Effects of Patient Characteristics on Performance of Self-Collected Samples for SARS-CoV-2 Testing

Appendix

Appendix Methods

Specimen Collection

Patients collected ≈2 mL raw saliva into a sterile 50 mL conical centrifuge tube. Patients were then advised to collect anterior nasal swab (ANS) samples by inserting a mini flocked tip swab into 1 anterior naris, twirling the swab for 10 s, removing the swab and placing it directly into the other naris, and twirling again for 10 s. Upon collection, ANS samples were stored in 3 mL universal viral transport media (Becton, Dickinson and Company, https://www.bd.com). All self-collected specimens were stored at 4°C or frozen (ANS samples only) before extraction. After interview and self-collection of specimens were completed, a nasopharyngeal swab (NPS) sample was collected by healthcare workers at Grady Memorial Hospital (Atlanta, Georgia, USA) using flocked foam swabs and placed into a vial of 3 mL Smart Transport Medium (MedSchenker, https://medschenker.com). Reverse transcription PCR (RT-PCR) on the NPS samples was performed the same day by the hospital laboratory and these results were used for clinical care per hospital protocol and not included in the diagnostic performance analysis. NPS samples were stored at 4°C and remnant Smart Transport Medium was aliquoted and transferred to the US Centers for Disease Control and Prevention (CDC; Atlanta) laboratory for RT-PCR.

Extraction and Testing Methods

Nucleic acid was extracted from 120 μL of viral transport media (ANS and NPS samples) or 120 μL whole saliva at CDC by using the Maxwell RSC 48 automated extraction platform and Maxwell RSC Viral Total Nucleic Acid Purification Kit (Promega, https://www.promega.com). Preprocessing was performed to liquify high-viscosity saliva specimens before extraction by using equal volumes of whole saliva and dithiothreitol and incubated for 30 min at room

temperature. RNA was eluted into 75 μL of nuclease-free water and a 5 μL sample was tested by using the CDC 2019-nCoV Real-Time Reverse transcriptase PCR Diagnostic Panel according to the emergency use authorization instructions for use (IFU) (*1*,*2*). Samples with amplification (cycle threshold <40) of both N1 and N2 gene targets were considered positive, amplification of only 1 N gene target was inconclusive, and amplification of neither N gene target was negative. Lower cycle threshold values represent higher viral RNA concentration. Some NPS aliquots from the hospital were stored outside of the IFU requirements (samples were stored at 4°C for >72 h after collection). Although stability of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) RNA has been demonstrated at 4°C in universal viral transport media for up to 14 days for other RT-PCR assays (*3*,*4*), an analysis excluding NPS aliquots stored outside of IFU requirements was performed to ensure storage conditions did not influence the findings.

Symptom Group and Clinical Case Definitions

Respiratory symptoms were defined as any of the following: runny nose/congestion, sore throat (upper respiratory); or cough, shortness of breath/difficulty breathing, wheezing, and chest pain (lower respiratory). Nonrespiratory symptoms were defined as any of the following: fever (measured or subjective), muscle/body aches, headache, chills, fatigue, loss of smell, loss of taste, nausea, vomiting, and diarrhea. COVID-19–like symptoms were defined as fever (measured or subjective) and cough or shortness of breath/difficulty breathing (*5*). Council of State and Territorial Epidemiologists clinical criteria for COVID-19 reporting was defined as any of the following: cough, shortness of breath/difficulty breathing, new smell disorder, or new taste disorder or ≥2 of the following: fever (measured or subjective), chills, myalgia, headache, sore throat, nausea or vomiting, diarrhea, fatigue, or congestion/runny nose (*6*). Influenza-like illness was defined as measured fever and cough or sore throat (*5*). The World Health Organization defines acute respiratory infection as any shortness of breath/difficulty breathing, cough, sore throat, or congestion/runny nose (*7*).

Appendix Results

Storage Requirement Analysis

Among 1,006 patients with NPS RT-PCR results, 64 NPS samples did not meet the IFU storage requirement of 4°C for ≤72 h from collection. These 64 specimens were received and

tested a median of 4 d after collection (range 4–5 d). The overall sensitivity of ANS samples compared with NPS samples was 59% (95% CI 47%–70%); excluding the specimens that did not meet storage requirements slightly changed the sensitivity (58%; 95% CI 46%–69%). The overall sensitivity of saliva samples compared with NPS samples was 68% (95% CI 55%–78%); excluding the specimens that did not meet storage requirements slightly changed the sensitivity point estimate (67%; 95% CI 54–78). There was no change in specificity. Among those with an RT-PCR result from Grady Memorial Hospital (n = 983), there was no difference in NPS result concordance of CDC RT-PCR results with Grady RT-PCR results among those that did not meet the storage requirement and those that did meet the storage requirement (61/62, 98.4% vs. 907/921, 98.5%; p = 1.0 by Fisher exact test).

Sensitivities of Various Sample Types Compared with Any Positive Result

Because NPS samples do not detect all SARS-CoV-2 infections, we reran the sensitivity analysis with a combined variable for any positive result from ANS, saliva, or NPS samples as the comparator. We calculated sensitivity and 95% CI of self-collected specimens within patient characteristic subgroups to evaluate how patient differences might affect specimen performance. We determined statistically significant sensitivity differences between overall and subgroups using a 1-sample, 2-way test of proportions ($p<0.05$). Among 1,076 per-protocol patients, 85 (7.9%) had $\geq$1 ANS, saliva, or NPS sample test positive for SARS-CoV-2. Among 1,063 participants with a definitive ANS sample result, ANS sample sensitivity compared with any positive was 56% (95% CI 45–67) (Appendix Table). Compared with the ANS versus NPS sample analysis, the only change in statistical significance was the sensitivity among those reporting symptom onset 3–7 d before enrollment was not significantly different than the overall sensitivity. Among 989 participants with a definitive saliva sample result, sensitivity of saliva compared to any positive result was 70% (95% CI 59–80). Compared with the saliva versus NPS sample analysis, the only change in statistical significance was the sensitivity among those with a previous positive result was not significantly different than the overall sensitivity. Among 1,075 participants with a definitive ANS or saliva sample result, sensitivity of self-collected combination compared to any positive was 73% (95% CI 62–82). Compared with the self-collected combination versus NPS sample analysis, the only change in statistical significance was the sensitivity among those reporting symptom onset 3–7 d before enrollment was not significantly different than the overall sensitivity.
