United States.

## B. STAGES OF HIV INFECTION—CASE DEFINITIONS

Both the 2008 and 2014 HIV case definitions were used to classify HIV infection among adults and adolescents and among children [13, 14]. In the following lists, some bulleted items are paraphrases, not quotations, from the published surveillance case definitions. The intention is to emphasize the differences between the 2008 and 2014 case definitions.

### B1. 2008 Case Definition

The 2008 case definition was used to classify cases diagnosed through 2013. For adults and adolescents, this definition incorporates an HIV infection staging system that includes AIDS (HIV infection, stage 3). The 2008 stages of HIV infection are defined as follows:

- **HIV infection, stage 1:** No AIDS-defining opportunistic illness (OI) and either CD4+ T-lymphocyte (CD4 lymphocyte) count of  $\geq 500$  cells/ $\mu\text{L}$  or CD4 percentage of total lymphocytes of  $\geq 29$ .
- **HIV infection, stage 2:** No AIDS-defining OI and either CD4 lymphocyte count of 200–499 cells/ $\mu\text{L}$  or CD4 percentage of total lymphocytes of 14–28.
- **HIV infection, stage 3 (AIDS):** Documentation of an AIDS-defining OI or either a CD4 lymphocyte count of  $< 200$  cells/ $\mu\text{L}$  or CD4 percentage of total lymphocytes of  $< 14$ . Documentation of an AIDS-defining OI supersedes a CD4 lymphocyte count or percentage that would not, by itself, be the basis for a stage 3 (AIDS) classification.
- **HIV infection, stage unknown:** No reported information on AIDS-defining OIs and no information available on CD4 lymphocyte count or percentage.

## B2. 2014 Case Definition

In 2014, the HIV surveillance case definition was revised to adapt to changes in diagnostic criteria [13]; the laboratory criteria for defining a confirmed case of HIV infection were changed to accommodate multitest algorithms that did not include previously required tests (e.g., Western blot). New to the case definition is the inclusion of criteria for differentiating HIV-1 and HIV-2 infections and for recognizing early HIV infection (stage 0), during which viral loads may be high enough and CD4 T-lymphocyte counts low enough to be misclassified as stage 3 (AIDS). The 2014 case definition was used to classify cases diagnosed in 2014 and later. It is similar to the 2008 case definition except for the following:

1. inclusion of criteria for stage 0
2. inclusion of CD4 lymphocyte testing criteria for stage 3 in children
3. changes in the cutoffs for CD4 percentage of total lymphocytes used for classification of stages 1 and 2 in persons aged 6 years and older [3]

The stages of HIV infection in the 2014 case definition are based on age-specific CD4 lymphocyte counts or percentages of total lymphocytes and are defined as follows:

- **HIV infection, stage 0:** First positive HIV test result within 6 months after a negative HIV test result. The stage remains stage 0 until 6 months after the first positive test result. After 6 months, the stage may be classified as 1, 2, 3, or unknown if based on a CD4 test result or the diagnosis of an OI. The diagnosis of an AIDS-defining condition or a low CD4 test result before the 6 months have elapsed does not change the stage from stage 0 to stage 3.
- **HIV infection, stages 1, 2, and 3:** Documentation of an AIDS-defining OI (excluding stage 0 as described above) is stage 3. Otherwise, the stage is determined by the lowest CD4 lymphocyte test result:
  - Stage 1—CD4 lymphocyte count of  $\geq 500$  or a CD4 percentage of total lymphocytes of  $\geq 26$
  - Stage 2—CD4 lymphocyte count of 200–499 or a CD4 percentage of total lymphocytes of 14–25
  - Stage 3—CD4 lymphocyte count of  $< 200$  or a CD4 percentage of total lymphocytes of  $< 14$  or documentation of an AIDS-defining condition.
- **HIV infection, stage unknown:** No reported information on AIDS-defining OIs and no information available on CD4 lymphocyte count or percentage.

The transition to CD4 lymphocyte–based criteria for stage 3 (AIDS) among children has resulted in an increase in the number of annual stage 3 (AIDS) classifications among pediatric cases diagnosed after 2013. Before implementation of the 2014 revised case definition, an OI diagnosis was required for a pediatric case to meet the criteria for stage 3 classification.

## C. AREAS WITH COMPLETE LABORATORY REPORTING

As of December 31, 2020, 45 jurisdictions (44 states and the District of Columbia) had met the following criteria for the collection and reporting of CD4 and viral load test results:

- The jurisdiction’s laws/regulations required the reporting of all levels of CD4 and viral load results to the state or local health department (Table 14).
- Laboratories that perform HIV-related testing for the jurisdiction had reported a minimum of 95% of HIV-related test results to the state or local health department.
- By December 31, 2020, the jurisdiction had reported (to CDC) at least 95% of all CD4 and viral load test results received from January 2018 through September 2020.

The 44 states are Alabama, Alaska, Arizona, Arkansas, California, Colorado, Connecticut, Delaware, Florida, Georgia, Hawaii, Illinois, Indiana, Iowa, Louisiana, Maine, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, Montana, Nebraska, Nevada, New Hampshire, New Mexico, New York, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, Rhode Island, South Carolina, South Dakota, Tennessee, Texas, Utah, Virginia, Washington, West Virginia, Wisconsin, and Wyoming. Data from these states and the District of Columbia were used to populate Tables 1a–d, 2a–d, 3a–d, and 4a–b.

## D. TABULATION AND PRESENTATION OF DATA

The data in this report include information received by CDC through December 31, 2020. The data are organized into 2 sections: National Profile and Special Focus Profiles. For both the National Profile and Special Focus Profiles, figures are presented.

1. Tables 1a–d present data for stage of disease at time of diagnosis during 2019.
2. Tables 2a–d present data for on linkage to HIV medical care were based on persons whose infection was diagnosed during 2019 and who resided in any of the 45 jurisdictions at the time of diagnosis; and viral suppression within 6 months of diagnosis was measured for persons whose infection was diagnosed during 2019.
3. Tables 3a–d present data on receipt of and retention in HIV medical care were based on persons whose infection was diagnosed by year-end 2018, who resided in any of the 45 jurisdictions as of their most recent known address, and who were alive at year-end 2019.
4. Tables 3c–4b present data for viral suppression among persons whose infection was diagnosed by year-end 2018, who resided in any of the 45 jurisdictions as of their most recent known address during 2019, and who were alive at year-end 2019.
5. Table 5 presents data for prevalence-based HIV care continuum for persons living with HIV infection (diagnosed or undiagnosed) at year-end 2019.
6. Tables 6a–d present data for stage 3 (AIDS) at time of HIV diagnosis from 2015–2019.
7. Tables 7a–f present data of deaths for persons with diagnosed HIV infection and of persons with infection ever classified as stage 3 (AIDS) from 2015–2019.
8. Tables 8a–f present survival for >3 years for persons with diagnosed HIV infection and for persons whose infection had ever been classified as stage 3 (AIDS) from 2011–2016.
9. Tables 9a/b presents PrEP data.
10. Tables 10a/b presents data for infants with infection attributed to perinatal transmission from 2015–2019.

### D1. Definitions and Data Specifications

#### D1.1 Stage 3 (AIDS) and stage of disease at time of diagnosis of HIV infection

Data on persons with HIV infection, stage 3 (AIDS), include persons whose infection has ever been classified as stage 3 (AIDS). These data do not necessarily represent the current stage of disease.

Because a complete assessment of stage of disease at time of HIV diagnosis relies on complete laboratory data (all CD4 values) so that earlier stages of disease (stage 0, 1, or 2) can be assessed, stage of disease at time of diagnosis was calculated for the 45 jurisdictions that reported complete laboratory data (Tables 1a/b).

Information on stage 3 (AIDS) is available for all 50 states, the District of Columbia, and 6 U.S. dependent areas, even when not all CD4 values are reportable; therefore, stage 3 (AIDS) at time of HIV diagnosis was calculated for persons in all areas (Tables 6a–d).

Stage of disease at time of diagnosis (i.e., HIV infection, stage 0, 1, 2, 3 [AIDS], or unknown; Tables 1a–d) and stage 3 (AIDS) at time of HIV diagnosis (Tables 6a–d) were determined by using the first CD4 test result or documentation of an AIDS-defining condition  $\leq 3$  months after the HIV diagnosis date during 2019, unless documentation indicated disease stage 0. If  $\geq 2$  events occurred during the same month and could thus qualify as “first,” the following conditions were applied:

- If an AIDS-defining condition was documented, the AIDS-defining condition was used; if a CD4 count or a CD4 percentage had been reported and an AIDS-defining condition was documented, the AIDS-defining condition was used.
- If an AIDS-defining condition was not documented, but a CD4 count and a CD4 percentage had been reported, the CD4 count was used.
- If an AIDS-defining condition was not documented, but  $>1$  CD4 count had been reported, the lowest CD4 count (indicative of the most severe disease state) was used.
- If an AIDS-defining condition was not documented and a CD4 count had not been reported, but a CD4 percentage had been reported, the CD4 percentage was used. If  $>1$  CD4 percentage was reported, the lowest CD4 percentage (indicative of the most severe disease state) was used.

For stage of disease at time of diagnosis, infections were classified as “stage unknown” if the month of HIV diagnosis was missing, or if,  $\geq 3$  months after HIV diagnosis, neither a CD4 count nor a CD4 percentage had been determined and no AIDS-defining condition was documented.

## **D1.2 Linkage to, and receipt of, HIV medical care**

National guidelines for the clinical care and treatment of adults and adolescents living with HIV [15] recommend initiation of treatment immediately at time of HIV diagnosis regardless of viral load or CD4 count. Initiation of treatment immediately (or as soon as possible after HIV diagnosis) is to increase treatment uptake and linkage to care, decrease the time to viral suppression for individual patients, and improve the rate of viral suppression among persons with HIV. CD4 and viral load testing is still recommended for use in clinical practice to direct the course of treatment and assess effectiveness of treatment.

For special patient populations with HIV such as transgender and nonbinary persons, knowledge of their unique care and service needs are critical to reduce barriers to engagement in care, improve health, and reduce the risk of HIV transmission to sexual partners. For transgender males and nonbinary persons of childbearing potential, a pregnancy test should be performed prior to antiretroviral therapy (ART) initiation and selection of treatment should be based on their clinical history and pregnancy potential needs. Otherwise, ART-naïve patients who are pregnant should be started on treatment based on perinatal guidelines and counseled during pregnancy for their health and to prevent HIV transmission to the fetus.

For all transgender and nonbinary persons, clinical outcomes, potential adverse effects, treatment goals, and the patient’s current hormone levels should be considered when determining the appropriate doses of hormone and androgen blockers. Clinical treatment effects and hormone levels should be routinely monitored with appropriate titrations of estradiol, testosterone, or androgen blockers, as needed. Interpretation of laboratory results is dependent on patient physiology and the specific test being performed as recommended in the guidelines from the Center of Excellence for Transgender Health.

For patients who are not taking ART, CD4 count should be monitored every 3–6 months. For virally suppressed patients who have taken ART for  $\geq 2$  years, viral load testing is recommended every 3 to 4 months or as clinically indicated to confirm continuous viral suppression. For virally suppressed patients who have taken ART for  $> 2$  years, viral load testing at 6-month intervals may be considered. For virally suppressed patients with treatment modifications due to drug toxicities or regimen simplification, viral load testing is recommended 4 to 8 weeks after treatment modification to confirm regimen effectiveness. For virally suppressed patients whose CD4 counts have consistently ranged from 300 to 500 cells/ $\mu\text{L}$  for  $\geq 2$  years, annual monitoring of CD4 count

is recommended. For virally suppressed patients whose CD4 counts have consistently been  $> 500$  cells/ $\mu\text{L}$  for  $\geq 2$  years, continued CD4 monitoring is optional.

Frequent monitoring of CD4 count, especially among persons with higher counts ( $>300$  cells/ $\mu\text{L}$ ) and consistently suppressed viral loads, is generally not required for patient management. However, if clinically indicated, the CD4 count should be monitored more frequently (e.g., when changes in a patient's clinical status decrease CD4 count and thus prompt the need for prophylaxis for opportunistic infection).

The data on linkage to HIV medical care were based on persons whose infection was diagnosed during 2019 and who resided in any of the 45 jurisdictions at the time of diagnosis (Tables 2a–d). Linkage to HIV medical care within 1 month after HIV diagnosis was measured by documentation of  $\geq 1$  CD4 (count or percentage) or viral load tests performed  $\leq 1$  month after HIV diagnosis, including tests performed on the same date as the date of diagnosis. Linkage to HIV medical care within 3 months after HIV diagnosis was measured by documentation of  $\geq 1$  CD4 (count or percentage) or viral load tests performed  $\leq 3$  months after HIV diagnosis, including tests performed on the same date as the date of diagnosis.

The data on receipt of HIV medical care were based on persons whose infection was diagnosed by year-end 2018, who resided in any of the 45 jurisdictions as of their most recent known address, and who were alive at year-end 2019 (Tables 3a–d). Receipt of any HIV medical care was measured by documentation of  $\geq 1$  CD4 or viral load tests performed during 2019. Retention in care (receipt of continuous HIV medical care) was measured by documentation of  $\geq 2$  CD4 or viral load tests performed  $\geq 3$  months apart during 2019.

For analyses of linkage to, and retention in, care, the month and the year of the earliest HIV-positive test result reported to the surveillance system were used to determine the diagnosis date. Test results were excluded if the month of the sample collection was missing. For linkage to care, data were excluded if the month of diagnosis was missing. For receipt of care, retention in care, and viral suppression, data were excluded if the date of death (where applicable) occurred before the year of interest or was missing.

### **D1.3 Viral suppression**

Viral suppression was measured among persons whose infection was diagnosed by year-end 2018, who resided in any of the 45 jurisdictions as of their most recent known address during 2019, and who were alive at year-end 2019 (Tables 4a/b). Viral suppression was defined as a viral load result of  $< 200$  copies/mL at the most recent viral load test. The cutoff value of  $< 200$  copies/mL was based on the following definition of virologic failure: viral load of  $\geq 200$  copies/mL. If multiple viral load tests were performed during the same month and could thus qualify as “most recent,” the highest viral load (most severe) was selected. If the numerical result was missing or the result was a logarithmic value, the interpretation of the result (e.g., below limit) was used to determine viral suppression. Virologic failure may indicate lack of adherence to ART.

Viral suppression within 6 months of diagnosis was measured for persons whose infection was diagnosed during 2019 and who resided in any of the 45 jurisdictions at the time of diagnosis (Tables 2a–d). Viral suppression was defined as a viral load result of  $< 200$  copies/mL at any viral load test within 6 months of an HIV diagnosis made during 2019.

### **D1.4 Deaths**

Persons whose HIV infections are reported to the National HIV Surveillance System (NHSS) are assumed to be alive unless their deaths have been reported to CDC. Death data were based on deaths of persons with diagnosed HIV infection and of persons with infection ever classified as stage 3 (AIDS), regardless of the cause of death. Jurisdiction-level data were based on area of residence at death. If information on residence at death was not available, the state where a person's death occurred was used. Data for the year 2019 are preliminary and based on death data received by CDC through December 2020.

Monitoring receipt of HIV medical care, retention in HIV medical care, viral suppression at most recent test, deaths and survival of persons with diagnosed HIV infection, and the prevalence-based HIV care continuum is dependent upon complete death ascertainment conducted by HIV surveillance programs for reporting to CDC. Due to incomplete reporting of deaths for the year 2019, death data for Kansas, Massachusetts, Mississippi, North Dakota, Nevada, Vermont, and the U.S. Virgin Islands should be interpreted with caution. Please use caution when interpreting trend data: the numbers for the most recent year are subject to uncertainty.

## **D1.5 Survival analyses**

The Kaplan-Meier method was used to estimate the probability of survival (Tables 8a–f) for >3 years (36 months) for persons with diagnosed HIV infection and for persons whose infection had ever been classified as stage 3 (AIDS). To allow  $\geq 3$  years from the time of HIV diagnosis to a death date on or before December 31, 2019, tables were limited to data on persons whose diagnosis or stage 3 (AIDS) classification was made during 2011–2016. The results of survival analyses for areas with <100 diagnoses per year (i.e., 600 during the 6-year period) were unstable and therefore are not presented in this report.

## **D1.6 Perinatally acquired HIV infection**

Table 10a presents data for infants with infection attributed to perinatal transmission and reported to NHSS through December 2020. The data include all persons reported to NHSS with infection attributed to perinatal exposure, regardless of place of birth. Table 10b presents a subset of data from Table 10a: the data include only the persons whose case record denoted the United States as place of birth or residence at birth. The data on persons with perinatally acquired infection that are presented in Table 10b do not include persons who were born in a U.S. dependent area or a foreign country or whose residence at birth was unknown or missing from the case record.

## **D1.7 Preexposure prophylaxis (PrEP) coverage**

PrEP coverage, reported as a percentage, is defined as the number of persons aged  $\geq 16$  years classified as having been prescribed PrEP during the specified year divided by the estimated number of persons aged  $\geq 16$  years who had indications for PrEP during the specified year (Tables 9a/b, A5, S7a/b).

Number of persons prescribed, which is reported as a case count, is defined as the number of persons aged  $\geq 16$  years classified as having been prescribed PrEP during the specified year.

PrEP coverage is an EHE indicator that is not a reportable disease or condition and is not reported to NHSS. Multiple data sources, described below, are used to calculate PrEP coverage. Please use caution when interpreting PrEP data. Different data sources were used in the numerator and denominator to calculate PrEP coverage.

### ***D1.7.1 Persons prescribed PrEP***

National pharmacy data from the IQVIA Real-World Longitudinal Prescriptions database (hereafter, IQVIA database) are used to classify persons aged  $\geq 16$  years who have been prescribed PrEP in the specific year. The IQVIA database captures prescriptions from all payers and represents approximately 92% of all prescriptions from retail pharmacies and 60%–86% from mail-order outlets in the United States. The database does not include prescriptions from some closed health care systems that do not make their prescription data available to IQVIA. Therefore, these are minimum estimates of PrEP coverage. The database includes antiretroviral drugs prescribed, demographic variables of persons to whom the drugs were prescribed, and medical claims for these persons. IQVIA acquires medical claims and race/ethnicity data from various sources, including ambulatory, hospital, and consumer databases, and links these data to persons in the prescription database. The annual number of persons classified as having been prescribed PrEP was based on a validated algorithm that discerns whether tenofovir disoproxil fumarate and emtricitabine (TDF/FTC) were prescribed for PrEP after excluding prescriptions for HIV treatment, hepatitis B treatment, or HIV postexposure prophylaxis [16, 17].

Tenofovir alafenamide and emtricitabine (TAF/FTC) was approved as an alternative drug for PrEP by the U.S. Food and Drug Administration (FDA) in October 2019. Starting in 2019, TAF/FTC was included in the algorithm to classify the number of persons prescribed PrEP.

The number of persons classified as having been prescribed PrEP is reported by sex, age group, and race/ethnicity. Transmission category data are not available in the IQVIA database and race/ethnicity data are available for < 40% of persons with PrEP prescriptions. Please use caution when interpreting PrEP data by race/ethnicity. Race/ethnicity categories available in the IQVIA data include White, Black, Hispanic/Latino, and other. The number of persons prescribed PrEP for each racial/ethnic group presented in this report was extrapolated by applying the racial/ethnic distribution of known records to those for which data on race/ethnicity were unknown.

### *D1.7.2 Preexposure prophylaxis (PrEP) coverage—geographic designations*

In the IQVIA database, a person's location is reported as a 3-digit ZIP code prefix (hereafter, ZIP3) assigned by the U.S. Postal Service. To estimate the number of persons prescribed PrEP at the state or county level, a probability-based approach used to crosswalk between ZIP3s and states/counties by using the most recent data from (a) U.S. Census Bureau's American Community Survey (ACS) 5-year estimates by ZIP code Tabulate Area (ZCTA) [18], and (b) the U.S. Department of Housing and Urban Development's ZIP Code Crosswalk Files [19]. Because of reliability concerns, subnational estimates of <50 are not included in this report.

### *D1.7.3 Persons with indications for PrEP*

ACS and U.S. Census Bureau files were used to estimate the number of MSM (men who have sex with men) in a jurisdiction [20, 21]. Next, behavioral data from the National Health and Nutrition Examination Survey (NHANES) were used to estimate the proportion of HIV-negative MSM with indications for PrEP [22]. For 2018 denominator, this proportion was updated with recent NHANES data.

The number of HIV-negative MSM with indications for PrEP was multiplied by the ratio of percentage of HIV diagnoses during the specified year attributed to other major transmission risk groups compared to the percentage among MSM in a given state or county. The estimated number of persons with indications for PrEP in the 3 major transmission risk groups (MSM, heterosexuals, PWID [persons who inject drugs]) in each jurisdiction were then summed to yield a state or county-specific estimate. State estimates were then summed for a national total of persons with indications for PrEP [23]. Jurisdictional estimates were rounded to the nearest 10. Beginning in 2017, methods were adjusted to provide the estimated number of persons of other races/ethnicities (including Asian persons and persons in other race/ethnic groups), in addition to Black or African American, Hispanic or Latino, and White persons. Also beginning in 2017, an adjustment was applied to calculate an estimated number of persons with PrEP indications in counties with suppressed data for the number of HIV diagnoses in some transmission risk groups, age groups, or race/ethnicity groups.

The tables included in this report provide updated data on PrEP coverage for the years 2017 and 2018 and preliminary data for the year 2019 and for the year 2020 (from January through September) using the IQVIA data reported through September 2020. The data sources used to estimate the number of persons with indications for PrEP have different schedules of availability. Consequently, the availability of a denominator lags the availability of a numerator by approximately 1 year. PrEP coverage data with a lagged denominator are considered preliminary. For this release of HIV Surveillance Data Tables, 2017 denominators were used for 2017 PrEP coverage data; 2018 denominators were used for 2018, 2019, and 2020 PrEP coverage data. In addition to being preliminary, data for the year 2020 should be interpreted with awareness of the impact of the COVID-19 pandemic on filling PrEP prescriptions in state/local jurisdictions.

## D2. Rates

Rates per 100,000 population were calculated for (1) the numbers of diagnoses of HIV infection, (2) the numbers of deaths of persons with diagnosed HIV infection, and (3) the numbers of persons living with diagnosed HIV infection.

The population denominators used to compute the rates for the 50 states, the District of Columbia, and Puerto Rico were based on the Vintage 2019 postcensal estimates file (for years 2015–2019) from the U.S. Census Bureau [24]. The population denominators for American Samoa, Guam, the Northern Mariana Islands, the Republic of Palau, and the U.S. Virgin Islands were based on estimates and projections from the U.S. Census Bureau's International Data Base [25]. Each rate was calculated by dividing the total number of diagnoses (or deaths or prevalence) for the calendar year by the population for that calendar year and then multiplying the result by 100,000. The denominators used for calculating the rates specific to age, sex at birth, and race/ethnicity were computed by applying the appropriate vintage estimates for age, sex at birth, and race/ethnicity for the 50 states and the District of Columbia [24]. The same method was used to calculate the denominators for Puerto Rico, with the exception of race/ethnicity estimates; these data are not available for Puerto Rico (see next paragraph). For the other 5 U.S. dependent areas, estimates from the U.S. Census Bureau's International Data Base were used for age- and sex-specific population denominators [25].

CDC currently does not provide subpopulation rates by race/ethnicity for the 6 U.S. dependent areas because the U.S. Census Bureau does not collect information from all dependent areas. Rates for gender and transmission categories are not provided in this report because of the absence of denominator data from the U.S. Census Bureau, the source of data used for calculating all rates in this report.

In the tables displaying data on perinatally acquired HIV infection (Tables 10a/b), rates were calculated per 100,000 live births [26].

The standard used for reporting trends in numbers and percentages is an increase or a decrease of 5% or more during the specified time frame (e.g., when comparing 2015 and 2019). The exceptions to this standard are where population sizes or numbers were small (i.e., less than 12) or percentages were based on small numbers or population sizes.

Prevalence trends and data reflect persons living with diagnosed HIV infection, regardless of stage of disease, (Figures 9, 10, 36, and 37; Tables 15a/b–22 and A2) at the end of a given year during 2015–2019. Because of delays in the reporting of deaths, prevalence data are based on a 12-month reporting delay to allow data to be reported to CDC. For tables presenting prevalence data, region or area of residence is based on most recent known address as of the end of the specified year. Data for the year 2019 are preliminary and based on death data received by CDC as of December 31, 2020. Trends through 2019 should be interpreted with caution. Due to incomplete reporting of deaths for the year 2019, prevalence data for Kansas, Massachusetts, Mississippi, Nevada, North Dakota, Vermont, and the U.S. Virgin Islands should be interpreted with caution.

### D2.1 Rates of deaths

In tables displaying data on deaths of persons with diagnosed HIV infection and deaths of persons with infection ever classified as stage 3 (AIDS) (Tables 7a–f), rates were calculated in 3 ways:

- **Rates of deaths per 100,000 population:** Each rate was calculated by dividing the total number of deaths for the calendar year by the population for that calendar year and then multiplying the result by 100,000.
- **Rates of deaths per 1,000 persons living with diagnosed HIV infection or living with infection ever classified as stage 3 (AIDS):** Rates were calculated by dividing the reported total number of deaths of persons with diagnosed HIV infection (or with infection classified as stage 3 [AIDS]) during the calendar year by the sum of the number of persons living with a diagnosis of HIV infection (or with infection classified

as stage 3 [AIDS]) at the end of the previous calendar year plus the number of diagnoses of HIV infection (or stage 3 [AIDS] classification) during the current calendar year; the result was then multiplied by 1,000.

- **Age-adjusted rates of deaths per 100,000 population and per 1,000 persons living with diagnosed HIV infection or living with infection ever classified as stage 3 (AIDS):** Tables 7c and 7f include age-adjusted rates by area of residence in addition to crude rates. A standard population distribution was used to adjust death rates per 100,000 population and per 1,000 persons living with diagnosed HIV infection (or with infection ever classified as stage 3 [AIDS]). The age-adjusted rates are rates that would have existed if the age distribution of the designated population and the age distribution of the standard population were the same. The use of the U.S. 2000 standard population in calculating age-adjusted rates was based on recommendations by the National Center for Health Statistics [27, 28].

## E. DEMOGRAPHIC INFORMATION

### E1. Age

The designation “adults and adolescents” refers to persons aged 13 years and older, “young adults” refers to persons aged 20–24 years (unless noted otherwise), and “adolescents” refers to persons aged 13–19 years; the designation “children” refers to persons aged less than 13 years.

All tables in this report reflect data on persons aged 13 years and older, with the exception of Tables 9a/b (PrEP coverage) and Tables 10a/b (perinatally acquired HIV infection, birth years 2015–2019).

- Tables 3a–d and 4a/b (receipt of care and viral suppression): age was based on the person’s age at year-end 2018.
- Table 5 (prevalence): age was based on the person’s age at the end of the specified year.
- Tables 7a–f (deaths): age was based on the person’s age at the time of death.
- All other tables: age was based on the person’s age at the time of HIV diagnosis.

### E2. Sex and Gender

#### E2.1 Sex at birth

Sex designations in this report are based on a person’s sex at birth.

#### E2.2 Gender

*Gender identity* refers to a person’s internal understanding of their own gender, or gender with which a person identifies. HIV surveillance personnel collect data on gender identity, when available, from sources such as case report forms submitted by health care or HIV testing providers and medical records, or by matching with other health department databases (e.g., Ryan White program data). In May 2013, CDC issued guidance to state and local programs on methods for collecting data on transgender persons and working with transgender-specific data. However, characterization of HIV infection among transgender persons may require supplemental data from special studies. A person’s transgender status in NHSS is determined based on two variables: sex assigned at birth and current gender identity. Both variables are examined, using a two-step approach, to assess transgender status. Although not used in this report, *cisgender* is a term used to indicate that a person’s sex assigned at birth and current gender identity are the same (i.e., a person assigned male at birth and who currently identifies as a man is a cisgender male).

## Categories

- **Male:** persons assigned “male” sex at birth and current gender identity is not “transgender male-to-female” or “additional gender identity” (current gender identity can be listed as “male,” “female,” “transgender female-to-male,” “unspecified,” or left blank).
- **Female:** persons assigned “female” sex at birth and current gender identity is not “transgender female-to-male” or “additional gender identity” (current gender identity can be listed as “male,” “female,” “transgender male-to-female,” “unspecified,” or left blank).
- **Transgender male-to-female** (transgender MTF): persons assigned “male” sex at birth and current gender identity is “transgender male-to-female.”
- **Transgender female-to-male** (transgender FTM): persons assigned “female” sex at birth and current gender identity is “transgender female-to-male.”
- **Additional gender identity** (AGI): persons assigned “male” or “female” sex at birth and current gender identity is “additional gender identity.” AGI includes “bigender,” “gender queer,” and “two-spirit.”

## E3. Race and Ethnicity

In the *Federal Register* [29] for October 30, 1997, the Office of Management and Budget (OMB) announced the Revisions to the Standards for the Classification of Federal Data on Race and Ethnicity. Implementation by January 1, 2003, was mandated. At a minimum, data should be collected for persons in the following race categories:

- American Indian or Alaska Native
- Asian
- Black or African American
- Native Hawaiian or other Pacific Islander
- White

Additionally, systems must be able to retain information when multiple race categories are reported. In addition to data on race, data on 2 categories of ethnicity should be collected:

- Hispanic or Latino
- not Hispanic or Latino

The Asian or Pacific Islander category displayed in annual surveillance reports published prior to the 2007 surveillance report was split into 2 categories: (1) Asian and (2) Native Hawaiian or other Pacific Islander. The Asian category (in tables where footnoted) includes the cases in Asian/Pacific Islander persons (referred to as legacy cases) that were reported before the implementation of the new race categories in 2003 (e.g., cases of HIV infection that were diagnosed and reported to CDC before 2003 but that were classified as stage 3 [AIDS] after 2003) and a small percentage of cases that were reported after 2003 but that were reported according to the old race category (Asian/Pacific Islander). In tables of diagnoses of HIV infection during 2015–2019, the Asian category does not include Asian/Pacific Islander cases because these cases were diagnosed after 2003 and were reported to CDC in accordance with OMB’s Revisions to the Standards for the Classification of Federal Data on Race and Ethnicity [29].

This report also presents data for persons for whom multiple race categories are reported (i.e., multiracial). In this report, persons categorized by race were not Hispanic or Latino. The number of persons reported in each race category may, however, include persons whose ethnicity was not reported.

Race and ethnicity are not risk factors but are instead markers for many underlying problems of greater relevance to health, including socioeconomic status and cultural behavior-characteristics, which are social and not biological [30, 31]. Racial and ethnic differences in health are more likely to reflect profound differences in people's experience based on the relatively advantaged or disadvantaged position in society into which they are born [31, 32]. Social determinant of health factors, shaped by income, education, wealth, and socioeconomic conditions, vary systematically by race and ethnicity and are important in explaining differences in health outcomes [32].

Demographic information for the live birth registry is based on that of the mother [26]. Therefore, Tables 10a/b, which present estimated numbers and rates of perinatally acquired HIV infection, categorize race/ethnicity according to the mother's race/ethnicity.

## E4. Transmission Categories

*Transmission category* is the term for the classification of cases that summarizes an adult's or adolescent's possible HIV risk factors; the summary classification results from selecting, from the presumed hierarchical order of probability, the 1 (single) risk factor most likely to have been responsible for transmission. For surveillance purposes, a diagnosis of HIV infection is counted only once in the hierarchy of transmission categories [33]. Adults or adolescents with more than 1 reported risk factor for HIV infection are classified in the transmission category listed first in the hierarchy. The exception is men who had sexual contact with other men *and* injected drugs; this group makes up a separate transmission category.

### Hierarchical Categories

- **Male-to-male sexual contact:** men who have had sexual contact with men (i.e., homosexual contact) and men who have had sexual contact with both men and women (i.e., bisexual contact)
- **Injection drug use (IDU):** persons who have injected nonprescription drugs
- **Male-to-male sexual contact *and* injection drug use** (male-to-male sexual contact and IDU): men who have had sexual contact with other men and injected nonprescription drugs
- **Heterosexual contact:** persons who have ever had heterosexual contact with a person known to have, or with a risk factor for, HIV infection
- **Perinatal:** persons infected through perinatal transmission but aged 13 years and older at time of diagnosis of HIV infection. Prevalence data and tables of death data includes persons infected through perinatal transmission but aged 13 years and older during the specified year or at death.
- **Other:** all other transmission categories (e.g., blood transfusion, hemophilia, risk factor not reported or not identified).

Cases of HIV infection reported without a risk factor listed in the hierarchy of transmission categories are classified as "no identified risk (NIR)." Cases classified as NIR include cases that are being followed up by local health department staff; cases in persons whose risk-factor information is missing because they died, declined to be interviewed, or were lost to follow-up; and cases in persons who were interviewed or for whom other follow-up information was available but for whom no risk factor was identified.

Because a substantial proportion of cases of HIV infection are reported to CDC without an identified risk factor, multiple imputation is used to assign a transmission category to these cases [33]. Multiple imputation is a statistical approach in which each missing transmission category is replaced with a set of plausible values that represent the uncertainty about the true, but missing, value [34]. Each resulting data set containing the plausible values is analyzed by using standard procedures, and the results from these analyses are then combined to produce the final results. In tables displaying transmission categories, multiple imputation was used for adults and adoles-

cents, but not for children (because the number of cases in children is small, missing transmission categories were not imputed).

## **F. GEOGRAPHIC DESIGNATION**

### **F1. Area of Residence**

Data by area of residence reflect the address at the time of stage 3 (AIDS) classification or at the time of diagnosis of HIV infection for Tables 1b, 2b, 6c/d, 7c/f, 8c/f, and A1–A2. In Tables 3b, 4b, and A3–A4, area of residence is based on most recent known address as of December 31 of the specified year. For the death tables (7c/f), area of residence is based on residence at death. When information on residence at death is not available, the state where a person’s death occurred is used. For PrEP data, please see the Preexposure Prophylaxis (PrEP) Coverage—Geographic Designations section.

### **F2. U.S. Census Regions**

Data by region reflect the address at the time of diagnosis of HIV infection for tables that present number of diagnoses (Tables 2a, 6a/b, 8a/b–d/e, S8a–S10a). For the death tables (7a/b–7d/e), region is based on residence at death.

### **F3. Population Area of Residence**

In the Federal Register for June 28, 2010, OMB published revised standards for defining metropolitan statistical areas (MSAs) in federal statistical activities [35]. These standards, which provided for the identification of MSAs in the United States and Puerto Rico, replaced the 2000 standards. The adoption of the new standards was effective as of June 28, 2010. On February 28, 2013, OMB announced new MSA delineations based on the new standards and Census 2010 data [36]. Data by population area of residence reflect the address at the time of stage 3 (AIDS) classification or at the time of diagnosis of HIV infection for Tables 1c, 2a/c, 6a, and 8a/d. Tables 3a/c, 4a, and 7a, population area of residence is based on most recent known address as of December 31 of the specified year. For the death tables (7a/d), population area of residence is based in residence at death.

### **Other Acknowledgments**

We also thank the following staff and contractors of the Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, CDC for their contributions to the report (including graphics) and report website: Michael Friend (editing and desktop publishing); Dawn Smith; Joseph E. Logan; the Prevention Communications Branch: Brittany Petish, Fred Noble, Scott Outman (Web & Consumer Services Team); and the Division of Communication Services: Katherine Schlich and Juan Molina (CS324073) (Design Team).

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; OI, opportunistic illness (i.e., AIDS-defining condition); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Stage of disease at time of HIV diagnosis is based on the first CD4 test performed or documentation of an AIDS-defining condition ≤3 months after a diagnosis of HIV infection. Data are based on residence at time of diagnosis. Data not provided for states and associated counties that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: Idaho and New Jersey. Areas with incomplete reporting: Kansas, Kentucky, Pennsylvania, Vermont, and Puerto Rico.

<sup>a</sup> First positive HIV test result is within 6 months after a negative HIV test result. The diagnosis of an AIDS-defining condition or a low CD4 test result before the 6 months have elapsed does not change the stage from stage 0 to stage 3.

<sup>b</sup> Includes persons with no CD4 information.

<sup>c</sup> "Transgender male-to-female" includes individuals who were assigned "male" sex at birth but have ever identified as "female" gender. "Transgender female-to-male" includes individuals who were assigned "female" sex at birth but have ever identified as "male" gender.

<sup>d</sup> Additional gender identity examples include "bigender," "gender queer," and "two-spirit."

<sup>e</sup> Hispanic/Latino persons can be of any race.

<sup>f</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total. Data presented based on sex at birth and include transgender persons.

<sup>g</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>h</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, perinatal exposure or whose risk factor was not reported or not identified. Data not displayed because the numbers were too small to be meaningful.

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; OI, opportunistic illness (i.e., AIDS-defining condition); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Stage of disease at time of HIV diagnosis is based on the first CD4 test performed or documentation of an AIDS-defining condition ≤3 months after a diagnosis of HIV infection. Data are based on residence at time of diagnosis. Data not provided for states and associated counties that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: Idaho and New Jersey. Areas with incomplete reporting: Kansas, Kentucky, Pennsylvania, Vermont, and Puerto Rico.

<sup>a</sup> First positive HIV test result is within 6 months after a negative HIV test result. The diagnosis of an AIDS-defining condition or a low CD4 test result before the 6 months have elapsed does not change the stage from stage 0 to stage 3.

<sup>b</sup> Includes persons with no CD4 information.

<sup>c</sup> “Transgender male-to-female” includes individuals who were assigned “male” sex at birth but have ever identified as “female” gender. “Transgender female-to-male” includes individuals who were assigned “female” sex at birth but have ever identified as “male” gender.

<sup>d</sup> Additional gender identity examples include “bigender,” “gender queer,” and “two-spirit.”

<sup>e</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total. Data presented based on sex at birth and include transgender persons.

<sup>f</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>g</sup> Hispanic/Latino persons can be of any race.

**Table 1d. Stage of disease at time of HIV diagnosis during 2019 among males aged ≥13 years with infection attributed to male-to-male sexual contact, by race/ethnicity and age at diagnosis—44 states and the District of Columbia**

	Total No.	Stage 0 <sup>a</sup>		Stage 1 (CD4 ≥500 cells/μL or ≥26%)		Stage 2 (CD4=200–499 cells/μL or 14%–25%)		Stage 3 (AIDS) (OI or CD4 <200 cells/μL or <14%)		Stage unknown <sup>b</sup>

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; OI, opportunistic illness (i.e., AIDS-defining condition); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Stage of disease at time of HIV diagnosis is based on the first CD4 test performed or documentation of an AIDS-defining condition ≤3 months after a diagnosis of HIV infection. Data are based on residence at time of diagnosis. Data not provided for states and associated counties that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: Idaho and New Jersey. Areas with incomplete reporting: Kansas, Kentucky, Pennsylvania, Vermont, and Puerto Rico. Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total. Data presented based on sex at birth and includes transgender persons.

<sup>a</sup> First positive HIV test result is within 6 months after a negative HIV test result. The diagnosis of an AIDS-defining condition or a low CD4 test result before the 6 months have elapsed does not change the stage from stage 0 to stage 3.

<sup>b</sup> Includes persons with no CD4 information.

<sup>c</sup> Hispanic/Latino persons can be of any race.

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; VL, viral load (copies/mL); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Data are based on residence at time of diagnosis. Linkage to HIV medical care was measured by documentation of ≥1 CD4 or VL tests ≤1 month or ≤3 months after HIV diagnosis. A VL test result of <200 copies/mL indicates HIV viral suppression. VL test results are within 6 months of diagnosis of HIV infection during 2019. Data not provided for states and associated counties that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: Idaho and New Jersey. Areas with incomplete reporting: Kansas, Kentucky, Pennsylvania, Vermont, and Puerto Rico.

<sup>a</sup> “Transgender male-to-female” includes individuals who were assigned “male” sex at birth but have ever identified as “female” gender. “Transgender female-to-male” includes individuals who were assigned “female” sex at birth but have ever identified as “male” gender.

<sup>b</sup> Additional gender identity examples include “bigender,” “gender queer,” and “two-spirit.”

<sup>c</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total. Data presented based on sex at birth and include transgender persons.

<sup>d</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>e</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, perinatal exposure, or whose risk factor was not reported or identified. Data not displayed because the numbers were too small to be meaningful.

<sup>f</sup> Hispanic/Latino persons can be of any race.

**Table 2d. Linkage to HIV medical care and viral suppression within 6 months of HIV diagnosis during 2019 among males aged ≥13 years with infection attributed to male-to-male sexual contact, by race/ethnicity and age at diagnosis—44 states and the District of Columbia**

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; VL, viral load (copies/mL); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Data are based on address of residence as of December 31, 2019 (i.e., most recent known address). Data for the year 2019 are preliminary and based on death data received by CDC as of December 2020. Data not provided for states and associated counties that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: Idaho and New Jersey. Areas with incomplete reporting: Kansas, Kentucky, Pennsylvania, Vermont, and Puerto Rico.

<sup>a</sup> Performed ≥3 months apart during 2019.

<sup>b</sup> VL test results are from the most recent test during 2019.

<sup>c</sup> “Transgender male-to-female” includes individuals who were assigned “male” sex at birth but have ever identified as “female” gender. “Transgender female-to-male” includes individuals who were assigned “female” sex at birth but have ever identified as “male” gender.

<sup>d</sup> Additional gender identity examples include “bigender,” “gender queer,” and “two-spirit.”

<sup>e</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total. Data are based on sex at birth and include transgender persons.

<sup>f</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>g</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, perinatal exposure, or whose risk factor was not reported or not identified.

<sup>h</sup> Includes Asian/Pacific Islander legacy cases (see Technical Notes).

<sup>i</sup> Hispanic/Latino persons can be of any race.

**Table 3d. Receipt of HIV medical care and viral suppression during 2019 among males aged ≥13 years with infection attributed to male-to-male sexual contact, by race/ethnicity and age group—44 states and the District of Columbia**

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; VL, viral load (copies/mL); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Data are based on address of residence as of December 31, 2019 (i.e., most recent known address). Data for the year 2019 are preliminary and based on death data received by CDC as of December 2020. Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total. Data presented based on sex at birth and include transgender persons. Data not provided for states and associated counties that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: Idaho and New Jersey. Areas with incomplete reporting: Kansas, Kentucky, Pennsylvania, Vermont, and Puerto Rico.

<sup>a</sup> Performed ≥3 months apart during 2019.

<sup>b</sup> VL test results are from the most recent test during 2019.

<sup>c</sup> Includes Asian/Pacific Islander legacy cases (see Technical Notes).

<sup>d</sup> Hispanic/Latino persons can be of any race.

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/ $\mu$ L) or percentage; VL, viral load (copies/mL); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Data are based on address of residence as of December 31, 2019 (i.e., most recent known address). A VL test result of <200 copies/mL indicates HIV viral suppression. VL test results are from the most recent test during 2019. Data for the year 2019 are preliminary and based on death data received by CDC as of December 2020. Data not provided for states and associated counties that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: Idaho and New Jersey. Areas with incomplete reporting: Kansas, Kentucky, Pennsylvania, Vermont, and Puerto Rico.

<sup>a</sup> Represents percentage of the total number for the column.

<sup>b</sup> Data should be interpreted with caution due to incomplete ascertainment of deaths that occurred during the year 2019.

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage [footnotes only]; RSE, relative standard error [footnotes only].

<sup>a</sup> Estimates derived by using HIV surveillance and CD4 data for persons aged ≥13 years at diagnosis (i.e., persons living with diagnosed or undiagnosed HIV infection). Estimates rounded to the nearest 100 for estimates of >1,000 and to the nearest 10 for estimates of ≤1,000 to reflect model uncertainty. Estimates with an RSE of 30%–50% are preceded by an asterisk (\*) and should be interpreted with caution because they do not meet the standard of reliability. Estimates with an RSE of >50% are not shown and are replaced by an ellipsis (...). Data previously published in *HIV Surveillance Supplemental Report 2021*;26(No. 1). <http://www.cdc.gov/hiv/library/reports/hiv-surveillance.html>.

<sup>b</sup> Reported to National HIV Surveillance System. Data previously published in *HIV Surveillance Supplemental Report 2021*;26(No. 1). <http://www.cdc.gov/hiv/library/reports/hiv-surveillance.html>.

<sup>c</sup> Estimates are the result of extrapolating data from the 45 jurisdictions with complete CD4 and viral load reporting by applying the percentage in the 45 jurisdictions (found in Table 4b) to the total number of people living with diagnosed HIV in the United States. Estimates rounded to the nearest 100 for estimates of >1,000 and to the nearest 10 for estimates of ≤1,000 to reflect model uncertainty.

<sup>d</sup> Includes Asian/Pacific Islander legacy cases (see Technical Notes).

<sup>e</sup> Hispanic/Latino persons can be of any race.

<sup>f</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column subtotals and total. Data presented based on sex at birth and include transgender persons.

<sup>g</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>h</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, perinatal exposure or whose risk factor was not reported or not identified.

Abbreviation: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage [footnotes only].

Note. Data are based on residence at time of diagnosis.

<sup>a</sup> Based on first CD4 test performed or documentation of an AIDS-defining condition ≤3 months after a diagnosis of HIV infection.<sup>b</sup> "Transgender male-to-female" includes individuals who were assigned "male" sex at birth but have ever identified as "female" gender. "Transgender female-to-male" includes individuals who were assigned "female" sex at birth but have ever identified as "male" gender.<sup>c</sup> Additional gender identity examples include "bigender," "gender queer," and "two-spirit."<sup>d</sup> Hispanic/Latino persons can be of any race.<sup>e</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total. Data presented based on sex at birth and include transgender persons.<sup>f</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.<sup>g</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, perinatal exposure or whose risk factor was not reported or not identified.

Abbreviations: pop, population; PWDH, persons with diagnosed HIV infection; CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Deaths of persons with diagnosed HIV infection may be due to any cause. Data are based on residence at death. When information on residence at death was not available, state at death (where a person's death occurred) was used. Data for the year 2019 are preliminary and based on death data received by CDC as of December 2020. Trends through 2019 should be interpreted with caution.

<sup>a</sup> Denominator was calculated as (No. PLWDH at the end of [year X–1]) + (No. new diagnoses during year X).

<sup>b</sup> "Transgender male-to-female" includes individuals who were assigned "male" sex at birth but have ever identified as "female" gender. "Transgender female-to-male" includes individuals who were assigned "female" sex at birth but have ever identified as "male" gender.

<sup>c</sup> Additional gender identity examples include "bigender," "gender queer," and "two-spirit."

<sup>d</sup> Includes Asian/Pacific Islander legacy cases (see Technical Notes).

<sup>e</sup> Hispanic/Latino persons can be of any race.

<sup>f</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total.

<sup>g</sup> Data presented based on sex at birth and include transgender persons.

<sup>h</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>i</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, perinatal exposure or whose risk factor was not reported or not identified.

<sup>j</sup> Includes persons of unknown race/ethnicity.

Abbreviations: pop, population; PWDH, persons with diagnosed HIV infection; CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Deaths of persons with diagnosed HIV infection may be due to any cause. Data are based on residence at death. When information on residence at death was not available, state at death (where a person's death occurred) was used. Data for the year 2019 are preliminary and based on death data received by CDC as of December 2020. Trends through 2019 should be interpreted with caution.

<sup>a</sup> Denominator was calculated as (No. PLWDH at the end of [year X–1]) + (No. new diagnoses during year X).

<sup>b</sup> Data should be interpreted with caution due to incomplete ascertainment of deaths that occurred during the year 2019.

**Table 7d. Deaths of persons aged ≥13 years with diagnosed HIV infection ever classified as stage 3 (AIDS), by year of death and selected characteristics, 2015–2019—United States**

Abbreviations: pop, population; PWA, persons with diagnosed HIV infection ever classified as stage 3 (AIDS); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Deaths of persons with diagnosed HIV infection ever classified as stage 3 (AIDS) may be due to any cause. Data are based on residence at death. When information on residence at death was not available, state at death (where a person's death occurred) was used. Data for the year 2019 are preliminary and based on death data received by CDC as of December 2020. Trends through 2019 should be interpreted with caution.

<sup>a</sup> Denominator was calculated as (No. PLWA at the end of [year X–1]) + (No. new diagnoses during year X).

<sup>b</sup> "Transgender male-to-female" includes individuals who were assigned "male" sex at birth but have ever identified as "female" gender. "Transgender female-to-male" includes individuals who were assigned "female" sex at birth but have ever identified as "male" gender.

<sup>c</sup> Additional gender identity examples include "bigender," "gender queer," and "two-spirit."

<sup>d</sup> Includes Asian/Pacific Islander legacy cases (see Technical Notes).

<sup>e</sup> Hispanic/Latino persons can be of any race.

<sup>f</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total.

<sup>g</sup> Data presented based on sex at birth and include transgender persons.

<sup>h</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>i</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, perinatal exposure or whose risk factor was not reported or not identified.

<sup>j</sup> Includes persons of unknown race/ethnicity.

Abbreviations: pop, population; PWA, persons with diagnosed HIV infection ever classified as stage 3 (AIDS); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Deaths of persons with diagnosed HIV infection ever classified as stage 3 (AIDS) may be due to any cause. Data are based on residence at death. When information on residence at death was not available, state at death (where a person's death occurred) was used. Data for the year 2019 are preliminary and based on death data received by CDC as of December 2020. Trends through 2019 should be interpreted with caution.

<sup>a</sup> Denominator was calculated as (No. PLWA at the end of [year X–1]) + (No. new diagnoses during year X).

<sup>b</sup> Data should be interpreted with caution due to incomplete ascertainment of deaths that occurred during the year 2019.

Abbreviation: asterisk (\*) indicates sample too small (<600 diagnoses during the 6-year period) for the calculation of meaningful survival estimates.

Note. Data are based on residence at time of diagnosis. Data exclude persons whose month of diagnosis or month of death is unknown.

<sup>a</sup> “Transgender male-to-female” includes individuals who were assigned “male” sex at birth but have ever identified as “female” gender. “Transgender female-to-male” includes individuals who were assigned “female” sex at birth but have ever identified as “male” gender.

<sup>b</sup> Additional gender identity examples include “bigender,” “gender queer,” and “two-spirit.”

<sup>c</sup> Hispanic/Latino persons can be of any race.

<sup>d</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total. Data presented based on sex at birth and include transgender persons.

<sup>e</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>f</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, perinatal exposure or whose risk factor was not reported or not identified. Data not displayed because the numbers were too small to be meaningful.

<sup>e</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>f</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, perinatal exposure or whose risk factor was not reported or not identified. Data not displayed because the numbers were too small to be meaningful.

**Table 8f. Persons with HIV surviving >3 years after stage 3 (AIDS) classification during 2011–2016, by year of diagnosis and area of residence—United States and 6 dependent areas**

Abbreviation: asterisk (\*) indicates sample too small (<600 diagnoses during the 6-year period) for the calculation of meaningful survival estimates.

Note. Data are based on residence at time of stage 3 (AIDS) classification. Data exclude persons whose month of diagnosis or month of death is unknown.

<sup>a</sup> Data should be interpreted with caution due to incomplete ascertainment of deaths that occurred during the year 2019.

**Table 9a. Number of persons prescribed PrEP, number of persons with PrEP indications, and PrEP coverage in 2019 among persons aged ≥ 16 years, by selected characteristics—United States**

	Persons prescribed PrEP <sup>a</sup>	Persons with PrEP indications <sup>b</sup>	PrEP coverage <sup>c</sup>
	No.	No.	%
<b>Sex at birth</b>			
Male	262,360	989,200	26.5
Female	21,955	227,010	9.7
<b>Age (yr)</b>			
16–24	38,316	246,290	15.6
25–34	116,012	434,680	26.7
35–44	66,005	238,470	27.7
45–54	38,718	173,420	22.3
≥55	25,413	123,350	20.6
<b>Race/ethnicity<sup>d</sup></b>			
Black/African American	38,284	468,540	8.2
Hispanic/Latino <sup>e</sup>	43,812	312,820	14.0
Other	11,953	131,180	9.1
White	190,415	300,650	63.3
<b>Total</b>	<b>284,464</b>	<b>1,216,210</b>	<b>23.4</b>

Abbreviations: PrEP, preexposure prophylaxis; n/a, not available.

<sup>a</sup> Estimated by using data from IQVIA pharmacy database reported through September 2020 based on an algorithm that included FDA-approved drugs for PrEP. Data for which values are unknown were not reported thus values may not sum to column total.

<sup>b</sup> Estimated by using 2018 data from National HIV Surveillance System, National Health and Nutrition Examination Survey, and U.S. Census Bureau's American Community Survey. Data are rounded to the nearest 10. Data for which values are unknown were not reported thus values may not sum to column total. The data sources used to estimate the number of persons with indications for PrEP have different schedules of data availability. Consequently, the availability of a denominator may lag the availability of a numerator. The 2018 denominators were used for 2019 PrEP coverage data.

<sup>c</sup> PrEP coverage, reported as a percentage, was calculated as the number who have been prescribed PrEP divided by the estimated number of persons who had indications for PrEP.

<sup>d</sup> Race/ethnicity data were only available for <40% of persons prescribed PrEP in 2019. Number prescribed PrEP and PrEP coverage for race/ethnicity reported in the table were adjusted by applying the distribution of records with known race/ethnicity to records with missing race/ethnicity.

<sup>e</sup> Hispanic/Latino persons can be of any race.

**Table 9b. Number of persons prescribed PrEP, number of persons with PrEP indications, and PrEP coverage in 2019 among persons aged ≥ 16 years, by area of residence—United States and Puerto Rico**

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; OI, opportunistic illness (i.e., AIDS-defining condition); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Stage of disease at time of HIV diagnosis is based on the first CD4 test performed or documentation of an AIDS-defining condition ≤3 months after a diagnosis of HIV infection. Data are based on residence at time of diagnosis. Data not provided for states and associated jurisdictions that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: New Jersey. Areas with incomplete lab reporting: Pennsylvania (excluding Philadelphia) and Puerto Rico.

<sup>a</sup> First positive HIV test result is within 6 months after a negative HIV test result. The diagnosis of an AIDS-defining condition or a low CD4 test result before the 6 months have elapsed does not change the stage from stage 0 to stage 3.

<sup>b</sup> Includes persons with no CD4 information.

**Table A2. Linkage to HIV medical care within 1 month and viral suppression within 6 months of HIV diagnosis during 2019 among persons aged ≥13 years, by area of residence—Ending the HIV Epidemic Phase I jurisdictions**

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; VL, viral load (copies/mL); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Data are based on residence at time of diagnosis. Linkage to HIV medical care was measured by documentation of ≥1 CD4 or VL tests ≤1 month or ≤3 months after HIV diagnosis. A VL test result of < 200 copies/mL indicates HIV viral suppression. VL test results are within 6 months of diagnosis of HIV infection during 2019. Data not provided for states and associated jurisdictions that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Area without laws: New Jersey. Areas with incomplete lab reporting: Pennsylvania (excluding Philadelphia) and Puerto Rico.

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; VL, viral load (copies/mL); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Data are based on address of residence as of December 31, 2019 (i.e., most recent known address). A VL test result of <200 copies/mL indicates HIV viral suppression. VL test results during 2019. Data not provided for states and associated jurisdictions that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: New Jersey. Areas with incomplete lab reporting: Pennsylvania (excluding Philadelphia) and Puerto Rico.

<sup>a</sup> Data should be interpreted with caution due to incomplete ascertainment of deaths that occurred during the year 2019.

**Table A5. Number of persons prescribed PrEP, number of persons with PrEP indications, and PrEP coverage in 2017 (recalculated), 2018 (updated), and 2019 among persons aged ≥ 16 years, by area of residence—Ending the HIV Epidemic Phase I jurisdictions**

San Juan Municipio	—	2,190 <sup>d</sup>	n/a	—	2,190	n/a	—	2,190	n/a

Abbreviations: PrEP, preexposure prophylaxis; n/a, not available; FDA, Food and Drug Administration [footnotes only]; NHSS, National HIV Surveillance System [footnotes only].

<sup>a</sup> Estimated by using data from IQVIA pharmacy database reported through September 2020 based on an algorithm that included FDA-approved drugs for PrEP. Data for which values are unknown were not reported; therefore, values may not sum to column total.

<sup>b</sup> Estimated using 2018 data from National HIV Surveillance System (NHSS), National Health and Nutrition Examination Survey, and U.S. Census Bureau's American Community Survey (ACS). Data are rounded to the nearest 10. Data for which values are unknown were not reported; therefore, values may not sum to column total. The data sources used to estimate the number of persons with indications for PrEP have different schedules of data availability. Consequently, the availability of a denominator may lag the availability of a numerator. In this table, 2017 denominators were used for 2017 PrEP coverage data and 2018 denominators were used for 2018 and 2019 PrEP coverage data.

<sup>c</sup> PrEP coverage, reported as a percentage, was calculated as the number who have been prescribed PrEP divided by the estimated number of persons who had indications for PrEP.

<sup>d</sup> Number of persons with PrEP indications in San Juan Municipio was unavailable in 2017 and 2018 data are used for 2017.

**Table S1. Stage of disease at time of HIV diagnosis during 2017 among persons aged ≥13 years, by race/ethnicity and selected characteristics—41 states and the District of Columbia**

	Total No.	Stage 0 <sup>a</sup>		Stage 1 (CD4 ≥500 cells/μL or ≥26%)		Stage 2 (CD4=200–499 cells/μL or 14%–25%)		Stage 3 (AIDS) (OI or CD4 <200 cells/μL or <14%)		Stage unknown <sup>b</sup>

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; OI, opportunistic illness (i.e., AIDS-defining condition); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Stage of disease at time of HIV diagnosis is based on the first CD4 test performed or documentation of an AIDS-defining condition ≤3 months after a diagnosis of HIV infection. Data are based on residence at time of diagnosis and are for cases reported to CDC as of December 2019. Data not provided for states and associated counties that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: Idaho, New Jersey, and Pennsylvania. Areas with incomplete lab reporting: Arizona, Arkansas, Connecticut, Kansas, Kentucky, Vermont, and Puerto Rico.

<sup>a</sup> First positive HIV test result is within 6 months after a negative HIV test result. The diagnosis of an AIDS-defining condition or a low CD4 test result before the 6 months have elapsed does not change the stage from stage 0 to stage 3.

<sup>b</sup> Includes persons with no CD4 information.

<sup>c</sup> "Transgender male-to-female" includes individuals who were assigned "male" sex at birth but have ever identified as "female" gender. "Transgender female-to-male" includes individuals who were assigned "female" sex at birth but have ever identified as "male" gender.

<sup>d</sup> Additional gender identity examples include "bigender," "gender queer," and "two-spirit."

<sup>e</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total. Data presented based on sex at birth and include transgender persons.

<sup>f</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>g</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, perinatal exposure or whose risk factor was not reported or not identified. Data not displayed because the numbers were too small to be meaningful.

<sup>h</sup> Hispanic/Latino persons can be of any race.

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; VL, viral load (copies/mL); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Data are based on residence at time of diagnosis and are for cases reported to CDC as of December 2019. Linkage to HIV medical care was measured by documentation of ≥1 CD4 or VL tests ≤1 month or ≤3 months after HIV diagnosis. A VL test result of <200 copies/mL indicates HIV viral suppression. VL test results are within 6 months of diagnosis of HIV infection during 2017. Data not provided for states and associated counties that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: Idaho, New Jersey, and Pennsylvania. Areas with incomplete reporting: Arizona, Arkansas, Connecticut, Kansas, Kentucky, Vermont, and Puerto Rico.

<sup>a</sup> “Transgender male-to-female” includes individuals who were assigned “male” sex at birth but have ever identified as “female” gender. “Transgender female-to-male” includes individuals who were assigned “female” sex at birth but have ever identified as “male” gender.

<sup>b</sup> Additional gender identity examples include “bigender,” “gender queer,” and “two-spirit.”

<sup>c</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total. Data presented based on sex at birth and include transgender persons.

<sup>d</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>e</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, perinatal exposure, or whose risk factor was not reported or identified. Data not displayed because the numbers were too small to be meaningful.

<sup>f</sup> Hispanic/Latino persons can be of any race.

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; VL, viral load (copies/mL); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Data are based on residence at time of diagnosis and are for cases reported to CDC as of December 2019. Linkage to HIV medical care was measured by documentation of ≥1 CD4 or VL tests ≤1 month or ≤3 months after HIV diagnosis. A VL test result of <200 copies/mL indicates HIV viral suppression. VL test results are within 6 months of diagnosis of HIV infection during 2017. Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total. Data presented based on sex at birth and include transgender persons. Data not provided for states and associated counties that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: Idaho, New Jersey, and Pennsylvania. Areas with incomplete reporting: Arizona, Arkansas, Connecticut, Kansas, Kentucky, Vermont, and Puerto Rico.

<sup>a</sup> Hispanic/Latino persons can be of any race.

**Table S5. Receipt of HIV medical care and viral suppression among persons aged ≥13 years with infection diagnosed by year-end 2016 and alive at year-end 2017, by race/ethnicity and selected characteristics—41 states and the District of Columbia**

<b>Total</b>	<b>40,502</b>	<b>34,761</b>	<b>85.8</b>	<b>26,694</b>	<b>65.9</b>	<b>28,349</b>	<b>70.0</b>	

Abbreviations: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage; VL, viral load (copies/mL); CDC, Centers for Disease Control and Prevention [footnotes only].

Note. Data are based on address of residence as of December 31, 2017 (i.e., most recent known address). Data are for cases reported to CDC as of December 2020. Data not provided for states and associated counties that do not have laws requiring reporting of all CD4 and viral loads, or that have incomplete reporting of laboratory data to CDC. Areas without laws: Idaho, New Jersey, and Pennsylvania. Areas with incomplete reporting: Arizona, Arkansas, Connecticut, Kansas, Kentucky, Vermont, and Puerto Rico.

<sup>a</sup> Performed ≥3 months apart during 2017.

<sup>b</sup> VL test results are from the most recent test during 2017.

<sup>c</sup> “Transgender male-to-female” includes individuals who were assigned “male” sex at birth but have ever identified as “female” gender. “Transgender female-to-male” includes individuals who were assigned “female” sex at birth but have ever identified as “male” gender.

<sup>d</sup> Additional gender identity examples include “bigender,” “gender queer,” and “two-spirit.”

<sup>e</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total. Data presented based on sex at birth and include transgender persons.

<sup>f</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>g</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, perinatal exposure, or whose risk factor was not reported or not identified.

<sup>h</sup> Includes Asian/Pacific Islander legacy cases (see Technical Notes).

<sup>i</sup> Hispanic/Latino persons can be of any race.

**Table S6. Receipt of HIV medical care and viral suppression during 2017 among males aged ≥13 years with infection attributed to male-to-male sexual contact, by race/ethnicity and age group—41 states and the District of Columbia**

<b>Total</b>	<b>161,185</b>	<b>1,221,080</b>	<b>13.2</b>	<b>226,541</b>	<b>1,216,210</b>	<b>18.6</b>

Abbreviations: PrEP, preexposure prophylaxis; n/a, not available; NHSS, National HIV Surveillance System [footnotes only].

<sup>a</sup> Estimated by using data from IQVIA pharmacy database and based on an algorithm that included FDA-approved drugs for PrEP. Data for which values are unknown were not reported; therefore, values may not sum to column total.

<sup>b</sup> Estimated by using 2017 and 2018 data from NHSS, National Health and Nutrition Examination Survey, and U.S. Census Bureau's American Community Survey (ACS). Data are rounded to the nearest 10. Data for which values are unknown were not reported; therefore, values may not sum to column total. The data sources used to estimate the number of persons with indications for PrEP have different schedules of data availability. Consequently, the availability of a denominator may lag the availability of a numerator. In this table, 2017 denominators were used for 2017 PrEP coverage data and 2018 denominators were used for 2018 PrEP coverage data.

<sup>c</sup> PrEP coverage, reported as a percentage, was calculated as the number who have been prescribed PrEP divided by the estimated number of persons who had indications for PrEP.

<sup>d</sup> Race/ethnicity data were only available for <40% of persons prescribed PrEP in each year. Number prescribed PrEP and PrEP coverage for race/ethnicity reported in the table were adjusted by applying the distribution of records with known race/ethnicity to records with missing race/ethnicity.

<sup>e</sup> Hispanic/Latino persons can be of any race.

Abbreviation: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage [footnotes only].

Note. Numbers less than 12, and rates and trends based on these numbers, should be interpreted with caution.

<sup>a</sup> Based on first CD4 test performed or documentation of an AIDS-defining condition ≤3 months after a diagnosis of HIV infection.

<sup>b</sup> “Transgender male-to-female” includes individuals who were assigned “male” sex at birth but have ever identified as “female” gender. “Transgender female-to-male” includes individuals who were assigned “female” sex at birth but have ever identified as “male” gender.

<sup>c</sup> Additional gender identity examples include “bigender,” “gender queer,” and “two-spirit.”

<sup>d</sup> Hispanic/Latino persons can be of any race.

<sup>e</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to column total.

<sup>f</sup> Data presented based on sex at birth and include transgender persons.

<sup>g</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>h</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, or whose risk factor was not reported or not identified.

<sup>i</sup> Data are based on residence at time of diagnosis of HIV infection.

Abbreviation: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage [footnotes only].

Note. Numbers less than 12, and rates and trends based on these numbers, should be interpreted with caution.

<sup>a</sup> Based on first CD4 test performed or documentation of an AIDS-defining condition ≤3 months after a diagnosis of HIV infection.

<sup>b</sup> Hispanic/Latino persons can be of any race.

<sup>c</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to the column subtotals and total.

<sup>d</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection.

<sup>e</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, or whose risk factor was not reported or not identified.

<sup>f</sup> Data are based on residence at time of diagnosis of HIV infection.

Abbreviation: CD4, CD4+ T-lymphocyte count (cells/μL) or percentage [footnotes only].

Note. Numbers less than 12, and rates and trends based on these numbers, should be interpreted with caution.

<sup>a</sup> Based on first CD4 test performed or documentation of an AIDS-defining condition ≤3 months after a diagnosis of HIV infection.

<sup>b</sup> Hispanic/Latino persons can be of any race.

<sup>c</sup> Data have been statistically adjusted to account for missing transmission category; therefore, values may not sum to the column subtotals and total.

<sup>d</sup> Heterosexual contact with a person known to have, or with a risk factor for, HIV infection

<sup>e</sup> Includes persons whose infection was attributed to hemophilia, blood transfusion, or whose risk factor was not reported or not identified.

<sup>f</sup> Data are based on residence at time of diagnosis of HIV infection.
