Search for Microplastics Literature for
The Microplastics Scoping Review

Author: Gaston Casillas, April Ellis, Candis Hunter

Description: Abstracts pulled from several databases relating to microplastics and the environment

Publication Date: 2022

Fundamentally sound?

> The article discusses the Institute of Scrap Recycling Industries (ISRI) 2016 Convention & Exposition regarding the plastic scrap on recycling chain at the Mandalay Bay Convention Center in Las Vegas, Nevada. It mentions the increase in plastic scrap pricing. It also presents the views of Mark Eramo, vice president at IHS Chemical, regarding chemicals production into plastic commodities.

Plastic waste: ecological and human health impacts. Science for Environment Policy In-depth Report. Plastic waste: ecological and human health impacts. Science for Environment Policy In-depth Report; 2011. :44 pp. many ref. Bristol, Science for Environment Policy, European Commission DG Environment News Alert Service.

> This report summarises and collates current research on the ecological and human health impacts of plastic waste in the environment. Using the Drivers Pressures State Impact Response (DPSIR) framework, & highlights major issues and concerns, as well as outlining questions around existing responses and possible strategies for the future.

SCS Participates in Phase One of the Circular Plastics Alliance.

> The article offers information on the working meetings of the Circular Plastics Alliance to promote value chain cooperation with the aim to ensure that 10 million tons of recycled plastics are used in new products by 2025. It mentions the views of Chief executive officers (CEO) Kevin McQuade, that SCS is working to make styrenics truly circular for use in food contact applications; and also mentions SCS reconfirmed its commitment to have a chemical recycling demo plant in place by 2020.

(1973). "REMOVING FINE PLASTIC PARTICLES FROM WASTE WATER." BELGIAN PATENT BE 798884. ISSUED AUGUST 16, 1973. DERWENT BELGIAN PATENTS REPORT, VOL. U, NO. 41, P D2, AUGUST, 1973.

> A PATENT FOR A METHOD OF REMOVING FINE PARTICLES OF PLASTIC MATERIAL, ESPECIALLY POLYVINYL CHLORIDE, FROM WASTE WATER HAS BEEN GRANTED. THIS TREATMENT PROCESS INCLUDES THE FOLLOWING STEPS: ADDING A SURFACTANT WHICH PRODUCES A FOAM IN THE WASTE WATER; SUBJECTING THE WASTE WATER TO THE ACTION OF A STREAM OF GAS BUBBLES; AND, REMOVING THE FOAM WHICH HAS ACCUMULATED AT THE SURFACE OF THE BATH AND CONTAINS A HIGH CONCENTRATION OF FINE PLASTIC PARTICLES BY RAKING. ESSENTIALLY COMPLETE REMOVAL OF THE FINE PLASTIC PARTICLES FROM THE WASTE WATER IS ACHIEVED USING A RELATIVELY SMALL QUANTITY OF SURFACE ACTIVE AGENT. (SANDOSKI-FIRL)

(1974). "REMOVING FINE PLASTIC PARTICLES FROM WASTE WATER." FRENCH PATENT FR 2182128, ISSUED DECEMBER 7, 1973. FRENCH PATENTS ABSTRACTS, VOL U, NO 5, P D7, MARCH 7, 1974.

A PROCESS FOR REMOVING FINE PLASTIC PARTICLES FROM WASTE WATER BY FLOTATION AFTER FOAMING WITH SURFACTANT AND A STREAM OF GAS BUBBLES HAS BEEN PATENTED. FINE PARTICLES OF PLASTIC MATERIAL, ESPECIALLY POLYVINYL CHLORIDE (PVC), ARE REMOVED FROM THE WASTE WATER BY ADDING A SURFACE ACTIVE AGENT, WHICH CAN PRODUCE A FOAM, TO THE WASTE WATER; SUBJECTING THE WASTE WATER TO THE ACTION OF A STREAM OF FINE GAS BUBBLES; AND, REMOVING THE FOAM WHICH HAS ACCUMULATED AT THE SURFACE OF THE BATH BY RAKING. THIS FOAM CONTAINS A HIGH CONCENTRATION OF PLASTIC PARTICLES. THE FOAM IS DEHYDRATED IN A CENTRIFUGE, OR BY A DRUM FILTER COATED WITH A FILTER AID. ALMOST COMPLETE ELIMINATION OF THE FINE PLASTIC PARTICLES FROM THE WASTE WATER IS ACHIEVED USING A RELATIVELY SMALL AMOUNT OF SURFACE ACTIVE AGENT. (MURPHY-FIRL)

(1990). "Soil and water conservation using plastics." KTBL Arbeitspapier **143**(107).

This publication contains twelve papers presented at the 1989 annual meeting of the German Society for plastic materials in agriculture. Four papers are concerned with various aspects of soil and water conservation through the use of plastics such as wide plastic tyres, plastic films and recycled plastic waste. The remainder of the papers deals with the use of plastics in construction and technology in horticulture and specialized cultures.

(1990). "Waste action." Environmental Action **21**(6): 4.

Reports on two solid waste proposals being addressed by Massachusetts legislators. Testimony supporting a Mass PIRG initiative to require `environmentally sound' packaging submitted by Lisa Collaton of the Environmental Action Foundation; Testimony backing legislation that would erase the `chasing arrows' symbol from the state's plastic resin coding system.

(1994). "13th International congress on plastics in agriculture. Volume 2. Proceedings of a conference held in Verona, Italy, 8-11 March 1994." Congresso internazionale del C.I.P.A. **422**.

This volume contains papers presented at the 13th International congress on plastics in agriculture. The papers presented cover many aspects of plastic usage in agriculture, including: irrigation and drainage systems and pipe networks; greenhouses and plastic tunnel construction technology; direct covers and mulches; and soil solarization. The optical properties of plastic films, and plastic waste management and recycling are also considered. Papers are mostly in Italian, with the remainder in English and French. Short bibliographies for each of the main conference topics are presented and a list of contributors is provided.

(1995). "Proceedings of a symposium on the improvement of vegetable industry in Taiwan held at Taichung District Agricultural Improvement Station, 25-26 May, 1994." Special Publication Taichung District Agricultural Improvement Station **37**(370).

This publication comprises the following contributions, presented at the symposium: Watermelon and muskmelon industry development and research in Taiwan; Production analysis of cucurbit vegetables for the recent ten years in Taiwan; Current situation and future prospect in production of solanaceous fruit vegetables in Taiwan; Current status and prospects of leguminous vegetables industry in Taiwan; Present situation and future development of heading leafy vegetables; Production of short-term leafy vegetables in Taiwan; Present status and perspective of flower vegetables production; Industries and researches of green onion (Allium fistulosum) and shallot (A. cepa var. aggregatum); Current status and future development of bamboo shoot industry in Taiwan; Asparagus industry and research in Taiwan; Present status on co-ba (Zizania latifolia Turcz. [Zizania caduciflora]) production; Present status and prospect of taro (Colocasia esculenta) and ginger (Zingiber officinale); Analysis of green garlic and garlic bulb production; Industry analysis on onion production; Production of radish and carrot in Taiwan; Current status and prospect of great burdock (Arctium lappa) industry in Taiwan; The relation of the nutrient of vegetable to human health; A review of disposal of agricultural plastic waste; Present status and future prospect of cultivation of native vegetables; and General discussion.

(1997). "Is there a need for new plastic resin?" BioCycle **38**(1): 6.
Reports on former East Hampton, New York recycling coordinator Peter Garnham's explanation of the properties of a new plastic resin called polyethylene napthalate (PEN) manufactured by Shell and Amoco. Federal government's approval of PEN for use in food packaging; Uncertainty concerning the resin's recyclability; PEN's potential as a beer bottle.

(2001). "Why Air Separation Works With Screen Overs But Not Compost." BioCycle **42**(9): 54.
Discusses how air separation of waste works. Challenges of air separation; Reasons for the difficulty in separating plastics from finished compost.

(2003). "Standard Classification for Standard Plastics Industry Bulk Box/Pallet Unit Size Classified By Bulk Density."
Scope: This classification covers containers used to hold plastic resins with bulk density (Test Methods D 1895) of 27 to 39 lb/ft (0.432 to 0.625 g/cm). This classification does not apply to any plastic resins with bulk density below 27 lb/ft (0.432 g/cm) or above 39lb/ft (0.625 g/cm). This standard does not apply to bulk boxes containing hazardous materials. This standard does not address box/pallet unitization requirements. This standard does not address requirements of plastic bag liners normally placed inside the corrugated bulk box before filling with plastic resin. This standard does not address tamping, shaking, or other compression methods of the resin filled bulk box to condense entrained air and increase headspace in the bulk box. This standard does not address blocking and bracing or other shipping requirements normally associated with bulk box unit deliveries. This standard does not address filled bulk box/pallet unit stack height. This standard does not address international shipping regulations of bulk box/pallet units. This standard does not address pallet opening sizes for pallet trucks. Units of MeasureThe value stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory requirements prior to use. This classification offers an organized collection of information or a series of options and does not recommend a specific course of action. This document cannot replace education or experience and should be used in conjunction with professional judgement. Not all aspects of this classification may be applicable in all circumstances. This ASTM standard is not intended to represent or replace the standard of care by which the adequacy of a given professional service must be judged, nor should this document be applied without consideration of a project's many unique aspects. The word "standard" in the title of this document means only that the document has been approved through the ASTM consensus process. 2003 ASTM International. All rights reserved.

(2003). "Standard Test Method for Determination of Effectiveness of Cleaning Processes for Reusable Medical Instruments Using a Microbiologic Method (Simulated Use Test)."

Scope: This test method is written principally for large medical instruments or instruments with internal channels or recesses (for example, flexible endoscopes) but may be used for any resuable medical instruments. This test method describes a procedure for testing the efficacy of a cleaning process for reusable medical instruments artificially contaminated with mixtures of microorganisms and simulated soil. The test method utilizes bacterial spores as tracers for foreign materials and quantifies their removal as a means of determining the efficacy of a cleaning process. The test method is designed for use by manufacturers of medical instruments and devices. However, it may also be employed by other individuals who have a knowledge of the instruments, techniques and access to appropriate facilities. Worst-case conditions can be represented by exaggerating a specific test parameter or otherwise intentionally simulating an extreme condition such as performing the test without cleaning solutions or utilizing instruments which are not new. The test procedure is devised to determine the efficacy of a cleaning process as applied to a particular instrument or group of instruments by simulating actual use situations. The test procedure may be performed on test instruments using a complete cleaning cycle or be limited to particular phases of the cycle such as precleaning, manual cleaning, automated cleaning, or rinsing. The test procedure is normally performed on a number of external and internal sites, but it may be restricted to one particular site on the instrument. A knowledge of microbiological and aseptic techniques and familiarity with the instruments is required to conduct these procedures. Note 1Because contamination of the surfaces of instruments may occur as a result of rinsing with tap water, bacteria-free water should be used for all rinsing when a water rinse step is part of the cleaning directions. Note 2Test methods to determine the effectiveness of cleaning medical instruments has only recently been actively debated, and research efforts are in their infancy. Because published experimental results are scarce, it is premature to dictate experimental reagents, conditions or acceptance criteria. Note 3The total elimination of the target organisms is not the goal of cleaning. Therefore, there will almost always be a number of microorganisms surviving on the test instruments unless one of the solutions or processes disinfects or sterilizes the test instrument. The results of various clinical and laboratory tests suggest that cleaning processes alone can produce a 102to 104log10reduction in bioburden. The exact reduction will depend upon the precise experimental conditions. The criteria for judging cleanliness should be determined and recorded before initiation of the test procedure. Note 4This test protocol employs target spores as indicators or tracers for foreign materials and monitors their removal by the cleaning process. It is certainly possible that other particulate target materials, such as microbeads (latex beads) could be used in place of microbes. These alternate approaches would be more practical in those circumstances where microbiological expertise is limited. This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. 2003 ASTM International. All rights reserved.

(2004). "CIVIL PROCEEDINGS." <u>National Environmental Enforcement Journal</u> **19**(9): 28-30.

The article presents information about several civil law suits in the United States. Some of the suits are: Michigan versus General Motors Corp., United States v. Chevron Phillips Chemical Co., and United States, Georgia, Illinois, Louisiana, and New Jersey v. CITGO Petroleum Corp. It informs that General Motors Corp. would pay $ 92,349 in civil fines to settle charges of air quality violations at its metal castings plant in Saginaw, Michigan. In addition, GM will spend $113,000 on two environmental projects to reduce mercury pollution and detect the release of mercury. The federal government recently filed a complaint alleging that Chevron Phillips and/or its predecessor failed to exercise sufficient care to prevent and address accidental releases of chemicals at the Pasadena, Texas, plastics complex, a plastic resin and specialty chemical manufacturing facility. Two accidental explosions occurred there in 1999 and 2000, which released 1,3 butadiene and other chemicals into the air and caused three deaths and injuries to almost one hundred workers at the facility.

(2004). "FORMER TIMES." Resource Recycling **23**(3): 9-9.
Recounts the issues and developments related to waste management in 1984 and 1994. Increase in polyethylene terephthalate bottle scrap recovery; Inauguration of an experiment for the simultaneous collection of solid waste and multi-material recyclable; Issues on recycled content products.

(2004). "In Brief." Environment **46**(6): 6-6.
Presents briefs related to science. Findings by a U.S. Geological Survey team that a godwit shore bird travelled more than 7,700 miles from Alaska to New Zealand; Development of a climate model at the Pacific Northwest National Laboratory which can predict the effects of global warming in the Sierra Nevada range; Technology used by GH Raisoni College of Engineering in India to convert plastic waste into fuel for automobiles.

(2004). "Ocean awash with plastic particles." Ecologist **34**(6): 8-8.
Reports on the clogging of the oceans with microscopic pieces of plastic according to a study in the journal "Science." Outcome of the ingestion of the plastic particles by small marine animals such as lugworms and barnacles; Possible sources of the plastic particles; Statement issued by the study author Richard Thompson regarding disposal of litter.

(2004). "Plastics Recycling Forges Ahead in Europe." Business & the Environment with ISO 14000 Updates **15**(11): 11-11.
Reports on the increase in plastics recycling in Europe between 2001 and 2002, according to statistics issued by the industry organization, PlasticsEurope. Overall increase in the amount of plastic waste recovered; Amount of plastics going to landfill between 2001 and 2003; Total post-user plastics waste.

(2005). "Farms to target plastics waste." Materials Recycling Week **186**(19): 5-5.
The article reports that farm plastics collection and recovery in England will be the focus of a £1 million scheme funded by the Business Resource Efficiency and Waste Programme. Farm packaging waste is covered by the Producer Responsibility Obligations, Packaging Waste Regulations, but little or no plastic waste is collected. The successful application for funding was made by the Agricultural Waste Stakeholders Forum in anticipation of the Agricultural Waste Regulations that will be introduced early next year.

(2005). "JAPAN'S TAX ON PLASTIC SACKS." New Scientist **186**(2504): 4-4.
The article informs that Japan, has decided that plastic shopping bags are a major environmental problem. Its Ministry of the Environment announced plans on June 13 to introduce a bill to make shoppers pay for them. Japan churns out 460 million tonnes of waste annually, and much of it is incinerated, releasing harmful dioxins. A survey by Kyoto city showed that 10 per cent of its plastic waste comes from bags. Similar levies in Ireland and Taiwan have reduced plastic bag waste by 90 per cent and 69 per cent respectively

(2005). RECYCLING'S VITAL SIGNS. **24:** 56-56.

Presents statistics on the recycling industry in the U.S. from 2004 to 2005. Paper and paperboard production in 2004; Recovered paper consumption for 2004; Steel production through February 2005; Scrap plastics exports through January 2005.

(2006). "California legislature takes next step." Resource Recycling **25**(6): 8-8.

The article reports on the passage of assembly bill 2449 in California, which requires stores with at least 40,000 square feet in retail space to establish their own recycling program. The bill was part of California's recycling campaign to reduce plastic litter and waste throughout the state. The residents use over 19 billion plastic grocery bags each year, which creates 147,038 tons of unnecessary landfill waste. Each year, litter collection for beaches, state highways, cities, and counties costs the state around $303.2 million.

(2006). "DRINK AND DRIVE." Materials Recycling Week **188**(13): 6-6.

The article reports that the company GE Plastics has launched its Valox iQ and Xenoy iQ resins for the automotive industry in Japan. In terms of both eco-responsibility and high performance, Valox iQ and Xenoy iQ resins represent one of the most significant technological breakthroughs. The resins are made with polybutylene terephthalate(PBT)-based polymers derived from 85% post-consumer plastic waste. According to the company, if all PBT was replaced with Valox iQ and Xenoy iQ resins, it would have created an outlet for 22.5 billion waste bottles. The resins are suitable for automotive applications such as connectors, lighting bezels, energy absorbers and body panels as well as in the consumer electronics and transportation industries.

(2006). "GREEN GONG." Materials Recycling Week **187**(25): 6-6.

The article announces the MBE award given to Robert Tyldesley during the celebration of the Queen's birthday. Tyldesley, a Green entrepreneur has been awarded because of his services to waste management. Tyldesley and his group have introduced a system of making roof tiles and paving slabs using ordinary household plastic waste. The system still works even if the plastic wastes are contaminated with food wastes. The system is being used in many developing countries, and it is soon to be launched in European countries.

(2006). "notes." Materials Recycling Week **188**(14): 35-35.

The article presents notes related to the "Materials Recycling Week" periodical's Materials Guide Prices. The guide provides prices in British pounds per tonne for green waste, nonhazardous waste, wood, glass containers, paper, plastic bottles, and packaging recovery notes (PRNs). Plastic bottles include clear polyethylene terephthalate, natural high-density polyethylene, colored high-density polyethylene, and mixed. Paper products include white office, mixed office, newspapers, and magazines. Prices are detailed for bagged and loose green waste.

(2006). "STATE & PROVINCE WATCH." Resource Recycling **25**(8): 12-13.

The article presents several news items related to the recycling policies and programs of the states and provinces of the U.S. House Bill 1074, a Colorado state bill, extended the states' waste tire recycling development fee till July 1, 2012. A plastic recycling law has been passed in the legislative session of New Jersey, which makes it mandatory for every rigid plastic packaging container to contain a minimum of 50 percent recycled content by January 1, 2006.

(2006). "Upturn in PET bottle recycling." Recycling International(8): 17-17.

The article reports on the 790,000 tons of post-consumer polyethylene terephthalate (PET) plastic bottles that are collected for recycling in Europe in 2005, a 15.1% increase from 2004, according to PET packaging trade association Petcore. The increase in PET collection in Europe was led by Germany with 32% increase in collection is recorded, while an increase in collection were also reported in Poland and France. An increase in the collection of PET plastic mostly in the form of mixed plastic waste is recorded in Great Britain and Ireland. Other statistics of PET recycling its provided.

(2006). "WEEE TAKER." Materials Recycling Week **188**(17): 6-6.
The article reports that recycling operations will be started at the mixed plastic waste recycling facility of Axion Recycling Ltd. in Salford by February 2007. According to the company, the facility would be among the major recycling facilities with advanced technologies in Europe. Commingled plastic waste will be recycled at the facility. Compliance schemes would be benefited by the facility. High-quality plastic polymer compounds could be formed from the facility's recycled waste. Axion claims that the facility would mainly handle electrical and electronic equipment waste.

(2007). "20 YEARS AGO." Resource Recycling **26**(10): 15-15.
The article reports the plastic waste issue in the late 1987 in the U.S. The section describes how plastics, most notably, plastic waste, as a major issue of national recycling efforts. It also reflects on how prominent manufactures in the U.S handle the issue on plastic waste. It documents the initiative done by Wellman Incorporated in Shrewsbury, New Jersey, to prove that post-consumer plastic scrap could be a useful and profitable resource. According to the report, the company utilized plastics scrap to produce a non-woven nylon resin that could be used in the production of such secondary products as carpet and tennis ball felt, as well as within automotive, electrical and industrial applications.

(2007). "China is top buyer of Australia recyclables." Plastics News **18**(46): 7-7.
The article reports that according to a new Plastics and Chemicals Industries Association recycling survey, China was Australia's top buyer of recycled plastics in 2005. The top two recycled resins were PET and high density polyethylene. Of 293 million pounds of PET consumed in Australia, 52 million pounds exported for recycling. A total 183 million pounds of unprocessed waste plastic was exported for reprocessing due to continuing China's strong demand.

(2007). "CHINESE EMPORIUM TRADING." Materials Recycling Week **190**(6): 11-11.
The article presents a discussion about Chinese Emporium Trading, an accredited exporter of plastic wastes from Great Britain to China for recycling. The company's managing director Chao Shu Au mentions that they are a typical small operator that purchases plastic waste from waste management companies which gathers it from British households and businesses. He also mentions that they inspect the plastic materials first before they agree to buy it. The materials were also said to be baled to achieve the require weight of 20 tons to be able to ship it. It was also discussed that the materials has to undergo another set of inspections once it reaches China before being processed and remanufactured.

(2007). "CHOICE WASTE MANAGEMENT." Materials Recycling Week **190**(6): 11-11.
The article presents a discussion about Choice Waste Management, the accredited exporter and winner of the 2005 to 2006 China Business Award for the UK Exporter of the Year. It was mentioned that the company sends most of British plastic wastes to China. Their chief executive

officer Raj Iqbal stated that most of the materials go to China by passing through Hong Kong, where it stays to be manufactured into new products such as garden furnitures, toys and packs for mobile phones. He also said that they only export materials which has been graded by the Basel Convention. The materials were also reported to be checked for quality by customs when it reach Hong Kong or China before being released into different factories. All the wastes were said to be properly handled.

(2007). "CLEANING TECHNOLOGY BOOST TO MIXED COLLECTIONS." Materials Recycling Week **190**(23): 6-6.

The article reports that Great Britain agent Axion Recycling exhibited a dry cleaning technology at Dusseldorf K2007 in Germany. According to an Axion spokesman, the technology attracted encouraging levels of inquiries from Great Britain-based companies interested in improving their recycling processes for the rapidly growing plastic waste stream. Technical director Keith Freegard stressed that the technology enables more effective recycling of the dirty portion of mixed plastic wastes, particularly food packaging.

(2007). "Davy Jones' litter." Earth Island Journal: 9-9.

The article reports on the results of a study by Greenpeace which indicate the detrimental effects of an artificial Sargasso Sea of discarded plastic garbage in the North Pacific on marine life. Ocean currents have collected the floating debris into a vortex between California and Hawaii which were described the Greenpeace spokespeople as the size of the State of Texas. Further, plastic pollution have been shown to have higher concentartions in the tropics and in shipping lanes, as well as in convergence zones.

(2007). "Drastic Plastic." Earth Island Journal **22**(3): 6-6.

The article reports that the Uganda government has imposed a ban on plastic bags. Ugandan Finance Minister Ezra Suruma stated that the ban has been imposed to encourage producers and consumers to minimize their use, as plastic bags cause serious environmental concerns because of their low disposal rate. Besides, enabling the spread of disease, plastic bags often pollute water supplies when they collect in wetland areas. Bags that are burned release toxic chemicals, increasing air pollution. It is stated that most cities in Uganda have the resources to properly dispose only about 10% of the trash produced. The ban states that companies will not be able to produce, import, or use plastic bags.

(2007). "Firm fined over shredder injury." Materials Recycling Week **190**(23): 6-6.

The article reports that Southampton, England-based plastics recycler Associated Polymer Resources has been prosecuted and fined for health and safety failures that could have killed employee Ken Ransom, who fell into a shredder. Health & Safety Executive (HSE) investigating inspector James Barrie noted that Ransom was lucky not to die, and suffered the loss of his right arm and part of his right shoulder, the loss of his left arm to the elbow, and damage to his scalp. Ronald Wilkinson, trading as Associated Polymer Resources, was found guilty on two health and safety charges for failing to provide safe operating systems.

(2007). "FOOD-GRADE PLASTICS GET RECYCLING PLANT." Materials Recycling Week **189**(11): 4-4.

The article announces the opening of Closed Loop London (CLL), the first food-grading plastics recycling plant, through the funding agreement of private and public sector in Great Britain. The plant offers reprocessing capacity for 35,000 tonnes of polyethylene terephthalate a year. According to CLL managing director Chris Dow, the development of the facility is the realization

of a three-year vision to end the loop on plastics recycling in the country. The country will have a world-class facility for processing its plastic waste and does not need to export the material into a low-grade application.

(2007). "FORMER TIMES." Resource Recycling **26**(9): 15-15.
The article recounts the evolution of the recycling trend in the U.S. In 1987, it has been found that plastic waste was the major issue in recycling. The economy of the domestic plastics industry was growing through the first half of 1987, and the production of plastics resins has also totaled by 23.6 billion pounds. The officials claimed that the recovery numbers will only increase if the recycling industry would integrate the high-density polyethylene in statewide recycling programs. On the other hand, in 1990s, the deinked pulp (DIP) sector has been viewed to be one of the industry's great success. However, many experts are looking on the possibilities of survival if the objectives can be realized.

(2007). "FROM THE ROAD TO THE ROOF." Recycling Today **45**(11): 31-31.
The article reports on a study which investigated the behavior of scrap plastics when blended with rubber powder derived from post-consumer tires funded by the Waste and Resources Action Programme (WRAP). Included in the trial is the creation of a new replica slate roofing tile incorporating a high percentage of recycled material. WRAP is said to be looking at supporting standard testing to provide accreditation for the use of the research's product in the marketplace.

(2007). "Microplastics pose hidden pollution risk." New Scientist **196**(2628): 20-20.
The article reports on the study by Emma Teuten and colleagues at the University of Plymouth, England indicating that microscopic grains of plastic in the sea accumulate carcinogenic pollutants which build up in the food chain. Teuten and colleagues demonstrated that grains of plastics are much better than grains of silt or sand in adsorbing pollutant phenanthrene from water. It cites that lugworms may accelerate the arrival of toxins in food by gorging themselves on grains of waste plastic.

(2007). "NO MORE PLASTIC WASTE, SAYS NZ MINISTER." Clean Air & Environmental Quality **41**(2): EI8-EI8.
The article reports on the statement of New Zealand environment minister David Benson-Pope about the recycling of all plastic packaging in the country and the government's plan to work with the local government and industry to stop the dumping of plastics into landfills. Benson-Pope visited four of the country's largest recycling facilities covering glass, plastic, paper, and metal to check whether these facilities have implemented the recycling concept and their focus on reducing the amount of waste.

(2007). "Recycle -- if you think you've got the bottle!" Sustain' Magazine **8**(4): 69-69.
The article reports on the signing of a joint private- and public-sector funding agreement that will create the first plant in Great Britain to recycle plastics into material for food packaging. The plant, located in Dagenham, London, England and operated by Closed Loop London, will transform the recycling of polyethylene terephathalate in Britain. The facility is scheduled to open in December 2007. It is reported that Marks & Spencer is the first major retailer to commit sending plastic waste from its stores in London, England to the Closed Loop London plant for recycling.

(2007). "Sharp develops plastics recycling technology." Recycling International(8): 10-10.

The article reports on the claim of consumer electronics manufacturer Sharp Corp. that it has developed a technology for separating and recovering high-purity polypropylene (PP). The company says that using the technology it will be able to separate PP from plastic components retrieved from televisions, air conditioners, refrigerators and washing machines and convert them into high-quality plastics. In 2001, Sharp succeeded in creating a technology for closed-loop material recycling which allowed the repeated reuse of scrap plastic components that have a single resin.

(2007). "Sri Lanka boosts plastic recycling." Recycling International(9): 15-15.

The article focuses on the efforts by the Sri Lankan government to encourage plastic waste recycling in the country. In an effort to prevent the piling up of plastic wastes along the road side and to curb environmental pollution, the Central Environmental Authority has launched a program called the national post-consumer plastic waste management. The government plans to impose tax on plastic imports to help fund the collection and recycling of the waste. Authorities hope that raw plastic imports could be reduced by 20% after the first year of the program.

(2008). "AERT Receives Funding to Build Plastics Recycling Facility." Recycling Today **46**(2): 18-18.

The article reports on the completion of $13.5 million in financing by AERT Inc. to fund a plastic waste mining and reclamation facility dubbed Advanced Resource Recovery Project (ARRP) near Watts, Oklahoma. The facility is aimed at reducing the company's raw material costs and assuring a stable raw materials supply. The facility is expected to be operational by the end of 2008.

(2008). "AWS plastics upgrade goes live in Lincs…." Materials Recycling Week **192**(13): 8-8.

The article reports that the 14 million pounds-worth reprocessing facility of AWS Eco Plastics at Hemswell, Lincolnshire, England, has become completely operational. This key upgrade increases its recycling capacity four-fold to 15 tons of plastic waste per hour or 100,000 tons every year. The facility is designed to produce food-grade recycled plastics.

(2008). "Citigroup invests in MBA Polymers." Recycling International(7): 11-11.

The article reports on the funding secured by MBA Polymers from investment bank Citigroup and existing investors. The money will be used for further expansion for a company. The high-performance plastic resin manufacturer recovers high-value plastics from complex waste streams, extracting plastics from items such as household appliances and business equipment. It has developed a process to recover and separate plastics from each other.

(2008). "Ethanol Coproducts Eyed as Fillers in Plastics." Resource: Engineering & Technology for a Sustainable World **15**(6): 27-27.

The article reports on a study of the production of ethanol coproducts as a non-petroleum-based filler in plastics. It is conducted by USDA Agricultural Research Service (ARS) agricultural engineer Kurt Rosentrater. It uses molded blends of DDGS and phenolic plastic resin. Its results show that 25 to 50 percent concentration of DDGS can be used as fillers in plastics. It also manifests that the development of new bio-based manufactured products is possible and may lead to less use of petroleum in plastic products.

(2008). "INFORMATION SOURCES." Resource Recycling **27**(9): 48-48.

The article presents information sources related to recycling. Mandy Haggith introduces her new book titled "Paper Trails: Travels in the Global Paper Industry," published by Virgin Books. Research and Markets released a report, "Recycling of PVC and Mixed Plastic Waste," that analyzes the production and recyclability of materials made from virgin polymers. INFORM released a five-minute film, "The Secret Life of Paper," presenting the environmental impacts of paper production and consumption.

(2008). "ISO GUIDELINES FOR RECYCLING OF PLASTICS WASTE." Journal of Plastic Film & Sheeting **24**(3/4): 166-166.

The article offers information on the issuance of guidelines for plastic waste by TC61 Plastics group of the International Organization for Standardization (ISO). The ISO 15270:2008 provides guidance for the development of standards and specifications encompassing plastics waste recovery that includes recycling. It establishes the different options for the recovery of plastics waste originating from pre-consumer and post-consumer sources and establishing the quality requirements for it.

(2008). "Marine food chain threatened by plastic waste." Oryx **42**(3): 316-316.

The article discusses the effect of plastic wastes in oceans. It mentions that tiny plastic particles might attract toxic contents that can take in by organisms living underwater. According to the author, microscopic pollution has worse consequences than what is expected to happen. The researchers likewise say that microscopic plastic fragments produce pollutants like DDT insecticide that makes water contaminated. Moreover, plastic wastes stay on shores for a long time since it is difficult to degrade.

(2008). "Non-packaging plastic gets a quality boost." Materials Recycling Week **191**(1): 7-7.

The article reports on the Quality Protocol proposal for non-packaging plastic waste launched by the Environment Agency and Waste & Resources Action Programme (WRAP) in Great Britain. According to reports, the Quality Protocol aims to free one-third of all plastic from waste regulations to encourage more recycling. It mentions that with the protocol, million tonnes of plastic could be turned away from landfill every year. It was noted that a Quality Protocol can save businesses the time and costs associated with meeting waste regulations by clearly defining the standards required to collect, transport, store, recycle and reuse non-packaging plastic without risking human health and the environment.

(2008). "Plastics." Resource Recycling **27**(1): 36-36.

The article discusses the decreasing prices of virgin resin caused by plastic buyers who resisted the demand in price increase by virgin resin producers. The author mentions that a large amount of plastic buyers resisted the attempt of virgin resin producers to increase the price of resin prices. He explains that plastic buyers were aware of large volumes of price and recycled plastics that were available even at a time of record exports. The author also explains that virgin resin prices increase during the month of December.

(2008). "Plastics industry urged to intensify efforts at recycling, reuse." Popular Plastics & Packaging **53**(1): 58-59.

The article focuses on the need for the Indian plastics industry to find solutions on the collection, recycling and reuse of plastics waste in the country. According to Union Minister of State for Chemicals and Fertilisers B. K. Handique, there has been much advancement in technology for collection and processing of used plastics. Plexconcil chairman R. C. Lohia said export of processed plastic exports had actually come down. A project in the plastic consumer goods markets includes establishing display centres and warehousing facilities.

(2008). "Recession hits paper and plastic recyclate prices." ENDS (Environmental Data Services)(406): 4-5.

This article reports on the impact of the impending recession on the price for recyclable waste in Great Britain in 2008. The recession has led to a dramatic fall in the price for recyclable waste, with paper and plastic the most affected. The Department for Environment, Food and Rural Affairs (DEFRA) held a meeting on increasing storage space for recyclables until prices recovered. Glass is the only material that has not been affected by the recession.

(2008). "Standard Classification for Standard Plastics Industry Bulk Box/Pallet Unit Size Classified By Bulk Density."

Scope: This classification covers containers used to hold plastic resins with bulk density (Test Methods D 1895) of 27 to 39 lb/ft3(0.432 to 0.625 g/cm3). This classification does not apply to any plastic resins with bulk density below 27 lb/ft3(0.432 g/cm3) or above 39lb/ft3(0.625 g/cm3). This classification does not apply to bulk boxes containing hazardous materials. This classification does not address box/pallet unitization requirements. This classification does not address requirements of plastic bag liners normally placed inside the corrugated bulk box before filling with plastic resin. This classification does not address tamping, shaking, or other compression methods of the resin filled bulk box to condense entrained air and increase headspace in the bulk box. This classification does not address blocking and bracing or other shipping requirements normally associated with bulk box unit deliveries. This classification does not address filled bulk box/pallet unit stack height. This classification does not address international shipping regulations of bulk box/pallet units. This classification does not address pallet opening sizes for pallet trucks. The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory requirements prior to use.This classification offers an organized collection of information or a series of options and does not recommend a specific course of action. This document cannot replace education or experience and should be used in conjunction with professional judgement. Not all aspects of this classification may be applicable in all circumstances. This ASTM standard is not intended to represent or replace the standard of care by which the adequacy of a given professional service must be judged, nor should this document be applied without consideration of a project's many unique aspects. The word standard in the title of this document means only that the document has been approved through the ASTM consensus process. 2008 ASTM International. All rights reserved.

(2008). "Standard Test Method for Determination of Effectiveness of Cleaning Processes for Reusable Medical Instruments Using a Microbiologic Method (Simulated Use Test)."

Scope: This test method is written principally for large medical instruments or instruments with internal channels or recesses (for example, flexible endoscopes) but may be used for any resuable medical instruments. This test method describes a procedure for testing the efficacy of a cleaning process for reusable medical instruments artificially contaminated with mixtures of microorganisms and simulated soil. The test method utilizes bacterial spores as tracers for foreign materials and quantifies their removal as a means of determining the efficacy of a cleaning process. The test method is designed for use by manufacturers of medical instruments and devices. However, it may also be employed by other individuals who have a knowledge of the instruments, techniques and access to appropriate facilities. Worst-case conditions can be represented by exaggerating a specific test parameter or otherwise intentionally simulating an extreme condition such as performing the test without cleaning solutions or utilizing instruments which are not new. The test procedure is devised to determine the efficacy of a cleaning process as applied to a particular instrument or group of instruments by simulating actual use situations. The test procedure may be performed on test instruments using a complete cleaning cycle or be limited to particular phases of the cycle such as precleaning, manual cleaning, automated cleaning, or rinsing. The test procedure is normally performed on a number of external and internal sites, but it may be restricted to one particular site on the instrument. A knowledge of microbiological and aseptic techniques and familiarity with the instruments is required to conduct these procedures. Note 1Because contamination of the surfaces of instruments may occur as a result of rinsing with tap water, bacteria-free water should be used for all rinsing when a water rinse step is part of the cleaning directions. Note 2Test methods to determine the effectiveness of cleaning medical instruments has only recently been actively debated, and research efforts are in their infancy. Because published experimental results are scarce, it is premature to dictate experimental reagents, conditions or acceptance criteria. Note 3The total elimination of the target organisms is not the goal of cleaning. Therefore, there will almost always be a number of microorganisms surviving on the test instruments unless one of the solutions or processes disinfects or sterilizes the test instrument. The results of various clinical and laboratory tests suggest that cleaning processes alone can produce a 102to 104log10reduction in bioburden. The exact reduction will depend upon the precise experimental conditions. The criteria for judging cleanliness should be determined and recorded before initiation of the test procedure. Note 4This test protocol employs target spores as indicators or tracers for foreign materials and monitors their removal by the cleaning process. It is certainly possible that other particulate target materials, such as microbeads (latex beads) could be used in place of microbes. These alternate approaches would be more practical in those circumstances where microbiological expertise is limited. The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard. This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. 2008 ASTM International. All rights reserved.

(2008). "Steady Does It." Recycling Today **46**(3): 40-42.

The article presents an update on the status of the plastics recycling markets. Plastics reprocessors are said to report steady progress for commodity grades of secondary plastics, such as acrylonitrile butadiene styrene (ABS) and high impact polystyrene (HIPS), in the first quarter of 2008. According to one reprocessor, domestic consumers are not interested in paying much for polyvinyl chloride (PVC). It cites the possible impact of the problems that Plastech Engineered Products Inc. is having on the market.

(2008). "WRAP sets target for mixed plastics recycling." Recycling International(5): 9-9.

The article reports on the target sets by the government-supported Waste and Resources Action Programme (WRAP) for the opening of the first mixed plastics reprocessing plant in Great Britain

by 2011. The recycling plant will have the annual capacity to recycle approximately 40,000 tons of mixed plastics into food-grade polypropylene, according to the article. Mixed plastics account for at least 7 percent by weight of the domestic waste stream in Great Britain, according to WRAP. Each household produced an estimated 86 kilogram of plastic waste annually and the vast majority ends up in landfill, according to the article.

(2009). ""Liquid Wood" Could Ease World's Dependence on Plastic." Business & the Environment **20**(9): 11-12.

The article reports on the development of a new formula by Germany-based firm Tecnaro GmbH which enables a liquid wood to be molded like plastic. It says that the said formula consists of lignin, fiber and other additives. It notes that the invention is important because it can help address the growing number of plastic waste in the world.

(2010). "Axion gives recycled plastic a caffeine kick." Recycling International(4): 13-13.

The article reports on the polymer with coffee aroma that was developed by British recycling consultancy Axion Polymers from waste electrical and electronic equipment (WEEE) and post-consumer plastics with spent coffee grounds for London, England-based industrial design and product development firm, Re-worked.

(2010). "Construction Materials Manufacturer Asks Supreme Court to Require EPA to Clarify Rule." BNA's Environmental Compliance Bulletin **17**(10): 151-151.

The article reports on the clarification asks by US Technology Corp. to the U.S. Supreme Court pertaining to the rules set by Environmental Protection Agency (EPA) on solid waste regulation. It notes that the company uses spent materials containing plastic particles and paint chips that make the materials hazardous in which according to EPA in Ohio constitutes disposal. US Technology Corp. are asking EPA to interpret the 40 CFR 266.20 to determine if the blocks used really constitutes disposal.

(2010). "Sita to build plants that will turn mixed plastic waste into diesel." ENDS (Environmental Data Services)(430): 19-19.

The article reports on British waste company Sita's partnership with Cynar PLC to develop and construct ten pyrolysis plants to convert mixed waste plastic into diesel. The plants are designed to be small in order to avoid moving bulky and light materials around. The process for turning plastic waste into diesel involves heating shredded plastic in the absence of air to form a hydrocarbon gas, which will then be condensed and fractionated to produce a low-sulfur liquid fuel.

(2010). "THE SLOW PACE OF SUMMER." Recycling Today **48**(8): 32-34.

The article provides information on the performance of the plastics industry in the U.S. from June 2009 to June 2010. According to a broker of material along the Eastern Seabord, he finds plastic scrap generation to be declining for post-consumer material. He stresses that the downsizing of containers served as a factor contributing to the decline in generation. A reprocessor based in the Midwest says that prices for commodity grade plastics are receding.

(2011). "ACC Reports Growth in Rigid Plastics Recycling." Recycling Today **49**(4): 10-10.

This article discusses a report released by the American Chemistry Council (ACC) showing the increase in the collection and recycling of post-consumer non-bottle rigid plastics in the U.S. in 2009.

(2011). "CHINA CONTINUES TO DOMINATE." Recycling Today **49**(4): 42-43.
This article discusses the growth of the recycled plastics industry in China in 2011. It highlights strong domestic demand for post-consumer high-density polyethylene (HDPE) and polyethylene terephthalate (PET). It also shows increased interest of domestic buyers in low-density polyethylene (LDPE) film. In addition, the article observes a strong export market for recycled plastics.

(2011). "EASING BACK." Recycling Today **49**(11): 34-35.
The article offers an update on the status of the plastic scrap market in the U.S. as of November 2011. There remains to be stable generation and demand for plastic scrap, but prices are declining. The importation restrictions in China play a significant role in the decline, according to a Midwest-based reprocessor. Lower-grades of plastic scrap are not allowed to enter China. Companies in the U.S. such as Revolution Bag remains committed to collecting and processing post-consumer plastics.

(2011). "Events." Resource Recycling **30**(1): 50-51.
A calendar of events for 2011 is presented which includes the IERC 10th Annual International Electronics Recycling Congress, the Tennessee Recycling Coalition Conference and Trade Show, and the Plastic Recycling Conference.

(2011). "EXPORT MARKETS SOFTEN." Recycling Today **49**(7): 34-35.
The article presents a report on the market performance of plastics as of July 2011. Although the demand for secondary plastics is strong, demands for export to China have weakened due to new import duties imposed by the Chinese government. Other factors affecting the decrease in demand include wage increases in China, and difficulty in acquiring containers for overseas shipments. Domestic demand for secondary plastics remains healthy as consumers realize the advantages of recycled materials.

(2011). "Gearing Up." Recycling Today **49**(1): 28-28.
The article focuses on an increase in demand for secondary plastics. As of mid-December 2010, buying of recycled plastics was very strong with orders coming from both Chinese and U.S. consumers. Buyers in China have been stocking up in advance of Chinese New Year-related business closures. Meanwhile, scrap generation continue to increase in the U.S. as manufacturers look to increase recycled content in their products. Among companies looking to increase the amount of recycled polyethylene terephthalate (PET) used in its bottles is Naked Juice.

(2011). "Healthcare group to push plastics recycling in hospitals." Recycling International(4): 11-11.
The article reports that the Healthcare Plastics Recycling Council (HPRC) is leading a campaign with healthcare providers, manufacturers, and waste handlers to recycle plastic products that are being used in hospitals.

(2011). "In the market for plastics." Local Authority Waste & Recycling **19**(11): 33-33.
The article discusses the findings of an assessment of the plastics recycling market in Great Britain detailed in the "Plastics Recycling Market Report - UK 2011-2015 Analysis" released by the firm AMA Research in September 2011. Investment by the private sector in plastic recycling infrastructure is increasing. Volumes of recovered post-consumer plastics are likely to increase

further. There will be a new focus on recycling plastic waste locally instead of exporting the material to China.

(2011). "PLASTIC POLLUTION COALITION: Information Recycled, Reused, and Improved." Earth Island Journal **26**(1): 20-20.
The article offers information on the online information portal known as Plastic Free Times which organized by Plastic Pollution Coalition for environmental, social and health issues associated with the global plastic pollution crisis.

(2011). "Sailing the Plastic Seas." Our Planet: Weekly Newsletter of E Magazine: 7-7.
The article offers information on the impact of plastic waste particles, on the health of humans, birds and marine wildlife. It mentions that according to the United Nations Environment Programme (UNEP), 1,000,000 seabirds and 100,000 marine mammals die every year from plastic debris. It states that 80 percent of floating plastic waste comes from land.

(2011). "The Wide World of Recycling." Resource Recycling **30**(1): 10-10.
The article reports on developments in global plastic recycling. University of Warwick researchers have developed a technique to recycle plastic waste leftover from the holidays. The Israel Ministry of Environmental Protection has allocated a fund for the construction of waste treatment and recycling facilities. The Department of Environment, Food and Rural Affairs has considered to reduce its contribution to the Waste & Resources Action Programme (WRAP).

(2012). "HPRC to Study Plastic Scrap from Health Care Facilities." Recycling Today **50**(10): 32-32.
The article reports on the finalization of an agreement between Healthcare Plastics Recycling Council (HPRC) and Stanford University Medical Center concerning a six-month pilot study of plastic waste coming from health care facilities.

(2012). "Nextlife Adds Plastics Processing Line." Recycling Today **50**(1): 16-16.
The article reports on the opening of a new film-to-film processing line by Florida-based plastics recycling company Nextlife in Frankfort, Kentucky in an effort to expand its conversion of plastic waste materials into consumer products including packaging and film-to-film applications.

(2012). "Report Projects Benefits, Costs of Plastics-to-Energy Facilities." BNA's Environmental Compliance Bulletin **19**(11): 170-170.
The article discusses the report "Environmental and Economic Analysis of Emerging Plastics Conversion Technologies," which states that new technologies that convert nonrecycled plastic waste into energy or raw materials could provide environmental benefits and cost savings compared to landfill disposal. It has been informed that the report states that waste conversion create less heat and fewer air emissions in comparison to landifil disposal.

(2013). "...as UK performs badly with 70% sent to Landfill." Materials Recycling World **202**(19): 7-7.
The article reports that Great Britain is among the worst performing European countries in terms of sending plastics to landfills because it also sent 70% post-consumer plastic waste in landfills in 2012.

(2013). "ASIA." Materials Recycling Week **201**(10): 12-13.
This section offers news briefs on recycling in Asia as of March 2013. Taiwan is building a factory to recycle waste electrical and electronic equipment (WEEE) generated by consumers and

technology firms. Pakistan's Environmental Protection Department claims that the nation's scrap plastic market has been inundated without the proper facilities, leaving millions of people exposed to hazardous plastic waste. Experts have called for more waste education programs across the United Arab Emirates.

(2013). "Defra backs campaign to encourage plastics recycling." Materials Recycling World **202**(11): 8-9.
The article reports that the British Department of Environment, Food & Rural Affairs (Defra) will put in 20,000 British pounds to a campaign launched by plastics management charity Recoup to increase collection and recycling of packaging. The charity's "Plastic Matters" initiative will provide local authorities with consumer communication support and tools to encourage recycling. Main area of concern will be pots, tubs and trays whose recycling rate remained flat year-on-year at 19%.

(2013). "Exporters shun 'Green Fence' exposure." Recycling International(5): 44-45.
The article reports on the decision of Western recovered fibre exporters to suspend shipments to China. The move is attributed to concerns over the additional custom clearance delays and higher costs associated with the country's Green Fence regime. One European supplier to the region wanted to avoid exposure to the Green Fence and the possibility of having containers rejected for what he believes are unjustifiable reasons in some instances. INSET: Nine Dragons unveils six-line expansion plan.

(2013). "First map of plastic pollution in Australian waters." Ecos(190): 1-2.
The article focuses on the study by the researchers at The University of Western Australia and CSIRO-Wealth from Oceans Flagship on Australian sea surface contamination. The study shows that plastic particles, one of type of contaminants, are a result of the breakdown of disposable packaging and fishing gear that were made of polyethylene and polypropylene. The study also provides the first map of floating marine plastics distribution in Australian waters.

(2013). "MBA Polymers Calls for UK VAT Exemptions." Recycling Today **51**(4): 24-24.
The article reports on the request of MBA Polymers for the British government to suspend the value-added tax (VAT) on recycled plastics to help stimulate consumer demand and encourage investment in the plastics recycling industry. MBA Polymers Chief Executive Officer (CEO) noted the environmental and economic benefit from recycled plastics. He proposes an audit of downstream overseas plastic waste processors and a legislation to encourage post-consumer recycled plastics content in new products.

(2013). "MRW's pick of the latest new business." Materials Recycling World(0): 11-11.
The article presents information of contracts which are available for bidding. It includes contracts such as Scotland Excel for treatment of organic waste, North Tyneside Council for processing of recyclable materials, and Bristol & Weston National Health Survey (NHS) Purchasing Consortium for supply and delivery of plastic waste bags.

(2013). "Standard Classification for Standard Plastics Industry Bulk Box/Pallet Unit Size Classified By Bulk Density."
Scope: This classification covers containers used to hold plastic resins with bulk density (Test Methods D1895) of 27 to 39 lb/ft3(0.432 to 0.625 g/cm3). This classification does not apply to any plastic resins with bulk density below 27 lb/ft3(0.432 g/cm3) or above 39lb/ft3(0.625 g/cm3). This classification does not apply to bulk boxes containing hazardous materials. This

classification does not address box/pallet unitization requirements. This classification does not address requirements of plastic bag liners normally placed inside the corrugated bulk box before filling with plastic resin. This classification does not address tamping, shaking, or other compression methods of the resin filled bulk box to condense entrained air and increase headspace in the bulk box. This classification does not address blocking and bracing or other shipping requirements normally associated with bulk box unit deliveries. This classification does not address filled bulk box/pallet unit stack height. This classification does not address international shipping regulations of bulk box/pallet units. This classification does not address pallet opening sizes for pallet trucks. The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory requirements prior to use. This classification offers an organized collection of information or a series of options and does not recommend a specific course of action. This document cannot replace education or experience and should be used in conjunction with professional judgement. Not all aspects of this classification may be applicable in all circumstances. This ASTM standard is not intended to represent or replace the standard of care by which the adequacy of a given professional service must be judged, nor should this document be applied without consideration of a project's many unique aspects. The word standard in the title of this document means only that the document has been approved through the ASTM consensus process. 2013 ASTM International. All rights reserved.

(2013). "Young turtles at sea more likely to swallow plastic." Ecos(186): 1-2.

The article focuses on a study conducted by Chris Wilcox and Denise Hardesty from Commonwealth Scientific and Industrial Research Organization (CSIRO) Wealth from Oceans Flagships which reveals the probability of sea turtles for debris ingestion. It notes that turtle that eats or intake debris such as plastics has tendency to be killed. It adds that coastal cleanup activities must be conducted to resolve such problem.

(2014). "2014 2nd International Conference on Food and Agricultural Sciences, Auckland, New Zealand, 12-14 November 2014." International Proceedings of Chemical, Biological and Environmental Engineering **77**: 1-65.

This special issue features 13 articles specifically discussing the following topics: magnetic treatment of irrigation water and its effect on water salinity; anti-inflammation and anti-infection applicability of Tremella flava Chen fermented soya milk (TFS) in a BALB/c mice model; effect of age on the perception of functional foods by residents of Poland; effects of different molecular weights of chitosan coatings on postharvest qualities of 'nam dok mai' mango; sustainable rice-cattle integrated farming system for small landholders in Bulacan Province, Philippines; improvement of antioxidant status in Nile tilapia Oreochromis niloticus using hot water extract of waste mushroom stalk; short-term effect of alginate-biochar microbeads in corn germination; potential of green banana as biodegradable packaging films; drying characteristics of lemongrass in solar assisted chemical heat pump dryer; development of method to produce snacks supplemented with brewer's spent cassava; small scale sustainable farming activities in the United Arab Emirates: the case of the East Coast of the UAE; effect of gamma-ray radiation on morphological development of Orthosiphon stamineus (cat whisker); and, profile of microorganisms and amylose content of white corn flours of two local varieties as affected by fermentation process.

(2014). "Briefly." Oryx **48**(4): 471-480.
The article offers world news briefs. Topics discussed include the decline of wildlife that was linked to the increase in child slavery, the impacts of deforestation to fish ecology, and the risks of diclofenac drugs to eagles. Also mentioned are the effects of climate change to reptiles, the loss of biodiversity and destabilization of grasslands because of fertilizers, and the map that reveals the degree of plastic pollution in the ocean.

(2014). "The case of the missing plastic." Recycling International(7): 71-71.
The article discusses the findings of a study conducted by researchers at the University of Cadiz in Spain which reveals that there are only about 7,000 to 40,000 tons on plastic waste on the surface of the world's ocean. Topics covered include the findings that plastics floating of surface water only accounts for one percent of plastic pollution in the oceans and the possibility that most plastic waste can be found under the oceans.

(2014). "CLOSER TO HOME." Recycling Today **52**(2): 38-38.
The article focuses on the plan of some materials recovery facility (MRF) operators to sell secondary plastics to houses due to the continuing issues of exporting materials. Topics discussed include the avoidance of low-grade materials by Chinese consumers due to the enforcement of its government to reduce shipments of hazardous materials, the decline of plastic demand in India due to the change in import/export policy of plastic scrap, and the high demand of scrap plastic in Canada and Europe.

(2014). "DIY recycling the most energy efficient." Recycling International(3): 19-19.
The article discusses a study conducted by Michigan Technological University in the U.S. which indicated that turning commonplace plastic scrap into 3D printing filament consumes less energy than conventional recycling.

(2014). "GLOBAL NEWS ROUND-UP." Materials Recycling World **203**(8): 10-11.
This section presents news briefs about key developments in waste management across the world as of March 2014. It reports that the government of Hong Kong has launched a new scheme to slash the country's total food waste by 40% within the next nine years, while the Clinton Foundation has donated 250,000 U.S. dollars to a Haitian recycling plant that seeks to clean up the city of Port-au-Prince. In addition, U.S. exports of plastic scrap to China had dropped in value terms by 18% in 2013.

(2014). "Illinois Bans Products Containing Plastic Microbeads." BNA's Environmental Compliance Bulletin **21**(13): 205-205.
The article reports that Illinois on June 8, 2014 banned the manufacture and sale of consumer products such as facial scrubs, body washes which contain synthetic plastic microbeads to control water pollution in the Great Lakes and other waterways in the U.S.

(2014). "Ocean Debris." E THIS WEEK: 4-4.
The article discusses the impact of the marine debris such as plastic into the ocean and human health. It highlights the coverage of the disappearance of Malaysian Airlines Flight 370 which contribute to the movement of harmful invasive species that suffocate coral reefs. It also notes that the U.S. Environmental Protection Agency (EPA) encourages people to stop plastic pollution

in our oceans.

(2014). "Pop stars help tackle plastic waste." Recycling International(7): 21-21.
The article reports that singer will.i.am and Coca-Cola Co. have teamed up to launch a three-dimensional printer under the EKOCYCLE brand which uses recycled polyethylene terephthalate (PET) bottles.

(2014). "Research links trace toxic metals in seabirds to plastic pollution." Ecos(192): 16-17.
The article reports on the findings of the study conducted by researchers from the University of Tasmania which examines the toxic effects of marine plastic pollution ingestion by the sea birds Flesh-footed Shearwaters. The study found an increase in the number of birds ingesting plastic over the four-year study period. It was observed that birds with high levels of ingested plastic exhibited reduced body condition and increased contaminant load.

(2014). "The science is in: the solution to pollution is not dilution." Ecos(195): 6-7.
The article discusses a study conducted by Australian Nuclear Science and Technology Organisation (ANSTO) Professor Richard Banati and Monash University ecologist Dr. Jennifer Laver about the use of radioactive tracers and seabird feathers to investigate the extent of plastic pollution in the marine food chain. Topics include the degradation process of plastics floating in the oceans and the management of marine pollution.

(2014). "Scientists and adventurers team fight microplastics." Sierra **99**(4): 1-7.
The article presents the author's views on the Plastic Tides paddle boarding expedition around the coast of Bermuda. The expedition reportedly involved a group of friends led by Jordan Holsinger which collected water samples to document microplastic pollution. Studies have shown that microplastics have negatively affected marine ecosystems worldwide.

(2014). "Standard Test Method for Determination of Effectiveness of Cleaning Processes for Reusable Medical Instruments Using a Microbiologic Method (Simulated Use Test)."
Scope: This test method is written principally for large medical instruments or instruments with internal channels or recesses (for example, flexible endoscopes) but may be used for any resuable medical instruments. This test method describes a procedure for testing the efficacy of a cleaning process for reusable medical instruments artificially contaminated with mixtures of microorganisms and simulated soil. The test method utilizes bacterial spores as tracers for foreign materials and quantifies their removal as a means of determining the efficacy of a cleaning process. The test method is designed for use by manufacturers of medical instruments and devices. However, it may also be employed by other individuals who have a knowledge of the instruments, techniques and access to appropriate facilities. Worst-case conditions can be represented by exaggerating a specific test parameter or otherwise intentionally simulating an extreme condition such as performing the test without cleaning solutions or utilizing instruments which are not new. The test procedure is devised to determine the efficacy of a cleaning process as applied to a particular instrument or group of instruments by simulating actual use situations. The test procedure may be performed on test instruments using a complete cleaning cycle or be limited to particular phases of the cycle such as precleaning, manual cleaning, automated cleaning, or rinsing. The test procedure is normally performed on a number of external and internal sites, but it may be restricted to one particular site on the instrument. A knowledge of microbiological and aseptic techniques and familiarity with the instruments is required to conduct these procedures. Note 1:Because contamination of the

surfaces of instruments may occur as a result of rinsing with tap water, bacteria-free water should be used for all rinsing when a water rinse step is part of the cleaning directions. Note 2:Test methods to determine the effectiveness of cleaning medical instruments has only recently been actively debated, and research efforts are in their infancy. Because published experimental results are scarce, it is premature to dictate experimental reagents, conditions or acceptance criteria. Note 3:The total elimination of the target organisms is not the goal of cleaning. Therefore, there will almost always be a number of microorganisms surviving on the test instruments unless one of the solutions or processes disinfects or sterilizes the test instrument. The results of various clinical and laboratory tests suggest that cleaning processes alone can produce a 102to 104log10reduction in bioburden. The exact reduction will depend upon the precise experimental conditions. The criteria for judging cleanliness should be determined and recorded before initiation of the test procedure. Note 4:This test protocol employs target spores as indicators or tracers for foreign materials and monitors their removal by the cleaning process. It is certainly possible that other particulate target materials, such as microbeads (latex beads) could be used in place of microbes. These alternate approaches would be more practical in those circumstances where microbiological expertise is limited. The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard. This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. 2014 ASTM International. (2014). Updates. **33:** 1065-1068.

The article presents news briefs related to environmental protection as of December 2014. A report in the journal "Proceedings of the National Academy of Sciences of the U.S." estimated there are between 7,000 and 35,000 tons of plastic trash floating in the world's oceans. A 2013 report from the U.S. Department of Agriculture noted that natural microbes help farmers restore soil. The 2015 Annual Conference of the U.S. National Association of Environmental Professionals will held in Hawaii.

(2015). "AMERICAS." Materials Recycling World **204**(8): 14-14.

The article offers news briefs related to waste management and recycling in the Americas in April 2015. Topics include less recycling material per household in Calgary, Alberta, a recycled food container called evercycle launched by aluminium producer Novelis Inc., and the recycling campaign in Mexico to reduce plastic waste on beaches. It also notes the decline of scrap metal theft in Broome County, New York.

(2015). "EPA Lacks Authority Over Microbead Discharges." BNA's Environmental Compliance Bulletin **22**(11): 172-172.

The article reports that the U.S. Environmental Protection Agency (EPA) lacks Clean Water Act authority to regulate consumer use of plastic microbeads that are entering wastewater discharged to treatment facilities.

(2015). "Eureka! Finding solutions to plastic pollution." Ecos(209): 1-3.

The article focuses on research activities of the marine debris team of the Commonwealth Scientific & Industrial Research Organization of Australia, which has been selected as a finalist of the 2015 Eureka Prize. It states that CSIRO Oceans and Atmosphere project used interdisciplinary research to understand the sources and distribution of marine debris, and mentions plastic pollution as a major threat to marine ecosystems.

(2015). "Law Makes Wisconsin Eighth State To Ban Microbeads From Consumer Products." BNA's Environmental Compliance Bulletin **22**(15): 237-237.

The article reports on the Senate Bill 15 signed by Wisconsin Governor Scott Walker which aims to prohibit production and sale of personal care products like facial scrubs and cosmetics that contain synthetic plastic microbeads.

(2015). "MARKETS & PRICES." Materials Recycling World **204**(6): 37-37.

This section offers news and reports across the secondary materials sector in Great Britain and abroad. The World Gold Council has reported a gold price fall to a seven-year low in 2014. Due to the weakening of the Euro against the pound, recovered plastic merchants in Great Britain have reported difficulties in export markets. A decline in the prices has been reported by recovered textiles suppliers to British collectors.

(2015). "MICROBEAD BAN SIGNED BY CALIFORNIA GOVERNOR." BioCycle **56**(9): 8-10.

The article reports that a bill is passed from California Governor, Jerry Brown which ban the sale of personal care products containing plastic microbeads. According to Assembly Member Richard Bloom, toxic microbeads are gathering in rivers and oceans at high levels resulting in increase cleanups costs to taxpayers and decrease ocean health. It states that many natural alternatives including apricot shells and cocoa beans have been used instead of plastic microbeads.

(2015). "States Begin to Ban Microbeads." Skin Deep **13**(4): 45-45.

(2015). Timely scientific opinions. **11:** 519-519.

The article summarizes studies concerning environmental assessment and management as of October 2015. Topics discussed include the need for transparency in test programs for ballast water discharge treatment, microplastics as a global pollutant and the chemical and physical effects of nanoparticle ecotoxicity.

(2016). "CALIFORNIA PASSES BAN ON PLASTIC MICROBEADS." Resurgence & Ecologist(294): 4-4.

The article reports that California State Senate had passed a bill that bans the use of plastic microbeads in cosmetic and personal hygiene products such as shampoos, soaps and toothpaste. Topics discussed include debate of environmentalists on biodegradable plastics and standard plastic beads, views of Richard Bloom California State assembly member, on effect of microplastic pollution in aquatic environments and wildlife, concerns for Great Pacific Garbage Patch in North Pacific Ocean.

(2016). "End of microbeads?" New Scientist **230**(3077): 7-7.

The article reports that the British Parliament's Environmental Audit Committee will determine whether plastic microbeads should be banned in cosmetic products as about 16 to 86 tonnes of microbeads from facial exfoliants are washed down and end up in water every year.

(2016). "Government confirms plans to ban cosmetic microbeads." ENDS (Environmental Data Services)(500): 5-5.

The article reports on the British government proposals to ban the sale and manufacture of

cosmetics and personal care products containing microbeads in 2016.

(2016). "In the Congress." Environmental Law Reporter: News & Analysis **46**(2): 10158-10162.

The article presents U.S. Congressional Record from December 1, 2015 to December 31, 2015. S. 209 would amend the Indian Tribal Energy Development and Self-Determination Act of 2005. H.R. 1321 which would prohibit the sale or distribution of cosmetics containing synthetic plastic microbeads. S. 2152 would establish a comprehensive U.S. government policy to encourage efforts of countries in sub-Saharan Africa to develop power solutions.

(2016). "INDUSTRY NEWS." Skin Deep **14**(2): 13-14.

The article offers news briefs related to the skin care industry in the U.S. as of February 2016. President Barack Obama signed a bill that bans plastic microbeads used as skin exfoliants. The Virtual Stylist Lash & Brow application (app) was launched to help lash and brow experts cater to their clients' needs. Skin Authority chief executive officer Celeste Hilling developed the My Skin Authority app to make it easier for estheticians connect with their clients.

(2016). Microplastic pollution in lakes and lake shoreline sediments – A case study on Lake Bolsena and Lake Chiusi (central Italy). **213:** 648-657.

Rivers and effluents have been identified as major pathways for microplastics of terrestrial sources. Moreover, lakes of different dimensions and even in remote locations contain microplastics in striking abundances. This study investigates concentrations of microplastic particles at two lakes in central Italy (Lake Bolsena, Lake Chiusi). A total number of six Manta Trawls have been carried out, two of them one day after heavy winds occurred on Lake Bolsena showing effects on particle distribution of fragments and fibers of varying size categories. Additionally, 36 sediment samples from lakeshores were analyzed for microplastic content. In the surface waters 2.68 to 3.36 particles/m 3 (Lake Chiusi) and 0.82 to 4.42 particles/m 3 (Lake Bolsena) were detected, respectively. Main differences between the lakes are attributed to lake characteristics such as surface and catchment area, depth and the presence of local wind patterns and tide range at Lake Bolsena. An event of heavy winds and moderate rainfall prior to one sampling led to an increase of concentrations at Lake Bolsena which is most probable related to lateral land-based and sewage effluent inputs. The abundances of microplastic particles in sediments vary from mean values of 112 (Lake Bolsena) to 234 particles/kg dry weight (Lake Chiusi). Lake Chiusi results reveal elevated fiber concentrations compared to those of Lake Bolsena what might be a result of higher organic content and a shift in grain size distribution towards the silt and clay fraction at the shallow and highly eutrophic Lake Chiusi. The distribution of particles along different beach levels revealed no significant differences. [ABSTRACT FROM AUTHOR]

(2016). "Presence of microplastics and nanoplastics in food, with particular focus on seafood." EFSA Journal **14**(6).

Following a request from the German Federal Institute for Risk Assessment (BfR), the EFSA Panel for Contaminants in the Food Chain was asked to deliver a statement on the presence of

microplastics and nanoplastics in food, with particular focus on seafood. Primary microplastics are plastics originally manufactured to be that size, while secondary microplastics originate from fragmentation. Nanoplastics can originate from engineered material or can be produced during fragmentation of microplastic debris. Microplastics range from 0.1 to 5,000 micro m and nanoplastics from approximately 1 to 100 nm (0.001-0.1 micro m). There is no legislation for microplastics and nanoplastics as contaminants in food. Methods are available for identification and quantification of microplastics in food, including seafood. Occurrence data are limited. In contrast to microplastics no methods or occurrence data in food are available for nanoplastics. Microplastics can contain on average 4% of additives and the plastics can adsorb contaminants. Both additives and contaminants can be of organic as well of inorganic nature. Based on a conservative estimate the presence of microplastics in seafood would have a small effect on the overall exposure to additives or contaminants. Toxicity and toxicokinetic data are lacking for both microplastics and nanoplastics for a human risk assessment. It is recommended that analytical methods should be further developed for microplastics and developed for nanoplastics and standardised, in order to assess their presence, identity and to quantify their amount in food. Furthermore, quality assurance should be in place and demonstrated. For microplastics and nanoplastics, occurrence data in food, including effects of food processing, in particular, for the smaller sized particles (<150 micro m) should be generated. Research on the toxicokinetics and toxicity, including studies on local effects in the gastrointestinal (GI) tract, are needed as is research on the degradation of microplastics and potential formation of nanoplastics in the human GI tract.

(2016). "Ready to start." Recycling Today **54**(9): 1-2.
The article reports on U.S. recyclers' optimistic business outlook from the manufacturing sector in fall 2016. Topics discussed include the expected increased generation of manufacturing or retail packaging waste for the holidays, the steady to increasing domestic demand for recovered plastics, and the discouraging of plastic scrap imports by China and India. Also noted is the heavy buying of plastic scraps in regions where shipping rates are competitive for export.

(2016). "Update on the global economy." Materials Recycling World **205**(14): 54-54.
The article provides updates on the international secondary materials sector as of July 2016, including a surge in the paper export markets, declines in Brent crude oil prices, and the Indian government's decision to allow importation of solid plastic waste.

(2017). "Global study finds micro-plastic in 82% samples of Delhi's tap water." TIDEE (TERI Information Digest on Energy & Environment) **16**(3): 289-290.

(2017). "A Look at London's Plastic Waste Problem." Waste360: 1-1.
The article offers update on a report conducted by the London assembly environment committee in England which revealed the city's problem with plastic bottled water and urges London Mayor Sadiq Khan to address the issue in his environmental strategy. It informs about the effort of startup Skipping Rocks Lab to reduce plastic wastes. Other details in the report include a proposed deposit return scheme and statistical data on plastic bottled water consumption in London.

(2017). "Measures needed to keep soil and water free of microplastics." ENDS (Environmental Data Services)(512): 40-40.

(2017). "Microbeads ban 'under threat' from legislation overload." ENDS (Environmental Data Services)(509): 5-5.

(2017). "Microplastics a major problem for farm soils, study shows." ENDS (Environmental Data Services)(503): 36-36.

The article focuses on a study which showed that wide-spread application of sewage sludge from wastewater treatment plants is a major source of microplastics and little is known about how it affects the soil ecosystem, crops or livestock.

(2017). "Patch of Plastic Garbage Found Floating in the Arctic Ocean." Waste360: 17-17.

The article reports on the discovery of a new garbage patch floating in the remote, frozen regions of the Arctic Ocean. Scientists have warned about the effect of the garbage patch on wildlife. They found out that the garbage patch represents about three percent of the total plastic in the world's oceans. In response, some companies are turning plastic waste found in oceans into products.

(2017). "Plastic waste in aviation fuel takes off." Materials Recycling World: 1-1.

(2017). "Procter & Gamble, TerraCycle Create Bottle from Recycled Plastic and Ocean Plastic." Waste360: 3-3.

The article offers information on the initiative of Procter & Gamble Company to partner with TerraCycle for creating the Fairy Ocean Plastic bottle which is made from post-consumer recycled plastic and ocean plastic. It mentions the initiative as an effort to divert plastic waste from landfill and the ocean. It also presents views of Tom Szaky, chief executive officer of TerraCycle, regarding the same.

(2017). "TerraCycle and P&G Reach Recycling Milestone." Waste360: 1-1.

The article informs that Procter & Gamble has partnered with TerraCycle to create the Fairy Ocean Plastic bottle, which is made from 90 percent post-consumer recycled plastic and 10 percent ocean plastic, as of November 2017. It mentions that the bottle, which will be launched in 2018, aims to raise awareness of the issue of ocean plastic and what can be done to prevent plastic waste from reaching the ocean.

(2017). "UK Initiative Uses Drones to Detect Plastic Waste on British Beaches." Waste360: 1-1.

The article offers information about the working of executives Ellie Mackay and Peter Koehler regarding teaching drones to detect plastic waste in beaches of Great Britain and to track plastic waste dumped into the ocean.

(2017). "Wales consults on details of microbead ban in cosmetics: Making and selling personal care products conraining microbeads will be banned in Wales from next summer, according to a consultation." ENDS (Environmental Data Services)(513): 12-12.

(2018). "30 DAYS." Materials Recycling World **208**(8): 6-6.

(2018). "Aquariums Up the Ante to Cut Plastic Pollution." Waste360: N.PAG-N.PAG.

The article discusses the twenty-two top aquariums across the U.S. which have already eliminated five million straws in their coordinated campaign to reduce sources of plastic pollution, the cutting back on single-use plastic starting with plastic straws by Earth Day 2019.

(2018). "BIOCYCLE WORLD." BioCycle **59**(9): 6-9.

The article offers news briefs related to recycling of wastes. Topics discussed include three bills signed by California Governor Jerry Brown to address the public health and environmental threat imposed by plastic pollution and waste, the report “What a Waste 2.0: A Global Snapshot of Solid Waste Management to 2050" from World Bank on global waste, and the report "Seeing the Forest: Nature's Solution to Climate Change" by Dogwood Alliance.

(2018). "Briefly." Oryx **52**(4): 599-608.

The article offers news briefs on topics including plastic pollution, seabirds threatened by plastic ingestion and efforts to reduce plastic pollution.

(2018). "By the billion." Recycling Today: 1-3.

(2018). "California Governor Signs First Wave of Plastic Pollution Reduction Bills." Waste360: N.PAG-N.PAG.

The article informs that three key bills have been signed by Jerry Brown, governor of California, to date on the public health and environmental threat posed by plastic pollution and waste. It is noted that he has also signed renewable natural gas Coalition-sponsored bill AB 3187 at the state capitol. Senator Ben Allen said that California has shown possibility to switch from environmentally damaging food packaging to sustainable alternatives.

(2018). "China's New Import Policies Leave Tons of Plastic Waste with No Destination." Waste360: 5-5.

The article offers information on the contamination limits put in place for its plastic imports by China and its impact of the plastic waste across the globe. Topics discussed include the potential use of landfills to deal with the plastic waste, the new policy implemented by China to limit the acceptance of plastics and scrap paper from other countries, and the plastic waste generated by the U.S. and other countries.

(2018). "Consumer Goods Industry Moves to Act on Plastic Waste." Waste360: N.PAG-N.PAG.

The article focuses on the move of the Board of Directors of the Consumer Goods Forum (CGF) to release a statement which calls for the consumer goods industry to play a leading role in eliminating plastic waste on land and sea and endorses the Ellen MacArthur Foundation's New Plastics Economy vision. Information on the Ocean Conference taking place in Bali, Indonesia is presented.

(2018). "Dow Launches #PullingOurWeight Cleanup Campaign." Waste360: N.PAG-N.PAG.

The article focuses on Cleanup Campaign "PullingOurWeight" to remove waste from water launches by the Dow Chemical. Topics include cleanups at more than 50 locations across the globe to bring attention to the issue of ocean plastic pollution; views of Diego Donoso, president of Dow that the level of commitment from employees around the world, extended Dow family; and managing the lifecycle of plastics from design to disposal will retain the many social and economic benefits of plastics.

(2018). "Environment plan: highlights and reaction." Materials Recycling World **208**(2): 1-1.

(2018). "EPA Study Shows Plastic Waste Has Doubled Over Past Decade." Waste360: N.PAG-N.PAG.

The article highlights report of Environmental Protection Agency (EPA) hike in plastic waste.

Topics discussed include industrial plastic waste doubled over from past decade; making large amount of coffee cups which also included in commercial and business waste; and mention about replacement of organic waste into plastics as primary wastes in household dustbin.

(2018). "GOVER OUTLINES ACTION TO TAKE ON GOVE’S CHALLENGE." Materials Recycling World **208**(3): 7-7.

(2018). "ISRI Execs' Observations from Several Days in China." Waste360: 1-1.
The article focuses on lessons learned by executives from the Institute of Scrap Recycling Industries (ISRI) during several days of meetings with Chinese and U.S. government officials and other industry association leaders in Beijing in January 2018. It highlights notice of adoption of new contamination standards filed by China's Ministry of Environmental Protection (MEP) with a standard of 0.5% contamination for various materials, including scrap plastics and paper.

(2018). "Johnson & Johnson Signs New Plastics Economy Commitment." Waste360: N.PAG-N.PAG.
The article reports on the move of Johnson & Johnson Consumer Inc. to join in the effort New Plastics Economy Commitment, together with the Ellen MacArthur Foundation and the U.N. Environmental Programme, which strives to address plastic waste and the importance for a reform in consumer packaging.

(2018). THE LAST WORD, New Scientist Ltd. **239:** 59-59.
Questions and answers are provided to several topics, including the method of determining the amount of toilets needed at large events, marine plastic pollution and the safety measures taken for human drinking water.

(2018). "Long Island, N.Y., Responds to Shift in Recycling Market." Waste360: N.PAG-N.PAG.
The article offers information on the changes in recycling practices in several towns in Long Island, New York, after China imposed a ban on recyclables. Topics discussed include the use of dual stream process in Brookhaven, where residents alternate between paper and cardboard one week, and plastic and metals the next; the collection sites for glass; and the need for citizens to more vigilant about contamination.

(2018). "NAVIGATING SUSTAINABILITY IN UNCERTAIN TIMES." Resurgence & Ecologist(308): 5-5.
The article discusses the impact of the transformative trends to achieve sustainable development including the use of data and robots to combat soil degradation in farming, the elimination of plastic pollution through waste management and the use of blockchain in making transactions.

(2018). "Nestlé Aims to Make 100% Recyclable or Reusable Packaging by 2025." Waste360: N.PAG-N.PAG.
The article reports that the food company Nestlé has announced its commitment to make its packaging recyclable or reusable by the year 2025. It mentions views of Mark Schneider, chief executive officer (CEO) Nestlé, on plastic waste. It states that Nestlé will focus on areas like elimination of non-recyclable plastics, encouraging the use of plastics that allow better recycling rates and eliminating or changing the complex combinations of packaging materials.

(2018). No increase in marine microplastic concentration over the last three decades – A case study from the Baltic Sea. **621:** 1272-1279.

Microplastic is considered a potential threat to marine life as it is ingested by a wide variety of species. Most studies on microplastic ingestion are short-term investigations and little is currently known about how this potential threat has developed over the last decades where global plastic production has increased exponentially. Here we present the first long-term study on microplastic in the marine environment, covering three decades from 1987 to 2015, based on a unique sample set originally collected and conserved for food web studies. We investigated the microplastic concentration in plankton samples and in digestive tracts of two economically and ecologically important planktivorous forage fish species, Atlantic herring (Clupea harengus) and European sprat (Sprattus sprattus), in the Baltic Sea, an ecosystem which is under high anthropogenic pressure and has undergone considerable changes over the past decades. Surprisingly, neither the concentration of microplastic in the plankton samples nor in the digestive tracts changed significantly over the investigated time period. Average microplastic concentration in the plankton samples was 0.21 ± 0.15 particles m^{-3} . Of 814 fish examined, 20% contained plastic particles, of which 95% were characterized as microplastic (< 5 mm) and of these 93% were fibres. There were no significant differences in the plastic content between species, locations, or time of day the fish were caught. However, fish size and microplastic in the digestive tracts were positively correlated, and the fish contained more plastic during summer than during spring, which may be explained by increased food uptake with size and seasonal differences in feeding activity. This study highlights that even though microplastic has been present in the Baltic environment and the digestive tracts of fishes for decades, the levels have not changed in this period. This underscores the need for greater understanding of how plastic is cycled through marine ecosystems. The stability of plastic concentration and contamination over time observed here indicates that the type and level of microplastic pollution may be more closely correlated to specific human activities in a region than to global plastic production and utilization as such. (2018). "NOVAMONT UNVEILS ALTERNATIVE TO MICROBEADS IN COSMETICS." Recycling International: 45-45.

(2018). PLASTIC AHOY! Environmental Engineering. R. Andy. London, Professional Engineering Publishing Ltd. **31:** 3.
Pye discusses the problem on plastic pollution in the UK and the efforts to address such problem. Studies from Plymouth University and Ghent University in Belgium that show the presence of plastic in UK-caught fish and the ingestion of tiny pieces of plastic by people who eat seafood. A United Nations (UN) resolution was created to enable collective action to reduce and prevent marine pollution, while countries such as Sri Lanka, Kenya, and Zimbabwe banned the use of plastic.

(2018). "Plastic Waste and the Flint, Mich., Water Crisis." Waste360: N.PAG-N.PAG.
The article offers information about Water Crisis in Flint, Michigan due to lead-filled, tainted drinking and bathing water. Topics discussed include accumulation of 100 million plastic water bottles in the city; talks about figure out the waste generated from water crisis and response of

the city on the issue; and fundamental initiatives taken by the public-private partnerships and public communication to clean up plastic waste.

(2018). "Quarterly Comment by Trinity Chambers: Trinity Chambers, Newcastle." Environmental Law Review **20**(2): 109-129.

This quarter has seen the government announce its 25-year plan to protect the environment, the enactment of new statutory instruments and stimulating case law. The political will to combat damage to the environment appears to exist. A much-anticipated 25-year plan was announced by Theresa May in January (Guardian, 11 January 2018). Mrs May announced that the government hopes to eliminate all 'avoidable' plastic waste within 25 years. It has been observed with some cynicism that legislation does not yet appear to be forthcoming on such lofty ambitions. The legislation itself will require careful planning, a targeted approach to the most wasteful areas of commerce and society, together with a pragmatic approach to eradicate 'avoidable' plastic waste. While some remain sceptical of the government's aspiration, it has been noted that the charge on plastic bags has been successful. The government will next seek to agree a charter for the Commonwealth aiming to reduce the amount of plastic waste in the oceans (The Guardian, 11 January 2018). The government has given new powers to tackle illegal activity at waste sites. The Waste Enforcement (England and Wales) Regulations 2018 enter into force soon. The waste regulation and collection authorities can require waste to be removed where it has been unlawfully kept or disposed of. It is important to note that this includes waste that was initially deposited lawfully. The Environment Agency and the Natural Resource Body for Wales may now give notice or seek an order of the court to restrict access and the importation of waste to particular premises. His Royal Highness Okpabi was unsuccessful in the Court of Appeal against Shell. In a case (reported below), the Nigerian claimants sought to appeal against a decision that Shell (as parent company) did not owe them a duty of care in respect of pollution and environmental damage caused by oil leaks from pipelines and associated infrastructure operated by a subsidiary. In the judgment given by Sir Geoffrey Vos and Lord Justice Simon (Lord Justice Sales dissenting), the claimants were unable to demonstrate a properly arguable case that the parent company owed a duty of care to those affected. This judgment grapples with interesting legal issues concerning a company's duty of care and jurisdiction. [ABSTRACT FROM AUTHOR]

(2018). "The Reality of the Great Pacific Garbage Patch." Waste360: N.PAG-N.PAG.

The article focuses on the a report on the epidemic of plastic in the ocean. It mentions the National Oceanographic and Atmospheric Administration's Kevin O'Brien who oversees marine debris removal in the Pacific between California and Hawaii; and also mentions plastics floating in the ocean are exposed to several environmental factors that cause them to break down into smaller fragments, making them more difficult to remove.

(2018). "Recycling Facilities Fight Contamination in the Face of New Import Policies." Waste360: 2-2.

The article reports that recycling facilities across the U.S. have been working to clean up their end products or find new buyers in the wake of increase in the standard for contamination in

plastic waste imports under China's National Sword policy. It states that a significant percent of the material that comes to the Waste Management recycling sorting facility in Denver, Colorado is trash. It notes that the sorting process has become more important.

(2018). "THE SEABIRDS THAT SHUN PLASTIC." Resurgence & Ecologist(310): 4-4.
The article reports that Australian wedge-tail shearwaters eat plastic, stating that plastic in the body of seabirds is one of the best way to measure plastic pollution.

(2018). "Stanley Black & Decker Commits to Combat Plastic Pollution." Waste360: N.PAG-N.PAG.
The article reports on the partnership between Stanley Black & Decker and government of the U.S. to sign the Plastics Economy Global Commitment, an initiative of the Ellen MacArthur Foundation and United Nations Environment Programme. The Global Commitment represents a plan to eradicate waste and pollution driven by plastic packaging. It mentions views of Deb Geyer , from Stanley Black & Decker, on plastic pollution.

(2019). "Air Canada to Begin Reducing Single-use Plastics in 2019." Waste360: N.PAG-N.PAG.
The article reports that Air Canada airline company is reducing single-use plastics onboard aircrafts and its workplaces with aim of cutting down on plastic waste.

(2019). "All-consuming plastic." Chemical and Engineering News **97**(5): 28-33.
About a year ago, Philipp Schwabl, a research scientist and physician specializing in intestinal

diseases at the Medical University of Vienna, read an article about plastic pollution and started to connect the dots. About 8 million metric tons of plastic waste enters the oceans every year; eventually those bottles and bags break down into particles. Schwabl wondered whether tiny plastic particles - known as microplastics - are entering the food chain and being consumed by people and, if so, whether they could harm cells and tissue in the human gut. Schwabl could find no definitive answers, so he decided to undertake his own study. Serendipitously, he discovered that Bettina Liebmann, an analytical chemist who heads Environment Agency Austria's effort to analyze microplastics, was based a few minutes' bicycle ride away. The pair teamed up and in October 2018 released the outline of a small pilot study, now undergoing peer review, that they say is. 2019 Chemical & Engineering News.

(2019). "Atlanta's Plastic Waste Takes on New Life as Host Committee Uniforms." Waste360: N.PAG-N.PAG.

The article reports that Hartsfield-Jackson Atlanta International Airport (ATL) is promoting the importance of recycling and is also supporting a circular economy by collecting plastic bottles to be transformed into REPREVE recycled fiber for use in athletic and fashion apparel.

(2019). "Bacardi, Lonely Whale Urge Unicode to Remove all Plastic Straw Emojis." Waste360: N.PAG-N.PAG.

The article discusses a partnership between spirits company Bacardi Ltd. and the organization Lonely Whale to eliminate one billion single-use plastic straws by 2020. Topics discussed include the views of Jacob Briars, global advocacy director for Bacardi, on the impact of plastic waste on marine life, a collection of Giphy stickers released by Bacardi and Lonely Whale, and the views of Dune Ives,the executive director of Lonely Whale, on eliminating single-use plastic straws.

(2019). "EU Says No to Single-Use Plastics." Earth Island Journal **34**(2): 4-4.
The article focuses on the move of the European parliament to ban single-use plastic products including food containers, cutlery, straws, and stirrers, in an effort to tackle plastic trash that is littering the beaches and polluting the oceans. The implementation of the ban into force in 2021 which means that European Union's (EU’s) 28 member states will soon join another 27 countries around the world that have imposed regulations on single-use plastic is mentioned.

(2019). "EU Votes to Ban 10 Types of Single-use Plastics by 2021." Waste360: N.PAG-N.PAG.
The article reports that European Parliament voted in favor of banning different types of plastics by the year 2021 It mentions that the banned items will comprise several items found ion the European Union (EU) beaches like plates, straws, balloon sticks, food and beverage containers made of expanded polystyrene and products made of oxo-degradable plastic. It presents information on concerns about plastic pollution.

(2019). "Ferguson to Swim Perimeter of Easter Island in Fight Against Plastic." Waste360: N.PAG-N.PAG.
The article focuses on the plastic pollution awareness campaign "Swim Against Plastic: Easter Island" which was announced by nonprofit organizations Plastic Oceans International and Breathe Conservation. The campaign will feature former South African national swimmer Sarah Ferguson and Breathe Conservation founder Sarah Ferguson who will attempt to set a world record. Education and beach cleanups on Easter Island in March 2019 will also be held.

(2019). "Florida Lawmakers Consider Ban on Plastic Straw Bans." Waste360: N.PAG-N.PAG.
The article focuses on the issue of banning the use of plastic straws by the Florida lawmakers due to the environmental concerns. Topic incudes environmental damage caused by plastic straws, growing war against the environmental impact of plastic, and the ban on municipal regulation of sunscreens that harm coral reefs.

(2019). "Groups Call on Canadian Government to Act on Plastic Pollution." Waste360: N.PAG-N.PAG.

The article discusses Canadian Government to act on plastic pollution. Topics include twelve ocean conservancy and environmental groups on requesting for Canada's environment and health ministers to take immediate action; require recycled plastics to be used in making products and packaging; views of Chloé Dubois, president of The Ocean Legacy Foundation on discarding of plastic bottles, bottle caps, and cigarette butts.

(2019). "Invisible, but ubiquitous." New Scientist **244**(3259): 3-3.

Microplastics are in our air, food and water. Are there health implications?

(2019). "Iowa, Tennessee Pass Bills Supporting Advanced Plastics Recycling." Waste360: N.PAG-N.PAG.

The article reports on legislative bills supporting advanced recycling facilities to convert plastic waste into raw material, passed by Iowa and Tennessee.

(2019). "Keep New Hanover Beautiful, TerraCycle Hit Cigarette Recycling Milestone." Waste360: N.PAG-N.PAG.

The article reports that the firm TerraCycle Inc. in 2017 joined forces with North Carolina-based Keep New Hanover Beautiful (KNHB), a Keep America Beautiful affiliate, to collect and recycle cigarette butts outside of county buildings, local bars, restaurants, Wilmington International Airport and along Wrightsville Beach. It is noted that the aim of the KNHB is to minimize waste and reduce hazardous plastic waste.

(2019). "Keurig Dr Pepper Launches New Corporate Responsibility Strategy." Waste360: N.PAG-N.PAG.

The article highlights the announcement of unified corporate responsibility (CR) commitments by the Keurig Dr Pepper (KDP) company for improvement and increase in recycling. Topics include focusing of CR platform on environment, supply Chain, health & wellbeing and communities; views of KDP chairman Bob Gamgort on the issue of plastic waste in the environment; and new packaging goals of company that use of post-consumer recycled content & recyclable or compostable packaging by 2025.

(2019). "L'Occitane, Loop Industries Agree to Transition to 100% Sustainable PET Plastic." Waste360: N.PAG-N.PAG.

The article reports the signing of a supply agreement by natural cosmetics manufacturer L'Occitane Group with sustainable plastic company Loop Industries for obtaining Loop-branded sustainable polyethylene terephthalate (PET) plastic so as to implement it into its product packaging by 2022. Topics discussed include growth in demand for sustainable packaging solutions and the efforts of L'Occitane Group to reduce plastic pollution.

(2019). "Looking for solutions for safe food contact materials." DMZ, Lebensmittelindustrie und Milchwirtschaft **140**(21): 18-19.

This paper presents the International Conference of the Fresenius Academy discussions on EU food contact materials (FCM) legislation and new initiatives. Issues on mineral oil, petroleum hydrocarbon and microplastic residues in food, and the potential of packaging made from bio-based polymers as an environment-friendly plastic alternative are discussed.

(2019). "MALAYSIA CLOSES ILLEGAL PLASTIC RECYCLING FACILITIES." Recycling Today: 1-3.

(2019). "Maryland Becomes Second State to Ban Plastic Foam Containers." Waste360: N.PAG-N.PAG.

The article reports that Maryland has put ban on polystyrene foam cups and containers. It mentions views of Maryland resident and Oceana Chief Policy Officer Jacqueline Savitz, on plastics crisis, and consumer goods. It informs that Maryland has been a leader when it comes to addressing plastic pollution crisis. It informs that the U.S. Public Interest Research Group's Zero Waste Director Alex Truelove issued.

(2019). "New Global Alliance to End Plastic Waste Has Launched." Waste360: N.PAG-N.PAG.

The article reports the launch of Alliance to End Plastic Waste (AEPW), which include companies from the plastics and consumer goods value chain, to develop solutions to eliminate plastic waste in the environment, especially from land to the ocean.

(2019). "Oceanic Society, SC Johnson to Drive Engagement on Ocean Conservation." Waste360: N.PAG-N.PAG.

The article highlights about a campaign named "Five for 50" organized by Oceanic Society in 2019 to build public awareness around Oceanic Society's conservation goals centered on plastic pollution, climate change and, fisheries management.. Topic includes five expeditions of the "Five for 50" campaign exploring marine habitats and critical conservation issues; sponsored and support of oceanic society by SC Johnson; and expeditions' destinations.

(2019). "P&G: 2020 Olympic Medals Podiums Created from Recycled Plastic." Waste360: N.PAG-N.PAG.

The article focuses on the fast-moving consumer goods (FMCG) company Procter & Gamble (P&G) creating medals with recycled materials. It discusses the medals created for the Olympic games in partnership with Tokyo 2020 Organizing Committee, the Tokyo 2020 Podium Project in host-country Japan, and sustainability for positive impact on environment.

(2019). PATHWATER Introduces Reusable Water Bottle Packaging**:** N.PAG-N.PAG.

The article reports that PathWater has introduced its first reusable bottled water to help end single-use plastic pollution.

(2019). "Pennsylvania Lawmakers Introduce "Zero Waste PA" Legislative Package." Waste360: N.PAG-N.PAG.

The article focuses on Zero Waste PA, a package of 13 legislative bills announced by Democratic state lawmakers in Pennsylvania to tackle environmental and health problems caused by Styrofoam waste and single-use plastics

(2019). "People, Projects, and Programs News from the field." Sustainability: The Journal of Record **12**(5): 239-247.

Coal-driven air pollution in China has become so bad that solar panels are unable to function at maximum efficiency because not enough sunlight can break through. U.S. cities are ramping up their clean energy efforts, notably with stricter energy-saving rules for buildings, but only a few cities appear to be on track to meet their community-wide climate goals, according to the American Council for an Energy-Efficient Economy (ACEEE). The City Clean Energy Scorecard tracks policy efforts by 75 cities to advance renewable energy and energy efficiency, and is the most-comprehensive national report that tracks city progress toward climate goals, Ribeiro adds. InterContinental Hotels Group (IHG), which owns Holiday Inn, Crowne Plaza, and Kimpton hotel chains, among others, is eliminating the travel-sized tubes from its 843,000 rooms worldwide. [Extracted from the article]

(2019). "Piling on the pressures to ecosystems." Science **366**(6467): 801.

A multitude of anthropogenic pressures and perturbations now assault the world's ecosystems. The air is enriched with carbon dioxide (CO2), temperature extremes and droughts happen with increasing frequency, and a wide range of pollutants accumulate in the soil and water, including pesticides, microplastics, and excess fertilizer. What is the overall impact of these changes—so-called global environmental change drivers (or factors)—on ecosystems and their functioning? Although a broad scope of scientific approaches is used, including observational studies and modeling, experiments remain key. On page 886 of this issue Rillig et al. (1) present an exciting new methodological approach to investigate how these multiple pressures affect ecosystems.

(2019). "Plastic hitches a ride with the wind." New Scientist **242**(3226): 18-18.

The article covers researching suggesting that microplastics can travel far distances through the air.

(2019). "Quick Studies." Nutrition Action Health Letter **46**(10): 7-7.

The article highlights several health-related studies. The American Heart Association and American College of Cardiology published its 2019 guidelines on what foods can cut the risk of having a heart attack or stroke. A study found that women assigned to exercise for 45 to 60 minutes at least three times a week all month experienced lesser menstrual pain. Canadian researchers found that some tea bags are made of microplastic and nanoplastic particles which can increase the risk of cancer.

(2019). "Red Lobster, Ocean Conservancy Partnership Highlights Ocean Preservation." Waste360: N.PAG-N.PAG.

The article reports on the partnership between Red Lobster and Ocean Conservancy, in order to support the protection and preservation of the oceans. It mentions information on focus of the partnership over the Global Ghost Gear Initiative, which focuses on driving solutions to the problem of lost and the Trash Free Seas Alliance, which unites leaders to mitigate plastic waste entering the oceans. It presents views of Kim Lopdrup, from Red Lobster, on seafood sustainability.

(2019). "Report: "Communities on the Frontlines of the Global Plastic Crisis"." Waste360: N.PAG-N.PAG.

The article highlights a report from the Global Alliance for Incinerator Alternatives who takes a look at how countries in southeast Asia are struggling to manage higher volumes of plastic waste as a result of China's ban on imports of mixed recyclable plastics. Topics discussed include that despite of efforts to recycle, consumers and municipal waste managers do not know where their recycling is going, or if it is being recycled at all.

(2019). "Second Ocean Heroes Bootcamp Empowers Youth to Beat Plastic Pollution." Waste360: N.PAG-N.PAG.

(2019). "SUEZ to Build Plastics Recycling Plant in Thailand." Waste360: N.PAG-N.PAG.

The article discusses Suez, utilities company on building of plastics recycling plant in Thailand. Topics include plant which aims for turning plastic waste into circular polymers in the Bang Phli district near Bangkok, Thailand; plant which convert 30,000 tons of collected polyethylene film waste into high quality post-consumer recycled plastic (PCR); and development in regional countries by improving drinking water, sanitation and waste management services.

(2019). "Tupperware Unveils Vision to Reduce Plastic, Food Waste by 2025." Waste360: N.PAG-N.PAG.

The article discusses Tupperware Brands on announcing of reduce plastic and food waste by 2025. Topics include company on introducing reusable, long-lasting plastic for the home; views of Tricia Stitzel, chairman and chief executive officer of Tupperware Brands on having business to change lives; and views of Mark Shamley, vice president of global social impact at Tupperware Brands on integrating sustainable practices by products, operations and supply chain.

(2019). "UP TO DATE: What's happened in recycling recently ... and what's on the horizon." Resource Recycling **38**(2): 7-7.

The article offers recycling news briefs in Canada and the U.S. The topics discussed include the 2019 Plastics Recycling Conference & Trade Show to be held at the Gaylord National Resort and Convention Center in National Harbor, Maryland on March 11-13, 2019, the creation of the Alliance to End Plastic Waste by top virgin plastic companies like LyondellBasell and Dow, and the estimated number of deaths in the solid waste industry of Canada and the U.S. from January to March 2019.

(2019). "Vermont to Ban Food Scraps from Trash Disposal by 2020." Waste360: N.PAG-N.PAG.

(2019). "Walmart Launches New Reusable Bag Campaign, Sustainability Goals." Waste360: N.PAG-N.PAG.

The article reports on an announcement by Walmart regarding its offering of reusable bags at its U.S. stores to customers for purchase to increase customer convenience. It states that the recent announcement by Walmart on a series of plastic waste reduction goals has led to the launch of the new reusable bag initiative.

(2019). "WALMART MAKES PLASTIC PACKAGING WASTE REDUCTION COMMITMENTS." Recycling Today: 3-3.

(2019). "Westlake Chemical Joins Global Alliance to End Plastic Waste." Waste360: N.PAG-N.PAG.

The article focuses on the announcement from Westlake Chemical Corporation regarding joining the Alliance to End Plastic Waste (AEPW), that was launched in January 2019. It aims to eliminate plastic waste in the environment, but delivers products that benefit lives every day from polyethylene that is used daily in food packaging, to vinyl pipe that is used to deliver clean drinking water.

(2019). "Windex Highlights World Oceans Day 2019 with Interactive Experience." Waste360: N.PAG-N.PAG.

The article discusses Windex, multi surface cleaner with vinegar which announced for launching of 100 percent ocean plastic bottle. Topics include receiving of Windex multi surface cleaner with vinegar ocean plastic bottle; making a donation to Swim Drink Fish, a nonprofit organization to create a swimmable, drinkable and fishable future; and sharing an experience on social channels of feeling to swim in ocean which polluted with solid waste.

(2019). "Working together to challenge plastic pollution." Resurgence & Ecologist(316): 66-66.
We're delighted to have joined Plastic Free North Devon (PFND) - a consortium set up to combat the global problem of plastic pollution through local action. The consortium includes charities, voluntary groups organisations working together across communities, tourism and business to make the biggest and most immediate impacts on the plastic problem in North Devon. PFND aims to Raise awareness of how the environment is affected by plastic Reduce the consumption of single-use plastics Remove plastic that has entered the natural environment Recycle or dispose of used plastic appropriately. [Extracted from the article]

(2019). "WWF Launches Activation Hub to Help Prevent Global Plastic Waste." Waste360: N.PAG-N.PAG.
The article reports that according to the World Wildlife Fund (WWF), global plastic pollution crisis is impacting oceans, communities, wildlife and people at an unprecedented rate. It presents views of Nik Sekhran, chief conservation officer of WWF, on plastic pollution. It mentions views of Francesca DeBiase, McDonald's executive vice president, on plastic pollution.

(2020). "Plastic pollution in the environment." Environmental Toxicology & Pharmacology **73**: N.PAG-N.PAG.

(2020). "A Weighty Issue." Earth Island Journal **34**(4): 5-5.
New research indicates that worms in microplastic-polluted soils don't do as well as their non-plastic-ingesting relatives. Specifically, scientists found that worms in soil contaminated with high density polyethylene (HDPE), which is commonly used to make bags and bottles, lost 3 percent of their body weight over 30 days, while worms in HDPE-free soil gained 5 percent of their body weight over the same amount of time. Given worms' role in soil ecosystems, the findings, published in the journal Environmental Science and Technology, raise some alarm for the health of soils across the world that are the foundation for our agricultural lands, forests, and grasslands. [Extracted from the article]

A, G. K., et al. (2020). "Review on plastic wastes in marine environment - Biodegradation and biotechnological solutions." Marine Pollution Bulletin **150**: 110733.
The marine plastic pollution has drastic effect on marine species. The importance in environmental issues increases the demand to develop a significant technology which does not burden the marine environment or marine life forms. To mitigate the foreseen problems of

micro and nanoplastic contamination, different biotechnological solutions has to be considered. Microbial communities exposed to plastic contaminated sites can adapt and form dense biofilms on the plastic surface and produce active catalytic enzymes. These enzymes can be able to degrade the synthetic polymers. In view of their high catalytic activity, microbial enzymes can be applicable for the degradation of synthetic polymers. This review highlights the toxicity of micro and nanoplastics on marine organisms, biodegradation of plastics and futuristic research needs to solve the issues of plastic pollution in marine environment.

Aandahl, E. M., et al. (2012). "Heterogeneity in the suppressive activity of human regulatory T cells-relevance for solid organ transplantation?" Transplantation **10S)**: 438.

Introduction: Human CD4+CD25+FOXP3+ regulatory T cells (Tregs) are crucial for maintaining peripheral tolerance. Depletion of Tregs precipitate widespread autoimmune disease whereas adoptive transfer of Tregs cells resolves autoimmunity and may foster immune tolerance after solid organ allotransplantation (SOT) in rodent models. In humans, the level and specificity of Treg immunosuppressive activity may have important implications for the propensity to organ rejection and level of immunosuppresison needed to avoid rejection reactions after SOT. Method(s): Peripheral blood mononuclear cells (PBMC) were isolated from buffycoats from healthy blood donors (n=64), and conventional T cells and Tregs were isolated by antibody-coated microbeads or by flow cytometry based cell sorting. The suppressive activity of Tregs was assessed in add-back experiments in co-cultures with anti-CD3/CD3/ CD28 stimulated effector T cells. Result(s): In add-back experiments, the immunosuppressive activity of untreated human Tregs varied widely. In order to specifically assess the contact-dependent immunosuppressive activity and exclude the contribution of secreted cytokines, Tregs were fixed in paraformaldehyde prior to add-back and co-culture. Tregs from 54% of the donors were fully active without the need of stimulation, whereas Tregs from the remainder were completely inactive prior to stimulation, but acquired full suppressive actitivity after 6 hours of anti-CD3/CD2/CD28 stimulation prior to fixation and add-back. In time-course experiments, inactive Tregs acquired immunosuppressive capacity incrementally during stimulation, and effector T cells were sensitive to inhibition of effector functions up to 24 hours after stimulation. Conclusion(s): Our results reveal great heterogeneity in the suppressive activity of Tregs that may have important implications for the disposition to immune related disease. The level of Treg activity may determine the risk for rejection after SOT, and guide the level of immunosuppressive treatment needed.

Abay, I., et al. (2005). "Removal and pre-concentration of phenolic species onto beta-cyclodextrin modified poly(hydroxyethylmethacrylate-ethyleneglycoldimethacrylate) microbeads." Chemosphere **61**(9): 1263-1272.

Poly(Hydroxyethylmethacrylate-Ethyleneglycoldimethacrylate), poly(HEMA-EGDMA), microbeads with 150-200 microm in size, was prepared by suspension polymerization. Beta-cyclodextrin was modified onto the polymeric microbeads using glutaraldahyde activation in an acidic medium at pH=2.5. FT-IR and TGA were used for the characterization of modified polymers and the determination of the nature of the interaction between phenolic compounds and the modified polymeric microbeads. Plain and beta-cyclodextrin modified microbeads were used in adsorption-desorption studies of phenolic species in single solution. Adsorption capacities of the phenolic species onto the plain microbeads were found to be 28.2, 17.0, 14.3, 9.8, and 1.92 mg/g polymer for o-chloro phenol, p-nitro phenol, p-chloro phenol, o-nitro phenol, and phenol, respectively. However, for beta-cyclodextrin modified microbeads, adsorption capacity of phenolic species was determined as 274, 365, 128, 182, and 87 mg/g for phenol, o-nitro phenol, p-nitro phenol, o-chloro phenol, and p-chloro phenol, respectively. Desorption ratio for the phenolic species was more than 90%, except for o-nitro phenol. Detection limits of the phenolic species were improved at least 500-fold for UV-Vis spectrophotometric detection, after the pre-concentration of all phenolic species used in this study. Adsorption time for the phenolic species onto beta-cyclodextrin-modified poly(HEMA-EGDMA) microbeads was found to be reasonable short (10-60 min) and suitable for the applications. Also, synthesized microbeads were useful for the repeated use for the removal and pre-concentration of phenolic species.

Abay, İ., et al. (2005). "Removal and pre-concentration of phenolic species onto β-cyclodextrin modified poly(hydroxyethylmethacrylate–ethyleneglycoldimethacrylate) microbeads." Chemosphere **61**(9): 1263-1272.

Abstract: Poly(Hydroxyethylmethacrylate–Ethyleneglycoldimethacrylate), poly(HEMA–EGDMA), microbeads with 150–200μm in size, was prepared by suspension polymerization. β-cyclodextrin was modified onto the polymeric microbeads using glutaraldahyde activation in an acidic medium at pH=2.5. FT-IR and TGA were used for the characterization of modified polymers and the determination of the nature of the interaction between phenolic compounds and the modified polymeric microbeads. Plain and β-cyclodextrin modified microbeads were used in adsorption–desorption studies of phenolic species in single solution. Adsorption capacities of the phenolic species onto the plain microbeads were found to be 28.2, 17.0, 14.3, 9.8, and 1.92mg/g polymer for o-chloro phenol, p-nitro phenol, p-chloro phenol, o-nitro phenol, and phenol, respectively. However, for β-cyclodextrin modified microbeads, adsorption capacity of phenolic species was determined as 274, 365, 128, 182, and 87mg/g for phenol, o-nitro phenol, p-nitro phenol, o-chloro phenol, and p-chloro phenol, respectively. Desorption ratio for the phenolic species was more than 90%, except for o-nitro phenol. Detection limits of the phenolic species were improved at least 500-fold for UV–Vis spectrophotometric detection, after the pre-concentration of all phenolic species used in this study. Adsorption time for the phenolic species onto β-cyclodextrin-modified poly(HEMA–EGDMA) microbeads was found to be reasonable short (10–60min) and suitable for the applications. Also, synthesized microbeads were useful for the repeated use for the removal and pre-concentration of phenolic species. [Copyright &y& Elsevier]

Abayomi, O. A., et al. (2017). "Microplastics in coastal environments of the Arabian Gulf." Marine Pollution Bulletin **124**(1): 181-188.

Eight sandy beaches along the coastline of Qatar and four sea surface stations on the eastern coast, adjacent to Doha Bay, were surveyed between December 2014 and March 2015. Microplastics, mainly low density polyethylene and polypropylene, were found in all samples of sediments and seawater. Blue fibers, ranging between 1 and 5mm, were the dominant type of particle present. Abundances on the sea surface varied between 4.38x10⁴ and 1.46x10⁶particles.km⁻², with the highest values being consistently found 10km offshore, suggesting the presence of a convergence zone. No significant temporal variability was detected for sea surface samples. The concentration of microplastics in intertidal sediments varied between 36 and 228particlesm⁻², with no significant differences

among the 8 beaches examined. These results show the pervasiveness of microplastic pollution in coastal environments of the Arabian Gulf. Potential local sources and sinks for microplastics are discussed.

Abbasi, S., et al. (2017). "Investigation of microrubbers, microplastics and heavy metals in street dust: a study in Bushehr city, Iran." Environmental Earth Sciences **76**(23): 1-19.

This study aimed to (1) investigate microrubbers (MRs) for the first time and identify microplastics (MPs) in street dust, (2) determine the physicochemical and mineralogical characteristics and morphology of dust particles, (3) understand the concentration and the possible source(s) of heavy metals/metalloids, (4) identify the chemical speciation and mobility potential of trace metals in urban street dusts, and (5) determine adverse health effects of street dust on children and adults living in the city of Bushehr in southwestern Iran. Generally, twenty four street dust samples were collected and analyzed. Calculated enrichment factors indicate high levels of contamination. Statistical analysis reveals that the two main sources of trace elements include road traffic emissions (Cu, Zn, Sb, Hg, Pb, Mo) and re-suspended soil particles (Al, Mn, Ni, Ti, Cd, Co). BCR sequential extraction results indicated that As, Zn, Cu, and Pb mainly occur in the exchangeable fraction and hence are highly bioavailable. X-ray powder diffraction analysis revealed the presence of calcite, dolomite, quartz, and magnetite. The size distribution of dust particles was also investigated using a scanning electron microscope (SEM), while elemental distribution was analyzed using an attached energy dispersive X-ray spectrometer (SEM–EDS) unit. Dust particles from heavy traffic areas are much finer compared with other investigated areas. MPs and MRs, mostly fibers and fragments, were detected in all samples [ranging from 210 to 1658 (MPs) and 44 to 782 (MRs) items/10 g dust] using fluorescence microscopy. The hazard index for As is higher than 10−4 for children and adults indicative of high risk. According to the calculated potential ecological risk index, Hg indicated moderate ecological risk in the street dust of the study area.

Abbasi, S., et al. (2019). "Geochemistry and environmental effects of potentially toxic elements, polycyclic aromatic hydrocarbons and microplastics in coastal sediments of the Persian Gulf." Environmental Earth Sciences **78**(15): 1-15.

Coastal areas are critical parts of the Persian Gulf with regard to high populations and economically driven activity. They pose major concerns because of the presence of toxic chemicals, and hence harmful effects on marine ecosystems. In this study, 14, 15 and 12 coastal sediment samples were collected in Bushehr province and analyzed, respectively, for potentially toxic elements (PTEs), polycyclic aromatic hydrocarbons (PAHs) and microplastics (MPs). The results showed that almost all PTEs were not significantly enriched. Most elements exhibited their highest levels at stations close to urban areas and along the pathway of ships and boats. Based on enrichment factor and statistical evaluations, two main sources of trace elements were identified: anthropogenic (Mo, Cu, Pb, As and Sb) and geogenic (Zn, Ni, Co, Mn, Fe, Cd, Cr and Al). Regarding MPs, a total of 577 pieces were observed with sizes ranging between 500 and 1000 µm. The dominant shape of the MPs was fibrous with the dominant colors being white and black. The concentration of total PAHs were fairly low in the sediments, with their source determined to be pyrogenic in origin.

Abbasi, S., et al. (2019). "Distribution and potential health impacts of microplastics and microrubbers in air and street dusts from Asaluyeh County, Iran." Environmental Pollution **244**: 153-164.

While the distribution and effects of microplastics (MPs) have been extensively studied in aquatic systems, there exits little information on their occurrence in the terrestrial environment and their potential impacts on human health. In the present study, street dust and suspended dust were collected from the city and county of Asaluyeh, Iran. Samples were characterized by various microscopic techniques (fluorescence, polarized light, SEM) in order to quantify and classify MPs and microrubbers (MRs) in the urban and industrial environments that are potentially ingestible or inhalable by humans. In < 5-mm street dust retrieved from 15 sites, there were an average of 900MPs and 250MRs per 15g of sample, with MPs exhibiting a range of colours and sizes (<100 to >1000mum). Most street dust samples were dominated by spherical and film-like particles and MRs largely made up of different sizes of black fragments and fibrous particulates. Airborne dust collected daily over an eight-day period at two locations revealed the ubiquity of fibrous MPs of sizes ranging from about 2mum to 100mum and an abundance of about 1 per m⁻³. These samples contained small MR fragments whose precise characteristics were more difficult to define. Based on the median concentrations in street dust, estimates of acute exposure through ingestion are about 5 and 15MPd⁻¹ and 2 and 7MRd⁻¹ for construction workers and young children, respectively. Quantities of inhalable particulates were more difficult to define but the potential toxicity of MPs and MRs taken in by this route was evaluated from assays performed using particulates isolated from street dusts in the presence of an artificial lung fluid. Both types of particle exhibited oxidative potential, with MPs displaying consumptions of different antioxidants that were comparable with corresponding values for a reference urban particulate dust but lower than those for London ambient particulate matter. Thus, MPs and MRs contribute towards the health impacts of urban and industrial dusts but their precise roles remain unclear and warrant further study.

Abbasi, S., et al. (2018). "Microplastics in different tissues of fish and prawn from the Musa Estuary, Persian Gulf." Chemosphere **205**: 80-87.

Commercially-important species of fish and a crustacean from four sites in the Musa estuary and a site in the Persian Gulf have been analysed for the presence and location of microplastics (MPs). A total of 828 MPs were detected in the guts (gastrointestinal tracts), skin, muscle, gills and liver of demersal and pelagic fish (Platycephalus indicus, Saurida tumbil, Sillago sihama, Cynoglossus abbreviatus) from all five sites and in the exoskeleton and muscle of the tiger prawn, Penaeus semisulcatus, from three sites. On an individual basis, MPs were most abundant in P. indicus (mean=21.8) and least frequently encountered in P. semisulcatus (mean=7.8), but when normalized on a mass basis, MPs ranged from 0.16 g⁻¹ for C. abbreviatus to 1.5 g⁻¹ for P. semisulcatus. Microscopic analyses (polarized light, fluorescence, SEM/EDS) revealed that MPs were mainly fibrous fragments (with a few angular fragments) of various colour and size (<100 micro m to >1000 micro m) and with strong C and O signatures. Additional particles detected that were distinctly different in colour, morphology, brittleness and elemental composition (part-metallic, and containing Cu) were suspected of being fragments of antifouling paint. The means of entry of MPs into tissues not involved in digestion are unclear but could be related to translocation or adherence. Regardless of the mode of accumulation, the presence of MPs in heavily fished species of fish and crustacean raises concerns about the potential transfer of synthetic materials into humans.

Abbodi, M. A. (2013). "Virotherapy targeting breast cancer stems cells by using Oncolytic Herps Simplex Virus." International Journal of Pharma and Bio Sciences **4**(4): B1143-B1147.

In the present study I isolated breast cancer stem cells from cell line MDA-MB231 by used CD44 MicroBeads separator. Cancer stem cells (CSCs) were identified by used PCR machine; here specific primers were designed for CD44 and CD24 genes, whereas CD44 positive for breast CSCs

and CD24 negative CSCs. MDA-MB231 cells and breast CSCs treated with G47DELTA vector. G47DELTA showed highly effect on both kinds of cells by killing over 90% of MDA-MB231 and over 80% of the CSCs in vitro. Virus used as therapy demonstrated that pathogenic microorganisms can be modify genetically and use for targeting diseases and oHSV can be used for treatment breast CSCs that are still not understood. This study demonstrates that oHVS effective against breast cancer stem cells and could be a beneficial method for treating cancer stem cells expressed in breast cancer.

Abbott, J. K. and U. R. Sumaila (2019). "Reducing Marine Plastic Pollution: Policy Insights from Economics." Review of Environmental Economics & Policy **13**(2): 327-336.

Marine plastic pollution is heavily driven by escaped plastic waste from land. Effectively reducing flows of plastic pollution into the oceans requires incentivizing efficient disposal decisions, discouraging production and consumption of products with low recyclability and reuse potential, and encouraging lower-impact, easily recyclable product and packaging designs. We examine the economic literature on waste management and integrated environmental policy to assess how particular policies target these individual pathways and can efficiently reduce flows of plastics into waterways. These policies include production/retail bans and standards, extended producer responsibility, price-based policies such as advance disposal fees and two-part instruments, and interventions grounded in behavioral economics and psychology. We also consider the applicability of these policies in coastal developing nations that often rely upon the informal sector for waste management services. We conclude by identifying important issues for future research. [ABSTRACT FROM AUTHOR]

Abdolahpur Monikh, F., et al. (2019). "Development of methods for extraction and analytical characterization of carbon-based nanomaterials (nanoplastics and carbon nanotubes) in biological and environmental matrices by asymmetrical flow field-flow fractionation." Environmental Pollution **255**: N.PAG-N.PAG.

Suitable methods and fit-for-purpose techniques are required to allow characterization of carbon-based nanomaterials (CB-NMs) in complex matrices. In this study, two methods were developed; a method for extraction and characterization of CB-NMs in biological media and a method for fractionation of natural organic matter (NOM) coated CB-NMs in environmental matrices. The former method was developed by extracting carbon nanotubes (CNTs: sized 0.75 × 3000 nm) and nanoplastics (sized 60, 200 and 600 nm) from eggshells and characterizing the extracted CB-NMs in terms of particle size distribution using asymmetrical flow field-flow fractionation (AF4) coupled with multi-angle light scattering (MALS). The latter method was developed using AF4-MALS to fraction NOM-coated CNT (sized 0.75 × 3000 nm) and nanoplastics (sized 60, 200 and 300 nm) in a simulated natural surface water and provide information about the size distribution of the CB-NM-NOM complexes. The developed AF4-MALS method successfully fractioned the CB-NM-NOM complexes based on hydrodynamic size and provided the size distribution of the complexes. The NOM corona did not shift significantly the median size of the CB-NMs. It influenced however the size distribution of the nanoplastics and CNTs. The sample preparation method failed to extract the CNTs (recovery <

20%) from the matrices of the eggshells while being successful for extracting the nanoplastics (recoveries > 60%). The AF4-MALS fractogram showed that the extraction method did not significantly influence the size distribution of the nanoplastics of 60 and 200 nm size, whereas the peak of 600 nm nanoplastics shifted towards a smaller hydrodynamic size. In conclusion, the developed sample preparation method followed by the developed AF4-MALS method can be applied for extraction, separation and characterization of CB-NMs in biological and environmental matrices. Thus, the methods have a high potential to be methods of choice to investigate CB-NMs in future studies. Image 1 • A method was developed to extract, separate and characterize CB-NMs and CB-NM-NOM complexes in environmental and biological media using AF4-MALS. • We extracted nanoplastics from simulated biological and environmental media. • The AF4-MALS method successfully separated CB-NMs from environmental samples. • The method characterized the CB-NMs in terms of size and size distribution. • NOM corona influences the size distribution of CNTs and nanoplastics. [ABSTRACT FROM AUTHOR]

Abdul Hasan Sathali, A. and J. Varun (2012). "Formulation, development and in vitro evaluation of Candesartan cilexetil mucoadhesive microbeads." International Journal of Current Pharmaceutical Research **4**(3): 109-118.

Mucoadhesive microbeads of candesartan cilexetil was designed in order to obtain a unique drug delivery system which would remain in the small intestine and prolong the residence time at the absorption site by intimate contact with the mucus layer thereby increase bioavailability, reduce the frequency of dose administration and also to prolong the drug release. The mucoadhesive microbeads were prepared by ionotrophic gelation method using sodium alginate, xanthan gum, pectin in combination with 1% chitosan using different crosslinking agents including calcium chloride (ca2+), zinc chloride (zn2+), barium chloride (ba2+) and lead nitrate (pb2+) ions in different ratios. The microbeads were evaluated for percentage yield, bead size, entrapment efficiency, swelling index, entrapment efficiency, mucoadhesion study by in vitro wash off test and scanning electron microscopy (SEM) analysis were investigated. Infrared spectroscopy studies (IR) confirmed the absence of any drug interaction with polymers. DSC analysis revealed that the drug was uniformly distributed in the beads. The mean particle size increases with increasing the polymer concentration. SEM photomicrograph showed microbeads with rough surface and spherical shape. The entrapment efficiency of all formulations was in the range between 70% and 90%. The swelling index decreased with increase in sodium alginate and divalent ions concentration. The results of in vitro mucoadhesive showed that the microbeads were remained adhered to mucus membrane for longer period of time. In vitro drug release studies were performed in simulated gastric fluid [SGF, pH 1.2] for 2 hours and phosphate buffer [pH 6.5] for 10 hours at 37+/-20C. In vitro drug release followed zero order kinetics, Korse Meyer & Peppas model. The diffusional exponent, n, (0.43 and 0.85) specified anomalous transport or non fickian type and controlled by diffusion through swollen matrix. The above observations suggested that the candesartan cilexetil can be developed as mucoadhesive drug delivery system with sodium alginate using calcium chloride as cross linking agent and 1% chitosan as mucoadhesive polymer.

Abdullah, J. J. and J. J. S. Mohammed (2015). "Control of soil pollution at dumping site by polytar mix formation within Erbil Province-Iraq." International Proceedings of Chemical, Biological and Environmental Engineering **83**: 1-6.

Over the past few years, the Erbil-Iraq city has produced 100 tons of solid waste daily yet there is no sanitary land fill for ultimate disposal of solid waste. For a long time, it has been a common practice to dispose of soil waste in open low-lying areas. Recently, the government commissioned a new process to separate solid wastes in to organic and inorganic fractions. In the present study, particular interest are plastics, because plastics are not eco-friendly as they are non-biodegradable or degrade very slowly, and could secrete pollutants including heavy metals into the soil. The binding property of plastics in its molten state has helped in discovering a method of safe disposal of plastic waste, which is their use in road laying. This study determines some common heavy metals in soil at depths of 0-15 cm the concentration of heavy metals including Co, Cr, Cu, Fe, Mn, Ni, Pb and Zn were determined, and Fe recorded highest value comparing with other metals. While, the main aim is to use the plastic waste to mix with bitumen. This mix has high Marshall Value, low penetration value and resistance to water penetration.

Abe, M., et al. (2010). "Microbial degradation of poly(butylene succinate) by Fusarium solani in soil environments." Polymer Degradation and Stability **95**(2): 138-143.

The use of mulch made of biodegradable plastic in agriculture is expected to help solve the problem of the enormous amount of plastic waste emission, and to save the labor of removing the mulch after harvesting crops. In this study, we isolated a microorganism possessing the ability to degrade one of the promising biodegradable plastics, poly(butylene succinate) (PBS), and investigated the degradation characteristics of the microorganism in soil environments. Fungal strain WF-6, belonging to Fusarium solani, that had not been reported could be isolated from farmland as the PBS-degrading microorganism. Strain WF-6 degraded 2.8 percent of the PBS in a 14-day experimental run in a sterile soil environment, as determined by measuring CO₂ evolution. Furthermore, we ascertained that the degradability of strain WF-6 was enhanced by co-culturing with the newly isolated bacterial strain Stenotrophomonas maltophilia YB-6, which itself does not show PBS-degrading activity. We then investigated the effects of cell density of the indigenous microorganisms in the soil environments on the degradability of the co-culture of strains WF-6 and YB-6 by inoculating these strains into non-sterilized and partially sterilized soils, which contained 10⁸, 10⁶, and 10³ CFU/g-dry solid of soil of indigenous microorganisms. The degradability strongly depended on the cell density level of the indigenous microorganisms and was remarkably diminished when the cell concentration level was the highest, 10⁸ CFU/g-dry solid. Quantitative PCR analysis revealed that the growth of strains WF-6 and YB-6 was inhibited in the non-sterile soil environment with the highest cell density level of the indigenous microorganisms.

Abedi, D., et al. (2012). "Optimization of the Expression of Genes Encoding Poly (3-hydroxyalkanoate) Synthase from Pseudomonas aeruginosa PTCC 1310 in Escherichia coli." Avicenna Journal of Medical Biotechnology **4**(1): 47-51.

Over the years, the use of plastics has complicated the problem of disposal of solid wastes. One strategy to reduce plastic waste is the use of biodegradable plastics. A group of these plastics are polyhydroxyalkanoates (PHAs). To date more than 250 different microorganisms are known to synthesize and accumulate PHA. Most Pseudomonas strains are able to accumulate mcl-PHA. In previous studies, the phaC1 and phaC2 genes were identified in Pseudomonas aeruginosa

(P.aeruginosa) PTCC 1310 and were cloned. The aim of this study was to express these genes and optimize the conditions for their expression. The inserts obtained from vectors pTZPHAC1 and pTZPHAC2 were subcloned into pET15b expression vector. After transformation of competent Escherichia coli (E.coli) BL21 (DE3) cells with recombinant plasmids, expression was induced using IPTG. By changing expression conditions such as IPTG concentration, time and temperature of incubation with IPTG, the expression conditions for these enzymes were optimized, and the obtained results were compared using proper statistical analysis. The PHA synthase genes were induced with IPTG and the expressed 62 kDa protein was observed and purified. By changing expression conditions, 1 mM IPTG, 37 degreeC and a 2 hr incubation provided the highest level of protein production in E.coli cells. These results suggest that induction condition of PhaC genes can influence expression of PHA synthase enzymes.

Abidli, S., et al. (2019). "Microplastics in commercial molluscs from the lagoon of Bizerte (Northern Tunisia)." Marine Pollution Bulletin **142**: 243-252.

Microplastic (MP) pollution was investigated, for the first time, in six commercial molluscs collected from the lagoon of Bizerte during March 2018. The objective of this study was to determine the bioavailability of MPs to marine organisms and their risk for consumers of seafood. MP concentrations varied from 703.95+/-109.80 to 1482.82+/-19.20 items kg⁻¹ wet weight. Three types of coloured MPs, including fibres, fragments and films were recovered. Fibres were the most common MP type isolated in each species. The most common size class was 0.1-1mm. The FTIR-ATR analysis confirmed the presence of two polymer types polyethylene and polypropylene. Our results suggest that MP pollution was widespread and exhibited a relatively high level in commercial molluscs collected from Bizerte lagoon, suggesting trophic transfer in the food web and human exposure risks by diet. More investigations on MPs should be conducted in seafood and other marine organisms.

Abidli, S., et al. (2017). "The first evaluation of microplastics in sediments from the complex lagoon-channel of Bizerte (Northern Tunisia)." Water, Air, and Soil Pollution **228**(7).

Microplastics (MPs) in sediments from the complex lagoon-channel of Bizerte were investigated, for the first time, to evaluate the occurrence and abundance of MPs in Tunisia. After density separation in saline solution, MPs were counted by a stereomicroscope. The number of MPs was at the range of 3-18 items/g sediment (3000-18,000 items/kg dry sediment) and the most contaminated site was of Menzel Abderrahmane (MA) followed by Carrier Bay (CB), Menzel Jemil (MJ) and Channel of Bizerte (C). The MPs gathered during the survey varied in size from 0.3 to 5 mm, and appear in a variety of shapes and colours. The dominant shape was fibre (88.88% in MA, 91.00% in CB, 82.35% in C and 21.05% in MJ). The rest of MPs are fragments whilst no micro beads were found. Colours are clear, white, blue, green, red and black. Cities discharges, fishing activity and industrial production sites are the most likely sources of MPs. This first work provides original data on the presence of MPs that determines their bioavailability to organisms as seafood, and then possibly transfers of to human. The high MP concentrations registered in the complex lagoon-channel of Bizerte suggest that this site is a hotspot for MP pollution and there is an urgency to understand their origins and effects on marine life. The results will provide useful background information for further investigations.

Abou-Hany, R. A., et al. (2015). "Tailoring molecularly imprinted polymer beads for alternariol recognition and analysis by a screening with mycotoxin surrogates." Journal of Chromatography. A **1425**: 231-239.

Molecularly imprinted porous polymer microspheres have been prepared for selective binding of alternariol (AOH), a phenolic mycotoxin produced by Alternaria fungi. In order to lead the synthesis of recognition materials, four original AOH surrogates have been designed, prepared and characterized. They bear different number of phenol groups in various positions and different degree of O-methylation on the dibenzo[b,d]pyran-6-one skeleton. A comprehensive library of mixtures of basic, acidic or neutral monomers, with divinylbenzene or ethyleneglycol dimethacrylate as cross-linkers, were polymerized at a small scale in the presence of the four molecular mimics of the toxin molecule. This polymer screening has allowed selection of the optimal composition of the microbeads (N-(2-aminoethyl)methacrylamide, EAMA, and ethylene glycol dimethacrylate). The latter are able to bind AOH in water-acetonitrile (80:20, v/v) with an affinity constant of 109+/-10mM(-1) and a total number of binding sites of 35+/-2mumolg(-1), being alternariol monomethylether the only competitor species. Moreover, (1)H NMR titrations have unveiled a 1:2 surrogate-to-EAMA stoichiometry, the exact interaction sites and a binding constant of 1.5x10(4)M(-2). A molecularly imprinted solid phase extraction (MISPE) method has been optimized for selective isolation of the mycotoxin from aqueous samples upon a discriminating wash with 3mL of acetonitrile/water (20:80, v/v) followed by determination by HPLC with fluorescence detection. The method has been applied, in combination to ultrasound-assisted extraction, to the analysis of AOH in tomato samples fortified with the mycotoxin at five concentration levels (33-110mugkg(-1)), with recoveries in the range of 81-103% (RSD n=6). To the best of our knowledge, this is the first imprinted material capable of molecularly recognizing this widespread food contaminant.

Abraham, A. and P. Chakraborty (2019). "A review on sources and health impacts of bisphenol A." Reviews on Environmental Health **19**: 19.

Bisphenol-A (BPA) is a synthetic chemical used in the manufacturing of polycarbonates and epoxy resins. This paper is a review of studies reporting the occurrences and concentrations of BPA in the environment and associated impact on human health. Studies have found that at high temperature conditions such as open burning of dumped waste in developing nations can relocate BPA from plastic waste into the environment. BPA is a proven endocrine disruptor capable of mimicking or blocking the receptors and altering hormone concentrations and its metabolism. Even though it is consumed in a low dose, it can stimulate cellular responses and affect body functions. Biomonitoring studies show that human and animal exposure to BPA is rapid and continuous. In-depth studies are needed to understand the fate of these compounds particularly in the developing nations and the associated adverse health impacts of BPA due to prolonged exposure.

Abreo, N. A. S., et al. (2015). "Nutrient Enrichment, Sedimentation, Heavy Metals and Plastic Pollution in the Marine Environment and its Implications on Philippine Marine Biodiversity: A Review." IAMURE. International Journal of Ecology and Conservation **15**: 111.

The authors conducted a review using opensourced journals on the effects of nutrient enrichment, sedimentation, heavy metals and plastic pollution in the marine environment and its implications on marine biodiversity. Lethal and sub-lethal effects were observed in different organisms that could affect marine biodiversity directly or indirectly. Human land use change, coastal construction activities, untreated sewage discharges, pesticides, mine tailings, uncollected, unsegregated and improperly dumped garbages and unabated garbage dumping at sea have been found to negatively influence marine biodiversity. In the Philippines, very few studies have been conducted with regards to marine pollution, especially on marine plastic debris, and even fewer studies have been made that tackles the effect of these stressors at an ecosystem level. Furthermore, this review has identified direct and indirect effects of pollution

stressors on marine organisms which include: mortality and reduced fitness, vulnerability to disease or sickness, habitat degradation, and food web simplification.

Absher, T. M., et al. (2019). "Incidence and identification of microfibers in ocean waters in Admiralty Bay, Antarctica." Environmental Science & Pollution Research **26**(1): 292-298.

Antarctic pristine environment is threatened by the presence of microplastics that occur in a variety of shapes and sizes, from fibers to irregular fragments. The aim of this study is to assess the abundance, distribution, and the characterization of the microfibers in zooplankton samples found in ocean waters in Admiralty Bay, Antarctica. The samples were collected at five points in Admiralty Bay during the XXIX Brazilian Antarctic Expedition in the austral summer of 2010-2011. A total of 603 microfibers were collected in 60 samples, with an average abundance of 2.40 (+/- 4.57) microfibers 100 m⁻³. Microfiber size ranging from ca. 10 to 22 mum in diameter of various lengths and colors (blue, red, black, and clear) was collected and characterized by scanning electron microscopy (SEM) and Raman spectroscopy. Most of these microfibers were entangled in various different zooplankton species and were identified as polymers composed mostly by polyethyleneglycols, polyurethanes, polyethylene terephthalates, and polyamides. The presence of such microfibers may cause the loss of biodiversity in the Antarctic continent, and the results presented herein can contribute to a better understanding of the impact caused by them within the food chain and human health. Graphical Abstract .

Abuid, N. J., et al. (2019). "Layer-by-Layer Cerium Oxide Nanoparticle Coating for Antioxidant Protection of Encapsulated Beta Cells." Advanced Healthcare Materials **8**(12): e1801493.

In type 1 diabetes, the replacement of the destroyed beta cells could restore physiological glucose regulation and eliminate the need for exogenous insulin. Immunoisolation of these foreign cellular transplants via biomaterial encapsulation is widely used to prevent graft rejection. While highly effective in blocking direct cell-to-cell contact, nonspecific inflammatory reactions to the implant lead to the overproduction of reactive oxygen species, which contribute to foreign body reaction and encapsulated cell loss. For antioxidant protection, cerium oxide nanoparticles (CONPs) are a self-renewable, ubiquitous, free radical scavenger currently explored in several biomedical applications. Herein, 2-12 alternating layers of CONP/alginate are assembled onto alginate microbeads containing beta cells using a layer-by-layer (LbL) technique. The resulting nanocomposite coatings demonstrate robust antioxidant activity. The degree of cytoprotection correlates with layer number, indicating tunable antioxidant protection. Coating of alginate beads with 12 layers of CONP/alginate provides complete protection to the entrapped beta cells from exposure to 100 x 10⁻⁶ m H₂ O₂ , with no significant changes in cellular metabolic activity, oxidant capacity, or insulin secretion dynamics, when compared to untreated controls. The flexibility of this LbL method, as well as its nanoscale profile, provides a versatile approach for imparting antioxidant protection to numerous biomedical implants, including beta cell transplantation.

The flexibility of this LbL method, as well as its nanoscale profile, provides a versatile approach for imparting antioxidant protection to numerous biomedical implants, including beta cell transplantation.

Acampora, H., et al. (2017). "Presence of plastic litter in pellets from Great Cormorant (Phalacrocorax carbo) in Ireland." Marine Pollution Bulletin **117**(1/2): 512-514.

Plastic pollution has been the subject of much research in the last decade. Seabirds can mistake plastic fragments for prey, which can perforate or block the digestive tract and cause ulcers. Most commonly, seabirds accumulate this indigestible matter in their stomachs, obtaining no nutrition and may die from starvation. Certain species of seabirds however, have the ability of regurgitating indigestible matter in the form of pellets. This study aimed to investigate the ingestion of plastics by live seabirds through the examination of regurgitated pellets (n=92) from a Great Cormorant (Phalacrocorax carbo) breeding colony and a winter roost in Ireland. Plastic prevalence was consistently 3.2% at both sites. The presence of plastic litter highlights the fact that all species of seabird are susceptible to interact with marine litter regardless of feeding habits, although at different rates. More research is needed to understand the driving factors involved in plastic ingestion among different species.

Acampora, H., et al. (2017). "Opportunistic sampling to quantify plastics in the diet of unfledged Black Legged Kittiwakes (Rissa tridactyla), Northern Fulmars (Fulmarus glacialis) and Great Cormorants (Phalacrocorax carbo)." Marine Pollution Bulletin **119**(2): 171-174.

Seabirds can interact with marine litter, mainly by entanglement or ingestion. The ingestion of plastics can lead to starvation or physical damage to the digestive tract. For chicks, it could additionally lead to reduced growth, affecting survival and fledging. This study quantified the ingestion of plastics by seabird chicks via an opportunistic sampling strategy. When ringing is carried out at colonies, birds may spontaneously regurgitate their stomach contents due to the stress or as a defence mechanism. Regurgitates were collected from nestlings of three different species: Black-legged Kittiwake (Rissa tridactyla, n=38), Northern Fulmar (Fulmarus glacialis, n=14) and Great Cormorant (Phalacrocorax carbo, n=28). Plastic was present in all species, with the highest frequency of occurrence (FO) in Northern Fulmar chicks (28.6%), followed by Black-legged Kittiwakes (7.9%) and Great Cormorants (7.1%). The observed load of plastics on chicks, which have not yet left the nest, highlights the pervasive nature of plastic pollution.

Accinelli, C., et al. (2019). "Degradation of microplastic seed film-coating fragments in soil." Chemosphere **226**: 645-650.

Encapsulating fungicides and/or insecticides in film-coatings applied to agronomic seeds has become a widely accepted method for enhancing seed germination and overall seedling health by protecting against many diseases and early-season insect pests. Despite advancements in seed film-coating technologies, abrasion of the seed coating can occur during handling and mechanical planting operations, resulting in variable amounts of detached fragments entering

the soil. The present study investigated the degradation in soil of these plastic-like, small-sized fragments, referred to here as microplastic coating fragments. Degradation of microplastic coating fragments in soil was found to be highly variable. The lowest degradation rate (<=48 days) was observed in fragments detached from seeds coated with a commercial polymer mixture, while fragments from a biodegradable plastic formulation degraded completely within 32 days. When spores of the plant growth-promoting bacterium, Bacillus subtilis, were incorporated into the bioplastic, degradation was even more rapid (<=24 days). The fragment degradation rate was unaffected by incorporating two commonly used neonicotinoid insecticides, imidacloprid or thiacloprid, into either coating formulations, but insecticide dissipation rates in soil were more rapid when added associated with seed coating fragments than when spiked in directly. Half-lives of these two insecticides were reduced by up to 27% in fragments from bioplastic-coated seeds. These results are consistent with variable and not easily predicted soil degradation rates for seed coating fragments, with enhanced dissipation of coating-entrapped pesticides and with a higher degradation rate for biodegradable seed coating incorporating selected microbial strains.

Accomando, W. P., et al. (2012). "A novel method for the detection of circulating NK cells in archived blood reveals a decrease in NK cells in head and neck squamous cell carcinoma." Cancer Research. Conference: 103rd Annual Meeting of the American Association for Cancer Research, AACR **72**(8 SUPPL. 1).

Patients with head and neck squamous cell carcinoma (HNSCC) frequently exhibit abnormal immune cell levels and activities, leading many to believe that progression of the disease is linked to evasion of immune surveillance. A more complete understanding of immune cell alterations could be obtained from analysis of archival samples, but this type of study is not possible using current immunodiagnostic methods. Combining information on cell lineage specific differentially methylated regions (DMRs) with methylation specific quantitative PCR (MS-qPCR) enables highly sensitive and accurate counts of individual cell types in archival blood and tissues. DNA methylation and mRNA expression in magnetic microbead (MACS) isolated, flow cytometry (FACS) validated normal human peripheral blood leukocytes were assessed using the Infinium HumanMethylation27 and Whole-Genome DASL HT (Illumina) microarrays. Cell-specific DMRs were identified by comparative analysis of DNA methylation and mRNA expression patterns between different cell lineages, and validated by MS-qPCR and pyrosequencing. Analysis of the microarray data revealed CpG loci significantly demethylated in NK cells compared to all other leukocyte lineages ($q < 0.1$) within genes exhibiting significantly increased mRNA expression in NK cells ($q < 0.1$). Pyrosequencing and MS-qPCR assays confirmed a NK cell specific demethylated region. The MS-qPCR assay was calibrated using known quantities of NK cell DNA to facilitate quantification of these cells in biological samples, and was then applied to archival peripheral blood DNA samples from 122 control donors and 122 HNSCC patients. Demethylation of the candidate region was significantly lower in HNSCC patient bloods compared with control bloods ($p < 0.001$), but was not significantly associated with age, gender, HPV16 (E6 and/or E7) serology, cigarette smoking, alcohol consumption, BMI, or disease treatment. Measurements from control samples were used to establish normal demethylation tertiles. Proportion of total HNSCC cases decreased significantly with increasing tertile ($p < 0.001$). Multivariate logistic regression controlling for age, gender, cigarette smoking, alcohol consumption, BMI, and HPV16 serology confirmed increased HNSCC risk for individuals in the lowest tertile (OR = 5.6, 95% CI: 2.0, 17.4) and second lowest tertile (OR = 4.9, 95% CI: 1.8, 16.1). The advent of DNA methylation based immunodiagnostic methods will make assessment of immune cell profiles in archived samples that have not undergone rigorous special handling

requirements possible. Using a novel NK cell specific demethylated region to detect and quantify NK cells in the blood, we have detected a HNSCC associated decrease in circulating NK cells that is independent of disease treatments, known exposures and other putative risk factors.

Acosta-Coley, I., et al. (2019). "Trace elements in microplastics in Cartagena: A hotspot for plastic pollution at the Caribbean." Marine Pollution Bulletin **139**: 402.

Microplastics are new pollutants considered a source of concern for the oceans worldwide. This research reports the concentrations of trace metals on microplastics collected on beaches from Cartagena, an industrialized city in the Caribbean. Mercury (Hg) was quantified using a Hg analyzer and forty-seven trace elements were assessed by ICP/MS. Most abundant microplastics in beaches were those with the lower degree of surface degradation features (SDF), categorized as white-new polyethylene pellets, followed by secondary microplastics (SM). Greater Hg levels were found in SM, white-degraded (WDP) and black pellets. Trace elements concentrations were linked to the degree of SDF registered in examined pellets, with larger concentrations in WDP. Compared to white-new pellets, Ba, Cr, Rb, Sr, Ce, Zr, Ni, Pb were the most accumulated elements in WDP, as their surface enhance the sorption processes. Microplastic pollution represents a toxicological hazard because its ability to accumulate and transport toxic elements.

Acosta-Coley, I. and J. Olivero-Verbel (2015). "Microplastic resin pellets on an urban tropical beach in Colombia." Environmental Monitoring and Assessment **187 (7) (no pagination)**(435).

Microplastics are a problem in oceans worldwide. The current situation in Latin America is not well known. This paper reports, for the first time, the presence of microplastics on an urban Caribbean beach in Cartagena, Colombia. Pellet samples were collected from a tourist beach over a 5-month period covering both dry and rainy seasons. Pellets were classified by color and their surface analyzed by stereomicroscopy, and some were characterized by infrared spectroscopy. The most abundant pellets were white, presenting virgin surfaces, with few signs of oxidation. This is congruent with a short residence time in the marine environment and primary sources possibly located nearby. The frequency of white pellets did not change with sampling period. Surface features identified in the pellets included cracks, material loss, erosion, adhesion, granulation, color change, and glazed surfaces. Reticulated granular pellets exhibited the greatest degradation, easily generating submicroplastics. Sample composition was mostly polyethylene, followed by polypropylene. This pollution problem must be addressed by responsible authorities to avoid pellet deposition in oceans and on beaches around the world. Adam, V., et al. (2019). "Toward an ecotoxicological risk assessment of microplastics: Comparison of available hazard and exposure data in freshwaters." Environmental Toxicology & Chemistry **38**(2): 436-447.

Microplastics have been detected in freshwaters all over the world in almost all samples, and ecotoxicological studies have shown adverse effects of microplastics on organisms. However, no risk assessment of microplastics has been performed specifically in freshwater so far. The aim of the present study was therefore to review all exposure and ecotoxicity data available for microplastics in freshwaters and to perform a preliminary probabilistic risk assessment. The exposure probability distribution was based on 391 concentrations measured in Asia, Europe, and North America. Because exposure data are mainly available in particle number-based metrics but results from hazard studies are mostly mass-based, the hazard results were converted into particle number concentrations. A statistical analysis of the hazard data showed that there was no significant influence of particle shape or type of polymer on the no-observed-effect concentration. The predicted-no-effect concentration (PNEC) was calculated as the fifth percentile of the probabilistic species sensitivity distribution, based on 53 values from 14 freshwater species, to have a mode of 7.4 x 10⁵ particles . m⁻³ (25th and 75th quantiles of 6.1 x 10⁵ and 1.3 x 10⁶ particles . m⁻³ , respectively). The exposure probability distribution was divided by the PNEC probability distribution to calculate risk characterization ratios (RCRs), with modes of 1.3 x 10⁻⁶ in North America, 3.3 x 10⁻⁶ in Europe, and 4.6 x 10⁻³ in Asia. Probability distributions associated with the RCRs showed that ecological risks cannot be entirely excluded in Asia, where 0.4% of the RCR values were above 1. Adamcova, M. and F. Simko (2018). "Multiplex biomarker approach to cardiovascular diseases." Acta Pharmacologica Sinica **39**(7): 1068-1072.

Personalized medicine is partly based on biomarker-guided diagnostics, therapy and prognosis, which is becoming an unavoidable concept in modern cardiology. However, the clinical significance of single biomarker studies is rather limited. A promising novel approach involves combining multiple markers into a multiplex panel, which could refine the management of a particular patient with cardiovascular pathology. Two principally different assay formats have been developed to facilitate simultaneous quantification of multiple antigens: planar array assays and microbead assays. These approaches may help to better evaluate the complexity and dynamic nature of pathologic processes and offer substantial cost and sample savings compared with traditional enzyme-linked immunosorbent assay (ELISA) measurements. However, a multiplex multimarker approach cannot become a generally disseminated method until analytical problems are solved and further studies confirming improved clinical outcomes are accomplished. These drawbacks underlie the fact that a limited number of systematic studies are available regarding the use of a multiplex biomarker approach in cardiovascular medicine to date. Our perspective underscores the significant potential of the use of the multiplex approach in a wider conceptual framework under the close cooperation of clinical and experimental cardiologists, pathophysiologists and biochemists so that the personalized approach based on standardized multimarker testing may improve the management of various cardiovascular pathologies and become a ubiquitous partner of population-derived evidence-based medicine.

Adebiyi-Abiola, B. B., et al. (2019). "Cleaning up plastic pollution in Africa." Science **365**(6459): 1249-1251.

Aderoju, O. M., et al. (2019). "PLASTIC WASTE FOR ELECTRICAL POWER GENERATION: A CASE STUDY IN NIGERIA." Revista de Gestão Ambiental e Sustentabilidade **8**(3): 538-553.

Nigerian is currently threatened by the quantity of waste plastics in its major cities. However, waste plastics has been a menace to the Nigerian environs (land and water) majorly and contributed to flood disasters and other environmental degradation events which has led to severe health risk. In view of this, the study aims to assess the waste plastics in Nigeria for electric power generation. The study devised two strategies (incentive-based approach, and the Extended Producer's Responsibility (EPR)) for the collection of waste plastics from the environment. This study is focused on the incineration of waste plastics with energy recovery; hence the proximate and ultimate analyses were carried out to determine the Higher Heat Value (HHV) and the Lower Heat Value (LHV) as well as to estimate the Power Generation Potential (PGP). The empirical results show that the HHV was evaluated as 568.96 kcal/kg and, the LHV

was evaluated as 561.55 kcal/kg. Again, the power generation potential (PGP) was enumerated using 100 tons of waste plastics and 4.83 million tons (81% of inadequately managed plastics) to arrive at about 0.6MW and 29,000MW respectively. This study contributes to the literature on the problems of waste plastics in Nigeria. Furthermore, it is likely to be a sustainable solution to the backlog of waste plastics in the environment and a supplementary solution to the erratic electric power supply. The results show that the quantity of waste plastics in Nigeria is likely to generate enough electricity to complement the existing source of power supply.Alternate abstract:Um dos grandes problemas da Nigéria, na atualidade, é a grande quantidade de residuos plásticos que sao produzidos nas suas principais cidades. Os residuos plásticos těm sido uma ameaça para os arredores daquelas cidades (em particular sobre o solo e sobre a água) e contribuem para desastres de inundaçao e outros eventos de degradaçao ambiental que conduzem a sérios riscos para a saúde humana. Assim, este estudo tem como objetivo avaliar o potencial dos residuos plásticos produzidos na Nigéria para a geraçao de energia elétrica. O estudo desenvolvido baseia-se em duas estratégias (uma abordagem baseada em incentivos e no principio da Responsabilidade Estendida do Produtor (REP)) para a coleta de residuos plásticos no meio ambiente. O foco deste trabalho está na incineraçao de residuos plásticos com recuperaçao da energia produzida. Assim, foram realizadas análises imediata e elementar para determinar o Poder Calorifico Superior (PCS) e o Poder Calorifico Inferior (PCI), bem como estimar o Potencial de Geraçao de Energia (PGE). Os resultados empíricos mostram que o PCS foi avaliado em 568.96 kcal/ kg e o PCI foi avaliado em 561.55 kcal/kg. Adicionalmente, foi determinado o Potencial de Geraçao de Energia (PGE) usando 100 toneladas de residuos plásticos e 4.83 milhöes de toneladas (81% de plásticos manuseados inadequadamente) obtendo-se, respetivamente, 0.6 MW e 29.0 MW. Este estudo contribui para a literatura como uma visao geral de gestao de residuos na Nigéria, focando-se nos problemas relacionados com os residuos plásticos. Além disso, o conceito proporciona uma soluçao sustentável para esta tipologia de residuos que afeta particularmente a envolvente das grandes cidades. Além disso, é provável que seja uma soluçao sustentável para a acumulaçao de residuos plásticos no meio ambiente e uma soluçao suplementar para a produçao de energia elétrica. Os resultados mostram que a quantidade de residuos plásticos produzidos na Nigéria, provavelmente, gerará eletricidade suficiente para complementar as fontes tradicionais de produçao de eletricidade.Alternate abstract:Uno de los principales problemas de Nigeria hoy en dia es la gran cantidad de residuos plásticos que se producen en sus principales ciudades. Los residuos plásticos han sido una amenaza para las afueras de esas ciudades (particularmente en el suelo y el agua) y contribuyen a los desastres de inundaciones y otros eventos de degradación ambient l que conducen a serios riesgos para la salud humana. Por lo tanto, este estudio tiene como objetivo evaluar el potencial de los residuos plásticos producidos en Nigeria para la generación de electricidad. El estudio desarrollado se basa en dos estrategias (un enfoque basado en incentivos y el principio de Responsabilidad Extendida del Productor (REP)) para la recolección de desechos plásticos en el medio ambiente. El objetivo de este trabajo es la incineración de residuos plásticos con la recuperación de la energia producida. Por lo tanto, se realizaron análisis inmediato y elemental para determinar el poder calorifico superior (PCS) y el poder calorifico inferior (PCI), asi como para estimar el potencial de generación de energia (PGE). Los resultados empiricos muestran que el PCS se calificó a 568.96 kcal/kg y el PCI se calificó a 561.55 kcal/kg. Además, el potencial de generación de energía (PGE) se determinó utilizando 100 toneladas de residuos plásticos y 4,83 millones de toneladas (81% de plásticos manejados incorrectamente), produciendo respectivamente 0.6 MW y 29.0 MW. Este estudio contribuye a la literatura como una visión general de la gestión de residuos en Nigeria, centrándose en cuestiones relacionadas con los residuos plásticos. Además, el concepto proporciona una

solución sostenible para esta tipologia de residuos que afecta particularmente a los alrededores de las grandes ciudades. Los resultados muestran que la cantidad de residuos plásticos producidos en Nigeria probablemente generará electricidad suficiente para complementar las fuentes tradicionales de producción de electricidad.

Adeyemi, O. and B. Ajayi (2018). "Investigation of properties of paper-plastic composite made from kraft paper and plastic wastes." Pro Ligno **14**(2): 53-58.
In this study, we investigated the compatibility of kraft paper and plastic wastes. Also, the physical and mechanical properties of the paper-plastic composite were determined. Pulverized kraft paper wastes and fine sachet water particles were weighed and mixed together using different mixing ratios (50% of paper & 50% of plastic (1:1), 33% of paper & 67% of plastic (1:2) and 25% of paper & 75% of plastic (1:3)). The method of composite production employed was extrusion method. The results of water absorption (WA) conducted on the paper-plastic composite material ranged between 0.03%-0.16% and 0.03%-0.20% for 2 and 24 hours respectively. The average values obtained for thickness swell (TS) ranged between 0.00%-0.23% and 0.00%-0.33% for 2 and 24 hours respectively. The average values obtained for tensile modulus ranged between 0.11 GPa to 0.33 GPa and the average values obtained for tensile strength ranged between 9.99 MPa to 15.12 MPa. The result obtained from this study shows that kraft paper wastes and water sachet wastes can be utilized as a composite material as they were compatible. In addition, 25% of paper & 75% of plastic waste (1:3) gives the best mixing ratio as indicated by the result with the most dimensionally stable and high strength properties.

Adrados, A., et al. (2013). "Pyrolysis behavior of different type of materials contained in the rejects of packaging waste sorting plants." Waste Management **33**(1): 52-59.
In this paper rejected streams coming from a waste packaging material recovery facility have been characterized and separated into families of products of similar nature in order to determine the influence of different types of ingredients in the products obtained in the pyrolysis process. The pyrolysis experiments have been carried out in a non-stirred batch 3.5 dm3 reactor, swept with 1 L min−1 N2, at 500 °C for 30min. Pyrolysis liquids are composed of an organic phase and an aqueous phase. The aqueous phase is greater as higher is the cellulosic material content in the sample. The organic phase contains valuable chemicals as styrene, ethylbenzene and toluene, and has high heating value (HHV) (33–40 MJ kg−1). Therefore they could be used as alternative fuels for heat and power generation and as a source of valuable chemicals. Pyrolysis gases are mainly composed of hydrocarbons but contain high amounts of CO and CO2; their HHV is in the range of 18–46 MJ kg−1. The amount of COCO2 increases, and consequently HHV decreases as higher is the cellulosic content of the waste. Pyrolysis solids are mainly composed of inorganics and char formed in the process. The cellulosic materials lower the quality of the pyrolysis liquids and gases, and increase the production of char. [Copyright &y& Elsevier]

Agamuthu, P. (2018). "Marine debris, plastics, microplastics and nano-plastics: What next?" Waste Management and Research **36**(10): 869-871.

Agamuthu, P. and P. N. Faizura (2005). "Biodegradability of degradable plastic waste." Waste Management & Research **23**(2): 95-100.

Plastic waste constitutes the third largest waste volume in Malaysian municipal solid waste (MSW), next to putrescible waste and paper. The plastic component in MSW from Kuala Lumpur averages 24% (by weight), whereas the national mean is about 15%. The 144 waste dumps in the country receive about 95% of the MSW, including plastic waste. The useful life of the landfills is fast diminishing as the plastic waste stays un-degraded for more than 50 years. In this study the compostability of polyethylene and pro-oxidant additive-based environmentally degradable plastics (EDP) was investigated. Linear low-density polyethylene (LLDPE) samples exposed hydrolytically or oxidatively at 60 degrees C showed that the abiotic degradation path was oxidative rather than hydrolytic. There was a weight loss of 8% and the plastic has been oxidized as shown by the additional carbonyl group exhibited in the Fourier transform infra red (FTIR) Spectrum. Oxidation rate seemed to be influenced by the amount of pro-oxidant additive, the chemical structure and morphology of the plastic samples, and the surface area. Composting studies during a 45-day experiment showed that the percentage elongation (reduction) was 20% for McD samples [high-density polyethylene, (HDPE) with 3% additive] and LL samples (LLDPE with 7% additive) and 18% reduction for totally degradable plastic (TDP) samples (HDPE with 3% additive). Lastly, microbial experiments using Pseudomonas aeroginosa on carbon-free media with degradable plastic samples as the sole carbon source, showed confirmatory results. A positive bacterial growth and a weight loss of 2.2% for degraded polyethylene samples were evident to show that the degradable plastic is biodegradable.

Agamuthu, P., et al. (2019). "Marine debris: A review of impacts and global initiatives." Waste Management & Research **37**(10): 987-1002.

Marine debris, defined as any persistent manufactured or processed solid material discarded, disposed of or abandoned in the marine and coastal environment, has been highlighted as a contaminant of global environmental and economic concern. The five main categories of marine debris comprise of plastic, paper, metal, textile, glass and rubber. Plastics is recognised as the major constituent of marine debris, representing between 50% and 90% of the total marine debris found globally. Between 4.8 and 12.7 million metric tonnes of consumer plastics end up in the world oceans annually, resulting in the presence of more than 100 million particles of macroplastics in only 12 regional seas worldwide, and with 51 trillion particles of microplastic floating on the ocean surface globally. The impacts of marine debris can be branched out into three categories; injury to or death of marine organisms, harm to marine environment and effects on human health and economy. Marine mammals often accidentally ingest marine debris because of its appearance that can easily be mistaken as food. Moreover, floating plastics may act as vehicles for chemicals and/or environmental contaminants, which may be absorbed on to their surface during their use and permanence into the environment. Additionally, floating plastics is a potential vector for the introduction of invasive species that get attached to it, into the marine environment. In addition, human beings are not excluded from the impact of marine debris as they become exposed to microplastics through seafood consumption. Moreover, landscape degradation owing to debris accumulation is an eyesore and aesthetically unpleasant, thus resulting in decreased tourism and subsequent income loss. There are a wide range of initiatives that have been taken to tackle the issue of marine debris. They may involve manual removal of marine debris from coastal and aquatic environment in form of programmes and projects organised, such as beach clean-ups by scientific communities, non-governmental organizations and the removal of marine litter from Europe's four regional seas, respectively.

Other initiatives focus on assessment, reduction, prevention and management of marine debris under the umbrella of international (the United Nations Environment Programme/Mediterranean Action Plan, the Oslo/Paris Convention) and regional organisations - that is, the Helsinki Commission. There are also a number of international conventions and national regulations that encourage mitigation and management of marine debris. However, it is argued that these initiatives are short-term unsustainable solutions and the long-term sustainable solution would be adoption of circular economy. Similarly, four of the sustainable developmental goals have targets that promote mitigation of marine debris by efficient waste management and practice of 3R. As evident by the Ad Hoc Expert Group on Marine Litter and Microplastics meeting, tackling the marine debris crisis is not a straightforward, one-size-fits-all solution, but rather an integrated and continuous effort required at local, regional and global level.

Agar, J., et al. (2018). "Dialysis plastic waste recycled as a concrete incorporative." Nephrology **23 (Supplement 3)**: 39.

Background: A global annual estimate of >900,000 tonnes of post-dialysis plastic waste (pdPW) is either incinerated or chemically disinfected for landfill - both at vast financial and environmental cost. But, as novel waste management systems [eg: A SteriMed 700] can shred then sterilize pdPW, we have explored incorporating pdPW into concrete as a potential re-use end product. Method(s): All p-dPW [lines, dialysers, saline bags, syringes, bi-bags etc.] were shredded and sterilized to a polypropylene plastic fiber 'shreddate' (PPfs). This was added as 0.5% and 1% by weight to concrete slurries. Pre-separated hard, soft, and all-mixed PPfs were separately tested in a 1% concentration for compressive strength (CS), tensile strength (TS), and water absorption (WA). Result(s): The mixed PPfs additive increased TS (0.5% mix = 0.8% increase: 1% mix = 8% increase). 1% PPfs modestly decreased CS (hard 9.9%: Soft 16.9%: Mixed 11.5% respectively). Added 1% PPfs did not immediately alter the rate of WA, but the mean delayed rate decreased by 30% across all three PPfs-concrete mixes. Discussion(s): The % mix, shape and size of PPfs fibers significantly influenced final concrete characteristics. The small reduction in CS is unlikely to have significant impact, but the increase in TS and the 30% reduction in WA are likely significant factors in reducing water penetration and corrosion. Conclusion(s): Concrete sequestration of pdPW may: (1) help solve the financial/environmental costs of pdPW disposal; and (2) significantly improve specific concrete characteristics. Improved long-term concrete behavior, water resistance, durability, and steel reinforcement corrosion protection may prove valuable, especially for coastal construction/building, or in marine structures (piers/retaining walls) that contact seawater. The potentially far-reaching implications of this research have prompted further testing.

Agar, J. W. (2012). "Personal viewpoint: hemodialysis--water, power, and waste disposal: rethinking our environmental responsibilities." Hemodialysis International **16**(1): 6-10.

While medical health professionals are trained to detect, treat, and comfort, they are not trained to consider the environmental impact of the services they provide. Dialysis practitioners seem particularly careless in the use of natural resources-especially water and power-and seem broadly ignorant of the profound medical waste issues created by single use dialysis equipment. If the data we have collected is an indication, then extrapolation of this data to a dialysis population currently estimated at ~2 million patients worldwide, a "world dialysis service" would use ~156 billion liters of water and discard ~2/3 of that during reverse osmosis. This waste occurs, despite the discarded water being high-grade "gray water" of potable standard. The same world dialysis service would consume 1.62 billion kWh of power-mostly generated from coal and other environmentally damaging sources. Our world dialysis service, based on ~2 kg of waste from each dialysis treatment, would generate ~625,000 tonnes of plastic waste-waste that would be potentially reusable if simple sterilizing techniques were applied to it at the point of generation. Dialysis services must begin to explore eco-dialysis potentials. The continued plundering of resources without considering reuse or recycling, exploration of renewable energy options, or the reduction of the carbon footprint of the dialysis process . . . is unsustainable. Sustainable dialysis practices should be a global goal in the coming decade.

Agar, J. W. M. (2011). "Eco-dialysis: Planning dialysis facilities for the future." Nephrology **1)**: 70.

Haemodialysis (HD) is a wasteful medical therapy. It places huge demands on water and power resources, utilizes poorly designed and badly insulated buildings, generates a vast per/patient carbon footprint, and creates extraordinary stresses on medical waste disposal. Yet, these environmental burdens can all be markedly reduced. In our HD facilities, simple, inexpensive and permanent systems now re-cycle our reverse osmosis reject water - up to 2/3rd of all HD-directed feed water. Capital investment costs have been rapidly recouped by institutional reductions in recurrent expenditure on water, while re-use has provided practical solutions to other institutional water uses: instrument sterilization, toilet flushing, laundry uses and landscape maintenance. Permanent, simple alternative power options are also effective. The power generated by a single 24 m2 solar array (total cost = $16, 219) at our 4 chair home HD training and respite unit exceeds all HD-process power consumption with grid reimbursements effectively subsidizing power costs out for >25 years. Minimization of the HD carbon footprint through improved recycling of packaging waste is commonly neglected by facilities. As infectious medical plastic waste, often still discarded into landfill, can now be effectively re-processed and incorporated into, for example, road surfacing, new paradigms of waste recycling must be explored. As European eco-architects now routinely use rooftop soil and vegetation to insulate buildings against both heat and cold, future HD unit design might also consider combining rooftop soil-insulation with HD reject-water (ed) vegetable horticulture to provide low-cost, facility-grown produce for dialysis staff and patient use. Clever design is not fanciful: rather, it is possible, practical and essential in the 21st century. All Australian HD services should unite to explore eco-dialysis potentials. An Australian 'green nephrology' program, similar to the NHS cooperative now spanning the UK, should be a defined ANZSN intent for the next decade.

Agarwal, R., et al. (2016). "A novel technique to study arteriovenous malformations in left ventricular assist device patients with gastrointestinal bleeding." Journal of Heart and Lung Transplantation **1)**: S247.

Purpose: Gastrointestinal bleeding (GIB) associated with arteriovenous malformations (AVMs) is the leading cause of morbidity in LVAD patients. Postulated mechanisms for AVM development exist however the distinct vascular biology of in-situ lesions has not been intimately studied. We present a novel method for isolating endothelial cells and performing proteomic profiling of AVMs. Method(s): We applied vigorous soft-bristle brushings to surface AVMs and adjacent non-bleeding mucosa (control) in 12 LVAD patients during routine endoscopy. No additional bleeding was provoked by this method. Brushing samples were washed and enriched using anti-human CD146 microbeads to isolate endothelial cells. Intracellular protein was extracted from AVMs and control and labeled fluoroscopically for differential in-gel analysis of protein expression. Patients with recurrent GIB were able to be serially sampled using this technique. Result(s): The results of our method in a patient with diffuse gastric AVMs are shown in Figures 1 and 2. We detected 2642 protein spots: 214 (8.1%) spots decreased, 281 (10.6%) spots increased, and 2147 (81.3%) spots were unchanged in control vs. AVMs. Conclusion(s): This study highlights a unique and safe methodologic approach for the study of AVM lesions in LVAD patients. We successfully isolated endothelial cells at time of endoscopy and explored proteomic profiling to detect differences in protein expression between pathologic AVM lesions and normal appearing GI tissue. Further study is needed to characterize specific protein markers and predictors for AVM-related GIB. (Figure Presented).

Agbo, I. A. and D. Abaye (2016). "Levels of Polychlorinated Biphenyls in Plastic Resin Pellets from Six Beaches on the Accra-Tema Coastline, Ghana." Journal of Health & Pollution **6**(11): 9-17.

Background: Polychlorinated biphenyls (PCBs) are organic compounds, known to be carcinogenic and banned by the Stockholm Convention. PCBs are hydrophobic substances able to accumulate in organic materials, including plastic pellets. Plastic resin pellets are industrial raw materials that are remolded finished products for industrial and domestic use, commonly used for packaging. Plastic resin pellets were chosen as the medium for monitoring hydrophobic contaminants because they are able to adsorb PCB contaminants. Pellets can be unintentionally washed into the ocean where hydrophobic contaminants such as PCBs are also deposited.

Objectives: We aimed to identify PCB congeners and quantify PCB pollution levels in the marine environment using resin plastic pellets collected from six beaches along the Accra-Tema coastline in Ghana.

Methods: Plastic resin pellets (5 g) were extracted with 200 mL of n-hexane for 16 hours by Soxhlet extraction. Concentrations of PCBs from the extracts were determined using gas chromatography with an electron capture detector.

Results: The individual PCB congeners detected were PCB 28, 52, 101, 105, 138, 153, 156 and 180. PCB 28 was detected at all six beaches, with a total concentration of 43.5 ng/g pellet (mean/beach 7.25 +/- 2.47 ng/g pellet; CV = 34%), while PCB 138 was only detected on one beach (Castle Beach) at a total concentration of 0.8 ng/g pellet. The concentration of PCBs ranged from 7.4 ng/g (Sunset Beach) to 47.5 ng/g (Castle Beach) (mean 16.4+/-15.4 ng/g per beach; CV=94%).

Discussion: PCB concentrations at Castle Beach have been studied previously, showing an increase from 39 ng/g to 47.5 ng/g, whereas levels decreased significantly from 28 ng/g to 14.2 ng/g in Sakumono Beach over the span of three years.

Conclusions: The concentrations of four detected PCB congeners (28, 52, 101 and 156) were significantly higher than the World Health Organization (WHO) allowable daily intake of 6 ng/g food per day for PCBs. A more efficient industrial and domestic waste disposal system is advocated for Ghana.

Aghababaei, A. and R. Kasaai (2013). "Studies on different properties of composite thin films made from waxy starch-citric acid and starch-methyl cellulose." Iranian Food Science & Technology Research Journal **9**(1): e68-Pe80.

Pollution arising from plastic waste materials caused a great worry for researchers who are interested in protection of environment. This problem shifts their subject to bio-polymers for applications in packaging industries. However, their low water barrier properties are a critical problem. The effects of citric acid and methyl cellulose on water vapor and oxygen permeabilities and mechanical properties of starch composite thin films have been studied. Water vapor permeability (WVP) has been measured using a vial coated by a film. Oxygen transmission rate (OTR) of a film was determined from measurement of peroxide value for a definite amount of oil that is placed in a vial and coated by the film. Mechanical properties were measured using a tensile machine. Increase in citric acid concentration up to 5% citric acid (w/w), resulted in a decrease in water vapor and oxygen permeabilities. A film containing 5% of citric acid exhibited a minimum value for WVP, whereas the value of WVP and elongation at the break increased and tensile strength decreased for a film containing 20% of citric acid (w/w). Increase in methyl cellulose up to 30% resulted in decrease in WVP and OTR.

Agorku, D., et al. (2014). "Depletion of mouse cells from human tumor xenografts significantly reduces bias in molecular analysis and improves culture of target cells." Cancer Research. Conference: 105th

Annual Meeting of the American Association for Cancer Research, AACR **74**(19 SUPPL. 1).

Human tumor xenografts represent the gold standard method for research areas like drug discovery, cancer stem cell biology, and metastasis prediction. They can be derived from primary human tumor material, serially transplanted tumor tissue, or cultured cells. When compared to in vitro cell culture models, human tumor xenografts show a higher validity for most assays (Rubio-Viqueira et al., 2009). During the growth phase in vivo, xenografted tissue is vascularized and infiltrated by cells of murine origin including heterogeneous lymphocyte subpopulations, fibroblasts, and endothelial cells. The level of infiltration is highly dependent on multiple factors like tumor subtype, growth rate, and region of transplantation. However, even when these factors are kept constant, the amount and composition of infiltrating mouse cells is highly variable. Due to this, some molecular downstream analyses are challenged. The contaminating mouse cells lead to cross hybridization of mouse derived molecules to human probes on microarrays and a significant reduction of sensitivity caused by measuring mouse signals during next-generation sequencing or proteome analysis. In addition, the culture of human tumor cells is frequently hampered by murine fibroblasts efficiently plating and overgrowing the target cells. To overcome these limitations, we have developed a fast and easy method allowing for the comprehensive depletion of all cells of murine origin. We have dissociated human tumor xenografts as well as normal murine tissue of multiple origins including skin, brain, kidney and lung followed by screening panels of cell surface markers to define an optimized combination of antibodies capable of binding all cells from all murine origins. Subsequently, we generated conjugates of suitable antibodies with paramagnetic nanoparticles (MicroBeads) and titrated all reagents to optimize the depletion efficiency by using magnetic cell sorting (MACS). Even tumors that contain high numbers of mouse cells (> 60%) can be cleaned up to purities of human tumor cells higher than 96% in less than 25 minutes. This depletion step substantially increased sensitivity during empiric cell surface marker screenings as well as during the isolation of tumor cell subpopulations. Finally, we show that downstream molecular analysis and culture of human tumor cells is significantly standardized upon removal of mouse contamination. Taken together, this novel method prevents inaccurate human tumor xenograft analysis caused by contamination with cells of murine origin. As antibodies specific only for mouse cells are used, the target cells stay "untouched" and the procedure can be used for all kinds of xenografted material without the need for a positive marker expressed on the human cells.

Agorku, D., et al. (2014). "A novel monoclonal antibody allowing for the isolation and analysis of Lgr5 positive cells from cell lines and primary human tissue." European Journal of Cancer **5)**: S30.

Introduction: Cancer stem cells (CSCs), also called tumor initiating cells, have gained substantial interest in the research field over the past few years. CSCs have been isolated from multiple tumor entities and were shown to play a crucial role during tumor growth and metastasis. However, there is still a major debate about specific cell surface markers capable of identifying CSCs in most tumor entities. The leucine-rich repeat-containing G-protein-coupled receptor (LGR) Lgr5 and its close homologues Lgr4 and Lgr6 associate with Wnt-receptors and act as R-spondin receptors thereby playing a central role in the modulation of Wnt/b-catenin signaling in normal and neoplastic stem cells (de Lau et al., 2011, Carmon et al., 2011). Initially described as a highly specific marker for stem cells in the small intestine, colon, hair follicle, stomach, and during kidney development (Barker et al., 2007, Jaks et al., 2008, Barker et al., 2010, Barker et al., 2012), Lgr5 positive cells were also shown to be crucial during the development and progression of cancer. It was shown that Lgr5 positive crypt stem cells are the cells-of-origin in intestinal cancer and that CSCs in human colorectal cancer can be identified and isolated based on Lgr5 expression (Barker et al., 2009, Kemper et al., 2012). However, the analysis of Lgr5

expressing cells is hampered by the lack of highly specific monoclonal antibodies. Material(s) and Method(s): We have developed a novel rat monoclonal antibody specifically binding to the extracellular domain of human Lgr5. Fluorochrome conjugates were generated allowing for the direct detection, enumeration, and analysis of Lgr5 expressing cells in cell lines and primary tissues. Furthermore, the antibody was evaluated for use in immunohistochemistry and western blot based detection of Lgr5. Subsequently, we generated conjugates of the novel antibody with superparamagnetic nanoparticles (MicroBeads) and titrated it to optimize the separation efficiency by using magnetic cell sorting (MACS). Result(s): Using stable transfectants for Lgr4 and Lgr6, we could prove that the antibody is not cross reactive with the close homologues of Lgr5. This is of particular importance for Lgr4, as this protein is also expressed on more differentiated progenitor cells. It was possible to detect cells expressing Lgr5 even at low levels in cell lines as well as in primary tissues using flow cytometry, immunohistochemistry, and western blot analysis. In addition, we generated a new magnetic cell separation (MACS) protocol that can be used as an easy and fast method to isolate Lgr5 positive cells from cell lines and primary human tissue. Using this method Lgr5 positive colon carcinoma cells as well as human skin stem cells were isolated at purities >95% and >75%, respectively. Conclusion(s): Taken together, we have developed a highly specific monoclonal antibody allowing for the analysis and isolation of Lgr5 positive cells from cell lines and primary tissues.

Agrawal, R., et al. (2015). "Assessment of red blood cell deformability by Optical tweezers in diabetic retinopathy." Investigative Ophthalmology and Visual Science **56 (7)**: 5183.

Purpose Haemorheological disturbances observed in diabetics have been postulated to play a role in the pathogenesis of diabetic microangiopathy. The present study was conducted to investigate the role of red blood cell (RBC) deformability and factors affecting RBC deformability in patients with diabetic retinopathy (DR) using modified optical tweezers method. Methods A pilot project was conducted as per declaration of tenets of Helsinki with ethics board approval (14/WM/1038). Bloods from age matched control and patients was collected for standard biochemical and hematological tests and for RBC deformability index (DI) assessment using Optical tweezers. A dual optical tweezers (two trapping beams) was made by splitting and recombining a single laser beam. RBCs were trapped directly (i.e. without microbead handles) in the dual optical tweezers where they adopt a "side-on" image. Results Blood from 8 healthy controls with mean age of 52.37yrs and 4 diabetic patients with mean age of 52.00yrs was analysed. Unstretched RBC length for control group was 6.847mum (+/-0.29, 95CI: 6.83-6.86) and 7.001 mum (+/-0.27, 95CI: 6.97-7.02) for diabetic RBCs (p<0.0001). Maximal stretched length for RBCs using two laser beams of optical tweezers was 7.362mum (+/-0.24, 95CI: 7.35-7.37) for control group and 7.401mum (+/- 0.262, 95CI: 7.37-7.42) for diabetic group (p=0.0021). DI was calculated by subtracting unstretched length of RBCs from maximal stretched length of RBCs. The DI for control group was 0.57 (+/-0.22, 95CI: 0.55-0.59) and that for diabetic RBCs was 0.39 (+/-0.26, 95CI: 0.37-0.42) (p<0.0001). With DI as dependent variable, we did bivariate analysis for age (yrs), hemoglobin, hematocrit, red blood cell count, mean corpuscular volume, red blood cell distribution width, platelet concentration, mean platelet volume, erythrocyte sedimentation rate, serum creatinine, total proteins, C-reactive protein, random blood glucose, HbA1C, total cholesterol and fibrinogen. None of the factors were found to be significantly correlated with DI on bivariate analysis. Conclusions DI of RBC from DR was significantly lower in comparison with normal healthy controls. None of the biochemical and hematological factors in the blood were found to a ect DI for RBCs.

Agrawal, R., et al. (2016). "Synthesis and molecular docking of terephthalic dihydrazide from poly(ethylene terepthalate) for antimicrobial activity and biochemical changes." Der Pharma Chemica **8**(1): 137-145.

The increasing use and generation of solid plastic wastes have imposed challenges of their disposal for the society. Thereby, the recycling and treatment of solid plastic waste to ecofriendly compound may help in sustaining and integrating the wastes for useful purpose. Herein, this paper the aminolysis of poly(ethylene terphthalate) (PET) is being carried out in presence of excess of hydrazine monohydrate to form terphthalic dihydrazide (TDH). The characterization and structural confirmation was done by FTIR, NMR, UV and thermal analysis. The derivatives of amide are related with broad spectrum biological activities including antimicrobial activities. This aromatic amide was further analysed for antifungal property by well diffusion method viz., MIC (minimum inhibitory concentration), zone of inhibition and biochemical changes. The synthesized aromatic amide showed broad spectrum antifungal property. The amide derivative was proposed as an inhibitor of Cytochrome P450- 14DM14, a-demethylase from Aspergillus niger and S12 protein of ribosomal subunit from Escherichia coli. Drug-likeness and hidden potential of compound and descriptors related to ADMET were deliberated to foresee pharmacokinetic properties of the molecule. Thereby molecular docking data study helped in evaluating probable mode of action of molecules in active site of receptor.

Aguado, A., et al. (2014). "Chemical depolymerisation of PET complex waste: hydrolysis vs. glycolysis." Journal of Material Cycles and Waste Management **16**(2): 201-210.

The huge increase in the generation of post-consumer plastic waste has produced a growing interest in eco-efficient strategies and technologies for their appropriate management and recycling. In response to this, PROQUIPOL Project is focused on developing, optimizing and adapting feedstock recycling technologies as an alternative for management for the treatment of complex plastic waste. Among the different plastic wastes studied, PROQUIPOL Project is working on providing a suitable treatment to the highly colored and complex multilayered post-consumer waste fractions of polyethylene terephthalate (PET) by chemical depolymerisation methods. Glycolysis and alkali hydrolysis processes have been studied with the aim of promoting the transformation of PET into the bis(2-hydroxyethyl) terephthalate monomer and terephthalic acid, respectively. In both cases operational conditions such as temperature, reaction time, catalyst to PET rate and solvent to PET rate have been considered to optimize product yield, achieving values near to 90 % and monomer purities over 95 % in both processes. This paper presents results obtained for each treatment as well as a simplified comparison of technical, economic and environmental issues.

Agyapong, D. and K. N. A. Arthur (2018). Sustainable business practices among MSMEs: Evidence from four Metropolitan Areas in Ghana. 13th European Conference on Innovation and Entrepreneurship, ECIE 2018, September 20, 2018 - September 21, 2018, Aveiro, Portugal, Academic Conferences and Publishing International Limited.

Pollution poses major health risks to man and other living creatures, especially in developing countries. Its sources include industrial emissions and improper waste by households and organisations. However, large firms have often been accused as the main actors of polluting water bodies, land and air. Despite this, some studies argue it is difficult to identify culprits for air and water pollution; hence, the need to analyse the business practices of MSMEs to determine their sustainability, since they contribute over 90% of businesses in developing countries. The study, therefore, looked at plastic pollutant, a major waste concern in Ghana. This is because, despite several government interventions in cleaning cities and towns of plastic waste; the problem still persists. Statistics indicate about 501,875 tons of plastic waste are generated annually, and it has created serious health and environmental risks such as the blocking of drains leading to flooding, the breeding of mosquitoes that spread malaria and the causing of severe aesthetic nuisance in terms of smell and appearance in communities. Using a mixed method, 500 MSMEs engaged in the production of Sachet Water in the Accra and Kumasi metropolis were sampled. Questionnaires and interviews were used to collect data. Data was analysed using descriptive and inferential statistics. The results showed that though MSMEs contribute significantly to plastic waste, they do not have any strategy for managing the waste generated. Furthermore, there is a map of complex network of actors in the plastic packaging chain, and therefore, it was concluded that the idea of plastic management policy should not target only sachet water producers. This study recommends that policy formulation aimed at dealing with this menace should target all actors in the plastic value chain including suppliers of plastic raw material, consumers of plastic packaged products, collectors of plastic waste as well as processors. 2018 Proceedings of the European Conference on Innovation and Entrepreneurship, ECIE. Ahmad, E., et al. (2015). "Fibrin matrices: The versatile therapeutic delivery systems." International Journal of Biological Macromolecules **81**: 121-136.

Fibrin sealants, that have been employed for over a century by surgeons to stop post surgery bleeding, are finding novel applications in the controlled delivery of antibiotics and several other therapeutics. Fibrinogen can be easily purified from blood plasma and converted by thrombolysis to fibrin that undergoes spontaneous aggregation to form insoluble clot. During the gelling, fibrin can be formulated into films, clots, threads, microbeads, nanoconstructs and nanoparticles. Whole plasma clots in the form of beads and microparticles can also be prepared by activating endogenous thrombin, for possible drug delivery. Fibrin formulations offer remarkable scope for controlling the porosity as well as in vivo degradability and hence the release of the associated therapeutics. Binding/covalent-linking of therapeutics to the fibrin matrix, crosslinking of the matrix with bifunctional reagents and coentrapment of protease inhibitors have been successful in regulating both in vitro and in vivo release of the therapeutics. The release rates can also be remarkably lowered by preentrapment of therapeutics in insoluble particles like liposomes or by anchoring them to the matrix via molecules that bind them as well as fibrin. Ahmadi, A., et al. (2014). "Synbiotic yogurt-ice cream produced via incorporation of microencapsulated lactobacillus acidophilus (la-5) and fructooligosaccharide." Journal of Food Science & Technology-Mysore **51**(8): 1568-1574.

Yogurt-ice cream is a nutritious product with a refreshing taste and durability profoundly longer than that of yogurt. The probiotic Lactobacillus acidophilus (La-5) cells either in free or encapsulated form were incorporated into yog-ice cream and their survivability were studied. Fructooligosaccharide (FOS) as a prebiotic compound at three levels (0, 4 & 8 % w/w) was added to yogurt-ice cream mix and its effects on some chemical properties, overrun and firmness of product were evaluated. The higher the incorporated FOS concentration, the lower were the pH value and higher the total solid content of treatments. FOS incorporation (8 %) significantly increased the overrun of treatments and reduced their firmness. The viable counts of free probiotics decreased from ~9.55 to ~7.3 log cfu/g after 60 days of frozen storage while that of encapsulated cells merely decreased less than 1 log cycle. Encapsulation with alginate microbeads protected the probiotic cells against injuries in the freezing stage as well as, during frozen storage.

Ahmed, T., et al. (2018). "Biodegradation of plastics: current scenario and future prospects for environmental safety." Environmental Science & Pollution Research **25**(8): 7287-7298.

Plastic is a general term used for a wide range of high molecular weight organic polymers obtained mostly from the various hydrocarbon and petroleum derivatives. There is an ever-increasing trend towards the production and consumption of plastics due to their extensive industrial and domestic applications. However, a wide spectrum of these polymers is non-biodegradable with few exceptions. The extensive use of plastics, lack of waste management, and casual community behavior towards their proper disposal pose a significant threat to the environment. This has raised growing concerns among various stakeholders to devise policies and innovative strategies for plastic waste management, use of biodegradable polymers especially in packaging, and educating people for their proper disposal. Current polymer degradation strategies rely on chemical, thermal, photo, and biological procedures. In the presence of proper waste management strategies coupled with industrially controlled biodegradation facilities, the use of biodegradable plastics for some applications such as packaging or health industry is a promising and attractive option for economic, environmental, and health benefits. This review highlights the classification of plastics with special emphasis on biodegradable plastics and their rational use, the identified mechanisms of plastic biodegradation, the microorganisms involved in biodegradation, and the current insights into the research on biodegradable plastics. The review has also identified the research gaps in plastic biodegradation followed by future research directions.

Ahmed, T. A., et al. (2008). "Fibrin: a versatile scaffold for tissue engineering applications." Tissue Engineering Part B-Reviews **14**(2): 199-215.

Tissue engineering combines cell and molecular biology with materials and mechanical engineering to replace damaged or diseased organs and tissues. Fibrin is a critical blood component responsible for hemostasis, which has been used extensively as a biopolymer scaffold in tissue engineering. In this review we summarize the latest developments in organ and tissue regeneration using fibrin as the scaffold material. Commercially available fibrinogen and thrombin are combined to form a fibrin hydrogel. The incorporation of bioactive peptides and growth factors via a heparin-binding delivery system improves the functionality of fibrin as a scaffold. New technologies such as inkjet printing and magnetically influenced self-assembly can alter the geometry of the fibrin structure into appropriate and predictable forms. Fibrin can be prepared from autologous plasma, and is available as glue or as engineered microbeads. Fibrin alone or in combination with other materials has been used as a biological scaffold for stem or primary cells to regenerate adipose tissue, bone, cardiac tissue, cartilage, liver, nervous tissue, ocular tissue, skin, tendons, and ligaments. Thus, fibrin is a versatile biopolymer, which shows a great potential in tissue regeneration and wound healing. [References: 198]

Ahn, H. R., et al. (2019). "The Intraocular Pressure-Lowering Effect of Persimmon leaves (Diospyros kaki) in a Mouse Model of Glaucoma." International Journal of Molecular Sciences **20**(21): 23.

The aim of this study was to evaluate the pharmacological efficacy of persimmon leaves in two glaucoma models, microbeads-induced ocular hypertension (OHT) and DBA/2 mouse. Thus, we demonstrated that Ethanol Extract of Diospyros kaki (EEDK) reduced elevated intraocular pressure (IOP) in both mouse models of glaucoma by measurements with a tonometer. In particular, we revealed that retinal ganglion cell loss and optic nerve damage caused by IOP elevation were markedly diminished as assessed by TUNEL assay, H&E staining, and fluorescent staining, while the expression of soluble guanylate cyclase (sGCalpha-1) increased, when EEDK was administered, as revealed by western blot. Moreover, the b-wave magnitude indicating

functional scotopic vision was significantly improved in EEDK-administered DBA/2 mice during the 10-week follow-up study, as observed with electroretinography. Collectively, our results suggested that EEDK could be an effective therapeutic and IOP-lowering agent for preventing and treating retinal degenerative diseases such as glaucoma.

Ahn, J., et al. (2015). "Human alpha-fetal protein immunoassay using fluorescence suppression with fluorescent-bead/antibody conjugate and enzymatic reaction." Biosensors and Bioelectronics **71**: 115-120.

The aim of the study was to develop a simple and rapid immunoassay using fluorescent microbeads and enzyme-substrate reactions to measure alpha-fetal protein (AFP) concentrations. We demonstrated the functionality of the fluorescent immunosensor using antibody-conjugated fluorescent latex beads (AB-FLBs) and horseradish peroxidase (HRP) to catalyze a reaction, where the products would precipitate and suppress the fluorescence of AB-FLBs. First, the AB-FLBs were incubated with antigen, biotinylated antibodies (bABs), and streptavidin-HRP (SAv-HRP) to form a sandwich-type immunoreaction. The mixture was then filtered through a membrane to concentrate the beads on a small area. After washing to remove unbound bABs and SAv-HRP, a chromogenic HRP substrate and H<inf>2</inf>O<inf>2</inf> were added to form precipitates on the FLB surface. The suppression of the fluorescence was measured with a fluorescent image analyzer system. Under optimized conditions, AFP could be measured at concentrations as low as 1 pg mL⁻¹ with a dynamic range up to 100 ng mL⁻¹. Copyright © 2015 Elsevier B.V.

Ahrendt, C., et al. (2019). "Microplastic ingestion cause intestinal lesions in the intertidal fish Girella laevifrons." Marine Pollution Bulletin **(no pagination)**(110795).

We exposed juvenile intertidal fish to different amounts of Poly(styrene-co-divinylbenzene) microplastics in their diet. We fed ten individuals with pellets containing 0.01 g, another ten fish with pellets containing 0.1 g of PS, and ten fish without plastic as control. After 45 days of treatment, the whole intestine was removed, and the histological evaluation started immediately. We evaluated inflammation due to leukocyte infiltration (Lk), circulatory disorders like Hypermeia (Hyp), and regressive changes in the intestinal tissue, assessing Crypt cell loss (Ccl) and Villi cell loss (Vcl). The severity of the lesions increased according to the microplastic concentration. In the fish group feeding on microplastics, we found that leukocyte infiltration and hyperemia were more severe in the higher exposure group compared to the lower exposure; and crypt cell loss and villi cell loss increased significantly due to Poly(styrene-co-divinylbenzene) microplastic physical abrasion. Ahuja, M., et al. (2016). "Sodium alginate-arabinoxylan composite microbeads: preparation and characterization." Journal of Pharmaceutical Investigation **46**(7): 645-653.

The objective of present study was to prepare composite microbeads of psyllium arabinoxylan and sodium alginate by ionotropic gelation method using calcium chloride as a cross linker and was further evaluated for release study. The effect of concentration of sodium alginate/arabinoxylan and concentration of calcium chloride on the entrapment efficiency and on % release were studied employing 2-factor, 3-level central composite experimental design. The results of the study revealed that interaction effect of the concentration of sodium alginate/arabinoxylan and calcium chloride influenced the entrapment efficiency and release of diclofenac sodium significantly. The optimal calculated parameters were found to be concentration of sodium alginate/arabinoxylan-5 and concentration of calcium chloride-0.75 M, that provided microbeads with entrapment efficiency-64.4 % and release of 28.5 % of the drug

over 8 h period of study. Further, arabinoxylan-sodium alginate mucoadhesive microbeads were found to sustain the release of diclofenac sodium over a period of 8 h following zero order kinetics with the mechanism of release being diffusion. Ahuja, P., et al. (2015). "Functional Imaging of Chemically Active Surfaces with Optical Reporter Microbeads." PLoS ONE [Electronic Resource] **10**(9): e0136970.

We have developed a novel approach to allow for continuous imaging of concentration fields that evolve at surfaces due to release, uptake, and mass transport of molecules, without significant interference of the concentration fields by the chemical imaging itself. The technique utilizes optical "reporter" microbeads immobilized in a thin layer of transparent and inert hydrogel on top of the surface. The hydrogel has minimal density and therefore diffusion in and across it is like in water. Imaging the immobilized microbeads over time provides quantitative concentration measurements at each location where an optical reporter resides. Using image analysis in post-processing these spatially discrete measurements can be transformed into contiguous maps of the dynamic concentration field across the entire surface. If the microbeads are small enough relative to the dimensions of the region of interest and sparsely applied then chemical imaging will not noticeably affect the evolution of concentration fields. In this work colorimetric optode microbeads a few micrometers in diameter were used to image surface concentration distributions on the millimeter scale.

Ai, X., et al. (2013). "Multiplex DNA sensor for BRAF and BRCA detection." Analytical Biochemistry **438**(1): 22-28.

In this article, a kind of simple, sensitive, and rapid quantum dots (QDs)-based multiplex DNA sensor is developed for the simultaneous detection of BRAF and BRCA DNA based on the "nano-on-micro" technique. In our strategy, capture DNA(BRCA) and DNA(BRAF) are simultaneously immobilized on the surface of amino-modified silica microbeads. After blocking with bovine serum albumin (BSA), different concentrations of target DNA(BRCA) and DNA(BRAF) are introduced to hybrid with complementary capture DNA(BRCA) and DNA(BRAF). After hybridization, QDs546-labeled probe DNA(BRAF) and QDs657-labeled probe DNA(BRCA) were added into the above solution so that the unreacted capture DNA(BRCA) and DNA(BRAF) could be detected by QDs657-labeled probe DNA(BRCA) and QDs546-labeled probe DNA(BRAF) simultaneously. We demonstrate that the proposed method is effective for detecting BRAF and BRCA DNA with high sensitivity. The sensor has great potential to expand its application to the early diagnosis of cancers such as breast cancer, ovarian cancer, and papillary thyroid carcinoma.

Aida Isma, M. I., et al. (2015). "Mixed Plastic Wastes Pyrolysis in a Fluidized Bed Reactor for Potential Diesel Production." International Journal of Environmental Science and Development **6**(8): 606-609.

Disposing of waste to landfill has becoming undesirable to the legislation pressures, rising costs and the poor biodegradable quality of polymer used. Feasible study on converting mixed plastic wastes by applying catalytic pyrolysis into valuable products had been carried out. Thermogravimetric analysis under various heating rates and particle sizes were determined. A 15 g/h of fluidized bed lab scale of fast pyrolysis unit was used. The pyrolysis processes were carried out at temperature of 400 super(o)C for 2 hours in non-catalytic and catalytic conditions with ratio catalyst to mixed plastic waste of 10:90. The properties of liquid products were analysed and compared using Fourier Transform Infrared Spectroscopy (FTIR) and High-Pressure Liquid Chromatography (HPLC). Under the experimental conditions, the maximum liquid yields with and without catalyst were 20 and 35 ml, respectively. FTIR results revealed that those functional groups detected are similar with commercial diesel together with HPLC results indicating diesel concentration.

Aizenshtein, E., et al. (2013). "Immunological complex for enhancement of innate immune response in passive vaccination." Vaccine **31**(4): 626-631.

Passive vaccination is used to treat a wide range of infections and cancer. However, this approach has some limitations. An immune complex termed Y-complex was developed to intensify the effect of the passive vaccine. The complex is composed of a microbead that carries specific antibodies and an inducer. It enables targeting of pathogen or abnormal cells, and stimulation of a desired response by innate immune cells, depending on the inducer. The production and efficacy of Y-complex as a passive immune prophylaxis is demonstrated in this study by its use in treating cow mastitis. In an in vitro assay, Y-complex inhibited propagation and induced phagocytosis of bacteria. In challenge experiments, cows were inoculated through the udder with Escherichia coli or Streptococcus dysgalactiae. Following treatment with Y-complex, no bacteria were isolated in the milk and N-acetyl- beta -D-glucosaminidase activity had returned to normal levels. Thus the Y-complex approach can be used as an effective treatment for mastitis. Due to its modularity, this approach may serve as a treatment for a variety of disease agents.

Akarsu, C., et al. (2017). "Microplastic threat to aquatic ecosystems of the municipal wastewater treatment plant." Turk Hijyen ve Deneysel Biyoloji Dergisi **74**(Suppl. 1): 73-78.

Objective: The effluent of domestic wastewater treatment plants are considered to be the greatest source of microplastics from cosmetic products and clothing fibers to the aquatic ecosystem. The aim of this study is to collect microplastic studies and to take a closer look at state of microplastic pollution. Method: For this purpose, Studies on the effect of the point where the effluent from the wastewater treatment plants are discharged, are determined. And the findings of these studies were put together. The compilation text included work done in the Americas, Europe, Australia and Asia.

Akdogan, Z. and B. Guven (2019). "Microplastics in the environment: A critical review of current understanding and identification of future research needs." Environmental Pollution **254**(Pt A): 113011.

Microplastics (plastic particles <5mm) are a contaminant of increasing ecotoxicological concern in aquatic environments, as well as for human health. Although microplastic pollution is widespread across the land, water, and air, these environments are commonly considered independently; however, in reality are closely linked. This study aims to review the scientific literature related microplastic research in different environmental compartments and to identify the research gaps for the assessment of future research priorities. Over 200 papers involving microplastic pollution, published between 2006 and 2018, are identified in the Web of Science database. The original research articles in 'Environmental Sciences', 'Marine/Freshwater Biology', 'Toxicology', 'Multidisciplinary Sciences', 'Environmental Studies', 'Oceanography', 'Limnology' and 'Ecology' categories of Web of Science are selected to investigate microplastic research in seas, estuaries, rivers, lakes, soil and atmosphere. The papers identified for seas, estuaries, rivers and lakes are further classified according to (i) occurrence and characterization (ii) uptake by and effects in organisms, and (iii) fate and transport issues. The results reveal that whilst marine microplastics have received substantial scientific research, the extent of microplastic pollution in continental environments, such as rivers, lakes, soil and air, and environmental interactions, remains poorly understood.

Akei, H., et al. (2006). "Surface tension influences cell shape and phagocytosis in alveolar macrophages." American Journal of Physiology **291**(4): 7.

The effect of surface tension on alveolar macrophage shape and phagocytosis was assessed in vivo and in vitro. Surface tension was regulated in vivo by conditionally expressing surfactant protein (SP)-B in Sftpb^sup -/-^ mice. Increased surface tension and respiratory distress were produced by depletion of SP-B and were readily reversed by repletion of SP-B in vivo. Electron microscopy was used to demonstrate that alveolar macrophages were usually located beneath the surfactant film on the alveolar surfaces. Reduction of SP-B increased surface tension and resulted in flattening of alveolar macrophages on epithelial surfaces in vivo. Phagocytosis of intratracheally injected fluorescent microbeads by alveolar macrophages was decreased during SP-B deficiency and was restored by repletion of SP-B in vivo. Incubation of MH-S cells, a mouse macrophage cell line, with inactive surfactant caused cell flattening and decreased phagocytosis in vitro, findings that were reversed by the addition of sheep surfactant or phospholipid containing SP-B. SP-B controls surface tension by forming a surfactant phospholipid film that regulates shape and nonspecific phagocytic activity of alveolar macrophages on the alveolar surface. [PUBLICATION ABSTRACT]

Akgol, S., et al. (2004). "Cu(II)-incorporated, histidine-containing, magnetic-metal-complexing beads as specific sorbents for the metal chelate affinity of albumin." Journal of Applied Polymer Science **93**(6): 2669-2677.

N-Methacryloyl-(L)-histidine methyl ester (MAH) was synthesized from metharyloyl chloride and histidine. Spherical beads with an average size of 150-250 m were obtained by the suspension polymerization of ethylene glycol dimethacrylate and MAH in an aqueous dispersion medium. Magnetic poly(ethylene glycol dimethacrylate-co-N-Methacryloyl-(L)-histidine methyl ester) [m-p(EGDMA-co-MAH)] microbeads were characterized with swelling tests, electron spin resonance, elemental analysis, and scanning electron microscopy. The specific surface area of the beads was 80.1 m2/g. m-p(EGDMA-co-MAH) microbeads with a swelling ratio of 40.2% and 43.9 mol of MAH/g were used for the adsorption of bovine serum albumin (BSA) in a batch system. The Cu(II) concentration was 4.1 mol/g. The adsorption capacity of BSA on the Cu(II)-incorporated beads was 19.2 mg of BSA/g. The BSA adsorption first increased with the BSA concentration and then reached a plateau, which was about 19.2 mg of BSA/g. The maximum adsorption was observed at pH 5.0, which was the isoelectric point of BSA. The BSA adsorption increased with decreasing temperature, and the maximum adsorption was achieved at 4°C. High desorption ratios (>90% of the adsorbed BSA) were achieved with 1.0M NaSCN (pH 8.0) in 30 min. The nonspecific adsorption of BSA onto the m-p(EGDMA-co-MAH) beads was negligible.

Akgul, S. U., et al. (2017). "Association Between HLA Antibodies and Different Sensitization Events in Renal Transplant Candidates." Transplantation Proceedings **49**(3): 425-429.

Background Human leukocyte antigen (HLA) allo-immunization is caused by various events such as blood transfusions, pregnancies, or organ transplantations, which can lead to sensitization. In this retrospective study, we evaluated different sensitization models and their effects on panel-reactive antibody (PRA) profiles of renal transplantation candidates. Methods Anti-HLA class I/II antibody screening tests were performed in 906 renal transplantation candidates with the use of a microbead-based assay (Luminex). Results Two hundred ninety-seven (32.8%) of the patients were determined as positive in terms of PRA, and 609 (67.2%) were negative. Sensitized and non-sensitized patients were compared separately in terms of each sensitization type. The

anti-HLA class I, II, and I+II positivity rates in patients sensitized only by blood transfusion were 13.1%, 6.3%, and 14.1%, the rates with pregnancy sensitization were 35.5%, 29%, and 45.2%, and rates with previous transplantation sensitization were 15.6%, 34.4%, and 38.9%, respectively. Prevalence of PRA positivity was significantly higher in patients with previous pregnancy than with transplantation and transfusion (odds ratio, 1.003; 95% confidence interval, 0.441-2.281; P =.031). The risk of developing HLA class I antibodies was higher in pregnancies (P <.001), and the risk of developing anti-HLA class II antibodies was higher in patients who had undergone a previous transplantation (P <.001). The rate of developing HLA-B antibodies in patients sensitized by pregnancy were significantly higher compared with sensitization after transfusion (P = .015), as was the rate of developing HLA-DQ antibodies in patients sensitized by previous transplantation compared with sensitization through pregnancy (P =.042). Conclusions In patients who are waiting for kidney transplantation, sensitization by pregnancy and transplantation have a significant impact on development of HLA class I and class II antibodies. Akhbarizadeh, R., et al. (2018). "Investigating a probable relationship between microplastics and potentially toxic elements in fish muscles from northeast of Persian Gulf." Environmental Pollution **232**: 154-163.

Although weekly consumption of fish is recommended, the presence of contaminants in seafood has raised many concerns regarding the benefits of fish intake. In the present study microplastics (MPs) and metals' concentration in muscles of both benthic and pelagic fish species from northeast of Persian Gulf were investigated and the risk/benefit of their consumption was assessed. The results demonstrated that MPs and Hg in all species and Se in benthic species increase with size, while relationship between other metals, and fish size is not consistent. Consumption of a meal ration of 300 and < 100 g/week for adults and children, respectively, is recommended since it would provide the required essential elements with no human health risk. On the other hand, the estimated intake of MPs from fish muscles revealed that the mean intake of MPs for P. indicus, E. coioides, A. djedaba, and S. jello consumption is 555, 240, 233, and 169 items/300 g-week, respectively. Moreover, the relationship between MPs and metals in fish muscles were positive for A. djedaba, and negative for E. coioides. Considering the chemical toxicity of MPs and metals, and their good linear relationships in some species, consumption of high doses of the studied fish may pose a health threat to the consumers.

Akhbarizadeh, R., et al. (2019). "Investigating microplastics bioaccumulation and biomagnification in seafood from the Persian Gulf: a threat to human health?" Food Additives & Contaminants. Part A, Chemistry, Analysis, Control, Exposure & Risk Assessment **36**(11): 1696-1708.

High bioavailability of microplastics (MPs) in the marine environment has raised serious concern during the last few decades. Nevertheless, the trophic transfer of MPs within edible parts of the marine food webs remain unknown. In this study, bioaccumulation, biomagnification, and potential human intake of MPs in muscles and gills of five popular commercial species (3 fish, 1 crab, and 1 prawn) from the Persian Gulf were investigated. The surface structure characteristics of the material and elemental composition signatures were used to screen for likely MPs and rule out non-plastics. Among the studied species, Penaeus semisulcatus and Epinephelus coioides displayed the highest (mean 0.360 items/g muscle) and lowest (mean 0.158 items/g muscle) MPs level in their muscles, respectively. The number of extracted MPs from the gills was higher than the muscle of the analyzed species, especially when it comes to scavengers and filter feeders such as (Liza klunzingeri, Portunus armatus, and P. semisulcatus).The results of the

trophic magnification factor (TMF) and biomagnification factor (BMF) calculation indicated that MPs were not biomagnified in edible parts of the marine food web of the Persian Gulf. Hence, contrary to previous belief, MPs trophic dilution occurs rather than magnification in edible parts of seafood. The assessment of human intake of MPs highlights the possible risks posed by seafood consumption to the the human population depending to a great extent on a seafood diet. Considering possible physical and chemical toxicity of MPs and their associated contaminants, routine consumption of high doses of the studied seafood should be controlled for vulnerable groups such as pregnant/lactating women and their children to ensure their safety.

Akhbarizadeh, R., et al. (2017). "Microplastics and potentially toxic elements in coastal sediments of Iran's main oil terminal (Khark Island)." Environmental Pollution **220**(Pt A): 720-731.

Marine pollutants are becoming a growing concern due to their ecological consequences. This study investigates the potential risk posed by microplastics and toxic elements in coastal sediments of Khark Island, the main oil export hub of Iran. Principal component biplots exhibited a significant positive correlation between microplastic quantities (ranging in shape and color) and concentration of heavy metals with industrial activity. Source identification of the heavy metals indicated both natural and anthropogenic origin. Quality and risk assessment of the sediments revealed low to moderate pollution of Zn, Mo, Pb, Cu, Cd and As in some stations.

Akin-Ajani, O. D., et al. (2019). "Date mucilage as co-polymer in metformin-loaded microbeads for controlled release." Journal of Excipients and Food Chemicals **10**(1): 3-12.

Mucilage from the fruit of the date palm (Phoenix dactylifera) was characterized and evaluated for the use as a polymer in controlled release metformin-loaded microbeads. Metformin-loaded (1%^w/<inf>w</inf>) microbeads were formed by the ionotropic gelation method using blends (2%^w/<inf>v</inf>) of date mucilage: sodium alginate in varying concentrations (20:80 C4, 25:75 C3, 33:67 C2, 50:50 C1) using zinc chloride (10%^w/<inf>v</inf>) as a crosslinking agent. Bead size and morphology, swelling index, entrapment efficiency and release properties were then measured. The dissolution profiles were fitted to kinetic equations to determine the kinetics and mechanisms of drug release while the similarity factor, f<inf>2</inf> was used to determine formulations with similar drug release patterns. The results showed that the date mucilage had crude fat content of 2.5%. The microbeads formed were spherical with bead sizes ranging from 0.44 to 1.99 mm except for the one prepared using blend C4 which was ellipsoidal. Drug entrapment efficiency ranged between 25.0 and 91.1%^w/<inf>w</inf> with alginate alone giving the least entrapment. Microbeads formulated with blends C2 and C3 had the slowest dissolution rates at t<inf>15</inf> < 9% in 240 hours. C3, however, had a higher entrapment efficiency and was considered the optimum formulation. All microbead formulations fitted the Korsmeyer-Peppas model with super case II transport mechanism except for the one made of sodium alginate alone, which had an anomalous (non-Fickian) diffusion. Secondary parameters of the Korsmeyer-Peppas' model showed that microbead formulations C2 and C3 provided controlled release for longer than 24 hours. Similarity factor, f<inf>2</inf> showed comparable release profiles between C2 and C3 (f<inf>2</inf>=94.2). This study shows that mucilage from the date fruit could potentially be used as a polymer in the formulation of controlled release metformin-loaded microbeads. Copyright © IPEC-Americas.

Akinfieva, O., et al. (2013). "New directions in quantum dot-based cytometry detection of cancer serum markers and tumor cells." Critical Reviews in Oncology-Hematology **86**(1): 1-14.

The use of fluorescent quantum dots (QDs) incorporated in or tagged with polymeric microbeads allows multiplexed coding of biomolecules. Compared to organic dyes, QDs are characterized by improved imaging capabilities, brightness, and photostability and may be used for simultaneous detection of multiple biomarkers. Development of QD conjugates and QD-encoded suspension arrays has given rise to new promising approaches to cell labeling, in vivo visualization, and diagnostic assay techniques. QDs have proved to be efficient donors for Forster resonance energy transfer (FRET) and are characterized by high multiphoton absorption coefficients. Implication of QD-based suspension arrays for identification of autoantibodies, tumor-specific T cells, and detection of circulating cancer cells by means of flow cytometry, holds considerable promise for earliest diagnosis of human abnormalities and effective monitoring of the therapeutic effects. This review summarizes recent advances in QD-based suspension arrays application to cancer diagnosis and attempts to predict their diagnostic potential in a future.

Akolade, J. O., et al. (2018). "Influence of formulation parameters on encapsulation and release characteristics of curcumin loaded in chitosan-based drug delivery carriers." Journal of Drug Delivery Science and Technology **45**: 11-19.

Drugs derived from plants with excellent chemotherapeutic effectiveness and relatively low toxicity may fail to scale through the phyto-drug discovery channel due to lack of appropriate drug delivery systems. These phytoceuticals need compatible carriers that will improve their stability, bioavailability and enhance their effectiveness. In this study, chitosan-based drug delivery carriers (DDCs) containing curcumin as phyto-drug model were prepared either via ionotropic gelation with tripolyphosphate or polyelectrolyte complexation with alginate. Influence of formulation parameters was evaluated using encapsulation and release characteristics as response indices. Crosslinking time, pH of chitosan solution and concentration of curcumin, alginate or tripolyphosphate significantly influenced the encapsulation efficiency, rate of curcumin release and mean release time (MRT) in simulated gastric fluid (SGF). Roughly spherical chitosan-based micro-beads with copious pores within the matrix and of improved encapsulation efficiency (82-93%) were prepared using optimized set of formulation parameters. Incorporation of alginate into the chitosan DDC reduced erosion of curcumin by 30% and extended MRT by 180 min in SGF without net delineating change in release profiles of curcumin in simulated physiological saline and intestinal fluids. Time-dependent in vitro study showed that radical scavenging activity ratio of curcumin was enhanced via encapsulation in chitosan-based DDCs. Copyright © 2018 Elsevier B.V.

Alabi, O. A., et al. (2019). "In vitro mutagenicity and genotoxicity of raw and simulated leachates from plastic waste dumpsite." Toxicology Mechanisms & Methods **29**(6): 403-410.

Increase in production of different types of plastics has led to increase in the amount of plastic waste generation worldwide. The chemical constituents of these plastic wastes have made their disposal an important economic and environmental health problem globally. This study assessed the mutagenic and genotoxic potential of plastic waste dumpsite raw and simulated leachates using the Ames Salmonella fluctuation test with Salmonella typhimurium strains TA98 and TA100, and the SOS chromotest with Escherichia coli PQ37. Physico-chemical parameters and organic constituents of the leachates were also analyzed. The result of the Ames test showed that the leachates are mutagenic even at low concentration. Also, the TA100 strain was the more responsive strain in terms of mutagenic index in the absence of metabolic activation. The SOS chromotest results complimented the Ames Salmonella fluctuation test results. Nevertheless, the E. coli PQ37 system was slightly more sensitive than the Salmonella assay for detecting mutagens and genotoxins in the tested leachates. Generally, simulated leachate showed a higher mutagenicity and genotoxicity than the raw leachate. Pb, Cd, Cr, Ni, Cu, As, PBDEs, PAHs, PCBs, and Bisphenol A contents analyzed in the leachates were believed to play significant role in the observed mutagenicity and genotoxicity in the microbial assays. These data showed that plastic waste constituents are capable of inducing DNA damage in exposed organisms and might induce similar damage in plants, animals and humans exposed to it, hence, great care should be taken to eliminate indiscriminate disposal of plastics in the environment.

Alam, F. C., et al. (2019). "Microplastic distribution in surface water and sediment river around slum and industrial area (case study: Ciwalengke River, Majalaya district, Indonesia)." Chemosphere **224**: 637-645.

Microplastic research in urban and industrial areas, including remote areas, have been conducted recently. However, there is still a lack of research about microplastic abundances in slum area. Ciwalengke River is located in Majalaya, Indonesia, which is dominated by slum and industrial areas that probably generate microplastics. This research was conducted to investigate the distribution of microplastic around the slum area for the first time. Surface water and sediment samples of the river were obtained at ten locations and grouped into six segments location based on different land use at the riverbank. Microplastic particles were identified using binocular microscope and categorized by shape and size. The average microplastic concentration were 5.85+/-3.28 particles per liter of surface water and 3.03+/-1.59 microplastic particles per 100g of dry sediments. Microplastic concentration in the sediment samples were found to have significant differences in location segment (Kruskal Wallis test, p-value=0.01165<0.05), but no significant differences were found in the water samples (Kruskal Wallis test; p-value=0.654>0.05). In addition, microplastic distribution was dominated by fiber particle. More fiber shape might be derived from the direct clothing of residents in the river and fabric washing process in the textile industries. This was also revealed by Raman spectroscopy test of several microplastic particles indicating that the type of microplastic were polyester and nylon.

Alam, R., et al. (2008). "Generation, storage, collection and transportation of municipal solid waste--a case study in the city of Kathmandu, capital of Nepal." Waste Management **28**(6): 1088-1097.

Solid waste management (SWM) services have consistently failed to keep up with the vast amount of solid waste produced in urban areas. There is not currently an efficient system in place for the management, storage, collection, and transportation of solid waste. Kathmandu City, an important urban center of South Asia, is no exception. In Kathmandu Metropolitan City, solid waste generation is predicted to be 1091 m(3)/d (245 tons/day) and 1155 m(3)/d (260 tons/day) for the years 2005 and 2006, respectively. The majority (89%) of households in Kathmandu Metropolitan City are willing to segregate the organic and non-organic portions of their waste. Overall collection efficiency was 94% in 2003. An increase in waste collection occurred due to private sector involvement, the shutdown of the second transfer station near the airport due to local protest, a lack of funding to maintain trucks/equipment, a huge increase in plastic waste, and the willingness of people to separate their waste into separate bins. Despite a substantial increase in total expenditure, no additional investments were made to the existing development plan to introduce a modern disposal system due to insufficient funding. Due to the lack of a proper lining, raw solid waste from the existing dumping site comes in contact with river water directly, causing severe river contamination and deteriorating the quality of the water.

Alassali, A., et al. (2019). "Classification of plastic waste originated from waste electric and electronic equipment based on the concentration of antimony." Journal of Hazardous Materials **380**: 120874.

The aim of this research is a preliminary assessment of antimony concentration in plastic fractions deriving from different e-waste. We considered microwave ovens, desktop computers, laptops, mobile phones, a TV case, a PC monitor and LED lamps (63 items in total). The plastic fraction ranged from 8%-wt in computers and microwave ovens, up to 40%-wt in cell phones and 59%-wt in LED lamps. Specific polymers were identified through Near Infrared spectroscopy. The samples followed three parallel procedures: acid digestion with aqua regia; conversion into ashes at 600degreeC then acid digestion with aqua regia; leaching according to UNI10802 reference procedure. Plastic components with significant amounts of antimony were the ones derived from desktop computers (25-1900mg/kg) and from microwave ovens (830mg/kg), yet their relative amount compared to the total weight of the item was limited. Items with larger plastic fractions showed lower concentrations of antimony (1-6mg/kg in mobile phones cases and 160-640mg/kg in plastic components of LED lamps). Leaching tests revealed that the analyzed plastic fractions could be mostly admitted in non-hazardous waste landfills. The analysis of ashed samples highlighted the need to further improve the acidic extraction procedure.

Alassali, A., et al. (2018). "Assessment of plastic waste materials degradation through near infrared spectroscopy." Waste Management **82**: 71-81.

Plastic waste is a relevant challenge for waste management sector and further technological means have to be urgently researched. The evaluation of plastic waste quality through non-destructive, cost-effective and mature technologies could be without any doubt a key issue. This study is aimed at the assessment of Near Infrared (NIR) spectroscopy for the generation of global degradation-prediction models able to forecast plastic ageing. The degradation of Polyethylene terephthalate (PET), Acrylonitrile Butadiene Styrene (ABS), Polypropylene (PP) and Polyethylene (PE) was achieved by thermal ageing (at 85 degreeC, 105 degreeC and 120degreeC and durations ranging from 4 to 504h), to simulate environmental outdoor conditions. Experimental data obtained for each plastic material were elaborated through partial least square (PLS) regression to obtain empirical models. For all inspected plastic materials, a good

correspondence between the variation in absorbance units and the change in chemical bonds vibrations was observed. The PLS models were afterwards calibrated (taking into account the different ageing conditions; first separately then including the ageing factors combined). A high accuracy (R² equal to 0.85-1.00) was observed in predicting ageing for PET and ABS, while the correspondence showed a 30% decrease for PE and PP. This study proves that NIR spectroscopy can be recommended as an effective tool to investigate plastics degradation, with some limitations for specific polymers that need further investigations.

Albano, C., et al. (2009). "Influence of content and particle size of waste pet bottles on concrete behavior at different w/c ratios." <u>Waste Management</u> **29**(10): 2707-2716.

Abstract: The goal of this work was to study the mechanical behavior of concrete with recycled Polyethylene Therephtalate (PET), varying the water/cement ratio (0.50 and 0.60), PET content (10 and 20vol%) and the particle size. Also, the influence of the thermal degradation of PET in the concrete was studied, when the blends were exposed to different temperatures (200, 400, 600°C). Results indicate that PET-filled concrete, when volume proportion and particle size of PET increased, showed a decrease in compressive strength, splitting tensile strength, modulus of elasticity and ultrasonic pulse velocity; however, the water absorption increased. On the other hand, the flexural strength of concrete-PET when exposed to a heat source was strongly dependent on the temperature, water/cement ratio, as well as on the PET content and particle size. Moreover, the activation energy was affected by the temperature, PET particles location on the slabs and water/cement ratio. [Copyright &y& Elsevier]

Al-Bihani, J., et al. (2012). <u>Durability Characteristics of Sustainable Pervious Pavement Materials</u>.

This study focused on the durability characteristics and moisture susceptibility of a porous plastic-based cementitious material (P-PBC) that is manufactured from plastic waste (PET), soil and aggregates. Use of this material will reduce storm water runoff and provide a pavement structure suitable for walkways, parking lots, recreational courts and other applications. It will also play a crucial role in current recycling programs by diverting large quantities of plastic from landfills and incinerators. P-PBC specimens were prepared in a two step procedure: (1) melting the PET flakes and mixing them with the soil at the melting temperature of plastic until a uniform mixture was attained and (2) thoroughly mixing the PET-soil mixture with the aggregates until uniformity was obtained. Specimens had a plastic to soil ratio (PSR), by weight of 0.75 and a plastic to aggregate ratio (PAR), by weight of 0.175. After compaction, prismatic specimens were cured for 24 hours and tested for freezethaw durability in accordance with the ASTM C666 test method. Results showed that the dynamic modulus of elasticity and modulus of rupture of the specimens decreased as the number of freeze-thaw cycles increased; in addition, moisture susceptibility tests were run according to the AASHTO T-283-89 test method. Results showed that the average tensile strength ratio of P-PBC specimens was greater than 70%, which indicated that P-PBC specimens were not susceptible to moisture.

Alcantara-Concepciona, V., et al. (2016). "Environmental impacts at the end of life of computers and their management alternatives in Mexico." <u>Journal of Cleaner Production</u> **131**: 615-628.

A Life Cycle Analysis of End-of-Life Computers was developed for management of computers discarded in Mexico for the year 2014 through LCA methodology (ISO 14044) and using specialized software named Umberto super(registered) version 5.5.4 with database Ecoinvent 2.2. The modeling consisted in the current scenario in Mexico (10% recycling) versus four alternative scenarios: 0% recycling, 25% recycling, 35% recycling and elimination of open dump disposal considering experience in other countries and real possibilities of medium-term management. All practices of management and recycling are considered in the model with changes in the recycling rates and installed infrastructure for different alternatives proposals. On the other hand, the model included that dismantling operations are done mostly with manual labor; transportation, extraction and processing of printed wiring boards, including local process of transforming, heating and melting of materials and considering recycling in Asian countries with all the environmental burdens processes involving transoceanic transportation and metallurgy. The majority of non-precious metals recycling was considered to take place locally. A substantial benefit was identified for all recycling scenarios, particularly in the elimination of open dump disposal and the recycling of 35% of the stream and was found that there was a high impact on climate change and adverse toxic effects to health and natural environments for the practice of accumulating waste in sanitary landfills and dumpsites as well as by burning of materials (plastics and others) in open areas. The use of recycled materials versus virgin materials was also beneficial up to 10 times for reduction in global warming potential impact and up to 3 times reduction for human toxic potential. Public policies might be recommended in order to protect health and environment. As public policy recommendations, it is proposed reinforcement the national infrastructure to collect EoL computers- and transformation of materials into new commercial products, and as a starting point for the recycling of all generated materials, including plastics and printed wiring boards, but should also include the promotion of research for the transformation of plastic waste and the implementation of new technologies that can be adopted by the national recycling industry and create new regulations that result in the production or import of EoL computers and other electronics with low levels of toxic substances as their main components. Other public policies should include the legal prohibition of use of landfills and dumps for containment of EoL computers and other electrical and electronic equipment.

Alchab, S., et al. (2011). "Blood-borne cancer cells in pulmonary veins in surgical non-small cell lung cancer (NSCLC)." Journal of Thoracic Oncology **2)**: S370-S371.

Background: Patients with NSCLC have a high risk of relapse even after complete surgical resection. The presence of cancer cells in the pulmonary venous blood draining the tumour may be a potential primary source of haematogenous dissemination even at the time of surgery. Method(s): A consecutive series of 16 patients with completely resected primary NSCLC, was studied. Blood samples were collected on EDTA from the pulmonary vein draining the tumor after vessel ligation. Within 2 hours, blood mononuclear cells were collected after Ficoll gradient centrifugation and cancer cells were selected after incubation with anti-CD326EpCAM microBeads and magnetic isolation [MACS Cell isolation Technology (Milteny Biotec France)]. Cytospins of the cells obtained either without (n:10) or after (n:6) magnetic isolation were immunolabelled with anti CK antibody [Pan-Cytokeratin Mouse Monoclonal Antibody NovocastraTM] for epithelial characterization. Preliminary experiments have been done using A549 cell line and peripheral blood mononuclear cells from donors. Result(s): Pulmonary venous blood sampling then isolation by Ficoll-Hypaque allowed to collect (20 +/- 10) ml of blood and (37 +/-10) x106 mononuclear cells or (1.8 x106) cells/ml. Using the magnetic isolation technique, it was possible to recover an average of 10 cytokeratinplus cancer cells per 20 x106 mononuclear cells or per 15 ml of blood. Cytokeratinplus cells were detected in respectively 7/10 and 6/6 patients without or after magnetic isolation. Detection of cancer cells without magnetic isolation which was a laborious and tedious method was obtained in 70% of the patients, while after isolation 100% of the samples contained cancer cells. This last method provided the necessary sensitivity for the detection and isolation of very small numbers of circulating tumor cells. Conclusion(s): This work has enabled us to develop a method for collecting tumor cells in the pulmonary venous blood draining NSCLC at time of surgery. The results show that it is an important phenomenon found in 81.25% of patients. This method allows to study more thoroughly the characteristics of circulating cancer cells in NSCLC.

Alcocer-Varela, J., et al. (2013). "Analysis of the expression of interferon regulatory factors on myeloid dendritic cells from systemic lupus erythematosus patients." Lupus **22 (1)**: 115.

Background: Dendritic cells (DC) are a key element between the innate and the adaptive immune response, they are considered professional antigen presenting cells, and the main source of type-I interferon (IFNI). Elevated levels of IFN- I have been detected in many autoimmune diseases in humans. The genomic and proteomic studies have shown that elevated serum levels of IFN-I and the interferon related genes overexpression are the molecular signature of systemic lupus erythematosus (SLE). The interferon regulatory factors (IRF) are among these upregulated genes. These transcription factors are induced by many different receptors, mainly toll-like receptors and interferon receptors. Diverse genetic association studies have found relationship between many IRF-5 polymorphisms and increased susceptibility to SLE in different ethnic groups. However these studies have been done with total mononuclear cells, which may not reflect specific DC alterations. The aim of this study was to evaluate the expression of IRF-3, 5 and 7 on myeloid DC (mDC) from SLE patients. Method(s): We included 34 patients with SLE diagnosis (17 with SLEDAI=0, 17 with SLEDAI>6) as well as 34 healthy controls. Peripheral blood mononuclear cells were isolated by Ficoll-Hypaque centrifugation. Monocytes were purified by positive selection with anti- CD14 mAb coated microbeads. mDC were generated by culturing monocytes for 6 days in presence of GM-CSF, IL-4 and for 2 additional days in presence of LPS to induce maturation. In vitro generated mDC were analyzed for HLA-DR, CD11c, CD40, CD80, IRF3 and IRF5 expression by flow cytometry. We also analyzed the expression of IRF3 IRF5 and IRF7 by Western Blot and real time PCR (RTPCR). Data were analyzed by the Mann-Whitney U test. Result(s): We found no differences between the expression of surface molecules (HLA-DR, CD11c, CD80 and CD40) on mature mDC from SLE compared with controls. Neither we found differences on IRF3 IRF5 and IRF7 expression analyzed by flow cytometry (IRF3: 24.85% vs 28% and MIF 31 vs 23.5; IRF5: 30.8% vs 32.5% and MIF 35.5 vs 28), Western Blot (IRF3: 0.77 vs 0.62, IRF5: 1.39 vs 1.42 and IRF7: 0.72 vs 0.96) and RT-PCR (IRF3: 1765.9 vs 1141.3 copies/ microliter; IRF5: 2975 vs 1970 copies/microliter and IRF7: 1163 vs 1772 copies/microliter). No differences were found between active and inactive SLE patients. Conclusion(s): mDC from SLE patients do not display abnormalities in the expression of IRF3, 5 and 7.

Aldana, A. A., et al. (2015). "The Cooperative Effect in Dendronized Chitosan Microbeads." Australian Journal of Chemistry **68**(12): 1918-1925.

The present study evaluates the cooperative effects of dendronized chitosan microbeads with tris- and hexa-functionalized dendrons for capturing copper and for further use as catalysts. The dendronized microbeads were characterized by infrared spectroscopy, scanning electron microscopy, thermogravimetry, swelling capacity analysis, and atomic absorption spectroscopy. A correlation between the number and type of functional groups at the dendritic surface of the

dendronized microbeads and the retention of copper highlights structural features of the cooperative effect. It is demonstrated that covalently bound dendrons can modulate the properties of chitosan, which has shown potential as a catalyst for the development of a novel materials.

Aldo, M., et al. (2011). "Carfilzomib-dependent selective inhibition of chymotrypsin-like activity of the proteasome leads to in vitro and in vivo anti-tumor effect in waldenstrom macroglobulinemia." Haematologica **2)**: 161-162.

Background. Selective inhibition of chymotrypsin-like (CT-L) activity of constitutive-(c20S) and immuno-(i20S) proteasome leads to a significant anti-neoplastic effect in a wide spectrum of hematologic tumors. Preclinical evaluation of new proteasome inhibitors with a more targeted inhibition of clonal cells is needed in order to increase efficacy and improve patient outcome. We evaluated the anti-tumor activity of Carfilzomib, a novel selective, irreversible peptide epoxyketone inhibitor of the CT-L activity of i20S and c20S, in WM.selective chymotrypsin- like (CT-L) proteasome inhibitor in WM, both in vitro and in vivo. Aims. 1) To evaluate the distribution of i20s and c20S in WM primary cells as compared to the related normal cellular counterpart. 2) To evaluate the anti-tumor properties of Carfilzomib in WM, both in vitro and in vivo. Methods. Primary WM cells were obtained from bone marrow (BM) of WM patients (CD19+ microbead selection). WM and IgM secreting low-grade lymphoma cell lines were used. Level of imunoproteasome (i20S) and constitutive proteasome (c20S) subunits were detected by an ELISA-based assay. Cytotoxicity, DNA synthesis were measured by MTT and thymidine uptake, respectively. Cell signaling and apoptotic pathways were determined by Western Blot. Effect of Carfilzomib on paracrine WM cell growth in the BM has been evaluated by looking at adhesion, migration and co-colture of WM cells with primary BM stromal cells (BMSCs). Drug synergism was calculated using CalcuSyn software. In vivo studies were perfomed using BCWM.1-GFP+/Luc+ cells injected into SCID mice, treated intra-venously with either Carfilzomib or vehicle. Detection of Carfilzomib-induced apoptosis has been validated ex vivo using WM cells isolated from BM of SCID mice treated with either vehicle or Carfilzomib. Measurement of human IgM has been performed on serum obtained from treated mice. Results. Primary WM cells which are characterized by higher expression of the i20S subunits as compared to c20S subunits, and they contain a higher i20S content as compared to normal CD19+ B-cells. Carfilzomib inhibited the CT-L activity of both i20S (LMP7) and c20S (beta5) in primary WM cells, leading to inhibition of proliferation and induction of cytotoxicity; supported by increased PARP-, caspase-9-, -8 and -3-cleavage, as well as induced activation of c-jun- N-terminal kinase and ER-stress in a dose-dependent manner. Carfilzomib targeted WM cells even in the context of BM milieu, where inhibition of adhesion and migration were observed, together with inhibition of WM growth even in presence of BMSCs. Combination of carfilzomib and bortezomib induced synergistic cytotoxicity in WM cells, as shown by enhanced PARP-, caspase-9- and -3-cleavage; and synergy in inhibiting the CT-L activity of the i20S and c20S. Antitumor activity of Carfilzomib has been validated in vivo, where carfilzomib- treated mice presented with a significant lower number of tumor cells (P<.05); increased percentage of apoptotic WM cells (P<.05); and reduced serum IgM levels (P<.05), as compared to control mice. Summary. These findings demonstrate for the first time that Carfilzomib targets WM cells both in vitro and in vivo, due to its anti- CT-L activity of both i20S and c20S proteasome, providing the framework for testing this compound in this disease.

Alessandri, I., et al. (2016). "Cavitands Endow All-Dielectric Beads With Selectivity for Plasmon-Free Enhanced Raman Detection of Nepsilon-Methylated Lysine." Acs Applied Materials & Interfaces **8**(24):

14944-14951.

SiO2/TiO2 microbeads (T-rex) are promising materials for plasmon-free surface-enhanced Raman scattering (SERS), offering several key advantages in biodiagnostics. In this paper we report the combination of T-rex beads with tetraphosphonate cavitands (Tiiii), which imparts selectivity toward Nepsilon-methylated lysine. SERS experiments demonstrated the efficiency and selectivity of the T-rex-Tiiii assays in detecting methylated lysine hydrochloride (Nepsilon-Me-Lys-Fmoc) from aqueous solutions, even in the presence of the parent Lys-Fmoc hydrochloride as interferent. The negative results obtained in control experiments using TSiiii ruled out any other form of surface recognition or preferential physisorption. MALDI-TOF analyses on the beads exposed to Nepsilon-Me-Lys-Fmoc revealed the presence of the Tiiii*Nepsilon-Me-Lys-Fmoc complex. Raman analyses based on the intensity ratio of Nepsilon-Me-Lys-Fmoc and cavitand-specific modes resulted in a dose-response plot, which allowed for estimating the concentration of Nepsilon-methylated lysine from initial solutions in the 1 x 10(-3) to 1 x 10(-5) M range. These results can set the basis for the development of new Raman assays for epigenetic diagnostics.

Alevizopoulos, K. (2015). "Hypertonic seawater solutions exhibit anti-inflammatory actions and improve nasal cell function in epithelial cell cultures isolated from an allergic human donor." Allergy: European Journal of Allergy and Clinical Immunology **101)**: 563.

Background: Hypertonic saline sprays are frequently used as adjunct agents providing symptomatic relief and/or reducing the need for prescribed medication in allergic rhinitis patients. Despite reported mechanisms of action including induction of osmotic gradients or mechanical removal of mucus in nasal epithelia, direct and conclusive evidence linking hypertonic saline solutions to inflammation reduction and improvement of nasal function are still lacking. Method(s): Airway epithelial cells isolated from an allergic human donor were cultured as 3-dimensional, fully differentiated cultures in the presence of HCPt (ammonium hexachloroplatinate IV), a wellknown respiratory allergen capable of inducing potent inflammatory responses in cells. To assess potential benefits of a hypertonic seawater solution comprising 2.3% NaCl (HSS), its effects on the secretion of HCPt-induced inflammatory mediators IL-8 and IL-6 were measured by ELISA over a time-course of 3 days. Cilia Beating Frequencies (CBF) of the nasal epithelia were also determined by digital high-speed video imaging at day 3 post HCPt challenge. Finally, effects of HSS on the mucociliary clearance of allergic cells were analyzed by measuring the speed of clearance of micro-beads added to the apical surface of cells by video imaging. Result(s): HCPt induced a potent inflammatory response as measured by strong IL-8 secretion in the supernatant of allergic epithelial cells (25-fold increase in Day 3). HSS (2.3% NaCl) was capable of blocking the HCPt-induced increase of IL-8. Similar effects were observed for IL-6 although the action of HSS was less profound in comparison to IL-8. Furthermore, treatment with HSS resulted in increased CBF of the nasal epithelia at day 3 post HCPt challenge. Directly proving the beneficial effects of the solution, measurements in naive allergic epithelia not treated with HCPt showed increased mucociliary clearance speed in response to seawater treatment. Of note, similar anti-inflammatory effects on IL-8 and IL-6 and increased CBF were observed in epithelia from normal human donors treated with bacterial lipopolysaccharide in the presence of HSS. Conclusion(s): Hypertonic seawater solutions comprising 2.3% NaCl have direct anti-inflammatory effects and improve nasal cell function in physiological cultures of epithelial cells isolated from an allergic donor. These results may help explain the beneficial effects observed with hypertonic solutions in allergic patients.

Alexiadou, P., et al. (2019). "Ingestion of macroplastics by odontocetes of the Greek Seas, Eastern Mediterranean: Often deadly!" Marine Pollution Bulletin **146**: 67-75.

Plastic pollution is an omnipresent problem that threatens marine animals through ingestion and entanglement. Marine mammals are no exception to this rule but their interaction with plastic remains understudied in the Mediterranean Sea. Here we highlight this problem by analyzing the stomach contents of 34 individuals from seven odontocete species stranded in Greece. Macroplastic (>5 mm) were found in the stomachs of nine individuals from four species (harbour porpoise Phocoena phocoena, Risso's dolphin Grampus griseus, Cuvier's beaked whale Ziphius cavirostris and sperm whale Physeter macrocephalus) with the highest frequency of occurrence in sperm whales (60%). Gastric blockage from plastic was presumably lethal in three cases, with plastic bags being the most common finding (46%). Plastic ingestion is of particular conservation concern for the endangered Mediterranean sperm whales. A regular examination of stranded cetaceans with a standardised protocol is critical for allowing spatiotemporal comparisons within and across species. Copyright © 2019 Elsevier Ltd

Alexy, P., et al. (2020). "Managing the analytical challenges related to micro- and nanoplastics in the environment and food: filling the knowledge gaps." Food Additives & Contaminants. Part A, Chemistry, Analysis, Control, Exposure & Risk Assessment **37**(1): 1-10.

This paper identifies knowledge gaps on the sustainability and impacts of plastics and presents some recommendations from an expert group that met at a special seminar organised by the European Commission at the end of 2018. The benefits of plastics in society are unquestionable, but there is an urgent need to better manage their value chain. The recently adopted European Strategy for Plastics stressed the need to tackle the challenges related to plastics with a focus on plastic litter including microplastics. Microplastics have been detected mainly in the marine environment, but also in freshwater, soil and air. Based on today's knowledge they may also be present in food products. Although nanoplastics have not yet been detected, it can be assumed that they are also present in the environment. This emerging issue presents challenges to better understand future research needs and the appropriate immediate actions to be taken to support the necessary societal and policy initiatives. It has become increasingly apparent that a broad and systematic approach is required to achieve sustainable actions and solutions along the entire supply chain. It is recognised that there is a pressing need for the monitoring of the environment and food globally. However, despite the number of research projects increasing, there is still a lack of suitable and validated analytical methods for detection and quantification of micro- and nanoplastics. There is also a lack of hazard and fate data which would allow for their risk assessment. Some priorities are identified in this paper to bridge the knowledge gaps for appropriate management of these challenges. At the same time it is acknowledged that there is a great complexity in the challenges that need to be tackled before a really comprehensive environmental assessment of plastics, covering their entire life cycle, will be possible.

Alfonso, M. B., et al. (2020). "Microplastics integrating the zooplanktonic fraction in a saline lake of Argentina: influence of water management." Environmental Monitoring & Assessment **192**(2): 117.

This study address for the first time in Argentina and the South American continent the effect of water management on the presence of microplastics (MPs) in a shallow lake, assessing their contribution to the zooplankton fraction. Water samples were collected in the lake and its principal affluent, an irrigation channel, from winter 2018 to summer 2019 with a zooplankton net (47 mum). MPs were present in all analyzed samples, with a dominance of fibers, black color, and <= 1000 mum range size. MPs concentration was maximum during summer at the lake (180 MPs m⁻³) while during spring (140 MPs m⁻³) at the channel. Rotifers and cyclopoids dominated the zooplanktonic fraction at both sites which range sizes (< 200 to 600 mum) included most of the size range found for MPs (50-950 mum). According to our results, the MPs found represents a potential risk for the first levels of the food web. In the lake, the concentration of MPs concerning total zooplankton abundance was higher when the channel was closed. Nevertheless, when the channel was open, the higher concentration in summer matches with the increase of tourism and an extraordinary rainfall. Our results suggest that while the runoff of agro-industrial waste regulates the MPs concentration in the channel, its water management, the touristic activities, and the runoff of MPs from nearby urban settlements regulate the concentration of MPs in the lake. These findings emphasize the need for better treatment of urban and agro-industrial waste that develops near continental aquatic systems, mainly in those where tourism activities are frequent and treatment facilities scarce.

Al-Harbi, M., et al. (2013). "Kinetic analysis and modelling of thermal degradation of perspex (PMMA) and perspex blend plastic waste." Canadian Journal of Chemical Engineering **91**(7): 1281-1288.

The thermal decomposition of pure perspex and a mixture of 50% perspex and 50% poly(ethylene terephthalate; PET) was carried out between 295 and 325 degree C using a thermogravimetric analyser (TGA) in air and nitrogen (N sub(2)) atmosphere. The weight losses of decomposition products were measured during these experiments. The thermal degradation process is slower in inert atmosphere than air, where oxidation reaction expedites the decomposition process. Kinetic rate constants (k), pre-exponential factor (A) and activation energy (E) for both pure prespex and a blend of perspex/PET were calculated for both air and N sub(2) conditions. The thermal degradation process followed a third-order reaction in air and second-order in N sub(2). A second-order (n=2) model for the pyrolytic process based on simultaneous reactions was developed using experimental data for pure and blend. The pyrolytic products are gases, liquids, waxes, aromatics and char, which can be ultimately used as raw material and fuel in various applications. It is important to note that the addition of PET to perspex was found to suppress/inhibit the decomposition of perspex compared with pure perspex. Pre-exponential factor (A) and activation energy (E) values support such an observation. copyright 2012 Canadian Society for Chemical Engineering

Alharbi, M., et al. (2017). "Label-free selective plane illumination microscopy of tissue samples." Journal of the Saudi Heart Association **29 (4)**: 326.

Introduction: There is an increasing demand for non-invasive, label-free, three-dimensional imaging techniques for characterisation of optically turbid samples such as tissue engineered constructs, used in Regenerative Medicine, and native tissue for medical diagnosis. Selective plane provide both high temporal and spatial information, deliver rapid results, are capable of assessing quality control criteria of engineered products and are applicable to a clinical environment. Many existing optical imaging techniques are not suitable for imaging samples that are non-transparent and turbid. In this project a unique technique which is Label-free Selective Plane Microscopy will be demonstrated. The imaging capabilities of this new method will be compared with existing techniques including bright field microscopy, fluorescence microscopy and confocal microscopy. Methodology: Test samples of polystyrene microbeads were prepared to simulate tissue. Red (6 micron in diameter) and clear microbeads (8 micron in diameter) were used to represent tissues that are and are not highly perfused with blood. For comparison with fluorescence imaging techniques, samples containing fluorescent beads were also prepared. The samples were imaged using bright field microscopy, Label-free Selective Plane Microscopy, fluorescence microscopy and confocal microscopy. Native tissue samples

were also studied and as above samples with different optical absorption and scattering properties. Chicken tendon and sheep kidney were used. Result(s): Label-free Selective Plane Microscopy have the capability to image highly scattering and absorbing tissue in 3D. Label-free Selective Plane Microscopy (SPIM) is a fast method for imaging tissue samples with high lateral and axial resolution and good depth penetration. Conclusion(s): Overall this method meets the demands of the current needs for 3D imaging tissue samples in a label-free manner. Label-free Selective Plane Microscopy directly provides excellent information about the structure of the tissue samples. This work has highlighted the superiority of Label-free Selective Plane Microscopy to current approaches to label-free 3D imaging of tissue.

Ali, K., et al. (2018). "Microplastic and mesoplastic contamination in canned sardines and sprats." Science of the Total Environment **612**: 1380-1386.

No report was found on the occurrence of microplastics in processed seafood products that are manufactured for direct human consumption. This study investigates the potential presence of micro- and mesoplastics in 20 brands of canned sardines and sprats originating from 13 countries over 4 continents followed by their chemical composition determination using micro-Raman spectroscopy. The particles were further inspected for their inorganic composition through energy-dispersive X-ray spectroscopy (EDX). Plastic particles were absent in 16 brands while between 1 and 3 plastic particles per brand were found in the other 4 brands. The most abundant plastic polymers were polypropylene (PP) and polyethylene terephthalate (PET). The presence of micro- and mesoplastics in the canned sardines and sprats might be due to the translocation of these particles into the edible tissues, improper gutting, or the result of contamination from the canneries. The low prevalence of micro- and mesoplastics sized >149 micro m, and the absence of potentially hazardous inorganic elements on them, might indicate the limited health risks associated with their presence in canned sardines and sprats. Due to the possible increase in micro- and mesoplastic loads in seafood products over time, the findings of this study suggest their quantification to be included as one of the components of food safety management systems.

Ali, K., et al. (2017). "Microplastics in eviscerated flesh and excised organs of dried fish." Scientific Reports **7**(1).

There is a paucity of information about the occurrence of microplastics (MPs) in edible fish tissues. Here, we investigated the potential presence of MPs in the excised organs (viscera and gills) and eviscerated flesh (whole fish excluding the viscera and gills) of four commonly consumed dried fish species (n=30 per species). The MP chemical composition was then determined using micro-Raman spectroscopy and elemental analysis with energy-dispersive X-ray spectroscopy (EDX). Out of 61 isolated particles, 59.0% were plastic polymers, 21.3% were pigment particles, 6.55% were non-plastic items (i.e. cellulose or actinolite), while 13.1% remained unidentified. The level of heavy metals on MPs or pigment particles were below the detection limit. Surprisingly, in two species, the eviscerated flesh contained higher MP loads than the excised organs, which highlights that evisceration does not necessarily eliminate the risk of MP intake by consumers. Future studies are encouraged to quantify anthropogenic particle loads in edible fish tissues.

Ali, K., et al. (2017). "Biomarker responses in zebrafish (Danio rerio) larvae exposed to pristine low-density polyethylene fragments." Environmental Pollution **223**: 466-475.

There are serious concerns over the adverse impacts of microplastics (MPs) on living organisms. The main objective of this study was to test the effects of MPs on the total length, weight, condition factor (CF), transcriptional level of antioxidant, anti and pro-apoptotic, and neurotransmitter genes, and the histopathology of the gill, liver, brain, kidney, and intestine in the larvae of zebrafish (Danio rerio). Fish were exposed to one of three levels of pristine low-density polyethylene (LDPE) fragments (5, 50, or 500 micro g/L) for 10 or 20 days. No significant changes were observed in any of the selected biomarkers across MP concentrations at days 10 or 20. The expression of casp9 (caspase 9, apoptosis-related cysteine protease), casp3a (caspase 3, apoptosis-related cysteine protease a) and cat (catalase), however, were significantly lower in the larvae sampled at day 20 than day 10. We provide evidence that virgin short-term exposure to LDPE fragments has minimal impact on biomarker responses in D. rerio larvae.

Ali, K., et al. (2016). "Virgin microplastics cause toxicity and modulate the impacts of phenanthrene on biomarker responses in African catfish (Clarias gariepinus)." Environmental Research **151**: 58-70.

Despite the ubiquity of microplastics (MPs) in aquatic environments and their proven ability to carry a wide variety of chemicals, very little is known about the impacts of virgin or contaminant-loaded MPs on organisms. The primary aim of this study was to investigate the impacts of virgin or phenanthrene (Phe)-loaded low-density polyethylene (LDPE) fragments on a suite of biomarker responses in juvenile African catfish (Clarias gariepinus). Virgin LDPE (50 or 500 micro g/L) were preloaded with one of two nominal Phe concentrations (10 or 100 micro g/L) and were exposed to the fish for 96 h. Our findings showed one or both Phe treatments significantly increased the degree of tissue change (DTC) in the liver while decreased the transcription levels of forkhead box L2 (foxl2) and tryptophan hydroxylase2 (tph2) in the brain of C. gariepinus. Exposure to either levels of virgin MPs increased the DTC in the liver and plasma albumin: globulin ratio while decreased the transcription levels of tph2. Moreover, MPs modulated (interacted with) the impact of Phe on the DTC in the gill, plasma concentrations of cholesterol, high-density lipoprotein (HDL), total protein (TP), albumin, and globulin, and the transcription levels of fushi tarazu-factor 1 (ftz-f1), gonadotropin-releasing hormone (GnRH), 11 beta -hydroxysteroid dehydrogenase type 2 (11 beta -hsd2), and liver glycogen stores. Results of this study highlight the ability of virgin LDPE fragments to cause toxicity and to modulate the adverse impacts of Phe in C. gariepinus. Due to the wide distribution of MPs and other classes of contaminants in aquatic environments, further studies are urgently needed to elucidate the toxicity of virgin or contaminant-loaded MPs on organisms.

Ali, M. F. (2006). The development of a microbead array for the detection and amplification of nucleic acids.

The focus of this doctoral thesis is on the development of a chip-based sensor array, composed of individually addressable agarose micro-beads, that is suitable for the real-time detection of DNA oligonucleotides. This research is consistent with recent trends in disease diagnostics following the miniaturization and integration of sample preparation and measurement steps towards portable devices capable of point of care analysis. Thus, the power and utility of this microbead array methodology for DNA detection is demonstrated here for the analysis of fluids containing a variety of similar short oligonucleotides. Hybridization times on the order of minutes with point mutation selectivity factors greater than 10,000 and limit of detection values of similar to 10 super(-13) M are obtained readily with this microbead array system. These analytical characteristics, here exhibited are competitive with some of the best direct DNA detection methodologies before reported. As an extension of this work, an integrated self quenching based sensing system within the bead format has shown clear efficacy for the detection of HIV gag isolates and Bacillus anthracis (Sterne) purified strains and allows for the rapid detection of 100bp sequences with sensitivities in the subnanomolar range. Additionally, due to the tailored immobilization of specific sequences on each sensor element, the multiplexed detection of various sequences utilizing diverse strategies has been demonstrated. Use of the micro-bead array in tandem with the hybridization capabilities of molecular beacons, constitutes a powerful tool for the heterogeneous elucidation of specific sequences. Concomitantly, successful collaboration with the Chen group on the development of a miniaturized enzyme based nucleic acid amplification device has been reported. Purified strains of Bacillus anthracis (Sterne) have been successfully amplified by the miniaturized polymerase chain reaction (PCR) chip as seen by gel electrophoresis. One of the long term aims of this general area of research will be to couple the glass micro chip-based PCR amplification of oligonucleotides with the real-time detection capabilities of a bead based array. These efforts serve to establish some precedent for the bead-based microfluidics approach to be implemented in the context of genomics testing for the next generation of health care.

Ali, M. I., et al. (2014). "Biodegradation of starch blended polyvinyl chloride films by isolated Phanerochaete chrysosporium PV1." International Journal of Environmental Science and Technology **11**(2): 339-348.

The accumulation of plastics in the environment is raising great concerns with respect to long-term environmental, economic and waste management problems. The aim of the present research was to investigate the biodegradability of starch blended polyvinyl chloride films in soil burial and controlled laboratory experiments using selective fungal isolates. Clear surface aberrations as color change and minor disintegration in polyvinyl chloride films were observed after 90 days and later confirmed through scanning electron microscopy. The fungal strains showing prominent growth and adherence on plastic films were isolated. One of the strains showing maximum activity was selected and identified as Phanerochaete chrysosporium PV1 by rDNA sequencing. Fourier transform infrared spectroscopy and nuclear magnetic resonance analyses indicated considerable structural changes and transformation in films in terms of appearance of new peaks at 3,077 cm⁻¹ (corresponding to alkenes) and decrease in intensity of peaks at 2,911 cm⁻¹ (C-H stretching). It was supported with a significant decrease in the molecular weight of polymer film from 80,275 to 78,866 Da (treated) through Gel permeation chromatography in shake flask experiment. Moreover, the biodegradation of starch blended polyvinyl chloride films was confirmed through release of higher CO₂ (7.85 g/l) compared to control (2.32 g/l) in respirometric method. So fungal strain P. chrysosporium PV1 has great potential for use in bioremediation of plastic waste.

Ali, W. H., et al. (2010). "Solid-phase extraction using molecularly imprinted polymers for selective extraction of a mycotoxin in cereals." Journal of Chromatography. A **1217**(43): 6668-6673.

The aim of this work was to develop a method for the clean-up of a mycotoxin, i.e. Ochratoxin A (OTA), from cereal extracts employing a new molecularly imprinted polymer (MIP) as selective sorbent for solid-phase extraction (SPE) and to compare with an immunoaffinity column. A first series of experiments was carried out in pure solvents to estimate the potential of the imprinted sorbent in terms of selectivity studying the retention of OTA on the MIP and on a non-imprinted polymer using conventional crushed monolith. The selectivity of the MIP was also checked by its application to wheat extracts. Then, after this feasibility study, two different formats of MIP: crushed monolith and micro-beads were evaluated and compared. Therefore an optimization procedure was applied to the selective extraction from wheat using the MIP beads. The whole procedure was validated by applying it to wheat extract spiked by OTA at different concentration levels and then to a certified contaminated wheat sample. Recoveries close to

100% were obtained. The high selectivity brought by the MIP was compared to the selectivity by an immunoaffinity cartridge for the clean-up of the same wheat sample. The study of capacity of both showed a significant higher capacity of the MIP.

Ali, Z. H., et al. (2019). "Environmental impact assessment of medical wastes shredding machine in Al-Hila teaching hospital-Babylon province, IRAQ." Indian Journal of Public Health Research and Development **10**(6): 963-967.

This study was carried out to assess the environmental impact of medical wastes shredding machine in Al- Hila Teaching Hospital- Babylon Province, IRAQ and samples of medical wastes received from various local health premises were identified and the percentage of each component in wet and dried forms were assessed. Several heavy metal ions were determined while air variables such as CO, NO<inf>2</inf> and SO<inf>2</inf> were measured in shredding machine location and surrounding environment. Regarding waste heavy metal content, current work has found that the highest mean concentration (1.473 +/- 0.786 micro g/kg) was recorded for cadmium ion which was within standard limit (1 - 3 micro g/kg) while both copper and ferrous ions gave mean value of 0.0163 +/- 0.005 micro g/kg and 0.679 +/- 0.431 micro g/kg respectively. In case of air gases, it was found that there were no significant differences between all measured gases in all measured siteswithin shredding room and surrounding environment where NO<inf>2</inf> mean values were 0.0194 +/- 0.006 ppm and 0.019 +/- 0.002 ppm respectively while SO<inf>2</inf> gave mean values of 0.033 +/- 0.002 ppm and 0.049 +/- 0.003 ppm respectively and CO mean concentrations have been found to be 0.026 +/- 0.023 ppm and 0.05 +/- 0.007 ppm respectively. Aliabad, M. K., et al. (2019). "Microplastics in the surface seawaters of Chabahar Bay, Gulf of Oman (Makran Coasts)." Marine Pollution Bulletin **143**: 125-133.

Current study aimed to evaluate the microplastics abundance in the surface waters of Chabahar Bay for the first time. 21 neuston net water samples were collected from 7 stations. Microplastics were visually counted by stereomicroscope, sorted into 4 size categories, 4 shape categories, and identified by ATR-FTIR spectroscopy. Density of microplastics varied from 0.07+/-0.03 to 1.14+/-0.27 with an average density of 0.49+/-0.43particle.m⁻³. Microplastics were mostly found in the shape of fibers. 69% of analyzed particles were polyethylene and polypropylene. Main colors of the collected microplastics were white, blue and red. The results showed that the largest number of microplastics was found at station near populated area. Therefore, it can be concluded that, there is a pressing-need to investigate the distribution of microplastics in sediments and biota of this Bay as well as their effects on marine life and human health.

Alimba, C. G. and C. Faggio (2019). "Microplastics in the marine environment: Current trends in environmental pollution and mechanisms of toxicological profile." Environmental Toxicology & Pharmacology **68**: 61-74.

The global plastics production has increased from 1.5 million tons in the 1950s to 335 million tons in 2016, with plastics discharged into virtually all components of the environment. Plastics rarely biodegrade but through different processes they fragment into microplastics and nanoplastics, which have been reported as ubiquitous pollutants in all marine environments worldwide. This study is a review of trend in marine plastic pollution with focus on the current toxicological consequences. Microplastics are capable of absorbing organic contaminants, metals and pathogens from the environment into organisms. This exacerbates its toxicological

profile as they interact to induced greater toxic effects. Early studies focused on the accumulation of plastics in the marine environment, entanglement of and ingestions by marine vertebrates, with seabirds used as bioindicators. Entanglement in plastic debris increases asphyxiation through drowning, restrict feeding but increases starvation, skin abrasions and skeletal injuries. Plastic ingestion causes blockage of the guts which may cause injury of the gut lining, morbidity and mortality. Small sizes of the microplastics enhance their translocation across the gastro-intestinal membranes via endocytosis-like mechanisms and distribution into tissues and organs. While in biological systems, microplastics increase dysregulation of gene expression required for the control of oxidative stress and activating the expression of nuclear factor E2-related factor (Nrf) signaling pathway in marine vertebrates and invertebrates. These alterations are responsible for microplastics induction of oxidative stress, immunological responses, genomic instability, disruption of endocrine system, neurotoxicity, reproductive abnormities, embryotoxicity and trans-generational toxicity. It is possible that the toxicological effects of microplastics will continue beyond 2020 the timeline for its ending by world environmental groups. Considering that most countries in African and Asia (major contributors of global plastic pollutions) are yet to come to terms with the enormity of microplastic pollution. Hence, majority of countries from these regions are yet to reduce, re-use or re-circle plastic materials to enhance its abatement. [ABSTRACT FROM AUTHOR]

Alimi, O. S., et al. (2018). "Microplastics and Nanoplastics in Aquatic Environments: Aggregation, Deposition, and Enhanced Contaminant Transport." Environmental Science & Technology **52**(4): 1704-1724.

Plastic litter is widely acknowledged as a global environmental threat, and poor management and disposal lead to increasing levels in the environment. Of recent concern is the degradation of plastics from macro- to micro- and even to nanosized particles smaller than 100 nm in size. At the nanoscale, plastics are difficult to detect and can be transported in air, soil, and water compartments. While the impact of plastic debris on marine and fresh waters and organisms has been studied, the loads, transformations, transport, and fate of plastics in terrestrial and subsurface environments are largely overlooked. In this Critical Review, we first present estimated loads of plastics in different environmental compartments. We also provide a critical review of the current knowledge vis-a-vis nanoplastic (NP) and microplastic (MP) aggregation, deposition, and contaminant cotransport in the environment. Important factors that affect aggregation and deposition in natural subsurface environments are identified and critically analyzed. Factors affecting contaminant sorption onto plastic debris are discussed, and we show how polyethylene generally exhibits a greater sorption capacity than other plastic types. Finally, we highlight key knowledge gaps that need to be addressed to improve our ability to predict the risks associated with these ubiquitous contaminants in the environment by understanding their mobility, aggregation behavior and their potential to enhance the transport of other pollutants.

Alivernini, S., et al. (2015). "Micro-RNA-34A and micro-RNA-155 unbalance is associated to IL-6/IL-6R pathway in CD14 cells and skin compartment of systemic sclerosis patients." Annals of the Rheumatic Diseases **1)**: A32.

Background and objectives MicroRNAs (miRs) are post-transcriptional regulators implicated in Systemic sclerosis (SSc). MiR- 34a and miR-155 are related to endothelial senescence and inflammation. The aim of the study is to investigate the expression of miR-34a and miR-155 in peripheral blood (PB) CD14 cells and in clinically involved and uninvolved skin paired samples in SSc. Materials and methods Twenty-seven patients with Raynaud phenomenon (RP) were enrolled, divided into 3 groups: long standing SSc (lsSSc) fulfilling the 1987 ACR criteria (n = 10), early SSc (eSSc) reaching 9 points using the Very Early Diagnosis of Systemic Sclerosis criteria (n = 9) and primary RP (n = 8) respectively. Matched healthy controls (HC) (n = 7) were enrolled. Immunostaining for CD68 was performed on paired skin tissues from SSc patients. miR-34a and miR-155 expression was evaluated by qPCR on CD14 cells isolated by CD14 specific microbeads from PB and on clinically involved and uninvolved skin paired samples. Using HumanTargetScan cross-referenced methodology, IL-6 receptor (IL6-R) was selected as target of miR-34a and miR-155 and experimentally confirmed by qPCR. IL-6 and IL-6R plasma levels were determined by ELISA. CD14 cells from PB of HC (n = 4) were cultured in RPMI, stimulated with IL-6 (30ng/ml) or LPS (100ng/ml) and collected after 48 h to assess miR-34a and miR-155 expression by qPCR. Results MiR-155 is over-expressed either in eSSc (p = 0.0002) and lsSSc (p = 0.04) compared to HC. MiR-34a expression is increased only in lsSSc compared to HC (p = 0.01). Primary RP patients did not differ for miR-155 and miR-34a expression from HC (p = 0.71). CD68 cells are over-represented in clinically involved skin compared to uninvolved skin paired samples (p = 0.02). MiR-34a is over-expressed in clinically involved skin samples compared to uninvolved skin (p = 0.04). IL-6R expression is significantly lower in lsSSc and eSSc patients compared to primary RP (p = 0.03 and p = 0.03). IL-6 plasma levels were higher in lsSSc (p = 0.01) as well as in eSSc (p = 0.003) compared to HC whereas no significant difference was found in IL-6R plasma levels. MiR-34a expression directly correlates with the skin score value (R = 0.52, p = 0.03) in SSc patients and with IL-6 plasma levels (R = 0.42; p = 0.01). SSc patients with digital ulcers have higher miR-34a expression than SSc patients without ulcers (p = 0.01). Finally, miR-34a and miR-155 are induced in CD14 cells by IL-6 and LPS in vitro stimulation. Conclusions MiR-34a and miR-155 expression is unbalanced in CD14 cells and paired skin samples of SSc patients linked to the IL-6/IL-6R pathway. MiRNA expression profile could help to differentiate patients with primary and SSc associated RP.

Alivernini, S., et al. (2011). "The role of microrna-34 and microrna-22 in dendritic cells and monocyte activation in rheumatoid arthritis." Arthritis and Rheumatism. Conference: Annual Scientific Meeting of the American College of Rheumatology and Association of Rheumatology Health Professionals **63**(10 SUPPL. 1).

Background/Purpose: MicroRNAs (miRs) are a novel class of post-transcriptional regulators that have been implicated in the pathogenesis of distinct human diseases, including Rheumatoid Arthritis (RA). We have previously shown that miR-34 family members and miR-22 are overexpressed in synovial fluid (SF) monocytes compared to matched peripheral blood (PB) monocytes in RA patients. The aim of this study was to investigate the functional role of miR-34 and miR-22 in the biology of monocytes and monocyte-derived DCs in the context of their abnormal activation in RA. Method(s): Expression of miR-34a and miR-22 in RA and osteoarthritis (OA) synovial tissues were evaluated by in situ hybridization. To characterize miR-34a positive cells, fluorescent in situ hybridization and immunostaining for CD68 were performed on RA tissues. Expression of miR-34a and miR-22 was evaluated by qPCR on DCs isolated by CD1c and CD304 specific microbeads from matched PB and SF of RA patients (n=3). Monocytes from PB of healthy donors (n=5) were isolated by CD14+ microbeads (AutoMACS) and transfected with miR-34a, miR-22 or control mimics. Cells were subsequently stimulated with LPS (10 ng/ml) or CL097 (1 mg/ml). DCs were generated from PB CD14+ cells stimulated with GM-CSF (100 ng/ml) and IL-4 (20 ng/ml) for 7 days. Once generated, CD14+ derived DCs (n=4) were transfected with miR mimics and stimulated as described above. After 18h of stimulation, supernatants were collected and evaluated for chemokine and cytokines levels (Luminex assay). To identify miR-34/22 targets HumanTargetScan cross-referenced with transcriptomic profile of SF CD14+ cells was employed. Identified targets were experimentally verified by miR luciferase assay and qPCR. Result(s): miR-34a and miR-22 are overexpressed in SF DCs compared to matched PB DCs in RA patients. In situ hybridisation showed that miR-34a and miR-22 are widely expressed in RA synovium compared to OA. Double immunofluorescence staining revealed that miR-34a is present in RA synovial tissue myeloid cells. Enforced overexpression of miR-34a but not miR-22 in PB monocytes increased TLR7/8 triggered TNF-alpha production. Overexpression of miR-34a and miR-22 in monocytes-derived DCs increased spontaneous, TLR4 and TLR7/8 triggered TNF-alpha production. In addition, miR-22 but not miR-34a induced production of chemokines and interferon alpha by DCs. Computational target ranking system cross-referenced with transcriptomic profile of RA SF CD14+ cells identified Axl and Tyro3, receptor tyrosine kinases involved in negative feedback mechanism limiting TLRs-induced myeloid cells activation, as potential direct targets for miR-34a and miR-22. Experimental validation confirmed that miR-34a and miR-22 target 3' UTR of Axl and Tyro3 mRNAs, respectively. Consistently, Axl and Tyro3 levels are downregulated in myeloid cells overexpressing miR-34a and miR-22, respectively. Conclusion(s): This study indicates that overexpression of miR-34a and miR-22 in myeloid cells can lead to the disregulation of their self-regulatory mechanism. Thus, high levels of miR-34a and miR-22 in synovial myeloid cells of RA patients may be responsible for an excessive pro-inflammatory activation of these cells.

Alivernini, S., et al. (2014). "microRNA-155 as an epigenetic regulator of B-cell activation in rheumatoid arthritis: In vivo and in vitro evidences." Arthritis and Rheumatology **10)**: S443.

Background/Purpose: MicroRNAs (miRs) are a novel class of posttranscriptional regulators. miR-155 was shown to be a regulator of B cell biology in haematological diseases as well as in myeloid cells in Rheumatoid Arthritis (RA). The regulation of the transcription factor PU.1 by miR-155 is required for the production of high-affinity IgG1 antibodies. The aim of this study was to investigate the expression of miR-155 in B cells of RA patients and its association with synovial inflammation. Method(s): 31 RA patients underwent ultrasound guided synovial tissue (ST) biopsy. ST samples were categorized through Hematoxiline and Eosine staining as diffuse or aggregate pattern. B cells from peripheral blood (PB) and matched synovial fluid (SF) of RA patients (n=19) and PB of healthy controls (HC) (n=10) were isolated by CD19+ microbeads (Mylteni). B-cell subsets were determined by Flow-Cytometry using IgD/CD27 classification and ZAP70 intracellular expression was assessed. IL-6 and BAFF levels in PB and SF were measured by ELISA. miR-155 expression was determined by qPCR on B cells from PB and SF and on ST of osteoarthritis (OA) (n=3), diffuse RA (n=5) and aggregate RA (n=5) patients. Finally, B cells from PB of HC (n=5) were isolated by CD19+ microbeads and cultured in RPMI with or without IL-6 (30 ng/ml), BAFF (20 ng/ml), IL-6+BAFF. Cells were collected after 24h, 48h and 72h to assess miR-155 and PU.1 expression by qPCR. Result(s): 14(45,2%) RA patients showed an aggregate synovial pattern in ST. RA patients with an aggregate synovial pattern were more likely anti-CCP positive compared to RA patients with diffuse pattern (p=0.05). Moreover, anti-CCP plasma levels directly correlates with the synovial aggregate grade (r=0.38; p=0.01). IL-6 and BAFF levels were higher in SF than in PB of RA patients regardless to the synovial pattern (p=0.001 for both). CD19+/IgD-CD27- and CD19+/ZAP70+ cells were overrepresented in PB of RA patients with an aggregate pattern (p=0.05 and p=0.04) compared to RA patients with a diffuse pattern.

Moreover, anti- CCP+ RA patients showed higher percentages of CD19+/IgD-CD27- and CD19+/ZAP70+ in the PB (p=0.01 for both) compared to anti-CCP- RA patients. miR-155 was over-expressed in PB B-cells compared to HC (p=0.0002). miR-155 was over-expressed in SF B-cells compared to matched PB B-cells (p=0.05) in RA patients. Moreover, anti-CCP+ RA showed higher miR-155 expression in PB B-cells compared to anti-CCP- RA patients (p=0.02) and HC (p=0.001). miR-155 was over-expressed in ST of aggregate RA compared to diffuse RA (p=0.03) and OA (p=0.03) patients respectively. Finally, IL-6 and BAFF in vitro stimulation of healthy B-cells induced an overexpression of miR-155 after 72h of incubation (p=0.04 and p=0.03). Consistently PU.1 was down-regulated after in vitro stimulation (p=0.01 and p=0.03). Conclusion(s): This study indicates that miR-155 is over-expressed in B-cells of RA patients and is associated to anti-CCP positivity and to an aggregate synovial pattern. IL-6 and BAFF, that are over-expressed in the SF environment, induce in vitro an over-expression of miR-155 in B-cells. Thus, miR-155 may represent a key regulator of B-cells in RA patients with an activated memory phenotype.

Alivernini, S., et al. (2018). "Interleukin-6 receptor inhibition, as first-line B-DMARD, affects b cell subpopulations distribution through epigenetic modifications in rheumatoid arthritispatients." Annals of the Rheumatic Diseases **77 (Supplement 2)**: 242.

Background: Despite IL-6R inhibition was found to influence B cell subpopulations distribution in Rheumatoid Arthritis (RA), no data are available on the effect on epigenetic signature of RA B cells by this treatment. It is well known that B cell maturation is under control of the microRNA-155 (miR-155)/PU.1 axis significantly influenced by IL-6 stimulation1. Objective(s): To investigate the effect of IL-6R inhibition on the epigenetic signature of B cells (miR-155/PU.1 axis) in RA patients. Method(s): Twenty-nine RA patients [18 (62.1%) female; 57.2+/-14.9 years old; disease duration 1.3+/-0.7 years] starting IL-6R inhibitor treatment as first b-DMARD, have been enrolled. At study entry and after 3-6-12-18 months follow-up, CD19⁺ cells were isolated from peripheral blood (PB) by magnetic microbeads (Miltenyi) and B cells subpopulations were assessed through FACS according to the IgD/ CD27 classification. MiR-155 and PU.1 endogenous expression was determined in PB-derived CD19⁺ cells by RT-PCR at baseline and after 3-6-12-18 months follow-up. IL-6 plasma level was assessed by ELISA at study entry for each patient. ACR/EULAR criteria were used to assess the response rate to IL-6R inhibitor treatment for each RA patient. PB-derived CD19⁺ cells of healthy individuals (HC) were used as comparison group. Result(s): At study entry, RA patients showed higher percentage of IgD⁻/CD27⁻ CD19⁺ cells (p<0.05) and IgD⁺/CD27⁺ CD19⁺ cells (p<0.05) than HC. Moreover, IgD⁻/CD27⁻ CD19⁺ cells percentage directly correlated with Disease Activity Score (p=0.04) and IL-6 plasma levels (p=0.06) in RA patients. IL-6R inhibition lead to DAS and SDAI remission achievement in 73.9% and 52.2% of RA patients after 18 months follow-up, respectively, and significantly reduced IgD⁻/CD27⁻ CD19⁺ cells percentage after 18 months follow-up (p<0.02). Stratifying RA patients based on the remission achievement during the follow-up, RA patients who achieved DAS remission under IL-6R inhibition showed a significant decreased of IgD⁻/ CD27⁻ CD19⁺ cells percentage compared to patients not achieving this outcome (p<0.05), reaching IgD⁻/CD27⁻ CD19⁺ cells percentage comparable to HC (p>0.05). Analysing the epigenetic profile in B cells of RA patients, at baseline, PB-derived CD19⁺ cells of RA patients showed significantly higher endogenous expression of miR-155 (p=0.04) than HC. Moreover, RT-PCR showed that IL-6R inhibition significantly

represses endogenous miR-155 expression in PB-derived RA B cells already after 3 months of treatment (p<0.05) and restores PU.1 expression in PB-derived B cells after 6 months (p<0.05) only in RA patients achieving disease remission. Conclusion(s): IL-6R inhibitor, used as first b-DMARD treatment, acts restoring B cells homeostasis through epigenetic modulation in RA. In particular, IL6-R inhibition significantly represses endogenous expression of miR-155 in PB-derived CD19⁺ cells conversely restoring PU.1 expression mirrored by the decrease of IgD⁻/CD27⁻ B cell rate in RA patients achieving disease remission.

Alivernini, S., et al. (2019). "STAT3/STAT5 balance as a biomarker in RA: CTLA4-Ig and T cell differentiation through STAT signaling." Annals of the Rheumatic Diseases **78 (Supplement 2)**: 1100.

Background: Regulatory T cells (Treg) play suppressive functions and are modulated by Abatacept (CTLA4-Ig). Limited data are available on CTLA4-Ig effect on Treg population in Rheumatoid Arthritis (RA). Objective(s): The aim of the study was to analyze if STAT3/STAT5 expression in CD4+ T cells in peripheral blood (PB) of RA patients at baseline predicts response to Abatacept treatment (after 12 months follow-up). Method(s): Early RA (ERA) and long-standing RA (LS-RA) patients with conventional DMARDs insufficient response were enrolled in this observational, investigative, monocentric, non-randomized, no profit study, and treated with CTLA4-Ig in combination with methotrexate. Each enrolled RA patients underwent peripheral blood sampling and CD4+ cells isolation using magnetic micro-beads at baseline and after 6-12 months follow-up. Flow cytometric analysis (FACS) for CD4 positive cells phenotype was performed to assess T-regulatory cells (Treg) as CD4+/CD25+/CD127- and CD4+/CD25+/Foxp3+, respectively. STAT3/STAT5 gene expression on CD4+ cells was performed by RT-PCR for each enrolled patient at every time-point follow-up. Low disease activity (LDA) and disease remission (DAS) achievement were assessed at 6 and 12 months follow-up (FU), respectively. Result(s): A total of 35 patients were enrolled in the study (16 ERA and 19 LS-RA, respectively). At baseline, ERA and LS-RA did not differ based on clinical parameters. Eight (22.9%) withdrew from the study because of treatment failure (n=6), severe infection (n=1) and death (n=1). LDA or DAS remission within twelve months follow-up were achieved in 28/34 (82.4%) and 16/34 (47.1%) patients, respectively, without any significant difference among ERA and LS-RA. There were no significant differences in the demographic and clinical characteristics of RA patients at study based on LDA or DAS remission status achievement within 12 months FU, even stratifying patients based on disease duration. FACS analysis showed CD4+/CD25+/CD127- and CD4+/CD25+/Foxp3+ cells decrease during CTLA4-Ig treatment (p=0.01 and p=0.02, respectively after 12 months FU), despite disease duration. RT-PCR revealed that PB CD4+ cells of RA patients achieving LDA, but not DAS remission, after CTLA4-Ig treatment have significantly lower endogenous expression of STAT3 and STAT5 compared to RA patients not achieving this outcome (p=0.03 and p<0.001, respectively). Moreover, baseline STAT3/STAT5 ratio in PB CD4+ cells of RA patients directly correlates with Treg cells percentages (CD4+/CD25+/CD127-cells (%): R=0.518, p=0.03; CD4+/CD25+/Foxp3+ cells (%): R=0.549, p=0.02, respectively). Finally, baseline STAT3/STAT5 expression ratio on CD4+ cells > 0.93 (obtained by ROC analysis: AUC:0.754+/-0.100; Sensitivity 75.0%, Specificity: 80.0%) arose as baseline predictor factor of LDA achievement in RA patients treated with CTLA4-Ig [OR(95%CIs): 12.0 (1.98-72.89)]. Conclusion(s): STAT3/STAT5 expression ratio in T cells at baseline identify RA patients better responding to CTLA4-Ig, which decreases Treg cells.

Alivernini, S., et al. (2015). "MicroRNA-155/PU.1 axis as an epigenetic regulator of b-cells in rheumatoid arthritis." Arthritis and Rheumatology. Conference: American College of Rheumatology/Association of

Rheumatology Health Professionals Annual Scientific Meeting, ACR/ARHP **67**(SUPPL. 10).

Background/Purpose: MicroRNA-155(miR-155) has been shown to be a key regulator of B cell biology by PU.1 regulation. However, the role of miR-155 in the activation of B cells in Rheumatoid Arthritis(RA) has not been explored. This study aimed to investigate miR-155 expression in RA B cells and its association with B cell driven pathologies such as levels of antibodies against citrullinated peptides(ACPA) and follicular structures in the synovial tissues(ST). Method(s): 60 RA patients underwent ST biopsy. Based on immunostaining for CD68, CD21, CD3 and CD20 cells, ST samples were categorized as diffuse or with follicular pattern. MiR-155 expression in RA ST and synovial B cells was evaluated by in situ hybridization(ISH). B cells from peripheral blood(PB) and matched synovial fluid(SF) of RA and PB of healthy controls(HC) were isolated by CD19+micro-beads. IL-6 and BAFF levels in PB and SF were measured by ELISA. MiR-155 and PU.1 expression in B cells from PB and SF of RA; and in ST samples of osteoarthritis(OA) and RA patients was determined by qPCR. Finally, PB-derived B cells were cultured with or without IL-6(30ng/ml) or BAFF(20ng/ml) and miR-155 and PU.1 expression was assessed by qPCR. Result(s): 29 out of 60 RA patients(49.2%) had follicular pattern in the ST biopsy. These patients were more likely ACPA positive compared to RA with a diffuse pattern(p=0.04). Moreover, ACPA plasma levels directly correlated with the synovial aggregate grade(r=0.39;p=0.01). IL -6 and BAFF levels were higher in SF than in PB of RA regardless of the synovial infiltrate pattern(p=0.001 for both). PB B-cells from ACPA positive RA showed higher miR-155 expression compared to ACPA negative RA(p=0.02) and HC(p=0.001). Furthermore, ISH showed that miR-155 was highly expressed in ST of follicular RA compared to diffuse RA(p=0.03). Double staining revealed that the majority of B cells within synovial follicular structures were miR-155 positive. qPCR further confirmed that miR-155 was significantly increased in ST of follicular RA compared to diffuse RA(p=0.03) and OA(p=0.03), respectively. Consistently, the expression of miR-155 target in B cells, PU.1 was found to be lower within synovial aggregates in RA. At the cellular level, miR-155 was highly expressed in PB-derived B-cells of RA compared to HC(p=0.0002). In addition, miR-155 was over-expressed in SF B-cells compared to matched PB B-cells(p=0.05) in RA. This was associated with reciprocal lower expression of PU.1 in SF-derived B-cells and within ST follicular structures compared to matched PB Bcells(p=0.001) and ST with a diffuse pattern, respectively. Finally, in vitrostimulation of HC B-cells with IL-6 and BAFF induced miR- 155(p=0.04 and p=0.03) and decreased PU.1(p=0.01 and p=0.03) expression. Conclusion(s): B-cells of RA show high expression of miR-155 that is associated with ACPA positivity, follicular synovial pattern and low expression of PU.1. IL-6 and BAFF that are significantly increased in the SF environment and induce miR-155 expression in B-cells in vitro are likely candidates for maintaining high levels of miR-155 in the synovial B cells. Thus, miR-155 may represent a key regulator of B-cells in RA patients.

Alivernini, S., et al. (2015). "MicroRNA-155/PU.1 axis as an epigenetic regulator of B-cell activation in rheumatoid arthritis." Annals of the Rheumatic Diseases **2)**: 195.

Background: MicroRNA-155 (miR-155) has been shown to be a key regulator of B cell biology. The regulation of the transcription factor PU.1 by miR-155 is required for high-affinity IgG1 production and B cell maturation. However, the role of miR-155 in the activation of B in Rheumatoid Arthritis (RA) has not been explored. Objective(s): To investigate miR-155 expression in RA B cells and its association with B cell activation and synovial inflammation. Method(s): 53 RA patients underwent synovial (ST) biopsy. ST samples were categorized on a basis of immunostaining for CD68, CD21, CD3 and CD20 cells as diffuse or aggregate pattern. MiR-155 expression in RA ST was evaluated by in situ hybridization (ISH)(n=15). B cells from peripheral blood (PB) and matched synovial fluid (SF) of RA (n=19) and PB of healthy controls

(HC)(n=10) were isolated by CD19+ microbeads. B-cell subsets were determined through Flow-Cytometry. IL-6 and BAFF levels in PB and SF were measured by ELISA. MiR-155 and PU.1 expression was determined by qPCR in B cells from PB and SF of RA (n=10) and on ST samples of osteoarthritis (OA)(n=3), RA diffuse (n=8) and RA aggregate (n=8) patients. Finally, HC PB B cells (n=5) were cultured with or without IL-6 (30ng/ml) or BAFF (20ng/ml) and miR-155 and PU.1 expression was assessed by qPCR. Result(s): 23 (43,4%) RA patients had an aggregate pattern of ST biopsy. RA with an aggregate pattern were more likely anti-CCP+ compared to RA with diffuse pattern (p=0.04).Moreover, anti-CCP plasma levels directly correlated with the synovial aggregate grade (r=0.39; p=0.01). IL-6 and BAFF levels were higher in SF than in PB of RA regardless of the synovial infiltrate pattern (p=0.001 for both). ISH showed that miR-155 was expressed at significantly higher levels in ST of aggregate RA compared to diffuse RA (p=0.03). qPCR further confirmed that miR-155 was significantly increased in ST of aggregate RA compared to diffuse RA (p=0.03) and OA (p=0.03) respectively. Consistently, PU.1 staining was found to be lower within synovial lymphoid aggregates in RA patients. On the single cell level, miR-155 was expressed significantly higher in RA PB B-cells compared to HC (p=0.0002). In addition, miR-155 was over-expressed in SF B-cells compared to matched PB B-cells (p=0.05) in RA. Consistently, PU.1 expression was lower in SF B-cells compared to matched PB B-cells (p=0.001). Moreover, anti-CCP+ RA showed higher miR-155 expression in PB B-cells compared to anti-CCPRA (p=0.02) and HC (p=0.001). CD19+/IgD-CD27- cells were significantly overrepresented in PB of aggregate compared to diffuse RA (p=0.04). Finally, IL-6 and BAFF in vitro stimulation of HC B-cells induced miR-155 overexpression (p=0.04 and p=0.03) whereas PU.1 was significantly down-regulated (p=0.01 and p=0.03). Conclusion(s): MiR-155 is over-expressed in B-cells of RA and is associated to anti-CCP positivity, an aggregate synovial pattern and a PU.1 lower expression. IL-6 and BAFF are significantly increased in the SF environment and induce in vitro miR-155 expression in B-cells. Thus, miR-155 may represent a key regulator of B-cells in RA patients with a memory phenotype.

Aljaibachi, R. and A. Callaghan (2018). "Impact of polystyrene microplastics on Daphnia magna mortality and reproduction in relation to food availability." PeerJ **6**: e4601.

Microplastics (MPs) in the environment continue to be a growing area of concern in terms of acute and chronic impacts on aquatic life. Whilst increasing numbers of studies are providing important insights into microparticle behaviour and impacts in the marine environment, a paucity of information exists regarding the freshwater environment. This study focusses on the uptake, retention and the impact of 2 micro m polystyrene MPs in the freshwater cladoceran Daphnia magna in relation to food intake (algae Chlorella vulgaris), with MP size chosen to approximately match the cell size of the algae. Daphnia were exposed to varied concentrations of MPs and algae. When exposed to a single concentration of MPs Daphnia almost immediately ate them in large quantities. However, the presence of algae, even at low concentrations, had a significant negative impact on MP uptake that was not in proportion to relative availability. As MP concentrations increased, intake did not if algae were present, even at higher concentrations of MPs. This suggests that Daphnia are selectively avoiding eating plastics. Adult Daphnia exposed to MPs for 21 days showed mortality after seven days of exposure in all treatments compared to the control. However significant differences were all related to algal concentration rather than to MP concentration. This suggests that where ample food is present, MPs have little effect on adults. There was also no impact on their reproduction. The neonate toxicity test confirmed previous results that mortality and reproduction was linked to availability of food rather than MP concentrations. This would make sense in light of our suggestion that Daphnia are selectively avoiding eating microplastics.

Al-Jaibachi, R., et al. (2019). "Examining effects of ontogenic microplastic transference on Culex mosquito mortality and adult weight." Science of the Total Environment **651**(Part 1): 871-876.

Microplastics (MPs) continue to proliferate and pollute aquatic and terrestrial environments globally. The impacts of MP pollution on ecosystems and their functioning remain poorly quantified, with most research hitherto focusing on marine ecosystems. There is a paucity of information on the impacts of MPs in freshwater ecosystems, despite the broad range of pathways through which MPs can proliferate and the extensive range of species which actively ingest MPs in these systems. Of particular interest are organisms that bridge aquatic and terrestrial habitats. The present study thus examines the uptake, ontogenic transference and effect of different concentrations (0, 50, 100 and 200 MPs mL⁻¹) and sizes (2 and 15 micro m) of polystyrene MPs between aquatic and terrestrial life stages of Culex pipiens complex mosquitoes. Both 2 and 15 micro m MPs transferred from the aquatic larval to terrestrial adult stage of Culex mosquitoes, and uptake correlated tightly with initial exposure concentration. However, neither concentration nor size of MPs significantly influenced mortality rates between the aquatic larval and terrestrial adult stage. There was also no impact of MPs on the weight of emerging mosquito adults. We thus demonstrate that MPs can be transferred ontogenically through organisms with complex life histories, presenting a potential pathway for dispersal of MPs into terrestrial environments. We also show that MPs exposure does not affect mortality rates between life stages of freshwater Culex populations. This suggests that MPs do not impact nutritional uptakes, with unhampered development to adulthood facilitating subsequent dispersal of MPs aerially and between freshwater and terrestrial habitats.

Al-Katib, A., et al. (2019). "Isolation and characterization of a CD34⁺ sub-clone in B-cell lymphoma." Blood. Conference: 61st Annual Meeting of the American Society of Hematology, ASH **134**(Supplement 1).

Non-Hodgkin's lymphoma (NHL) is the most common hematological malignancy in the US. Many types remain incurable despite response to initial therapy and achievement of complete remission (CR). Advanced laboratory techniques like multicolor flow cytometry (MCF) and polymerase chain reaction (PCR) have demonstrated persistence of rare malignant cell population post therapy referred to as minimal residual disease (MRD). However, the functional and biological characteristics of this population have not been fully elucidated. Established B-lymphoma cell lines (B-NHL) and patient-derived samples (PDS) were analyzed using 8-color FCM of leukemia and lymphoma antibody panels (28 antibodies). The CD34⁺ sub-population was enriched using in vitro exposure to 2-chlorodeoxyadenosine (2-CdA), and a CD34-coated magnetic beads isolation procedure (Miltenyi Biotech). Genetic analysis of CD34⁺ and CD34-/parent cell fractions was done by karyotyping, and by chromosomal microarray (CMA) using the oligonucleotide-single nucleotide polymorphism (Oligo-SNP), whole genome Agilent 180K GGXChip⁺SNP (Agilent Technologies, Inc). Sensitivity to chemotherapy was assayed by short-term in vitro exposure to drugs. Clonogenicity was determined by soft agar colony formation assay, and proliferation was determined using DNA staining with propidium iodide and flow cytometry. The side population was determined using the fluorescent vital dye Hoechst 33342 and flow cytometry. Analysis of three B-NHL cell lines revealed the presence of a minute sub-clone (<1%) of monotypic B-cells that expresses CD34. This sub-population enriched several folds in response to exposure of the cells to 2-CdA. Enrichment was highest in the follicular lymphoma cell line, WSU-FSCCL reaching more than 50 folds compared with control (13.2% vs 0.26%), followed by WSU-WM, 10-fold (2.36% vs 0.23%), and least in WSU-DLCL2 (1.25% vs 0.71%). Using a CD34 microbead positive selection technique, we were able to enrich the CD34⁺ population up to 80% purity. Western blots confirmed higher expression of CD34 protein in the enriched population compared with parent cells. Using StemPro media (Gibco by Life Technologies), CD34⁺ cell fraction of WSU-WM showed more sustained growth and viability in culture over 9-day period compared with parent cells. This technique allowed the generation of large number of CD34⁺ cells for further characterization. Except for CD34 expression, this cell fraction expressed identical phenotype, karyotype, SNP and MCA profile to parent cells. However, the CD34⁺ fraction was more proliferative with an increase in S-phase cells (~60% vs 20% in control cells) and Hoechst 33342-positive cells (~40%). These cells were clonogenic even in presence of the cytotoxic agents Doxorubicin and 2-CdA that completely inhibited colony formation in parent cells. Resistance to chemotherapy was also noticed in liquid culture. A CD34⁺ population within clonal B-cells was also detected in 8 of 8 PDS. The lowest number of CD34⁺ cells was detected in chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) and the highest (5.35%) was seen in Richter's transformation of CLL. The isolated CD34⁺ cells in this study show many features of what is known as Lymphoma Stem Cells implicated in resistance to therapy and disease recurrence. Its relatedness to MRD cells is uncertain, however, since CD34 is not routinely included in MRD antibody panel. The observation that CD34⁺ cells are genetically identical to parent cells suggests an epigenetic modification. This conclusion is supported by our finding that Ehd3 expression is dramatically reduced in the CD34⁺ cell population of WSU-DLCL2 compared with parent cells. Ehd3 was recently identified as an epigenetically-silenced gene in solid tumors and in hematological malignancies including leukemia and lymphoma. The Ehd3-encoded protein belongs to the family of C-terminal Eps15 homology domain-containing (EHD) prot ins, implicated in intracellular trafficking of tubular recycling endosomes (TRE), apoptosis, and cell cycle arrest. Further studies are underway to determine the contribution of Ehd3 to the biological and functional characteristics of the CD34⁺ cells in B-NHL. Utilizing the CD34⁺ monotypic B-cells in B-NHL as a model for screening new therapeutic agents and to identify potential new therapeutic strategies may lead to a more effective treatment of B-NHL.

Alkayyali, T., et al. (2019). "Microfluidic and cross-linking methods for encapsulation of living cells and bacteria - A review." Analytica Chimica Acta **1053**: 1-21.

Microencapsulation of living cells is a field that has been heavily investigated by many researchers over the past two decades. Numerous experimental setups have been developed to encapsulate living cells in microbeads using different microfluidic devices and materials. Previous studies have investigated different microfluidic devices and materials for use in cancer treatment, drug delivery, environmental remediation, food production, and cell culture contexts. Some of the current challenges to these setups are maintaining reasonable levels of cell viability, cell leaching, nutrient and oxygen diffusion, and ensuring uniform microbead shape and size distribution. Addressing these issues and identifying the most reproducible and convenient setup enables researchers to efficiently encapsulate living cells and further advance the biomedical field. The efficiency of microencapsulation in terms of cell viability and uniform microbead shape and size distribution are directly related to the type of device used and the cross-linking method applied. Hence, the focus of this review is to assess the effects of using T-junction, flow-focusing, and co-flow microfluidic devices as well as thermal, ionic, and photo cross-linking methods for the microencapsulation of living cells. Recent applications of bacteria microencapsulation using microfluidic systems since 2017 are presented.

Allam, A. N. and M. M. Mehanna (2016). "Formulation, physicochemical characterization and in-vivo evaluation of ion-sensitive metformin loaded-biopolymeric beads." Drug Development and Industrial Pharmacy **42**(3): 497-505.

The demand on the controlled release of short acting antidiabetic drug, metformin (MT), has been increased dramatically. Thus, boosting the development of new sustained release formulations with contents of multi-micro-scaled particles. This paved the way for the preparation of MT-loaded Gellan gum (GG) microbeads through inotropic gelation technique. The prepared beads were characterized for the following parameters; yield and loading efficiency particle size, particles morphology and topography, swelling behavior, and in-vitro release studies. In view of any possible interactions, differential scanning calorimetry and infrared spectroscopy were performed. As an ultimate evaluation, the relative bioavailability of the sustained release beads was studied in healthy volunteers after oral administration in a fasted state compared to commercially available immediate and extended release tablets using a new validated HPTLC method for MT assay in urine. Results obtained revealed that the formulated Gellan beads were spherical in shape with less smooth surface in the micron range with high yield and entrapment efficiency. In-vitro release studies of the prepared beads were achieved up to 8 h. The prolonged release of MT can be explained through various factors among them; the swelling of the biopolymer and the ionic interaction between the drug and the GG. After oral administration, the AUC<inf>0-24</inf>, t<inf>1/2</inf> and t<inf>max</inf> of the prepared beads were of 246.74 +/- 26.81 mg, 11.84 +/- 2.79 and 7.17 +/- 1.75 h, respectively, demonstrating its bioequivalence to the marketed products. In conclusion, the formulated GG microbeads exhibit potentials as an oral sustained release MT system. Copyright © 2015 Taylor & Francis.

Allen, A. S., et al. (2017). "Chemoreception drives plastic consumption in a hard coral." Marine Pollution Bulletin **124**(1): 198-205.

The drivers behind microplastic (up to 5 mm in diameter) consumption by animals are uncertain and impacts on foundational species are poorly understood. We investigated consumption of weathered, unfouled, biofouled, pre-production and microbe-free National Institute of Standards plastic by a scleractinian coral that relies on chemosensory cues for feeding. Experiment one found that corals ingested many plastic types while mostly ignoring organic-free sand, suggesting that plastic contains phagostimulents. Experiment two found that corals ingested more plastic that wasn't covered in a microbial biofilm than plastics that were biofilmed. Additionally, corals retained ~ 8% of ingested plastic for 24 h or more and retained particles appeared stuck in corals, with consequences for energetics, pollutant toxicity and trophic transfer. The potential for chemoreception to drive plastic consumption in marine taxa has implications for conservation. Copyright © 2017 Elsevier Ltd

Allen, B., et al. (2019). "Microplastic freshwater contamination: an issue advanced by science with public engagement." Environmental Science & Pollution Research **26**(17): 16904-16905.

Allen, S., et al. (2019). "Atmospheric transport and deposition of microplastics in a remote mountain catchment." Nature Geoscience **12**(5): 339-344.

Plastic litter is an ever-increasing global issue and one of this generation's key environmental challenges. Microplastics have reached oceans via river transport on a global scale. With the exception of two megacities, Paris (France) and Dongguan (China), there is a lack of information on atmospheric microplastic deposition or transport. Here we present the observations of

atmospheric microplastic deposition in a remote, pristine mountain catchment (French Pyrenees). We analysed samples, taken over five months, that represent atmospheric wet and dry deposition and identified fibres up to ~750 µm long and fragments ≤300 µm as microplastics. We document relative daily counts of 249 fragments, 73 films and 44 fibres per square metre that deposited on the catchment. An air mass trajectory analysis shows microplastic transport through the atmosphere over a distance of up to 95 km. We suggest that microplastics can reach and affect remote, sparsely inhabited areas through atmospheric transport.

Allione, A., et al. (2016). "Anticoagulants used in plasma collection affect adipokine multiplexed measurements." Cytokine **80**: 43-47.

Obesity is an important health problem worldwide. Adipose tissue acts as an endocrine organ that secretes various bioactive substances, called adipokines, including pro-inflammatory biomarkers such as TNF-alpha, IL-6, leptin and C-reactive protein (CRP) and anti-inflammatory molecules such as adiponectin. The deregulated production of adipokines in obesity is linked to the pathogenesis of various disease processes and monitoring their variation is critical to understand metabolic diseases. The aim of this study was to determine the plasma concentration of adipokines in healthy subjects by multiplexed measurements and the effect of anticoagulants on their levels. Plasma samples from 10 healthy donors were collected in two different anticoagulants (sodium citrate or heparin). All markers, excluding TNF-alpha, showed significantly higher concentrations in heparinized compared to citrate plasma. However, levels of adipokines in different plasma samples were highly correlated for most of these markers. We reported that different anticoagulants used in the preparation of the plasma samples affected the measurements of some adipokines. The importance of the present results in epidemiology is relevant when comparing different studies in which blood samples were collected with different anticoagulants.

Alloush, J., et al. (2014). "Contribution of tripartite motif proteins modulating membrane repair to the pathogenesis of autoimmune-mediated myositis." Arthritis and Rheumatology **10)**: S966-S967.

Background/Purpose: The idiopathic inflammatory myopathies are a heterogeneous group of diseases that result in autoimmunity toward muscles and lead to tissue destruction, but the pathogenesis remains largely unknown. Synaptotagmin VII-knockout (Syt VII^{-/-}) mice display mild myositis and we have previously demonstrated that combining this genetic defect with regulatory T-cell deficiency (FoxP3^{-/Y}) results in a robust inflammatory myositis when adoptively transferred into immunodeficient (RAG1^{-/-}) recipients. Interestingly, Syt VII^{-/-} mice have impaired sarcolemmal membrane resealing capacity, which allows exposure of intracellular antigens. Tripartite motif (TRIM) proteins have also been linked to membrane repair capacity and are associated with myopathy in human patients. Here, we examined protein expression levels and subcellular localization of several novel TRIM proteins linked to membrane repair capacity in muscle tissue from mice using the Syt VII^{-/-}/FoxP3^{-/Y} model of myositis. Method(s): Membrane repair was monitored in vitro in cells using an established assay where the membrane of cultured cells is physically disrupted by glass microbeads. Mouse skeletal muscle was collected from wild type mice exercised on a treadmill or RAG1^{-/-} mice adoptively transferred with lymph node preparations from Syt VII^{-/-}/FoxP3^{-/Y} mice. Tissue was analyzed by standard Western immunoblotting and by immunohistochemistry. Result(s): We identified multiple TRIM family proteins that can modulate membrane repair capacity in cultured cells. Our results show that TRIM27 translocates to the membrane of injured muscle cells in vivo, as shown by immunohistochemistry. Similarly, when mice were exposed to membrane disruption due to eccentric contractions during treadmill running, there was translocation of TRIM27 from a diffuse pattern to the damaged membrane. In skeletal muscle of RAG1^{-/-} mice, expression of several TRIM proteins, including TRIM27, was altered and displayed differential subcellular localization. Conclusion(s): We have identified altered expression and localization of TRIM proteins in muscle in this mouse model of myositis. These results highlight an association of decreased sarcolemmal membrane integrity in the development of myositis and suggest a mechanism that could be targeted for diagnostics and therapeutics in these diseases. (Figure Presented).

Al-Maaded, M., et al. (2012). "An Overview of Solid Waste Management and Plastic Recycling in Qatar." Journal of Polymers & the Environment **20**(1): 186-194.

Municipal solid waste management (MSWM) constitutes one of the most crucial health and environmental problems facing authorities in the Arabian Gulf. Recent literature on current solid waste management (SWM) in Qatar has been reviewed in this paper, and a focused study has been carried out to provide a review on the total amount of municipal solid waste generated, stored, collected, disposed as well as the constituents of the waste. The analysis showed that Qatar produced around 2,000,000 tons of solid municipal waste annually, corresponding to a daily generation rate per capita of about 2.5 kg. About 60% of MSW is organic material and about 300 kg is composed daily. Landfill and composting is considered the most appropriate waste disposal techniques in Qatar. Um-Al-Afai landfill has nearly 80% of MSW. Because of the increased migration in Qatar, there is a sharp rise in the volume and also in the variety of solid waste. It is important to alleviate societal concerns over the increased rate of resource consumption and waste production; thus, policy makers have encouraged recycling and reuse strategies to reduce the demand for raw materials and to decrease the quantity of waste going to landfill. An example of the benefit of mechanical recycling of plastics compared to land filling and composting was conducted by GaBi 4 life cycle analysis tool which showed the benefits to the global warming and human toxicity. Recycling is the favored solution for plastic waste management, because it has a lower environmental impact on the defined impact categories, from Global Warming Potential (GWP) and Human Toxicity Potentials (HTP) indicators. [ABSTRACT FROM AUTHOR]

Almari, B., et al. (2019). "Fabrication of Amyloid-beta-Secreting Alginate Microbeads for Use in Modelling Alzheimer's Disease." Journal of Visualized Experiments **149**: 06.

According to the amyloid cascade hypothesis, the earliest trigger in the development of Alzheimer's disease (AD) is the accumulation of toxic amyloid-beta (Abeta) fragments, eventually leading to the classical features of the disease: amyloid plaques, neurofibrillary tangles and synaptic and neuronal loss. The lack of relevant non-transgenic preclinical models reflective of disease progression is one of the main factors hindering the discovery of effective drug treatments. To this end, we have developed a protocol for the fabrication of alginate microbeads containing amyloid-secreting cells useful for the study of the effects of chronic Abeta production. Chinese hamster ovary cells previously transfected with a human APP gene, secreting Abeta (i.e., 7PA2 cells), were used in this study. A three-dimensional (3D) in vitro model for the sustained release of Abeta was fabricated by encapsulation of 7PA2 cells in alginate. The process was optimized to target a bead diameter of 500-600 mum for further in vivo studies. Optimization of 7PA2 cell encapsulation in alginate was performed altering fabrication parameters, e.g., alginate concentration, gel flow rate, electrostatic potential, head vibration frequency, gelling solution. Levels of secreted Abeta were analyzed over time and compared between alginate beads and standard cell culture methods (up to 96 h). A concentration of 1.5 x 10⁶ 7PA2 cells/mL and an alginate concentration of 2% (w/v) buffered with HEPES and subsequent gelation in 0.5 M calcium chloride for 5 min were found to fabricate the most stable microbeads. Fabricated microbeads were 1) of uniform size, 2) with an average diameter of 550 mum, 3) containing about 100-150 cells per microbead and 4) able to secrete Abeta. In conclusion, our optimized method for the production of stable alginate microbeads containing amyloid-producing 7PA2 cells might enable the modeling of important aspects of AD both in vitro and in vivo.

Almeida, C. M. R., et al. (2019). "Adsorption of Cd and Cu to different types of microplastics in estuarine salt marsh medium." Marine Pollution Bulletin **(no pagination)**(110797).

This study aimed to investigate if microplastics (MPs) type (polyethylene microspheres (mPE), fishing line fibers, film plastic bags MPs and bottle cap particles) and aging affect MPs capacity to sorb Cd or Cu in estuarine salt marsh medium. Tests were carried out in elutriate solution, a simple medium obtained by mixing rhizosediment (sediment in contact with plants roots) with the respective estuarine water, that can be used to simulate water-sediment exchanges in estuarine salt marsh environments. After 7 days of exposure, metals adsorption was only detected for film MPs. No differences were observed between virgin and aged MPs. Salinity also did not influence metal adsorption to mPE. Present results indicate that in estuarine salt marsh areas some types of MPs might adsorb metals, which could affect metals availability. Copyright © 2019 Elsevier Ltd

Almeida, E. L., et al. (2019). "In silico Screening and Heterologous Expression of a Polyethylene Terephthalate Hydrolase (PETase)-Like Enzyme (SM14est) With Polycaprolactone (PCL)-Degrading Activity, From the Marine Sponge-Derived Strain Streptomyces sp. SM14." Frontiers in Microbiology **10**: 2187.

Plastics, such as the polyethylene terephthalate (PET), are widely used for various industrial applications, due to their physicochemical properties which are particularly useful in the packaging industry. However, due to improper plastic waste management and difficulties in recycling, post-consumer plastic waste has become a pressing issue for both the environment and for human health. Hence, novel technologies and methods of processing plastic waste are required to address these issues. Enzymatic-assisted hydrolysis of synthetic polymers has been proposed as a potentially more efficient and environment-friendly alternative to the currently employed methods. Recently, a number of PET hydrolases have been described, and in particular a PETase derived from Ideonella sakaiensis 201-F6 (IsPETase), which appears to be the most efficient and substrate-specific bacterial PET hydrolase enzyme discovered to date. In order to further investigate this class of PETase-like enzymes, we employed an in silico-based screening approach on the biotechnologically relevant genus Streptomyces, including terrestrial and marine isolates; in a search for potential PETase homologs. From a total of 52 genomes analyzed, we were able to identify three potential PETase-like enzymes, all of which were derived from marine-sponge associated Streptomyces isolates. A candidate PETase-like gene (SM14est) was identified in Streptomyces sp. SM14. Further in silico characterization of the SM14est protein sequence and its predicted three-dimensional structure were performed and

compared to the well-characterized IsPETase. Both the serine hydrolase motif Gly-x1-Ser-x2-Gly and the catalytic triad Ser, Asp, His are conserved in both sequences. Molecular docking experiments indicated that the SM14est enzyme possessed the capacity to bind plastics as substrates. Finally, polyesterase activity was confirmed using a polycaprolactone (PCL) plate clearing assay which is a model substrate for the degradation of plastics; following heterologous expression of SM14est in Escherichia coli, with secretion being facilitated by the native Streptomyces signal peptide. These findings provide further insights into this important class of PETase-like enzymes.

Almeida, M., et al. (2019). "Polystyrene nanoplastics alter the cytotoxicity of human pharmaceuticals on marine fish cell lines." Environmental Toxicology & Pharmacology **69**: 57-65.

There is an increasing concern on the consequences of the presence of micro(nano)plastics to marine organisms. The present study aimed to provide information on the effects of polystyrene nanoplastics (PSNPs) to fish cells alone and combined with human pharmaceuticals, other emerging contaminants, using as biological models marine fish cell lines SAF-1 and DLB-1. Cells were exposed for 24 h to 100 nm PSNPs, starting at 0.001 up to 10 mg/L, to assess effects on viability and activity of catalase (antioxidant defense) and glutathione S-transferases (phase II biotransformation and antioxidant defense). The viability of cells was also evaluated after exposure to human pharmaceuticals alone and combined with PSNPs. Overall, PSNPs failed to be cytotoxic but data proved their ability to alter the toxicity of human pharmaceuticals. DLB-1 was the most sensitive cell line to PSNPs. Data support the use of marine fish cell lines in the study of the effects of micro(nano)plastics.

Almodovar, J., et al. (2013). "Gradients of physical and biochemical cues on polyelectrolyte multilayer films generated via microfluidics." Lab on a Chip **13**(8): 1562-1570.

The cell microenvironment is a complex and anisotropic matrix composed of a number of physical and biochemical cues that control cellular processes. A current challenge in biomaterials is the engineering of biomimetic materials which present spatially controlled physical and biochemical cues. The layer-by-layer assembly of polyelectrolyte multilayers (PEM) has been demonstrated to be a promising candidate for a biomaterial mimicking the native extracellular matrix. In this work, gradients of biochemical and physical cues were generated on PEM films composed of hyaluronan (HA) and poly(l-lysine) (PLL) using a microfluidic device. As a proof of concept, four different types of surface concentration gradients adsorbed onto the films were generated. These included surface concentration gradients of fluorescent PLL, fluorescent microbeads, a cross-linker, and one consisting of a polyelectrolyte grafted with a cell adhesive peptide. In all cases, reproducible centimeter-long linear gradients were obtained. Fluorescence microscopy, Fourier transform infrared spectroscopy and atomic force microscopy were used to characterize these gradients. Cell responses to the stiffness gradient and to the peptide gradient were studied. Pre-osteoblastic cells were found to adhere and spread more along the stiffness gradient, which varied linearly from 200 kPa-600 kPa. Myoblast cell spreading also increased throughout the length of the increasing RGD-peptide gradient. This work demonstrates a simple method to modify PEM films with concentration gradients of non-covalently bound biomolecules and with gradients in stiffness. These results highlight the potential of this technique to efficiently and quickly determine the optimal biochemical and mechanical cues necessary for specific cellular processes. © 2013 The Royal Society of Chemistry.

Almroth, B. C. and H. Eggert (2019). "Marine Plastic Pollution: Sources, Impacts, and Policy Issues."

Review of Environmental Economics & Policy **13**(2): 317-326.

Plastics have been instrumental in providing access to clean drinking water, medical applications, and improved hygiene and food safety. However, plastics also cause problems. More than 10 million tons of plastic enter the oceans annually. Marine plastic pollution has documented impacts on marine organisms and ecosystem services. The use of chemical additives in plastics also poses a potential threat to human health. While desirable, recycling of plastics is currently constrained by material and chemical complexity, limitations in available technologies, and market demands. This article provides a brief introduction to plastic materials, marine plastic pollution, and its potential effects on marine ecosystems and human health. We also discuss some of the policy and technical issues and suggest priorities for further research. [ABSTRACT FROM AUTHOR]

Almustapha, M. N., et al. (2019). "Modification of acidic and textural properties of a sulphated zirconia catalyst for efficient conversion of high-density polyethylene into liquid fuel." Environmental Science & Pollution Research **10**: 10.

Consumption of plastic has a rapid increase of about 8% per annum and reached to 400 million per tonnes approximately, where about 50% of plastic was disposed after using only once. Different techniques for treating this increased waste faced a number of issues related to cost and environmental and sustainable development. Catalytic conversion has been found as one of the most viable solutions to solve this problem. Sulphated zirconia (SZ) catalyst modified with calcium carbide (CC) was found to improve high-density polyethylene (HDPE) conversion into liquid fuel. The liquid content was improved from 39.0wt% to 66.0wt% at 410 degreeC. HDPE was converted 100% by weight using, SZ/CC with 66wt% liquid yield as compared to the conversion of approximately 98wt% with about 40wt% only liquid yield for the pure SZ. The composition of hydrocarbon liquid product was significantly changed from paraffin (16%) and aromatic (58%) to olefin (74%) and naphthenic (23%) compounds. This significant increase in liquid was related to changes in the acidic and textural characteristics of the new hybrid catalyst, SZ/CC where the total ammonia desorption of 337.0 mum NH₃/g for the SZ was modified to 23.4 mum NH₃/g for the SZ/CC. Both SZ and SZ/CC catalysts showed characteristics of mesoporous material, where the internal pore volume of SZ had reduced from 0.21 mL/g for SZ to 0.04 mL/g for SZ/CC. Furthermore, XRD analysis indicated the presence of a new compound, CaZrO₃ in the SZ/CC, which confirmed a chemical interaction between the SZ and CC through sintering of ZrO₂ and CaO. Therefore, the SZ/CC catalyst improves the liquid yield significantly and the selectivity towards olefinic and naphthenic compounds.

Alomar, C. and S. Deudero (2017). "Evidence of microplastic ingestion in the shark Galeus melastomus Rafinesque, 1810 in the continental shelf off the western Mediterranean Sea." Environmental Pollution **223**: 223-229.

Microplastic (<5 mm) ingestion has been recorded in Galeus melastomus, the blackmouth catshark, around the Balearic Islands. In total 125 individuals were analyzed for microplastic ingestion. Results have shown that 16.80% of the specimens had ingested a mean value of 0.34

+/- 0.07 microplastics/individual. Stomach fullness index ranged from 0.86 to 38.89% and regression analyses showed that fuller stomachs contained more microplastics. A higher quantity of filament type microplastics were identified compared to granular or hard plastic type. No significant differences were given between ingestion values of two locations over the continental shelf providing further evidence of the ubiquitous distribution of microplastics. The findings in this study reflect the availability of this man made contaminant to marine species in seafloor habitats. Based on results from this study, data on microplastic ingestion could be used to study trends in the amount and composition of litter ingested by marine animals in accordance with descriptor 10 of the Marine Strategy Framework Directive. Copyright © 2017 Elsevier Ltd

Alomar, C., et al. (2016). "Microplastics in the Mediterranean Sea: Deposition in coastal shallow sediments, spatial variation and preferential grain size." Marine Environmental Research **115**: 1-10.
Marine litter loads in sea compartments are an emergent issue due to their ecological and biological consequences. This study addresses microplastic quantification and morphological description to test spatial differences along an anthropogenic gradient of coastal shallow sediments and further on to evaluate the preferential deposition of microplastics in a given sediment grain fraction. Sediments from Marine Protected Areas (MPAs) contained the highest concentrations of microplastics (MPs): up to 0.90 +/- 0.10 MPs/g suggesting the transfer of microplastics from source areas to endpoint areas. In addition, a high proportion of microplastic filaments were found close to populated areas whereas fragment type microplastics were more common in MPAs. There was no clear trend between sediment grain size and microplastic deposition in sediments, although microplastics were always present in two grain size fractions: 2 mm > x > 1 mm and 1 mm > x 0.5 mm.

Alomar, C., et al. (2017). "Microplastic ingestion by Mullus surmuletus Linnaeus, 1758 fish and its potential for causing oxidative stress." Environmental Research **159**: 135-142.
A total of 417 striped red mullet, Mullus surmuletus, were analyzed to study microplastic ingestion and livers of fish were assessed to study effects of microplastics. Nearly one third (27.30%) of the individuals were quantified to ingest microplastics although there was no evidence of oxidative stress or cellular damage in the liver of fish which had ingested microplastics. A small increase in the activity of glutathione S-transferase (GST) of M. surmuletus was detected which could be suggesting an induction of the detoxification systems but these findings should be tested in laboratory conditions under a controlled diet and known concentration of microplastics. Fish from trammel fisheries, operating closer to land and targeting larger individuals, showed higher mean ingestion values than fish from trawling fisheries, and were related to body size, as microplastics ingested increased with total fish length. Consequently, ingestion values of microplastics were not related to sampling distance from land giving further evidence of the ubiquity of microplastics in the marine environment. Finally, Fourier Transform Infrared Spectroscopy (FTIR) analysis showed that the vast majority of microplastics were filament type and polyethylene terephthalate (PET) was the main identified component.

Al-Salem, S. M. (2019). "Influential parameters on natural weathering under harsh climatic conditions of mechanically recycled plastic film specimens." Journal of Environmental Management **230**: 355-365.
In this work, real life reclaimed plastic solid waste (PSW) secured from the municipal sector was mechanically recycled and compounded with virgin linear low density polyethylene (LLDPE). The compounding of the plastic film samples utilised the means of extrusion and blown filming to

produce various formulations of the blends containing up to 100% (by weight) of the PSW in the examined specimens. The film samples were compared to market products used in the State of Kuwait where PSW accumulation presents a major obstacle. Natural weathering under arid and harsh climatic conditions was also performed to determine the degradation extent of the film samples. Haze (%), light transmission (%) and the total change in colour (DELTAE) were measured as indicators to the degradation profile of the polymeric materials, in addition to tensile pull mechanical properties. Properties were noted to deteriorate as a function of weathering time and waste content. Statistical analysis was also performed on the properties measured and climatic conditions including airborne pollutants levels. The abundance of the secondary airborne pollutant (ozone) was determined to be a significant variable on the studied properties. This can be attributed to induced photo-oxidation the polymeric matrix is subjected to under such climatic conditions which increases oxygen diffusion throughout the polymeric matrix. Future development of the recycled blends studied in this work can be a route for the decrease of associated environmental stressors with virgin plastic resin conversion.

Al-Salem, S. M., et al. (2017). "A review on thermal and catalytic pyrolysis of plastic solid waste (PSW)." Journal of Environmental Management **197**: 177-198.

Plastic plays an important role in our daily lives due to its versatility, light weight and low production cost. Plastics became essential in many sectors such as construction, medical, engineering applications, automotive, aerospace, etc. In addition, economic growth and development also increased our demand and dependency on plastics which leads to its accumulation in landfills imposing risk on human health, animals and cause environmental pollution problems such as ground water contamination, sanitary related issues, etc. Hence, a sustainable and an efficient plastic waste treatment is essential to avoid such issues. Pyrolysis is a thermo-chemical plastic waste treatment technique which can solve such pollution problems, as well as, recover valuable energy and products such as oil and gas. Pyrolysis of plastic solid waste (PSW) has gained importance due to having better advantages towards environmental pollution and reduction of carbon footprint of plastic products by minimizing the emissions of carbon monoxide and carbon dioxide compared to combustion and gasification. This paper presents the existing techniques of pyrolysis, the parameters which affect the products yield and selectivity and identify major research gaps in this technology. The influence of different catalysts on the process as well as review and comparative assessment of pyrolysis with other thermal and catalytic plastic treatment methods, is also presented.

Al-Salem, S. M., et al. (2019). "Study of the degradation profile for virgin linear low-density polyethylene (LLDPE) and polyolefin (PO) plastic waste blends." The Journal of Material Cycles and Waste Management **21**(5): 1106-1122.

In this study, the properties of virgin linear low-density polyethylene (LLDPE) and its blends with reclaimed plastic solid waste (PSW) are investigated by thermogravimetry, differential scanning calorimetry (DSC), infrared spectroscopy and scanning electron microscopy (SEM). The PSW constituted polyolefin (PO) polymers recycled mechanically via extrusion/blown-film and exposed to accelerated weathering tests to determine the change in their degradation behaviour. The oxidation products determined using the FTIR analysis and thermal stability studies points toward the blend constituting 25% of waste by weight as the most stable. Changes in crystallinity of the polymers were attributed to the crystal size change as a consequence of the weathering mechanism. The DSC results revealed that both oxidation induction temperature (OIT) and crystallinity were affected by the PO waste content. This points towards the impact of polymers immiscibility and polydispersity within the matrix of the blends due to chain scission reaction and oxidation with the UV exposure.

Al-Salem, S. M., et al. (2019). "On the Kinetics of Degradation Reaction Determined Post Accelerated Weathering of Polyolefin Plastic Waste Blends." International Journal of Environmental Research & Public Health [Electronic Resource] **16**(3): 30.

Polyolefin (PO) polymers constitute the majority of consumer plastic commodities. The reliance on such materials make it near imposable to avoid touching one in any given day. Therefore, the accumulation of plastic solid waste (PSW) in developed and developing societies alike requires immediate attention to manage and valorize this type of waste. In this work, PSW originating from real life sources and virgin linear low-density polyethylene (LLDPE) films were compounded in a mechanical recycling effort. The recycled blends constituted up to 100% (by weight) of the waste material. Accelerated weathering (aging) was conducted on the blends, reaching threshold limit of exposure to study the major changes occurring on the recycled blends. Thermogravimetry and differential scanning calorimetry (DSC) were used to determine their characteristics and applicability for future recycling using thermo-chemical treatment (TCT) methods. Analytical solution methods following the international committee of thermal analysis and calorimetry (ICTAC) were followed in conducting the measurements and kinetic calculations alike. A novel analytical mathematical solution model is also introduced to determine both the pre-exponential factor (A_o) and apparent activation energy (E_a) of the degradation reaction. The model proved to be a more accurate analysis tool, and the work in whole enabled the determination of future plans for using such waste components as a feedstock to thermal units.

Alshawafi, A., et al. (2017). "Assessment of marine debris on the coastal wetland of Martil in the North-East of Morocco." Marine Pollution Bulletin **117**(1-2): 302-310.

Plastic waste at the coastal wetland in Martil beach in the North-East of Morocco is one of the problems that have appeared recently. This study aims to characterize the marine debris in the coast of Martil during the year 2015. The sampling is seasonally by type and size. The result shows, for the macro debris, the abundance of plastic (57%), lumber and paper (21.93%), cloth and fabric (7.8%), glass (5.42%), metal (4.40%), and rubber (3.4%). Micro debris is also present in the area in several forms such as wood, plants, and others by 75,63%. This was followed by the foam (26,95%), line (7,8%), and the film (1,23%). The seasonal variation (S1: January-March and S3: July to September) are the most polluted months of the year. The sources of marine debris are mainly tourism (beach users), land (run off), and commercial fishing in the four seasons of the year. Copyright © 2017 Elsevier Ltd

Al-Sid-Cheikh, M., et al. (2018). "Uptake, Whole-Body Distribution, and Depuration of Nanoplastics by the Scallop Pecten maximus at Environmentally Realistic Concentrations." Environmental Science & Technology **52**(24): 14480.

Previous studies of uptake and effects of nanoplastics by marine organisms have been conducted at what may be unrealistically high concentrations. This is a consequence of the analytical challenges in tracking plastic particles in organisms at environmentally relevant concentrations and highlights the need for new approaches. Here, we present pulse exposures of 14C-radiolabeled nanopolystyrene to a commercially important mollusk, Pecten maximus, at what have been predicted to be environmentally relevant concentrations (<15 μg L–1). Uptake was rapid and was greater for 24 nm than for 250 nm particles. After 6 h, autoradiography showed accumulation of 250 nm nanoplastics in the intestine, while 24 nm particles were dispersed throughout the whole-body, possibly indicating some translocation across epithelial

membranes. However, depuration was also relatively rapid for both sizes; 24 nm particles were no longer detectable after 14 days, although some 250 nm particles were still detectable after 48 days. Particle size thus apparently influenced the biokinetics and suggests a need for chronic exposure studies. Modeling extrapolations indicated that it could take 300 days of continued environmental exposure for uptake to reach equilibrium in scallop body tissues although the concentrations would still below 2.7 mg g–1. Comparison with previous work in which scallops were exposed to nonplastic (silver) nanomaterials of similar size (20 nm), suggests that nanoparticle composition may also influence the uptake tissue distributions somewhat.

Altinok, H., et al. (2008). "COVALENT IMMOBILIZATION OF INVERTASE ON CHEMICALLY ACTIVATED POLY (STYRENE-2-HYDROXYETHYL METHACRYLATE) MICROBEADS." Journal of Food Biochemistry **32**(3): 299-315.

ABSTRACTA carrier for invertase enzyme was synthesized from styrene (S) and 2- hydroxyethyl methacrylate (HEMA) in the form of microbeads. These poly (styrene-2-hydroxyethyl methacrylate), P(S-HEMA) microbeads were activated by epichlorohydrin (ECH) treatment for covalent immobilization. The free and immobilized invertase were assayed in the hydrolysis of sucrose to glucose, and the obtained results were compared. The optimum pH was 4.5 for free and 5.5 for immobilized invertase. The optimum temperature of invertase shifted from 45C to 55C upon immobilization. For free and immobilized enzymes, kinetic parameters were calculated as 4.1 10-3molL-1and 9.210-3molL-1fo r Km, and 6.610-2molL-1&# x2003; min-1and 4.110-1molL-1&# x2003; min-1for Vmax, respectively. After 1 month of storage at 4C, free enzyme retained 36% of its initial activity, while for the ECH-activated P(S-HEMA) immobilized enzyme, P(S-HEMA)-E, this value was observed as 67%. In repeated batch use, i.e., 20 times in 3 days, 78% retention of the initial activity was observed for P(S-HEMA)-E system.PRACTICAL APPLICATIONSImmobilization of enzymes are very important for many industrial applications, e.g., food, medicine, pharmacology, etc. Invertase converts sucrose to glucose and fructose, which have wide applications in food industry especially as sweeteners. Glucose-fructose mixture has much lower crystallinity compared to sucrose and therefore used in the production of noncrystallizing jams and creams. They are also used as liquid sweeteners. Immobilization enables repeated use, provides significant reduction in the operation costs, facilitates easy separation and speeds up recovery of enzyme and extends the stability of enzyme by protecting the active material from deactivation. Industrial application of immobilized invertase may decrease the production cost of glucose-fructose mixture because it could be used repeatedly for long periods. Although invertase is not a very expensive enzyme, the technique can also be applied to expensive ones for biotechnological productions.

Altomare, D. F., et al. (2008). "Carbon-coated microbeads anal injection in outpatient treatment of minor fecal incontinence." Diseases of the Colon & Rectum **51**(4): 432-435.

PURPOSE: Anal bulking agents are injected to pose a stronger obstacle to the involuntary passage of feces and gas. This prospective, multicenter study was designed to evaluate the safety and efficacy of Durasphere anal injection for the treatment of fecal incontinence.

PATIENTS AND METHODS: Thirty-three unselected patients with incontinence (24 females; mean age, 61.5 +/- 14 (range, 22-83) years) underwent anal bulking agent submucosal injection with carbon-coated microbeads (Durasphere) in the outpatient regimen. The causes of incontinence were obstetric lesions in 18.2 percent, iatrogenic in 36.4 percent, rectal surgery in 12.1 percent, and idiopathic in 33.3 percent. Previous unsuccessful treatments for fecal incontinence included diet and drugs in 16 patients, biofeedback training in 7 patients, sacral nerve modulation in 6 patients, sphincteroplasty in 2 patients, artificial bowel sphincter in 1 patient, and PTQ

macroplastique bulking agent in 1 patient. Under local anesthesia and antibiotic prophylaxis, a mean of 8.8 (range, 2-19) ml of Durasphere were injected into the submucosa by using a 1.5-inch, angled, 18-gauge needle.

RESULTS: After a median follow-up of 20.8 (range, 10-22) months, the median Cleveland Clinic continence score decreased significantly from 12 to 8 (P < 0.001) and the median American Medical System score from 89 to 73 (P = 0.0074), but the Fecal Incontinence Quality of Life did not change significantly (74 to 76, P = not significant). Anal manometry significantly improved (resting pressure increasing from 34 to 42 mmHg; P = 0.008) and squeezing pressure from 66 to 79 mmHg (P = 0.04). Two patients complained of moderate anal pain for a few days after the implant, one patient had asymptomatic leakage of the injected material through a mucosa perforation, and two had distal migration of the Durasphere along the dentate line.

CONCLUSIONS: Anal bulking agent injection is a safe treatment and can mitigate the severity of fecal incontinence by increasing anal pressure but does not significantly improve the quality of life.

Alvarez, G., et al. (2018). "The use of European shag pellets as indicators of microplastic fibers in the marine environment." Marine Pollution Bulletin **137**: 444-448.

Microplastic particles are abundant marine pollutants that are ingested by many seabirds. Some seabirds regurgitate non-digestible materials in the form of pellets and their analysis may be useful to study the abundance of plastic debris at the local scale. Here, we aimed to provide baseline data for the presence of microplastics in pellets regurgitated by European shags (Phalacrocorax aristotelis) (n=41) in the Iberia peninsula (NW Spain). We found microplastic fibers in 63% of pellets, suggesting that this type of plastic pollution is prevalent in the study area. According to Fourier Transform Infrared spectrometry, nylon fibers were the most abundant, followed by polyester. We also found that the presence of microplastics was higher in pellets containing remains of benthic fishes. Our results suggest that shag pellets may be useful to monitor microplastic pollution in coastal waters.

Alvarez-Hernandez, C., et al. (2019). "Microplastic debris in beaches of Tenerife (Canary Islands, Spain)." Marine Pollution Bulletin **146**: 26-32.

The occurrence and composition of microplastics (1-5 mm) was evaluated in six beaches of the island of Tenerife (Canary Islands, Spain). Two of them were located at the North coast (El Socorro and San Marcos) and the rest in the South littoral (Leocadio Machado, El Poris, Los Abriguitos and Playa Grande). Sampling was developed during the months of October, November and December 2018 (depending on the beach) above the high tide line. Isolated microplastics were identified by attenuated total reflection infrared spectroscopy. All the beaches showed a relatively low content of microplastics, below 3.5 g/m², which is also below 0.069 g/L of sand, except for Playa Grande, which showed an average content of 99 g/m² or 2.0 g/L of sand. Tar pollution (around 18%) was also found in Playa Grande. The major polymers found were polyethylene, polypropylene and polystyrene, accounting for 69%, 18% and 4%, respectively. Alves, V. E., et al. (2016). "Do different degrees of human activity affect the diet of Brazilian silverside Atherinella brasiliensis?" Journal of Fish Biology **89**(2): 1239-1257.

The aim of the present study was to test whether different degrees of human activity affect the diet of the Brazilian silverside Atherinella brasiliensis in two tropical estuaries. Fish were collected along the salinity gradient of two Brazilian estuaries, the heavily impacted Paraiba Estuary and the less impacted Mamanguape Estuary, in the dry and wet seasons. The findings confirm that A. brasiliensis has generalist feeding habits and is able to change its diet under different environmental conditions. The results indicate clear spatial (i.e. along the estuarine gradient) changes in diet composition in both estuaries, but diet was also influenced by the degree of anthropogenic disturbance. During the wet season in the nutrient enriched Paraiba Estuary, when human activity was higher, the diet of A. brasiliensis was poorer and dominated by few dietary items, reflecting the potential impoverishment of prey items in this heavily disturbed system. The specimens collected in the most affected estuary also had a greater frequency of micro-plastics and parasites in their stomachs, reflecting the greater degree of human disturbance in the estuary. The present findings suggest that the diet of A. brasiliensis could be a useful indicator of changes in the ecological quality of these and other tropical estuaries of the western Atlantic Ocean.

Alves, V. E. N. and G. M. Figueiredo (2019). "Microplastic in the sediments of a highly eutrophic tropical estuary." Marine Pollution Bulletin **146**: 326-335.

Given the implications of microplastics contamination in aquatic ecosystems and information scarcity about microplastic abundances in estuarine sediments, this study aimed to quantify and describe the microplastics in the sublittoral sediments from Guanabara Bay. Sediment samples were collected at four sites and three months, microplastics were separated and classified according to type, color, size, and polymer composition. High abundances of microplastic (160 to 1000 items kg⁻¹ or 4367 to 25,794 items m⁻²) occurred independent of area or period, indicating microplastics are widely spread in Guanabara Bay. The dominant microplastic in the sediment was the translucent polyester microfiber of <1 mm size; which is a secondary microplastic, possibly coming from washing machines wastes. The extremely high availability of microplastics in Guanabara Bay, compared to the majority of studies around the world, suggests high risk of contamination to benthic organisms and demersal fish, as they may be ingesting microplastics.

Amamiya, K., et al. (2019). "Evidence of transport of styrene oligomers originated from polystyrene plastic to oceans by runoff." Science of the Total Environment **667**: 57-63.

This study demonstrates for the first time that styrene oligomers (SOs), which are indicators of polystyrene (PS) plastic contamination in the environment, are transported from land to the ocean. Samples of sand and seawater were taken from the coastline of the Tokyo Bay over the past four years, and all samples of both sand and seawater were found to contain SOs such as styrene monomer (SM), styrene dimers (SD), and styrene trimers (ST), with the concentration distributions of these being in the order of ST>SD>SM. The concentrations of these SOs are linearly proportional to monthly precipitation. These results indicate that various land-based SOs sources are connected with the estuary, a substantial amount of which are transported into Tokyo Bay through runoff as overland flow. As a result, runoff by precipitation is a potential transport pathway of land-based SOs sources. This finding is of interest in terms of both the extent of PS plastic pollution and the transport of SOs to the ocean. CAPSULE ABSTRACT: The assessment of the transport of styrene oligomers (SOs) in the coastal environment is performed.

Amand, L. E. and H. Kassman (2013). "Decreased PCDD/F formation when co-firing a waste fuel and biomass in a CFB boiler by addition of sulphates or municipal sewage sludge." Waste Management **33**(8): 1729-1739.

Polychlorinated dibenzo-p-dioxins (PCDDs) and polychlorinated dibenzofurans (PCDFs) are formed during waste incineration and in waste-to-energy boilers. Incomplete combustion, too short residence times at low combustion temperatures (<700degreeC), incineration of electronic waste and plastic waste containing chlorine are all factors influencing the formation of PCDD/Fs

in boilers. The impact of chlorine and catalysing metals (such as copper and iron) in the fuel on PCDD/F formation was studied in a 12MW<inf>th</inf> circulating fluidised bed (CFB) boiler. The PCDD/F concentrations in the raw gas after the convection pass of the boiler and in the fly ashes were compared. The fuel types were a so-called clean biomass with low content of chlorine, biomass with enhanced content of chlorine from supply of PVC, and solid recovered fuel (SRF) which is a waste fuel containing higher concentrations of both chlorine, and catalysing metals. The PCDD/F formation increased for the biomass with enhanced chlorine content and it was significantly reduced in the raw gas as well as in the fly ashes by injection of ammonium sulphate. A link, the alkali chloride track, is demonstrated between the level of alkali chlorides in the gas phase, the chlorine content in the deposits in the convection pass and finally the PCDD/F formation. The formation of PCDD/Fs was also significantly reduced during co-combustion of SRF with municipal sewage sludge (MSS) compared to when SRF was fired without MSS as additional fuel. © 2013 Elsevier Ltd.

Amaya-Delgado, L., et al. (2006). "Hydrolysis of sucrose by invertase immobilized on nylon-6 microbeads." Food Chemistry **99**(2): 299-304.

A commercial extracellular invertase (EC 3.2.1.26) from Saccharomyces cerevisiae has been inmobilized by covalent bonding on novel microbeads of nylon-6 using glutaraldehyde. The enzyme was strongly bound on the support, immobilized with an efficiency factor of 0.93. The biocatalyst showed a maximum enzyme activity when immobilized at pH 5.0, but optimum pH activity for both immobilized and free invertases was 5.5. The optimum temperatures for immobilized and free enzymes were 60 and 65 degreeC, respectively. Kinetic parameters were determined for immobilized and free invertases: V<inf>max</inf> values were 1.37 and 1.06 mmol min⁻¹ mg⁻¹, respectively. The K<inf>m</inf> and K<inf>i</inf> values were 0.029 and 0.71 M for immobilized invertase and 0.024 and 0.69 M for free invertase. It was found that the thermal stability of the immobilized invertase with regard to the free one increased by 25% at 50 degreeC, 38% at 60 degreeC and 750% at 70 degreeC. The immobilized biocatalyst was tested in a tubular fixed-bed reactor to investigate its possible application for continuous sucrose hydrolysis. The effects of two different sugar concentrations and three flow rates on the productivity of the reactor and on the specific productivity of the biocatalyst were studied. The system demonstrated a very good productivity up to 2.0 M sugar concentration, with conversion factors of 0.95 and 0.97, depending on sucrose concentration in the feeding. This approach may serve as a simple technique and can be a feasible alternative to continuous sucrose hydrolysis in a fixed bed reactor for the preparation of fructose-rich syrup. © 2005 Elsevier Ltd. Ambrose, C. A., et al. (2002). "Diversion from landfill: Quality products from valuable plastics." Resources, Conservation and Recycling **36**(4): 309-318.

Mechanical recycling of 100% post-consumer plastic waste into high-quality products has been performed. The chemical and physical properties of these recycled materials have been compared with similar products manufactured from virgin resins. The properties of a blow-moulded bottle prepared from 100% post-consumer high-density polyethylene (HDPE) showed that this recycled polymer exceeded the materials specifications for virgin plastic designs. Similarly, a sample of thermoplastic polyolefin (TPO, 100% polypropylene), obtained entirely from shredder residue (SR) displayed sufficient material strength for future separation and reprocessing. © 2002 Elsevier Science B.V. Ambrose, K. K., et al. (2019). "Spatial trends and drivers of marine debris accumulation on shorelines in

South Eleuthera, The Bahamas using citizen science." Marine Pollution Bulletin **142**: 145-154.

This study measured spatial distribution of marine debris stranded on beaches in South Eleuthera, The Bahamas. Citizen science, fetch modeling, relative exposure index and predictive mapping were used to determine marine debris source and abundance. Citizen scientists quantified debris type and abundance on 16 beaches within three coastal exposures (The Atlantic Ocean, Great Bahama Bank and The Exuma Sound) in South Eleuthera. Marine debris, (~2.5cm or larger) on each beach was monitored twice between March-May and September-November 2013 at the same locations using GPS. Approximately, 93% of all debris items were plastic with plastic fragments (<=2.5cm) being the most common. There were spatial differences (p<=0.0001) in plastic debris abundance between coastal exposures. Atlantic Ocean beaches had larger quantities of plastic debris by weight and by meter (m) of shoreline. Stranded plastic may be associated with Atlantic Ocean currents associated with leakage from the North Atlantic sub-tropical gyre.

Ambrosini, R., et al. (2019). "First evidence of microplastic contamination in the supraglacial debris of an alpine glacier." Environmental Pollution **253**: 297-301.

Contamination by plastic debris has been documented in most regions of the world, but their occurrence in high mountain areas has not been investigated to date. Here we present the first report of the occurrence and amount of microplastic in any terrestrial glacier environment. In the supraglacial debris of the Forni Glacier (Italian Alps), we observed the occurrence of (mean+/-standard error) 74.4+/-28.3 items kg⁻¹ of sediment (dry weight). This amount is within the range of variability of microplastic contamination observed in marine and coastal sediments in Europe. Most plastic items were made by polyesters, followed by polyamide, polyethylene and polypropylene. We estimated that the whole ablation area of Forni Glacier should host 131-162 million plastic items. Microplastic can be released directly into high elevation areas by human activities in the mountain or be transported by wind to high altitude. The occurrence of microplastic on Forni Glacier may be due to the gathering of debris coming from the large accumulation area into the relatively smaller ablation area of the glacier, as a consequence of its flow and melting.

Amelineau, F., et al. (2016). "Microplastic pollution in the Greenland Sea: background levels and selective contamination of planktivorous diving seabirds." Environmental Pollution **219**: 1131-1139.

Microplastics have been reported everywhere around the globe. With very limited human activities, the Arctic is distant from major sources of microplastics. However, microplastic ingestions have been found in several Arctic marine predators, confirming their presence in this region. Nonetheless, existing information for this area remains scarce, thus there is an urgent need to quantify the contamination of Arctic marine waters. In this context, we studied microplastic abundance and composition within the zooplankton community off East Greenland. For the same area, we concurrently evaluated microplastic contamination of little auks (Alle alle), an Arctic seabird feeding on zooplankton while diving between 0 and 50 m. The study took place off East Greenland in July 2005 and 2014, under strongly contrasted sea-ice conditions. Among all samples, 97.2% of the debris found were filaments. Despite the remoteness of our study area, microplastic abundances were comparable to those of other oceans, with 0.99+or-0.62 m⁻³ in the presence of sea-ice (2005), and 2.38+or-1.11 m⁻³ in the nearby absence of sea-ice (2014). Microplastic rise between 2005 and 2014 might be linked to an increase in plastic production worldwide or to lower sea-ice extents in 2014, as sea-ice can represent a sink for microplastic particles, which are subsequently released to the water column upon melting. Crucially, all birds had eaten plastic filaments, and

they collected high levels of microplastics compared to background levels with 9.99 and 8.99 pieces per chick meal in 2005 and 2014, respectively. Importantly, we also demonstrated that little auks took more often light colored microplastics, rather than darker ones, strongly suggesting an active contamination with birds mistaking microplastics for their natural prey. Overall, our study stresses the great vulnerability of Arctic marine species to microplastic pollution in a warming Arctic, where sea-ice melting is expected to release vast volumes of trapped debris.

Amengual, O., et al. (2009). "Up-regulated expression of phospholipid scramblase 1 on monocytes in patients with antiphospholipid syndrome." Arthritis and Rheumatism **10)**: 2046.

Purpose: It is worldwide accepted that the interaction between phospholipid (PL)-binding proteins and antiphospholipid antibodies (aPL) triggers tissue factor expression, leading to thrombotic events in patients with antiphospholipid syndrome (APS), but the precise mechanisms underlying thrombosis in APS are not yet clarified. Normal circulating cells show an asymmetric distribution of PL in the membranes with amino-PL, such as phosphatidylserine (PS), restricted to the cytoplasmic leaflets. Externalization of PS occurs in activated cells and is crucial for the activation of the coagulation cascade, as PS serves as an assembly site for coagulation factors. Moreover, PS exposure is essential for the binding of PL-binding protein-aPL complexes to pro-coagulant cells, favoring aPL-mediated cell activation and thrombosis. One of the key molecules involved in the regulation of PS externalization is phospholipid scramblase 1 (PLSCR1) which catalyzes rapid transbilayer movement of PL between membrane leaflets. PLSCR1 was reported to be up-regulated by interferon alpha, but its role in APS pathogenesis is unknown. In this study, we examined the expression of PLSCR1 on pro-coagulant cells in patients with APS. Method(s): The study includes 40 patients with APS (35 women, mean age 50 yrs, [range 26-76 yrs]). 17 patients had primary APS and 23 were diagnosis as having systemic lupus erythematosus (SLE). Forty-three healthy individuals were included as a control group. Heparinized venous blood was collected from all the subjects. PBMC were isolated and monocytes purified using CD14 micro beads (Miltenyi Biotec). Total RNA was isolated and reverse- transcribed using SuperScriptTM First-Strand Synthesis System (Invitrogen). Quantitative Real-Time PCR was performed using gene-specific PLSCR1 Taq Man MGB Probe and the ABI PRISM 7000 Sequence Detection System. PS exposure on monocyte surface was evaluated by flow-cytometry using the Annexin-V Fluos labeling kit (Roche). Result(s): Monocytes from APS patients had higher levels of PLSCR1 mRNA expression than those from healthy controls (mean +/- SD; 2.4 +/- 1.2 vs. 1.3 +/- 0.4, p < 0.00001). Levels of PLSCR1 mRNA were significantly elevated in both group of APS patients compared to controls (2.2 +/- 0.9, 2.6 +/- 1.4, p= 0.001, p= 0.0003, primary APS and APS/SLE, respectively). However, the increased PS expression in patients with APS was minor compared to controls (20.6 +/- 8.2 vs. 17.8 +/- 5.8). Conclusion(s): Patients with APS have enhanced expression of PLSCR1 on monocytes. Even though the presence of PS on monocytes may be related not only to PLSCR1 expression but to several mechanisms, the up-regulation of PLSCR1 expression in APS might represent a contributing factor in the hypercoagulability in APS.

Amereh, F., et al. (2019). "Thyroid endocrine status and biochemical stress responses in adult male Wistar rats chronically exposed to pristine polystyrene nanoplastics (Electronic supplementary information (ESI) available. See DOI: 10.1039/c9tx00147f)." Toxicology Research **8**(6): 953-963.

Toxicity evaluations of micro- or nano-sized plastics in rodent species commonly employed for toxicity analyses based on which risk assessment for humans could be performed are still largely lacking. Given this knowledge gap, the present work was aimed at determining the potential

impact of chronic exposure to polystyrene nanoplastics (PS NPs) on the thyroid endocrine status and biochemical stress in a rat model. Young adult male rats were orally administered with PS NPs (1, 3, 6 and 10 mg kg−1 day−1) for five weeks. Thyroid hormones (THs) l-thyroxine (T4), l-triiodothyronine (T3), l-free triiodothyronine (FT3), and l-free thyroxine (FT4) as well as thyroid stimulating hormone (TSH) serum levels of normal rats and those exposed to PS NPs were compared. Serum levels of high-density lipoprotein (HDL), low-density lipoprotein (LDL), cholesterol, and creatinine, as well as glutamic oxaloacetic transaminase (GOT) and glutamic pyruvic transaminase (GPT) enzymes were also measured. Exposure to PS NPs suppressed the serum levels of T3 and circulating levels of THs, whereas TSH increased significantly. Though exposure to PS NPs did not affect the molar ratios of T3/T4, it induced a slight, but significant, increase in FT3/FT4. In addition, exposure to plastic nanoparticles showed signs of nephrotoxicity induction and kidney injury in exposed organisms as can be inferred from the significantly higher serum levels of creatinine in exposed groups. Our results provide clear evidence of an association between exposure to plastic NPs and thyroid endocrine disruption as well as metabolic deficit, and generate new leads for future research efforts.

Amine, K. M., et al. (2014). "Effect of palmitoylated alginate microencapsulation on viability of Bifidobacterium longum during freeze-drying." LWT Food Science and Technology **56**(1): 111-117.

In the present research the viability of microencapsulated Bifidobacterium longum 15708 by extrusion and spray technique was investigated. Native (NA) and O-palmitoylated (PA) alginate were used as matrix for immobilization. Beads obtained by extrusion were characterized to assess the encapsulation yield (EY). Higher EY (67%) was found for bacteria immobilized in 3% PA. The effects of freeze drying on viability of entrapped B. longum were evaluated. Results indicated that microbeads obtained by spray were the most effective in preserving bacterial viability with a loss of viability of 2 log after 24 h as compared to extrusion beads and free cells where a loss of 2.9 and 2.75 log were respectively observed. No significant difference (P>0.05) between NA and PA was observed. Scanning electron microscopy (SEM) analysis of beads showed globular structures and confirmed differences between the NA and PA alginates as to their appearance (porosity, fatty acid content), while the use of spray contributes to reduce the size of beads by 1/10. Present results showed that several alternatives such as beads size, alginate concentration, as well as polymer functionalization can be managed to allow probiotic viability.

Amiri, S., et al. (2017). "Enhancing purification efficiency of affinity functionalized composite agarose micro beads using Fe₃O₄ nanoparticles." Journal of Chromatography B: Analytical Technologies in the Biomedical & Life Sciences **1041-1042**: 27-36.

In this work, a series of magnetic and nonmagnetic agarose matrices were fabricated for protein purification. Certain amounts of Fe₃O₄ nanoparticles were encapsulated in agarose beads to form composite magnetic matrices with enhanced purification efficiency. Structure and morphology of prepared matrices were studied by optical and scanning electron microscopes, FT-IR, and BET-BJH analysis. The prepared matrices had regular spherical shape, followed by a uniform size distribution. By nanoparticles addition, the number of mesopores decreased while population of pores with radius <=10nm increased; thus, higher specific area achieved. According to VSM results, magnetization degree was one of the characteristics affected by agarose content of the beads. A dye ligand, Cibacron Blue F3GA (CB), was covalently bound to beads to adsorb Bovine serum albumin. CB concentration was determined by elemental analysis. It was shown that magnetic beads hold higher CB concentrations than nonmagnetic ones due to higher specific area. As a result, magnetic

8%-agarose beads had the highest affinity adsorption capacity in static experiments. Moreover, breakthrough curves were monitored to calculate dynamic binding capacity. And, it was shown that magnetic 4%-agarose had the highest adsorbing amount (6.00mg/mL). It was implied that pore diffusion in magnetic 4%-agarose may be the reason for higher dynamic capacity. Plus, column efficiency was evaluated. It was revealed that all magnetic beads had lower HETP (0.11, 0.12 and 0.11cm for magnetic 4, 6, and 8%-agarose beads) than nonmagnetic ones (P-value<0.05).

Amoatey, P. and M. S. Baawain (2019). "Effects of pollution on freshwater aquatic organisms." Water Environment Research **91**(10): 1272-1287.

This paper presents the reviews of scientific papers published in 2018 issues on the effects of anthropogenic pollution on the aquatic organisms dwelling in freshwater ecosystem at global scale. The first part of the study provides the summary of relevant literature reviews followed by field and survey based studies. The second part is based on categories of different classes/sources of pollutants which affect freshwater organism. This is composed of several sections including metals and metalloids, wastewater and effluents, sediments, nutrients, pharmaceuticals, polycyclic aromatic hydrocarbons, flame retardants, persistent organic pollutants, pharmaceuticals and illicit drugs, emerging contaminants, pesticides, herbicides, and endocrine disruptors. The final part of the study highlights the reviews of published research work on new pollutants such as microplastics and engineered nanoparticles which affect the freshwater organisms. PRACTITIONER POINTS: Heavy metals concentrations should be assessed at nano-scale in aquatic environment. Air pollutants could have long-term effects on freshwater ecosystem. Future studies should focus on bioremediations of freshwater pollution.

Amorim, M. J. B., et al. (2018). "Environmental impacts by fragments released from nanoenabled products: a multiassay, multimaterial exploration by the SUN approach." Environmental Science & Technology **52**(3): 1514-1524.

Nanoenabled products (NEPs) have numerous outdoor uses in construction, transportation or consumer scenarios, and there is evidence that their fragments are released in the environment at low rates. We hypothesized that the lower surface availability of NEPs fragment reduced their environmental effects with respect to pristine nanomaterials. This hypothesis was explored by testing fragments generated by intentional micronisation ("the SUN approach"; Nowack et al. Meeting the Needs for Released Nanomaterials Required for Further Testing: The SUN Approach. Environmental Science & Technology, 2016 (50), 2747). The NEPs were composed of four matrices (epoxy, polyolefin, polyoxymethylene, and cement) with up to 5% content of three nanomaterials (carbon nanotubes, iron oxide, and organic pigment). Regardless of the type of nanomaterial or matrix used, it was observed that nanomaterials were only partially exposed at the NEP fragment surface, indicating that mostly the intrinsic and extrinsic properties of the matrix drove the NEP fragment toxicity. Ecotoxicity in multiple assays was done covering relevant media from terrestrial to aquatic, including sewage treatment plant (biological activity), soil worms (Enchytraeus crypticus), and fish (zebrafish embryo and larvae and trout cell lines). We designed the studies to explore the possible modulation of ecotoxicity by nanomaterial additives in plastics/polymer/cement, finding none. The results support NEPs grouping by the matrix material regarding ecotoxicological effect during the use phase. Furthermore, control results on nanomaterial-free polymer fragments representing microplastic had no significant adverse effects up to the highest concentration tested.

Amrullah, A. (2016). "Gasoline and Synthetic Fuel from Plastic Waste: Study for Engine Performance."

International Journal of Manufacturing, Materials, and Mechanical Engineering **6**(2): 41-50.

Currently the use of motor gasoline from year to year increase. In 2010 the number of vehicles in Indonesia about 26,706,705 vehicles, in 2011 amounted to 30,769,093 vehicles and 2012 amounted to 38,156,278 vehicles. This resulted in the consumption of petroleum fuels and exhaust emissions in motor vehicles is increasing. To overcome these problems, conducted research on synthetic fuel which is one of the alternative fuel sources. This research was conducted at gasoline engine. Variations in fuel mixture gasoline and synthetic fuel. This research will be able to generate and determine the effect of fuel mixture gasoline-synthetic fuel on levels of exhaust emissions, to determine the effect of fuel mixture gasoline-synthetic fuel for engine performance. Based on the analysis of performance and exhaust emissions test on a gasoline engine, for most engine performance is good and efficient set at first to mix synthetic fuel.

Amyot, F., et al. (2002). "A new experimental method for the evaluation of the release profiles of drug-loaded microbeads designed for embolisation." Itbm-Rbm **23**(5): 285-289.

The development of a galenical form must take into account the drug's physico-chemical properties as well as the external conditions that govern its performances. In the case of loaded microbeads designed for embolisation, the drug-release kinetics strongly depends on the local hydrodynamic conditions. Currently the apparatuses recommended by the European Pharmacopoeia allow the measurement in vitro of these kinetics; but the measured kinetics are very different from those met in the in vivo embolisation procedures. A new methodology is presented for evaluating the controlled release of a drug from ion exchange resins for embolisation. Experimental and numerical data are reported on the release kinetics of two closely related galenical formulations (DEAE Trisacryl LS and QAE Trisacryl LS). © 2002 Editions scientifiques et medicales Elsevier SAS.

An, S. S., et al. (2004). "Role of heat shock protein 27 in cytoskeletal remodeling of the airway smooth muscle cell." Journal of applied physiology (Bethesda, Md. : 1985) **96**(5): 1701-1713.

Remodeling of the airway smooth muscle (ASM) cell has been proposed to play an important role in airway hyperresponsiveness. Using a functional assay, we have assessed remodeling of the cultured rat ASM cell and the role of heat shock protein (HSP) 27 in that process. To probe remodeling dynamics, we measured spontaneous motions of an individual Arg-Gly-Asp-coated microbead that was anchored to the cytoskeleton. We reasoned that the bead could not move unless the microstructure to which it is attached rearranged; if so, then its mean square displacement (MSD) would report ongoing internal reorganizations over time. Each bead displayed a random, superdiffusive motion; MSD increased with time as approximately t(1.7), whereas an exponent of unity would be expected for a simple passive diffusion. Increasing concentrations of cytochalasin-D or latrunculin-A caused marked increases in the MSD, whereas colchicine did not. Treatments with PDGF or IL-1beta, but not transforming growth factor-beta, caused decreases in the MSD, the extent of which rank-ordered with the relative potency of these agents in eliciting the phosphorylation of HSP27. The chemical stressors anisomycin and arsenite each increased the levels of HSP27 phosphorylation and, at the same time, decreased bead motions. In particular, arsenite prevented and even reversed the effects of cytochalasin-D on bead motions. Finally, ASM cells overexpressing phospho-mimicking human HSP27, but not wild-type or phosphorylation-deficient HSP27, exhibited decreases in bead motions that were comparable to the arsenite response. Taken together, these results show that phosphorylated HSP27 favors reduced bead motions that are probably due to stabilization of the actin cytoskeleton.

Anarte, C., et al. (2013). "What is the real effect of the annexin v columns on human sperm?" Fertility and Sterility **1)**: S447-S448.

OBJECTIVE: To know whether or not the AnnexinV columns reduce the percentage of apoptosis in human sperm. To assess the effect of the AnnexinV columns on the quality of the sperm samples. DESIGN: Retrospective observational trial. MATERIALS AND METHODS: We analyzed the proportion of apoptotic spermatozoa in 25 patients during the first four months of 2013. All subjects were involved in assisted reproduction treatments at Quiron Bilbao. We studied apoptotic spermatozoa in fresh samples, after capacitation and after sperm was filtered by MACS with AnnexinV microbeads (Annexin negative fraction) by using AnnexinV-FITC/ PI assay with flow cytometry. All patients had >15% of apoptotic spermatozoa in capacitated samples (which is our clinical practice cutoff point). Sperm parameters were measured according to the WHO 2010 criteria. RESULT(S): The average percentage of apoptosis in fresh samples is 31.88+/-22.46, 29,23+/-12.67 in capacitated samples and 13.4+/-7.53 after MACS. A high decrease was observed in concentration from fresh (30.45+/-31.09) and capacitated samples (10.14+/-8.55) comparing to the ones analyzed after MACS (1.42 +/-1.39). The percentage of progressive sperm was (47.93+/-23.87 in fresh 64.16+/-17.67 in capacitated samples and 52.64+/-27.33% after MACS) and the percentage of non-progressive spermatozoa (45.73+/-25.4%, 27.91+/-17.32 to 39.57+/-27.81%). CONCLUSION(S): The percentage of apoptosis in fresh samples is higher, since the seminal plasma has anticapacitating substances and therefore after capacitation this percentage of apoptosis is reduced. Different behaviours were observed in sperm quality parameters. Concentration decreases because apoptotic sperm remains in the filters. A slight increase is observed in the percentage of progressive sperm. Filtering the samples using MACS reduces the percentage of apoptosis but does not make it disappear completely, sowe still need to choose the best spermatozoa to try to get better fertilization rates and better quality embryos.

Anayo, J. M., et al. (2018). "Impact of ultra violet radiation on polyethylene packaged water exposed at varying conditions: Are we drinking micro-plastics?" American Journal of Biochemistry and Biotechnology **14**(1): 20-28.

The public is worried about how their health is impacted by microplastics in sachet water. This awareness has repercussion for water producing factories and public health organization in managing health hazard associated with microplastic ingestion. Many countries in Africa, with concern to Nigeria, the act of packaging water in polyethylene materials by water producing factories has become accustomed. These packaged products are popularly called pure water or sachets water. The packaged materials are made of antioxidants, stabilizers, plasticizers, lubricants, antimicrobials, anti-static and anti-blocking agents. Heat hindrance agents are usually incorporated to improve functionality of polyethylene. It was conceived that the polyethylene material if exposed to sun light radiation over a period of time, its components may leach into the potable water due to photolytic, photo-oxidative and thermo-oxidative reactions caused by fragmentation of the polyethylene material. This research was designed to evaluate the water quality/safety of polyethylene sachet-packaged exposed to direct sunlight at different days. Eighteen polyethylene packaged water were sampled from three different factories - Lion water, Galaxy and Ashor water in Nsukka area of Enugu State. They were exposed to sunlight at 31 to 33degreeC for (24, 48, 72, 96 and 120 h), respectively. Agilent gas chromatography tandem mass spectroscopy was used to analyze the exposed and unexposed (control) packaged water. Organic compounds such as low molecular weight substituted hydrocarbons, polycyclic aromatic hydrocarbons, trichloromethane, benzene, limonene, xylene, toluene and 2-hexanone were detected in all the exposed samples. These micoplastics which leached into water has been listed by the Agency for Toxic Substances and Disease Registry as potential human carcinogens. The concern now is whether we are drinking micoplastics. The only way out of this perceived health risk is to change the packaging material to prevent ingestion of microplastics in water. Anbumani, S. and P. Kakkar (2018). "Ecotoxicological effects of microplastics on biota: a review." Environmental Science & Pollution Research **25**(15): 14373-14396.

The ubiquitous presence of microplastics in the environment has drawn the attention of ecotoxicologists on its safety and toxicity. Sources of microplastics in the environment include disintegration of larger plastic items (secondary microplastics), personal care products like liquid soap, exfoliating scrubbers, and cleaning supplies etc. Indiscriminate usage of plastics and its poor waste disposal management pose serious concern on ecosystem quality at global level. The present review focused on the ecological impact of microplastics on biota at different trophic levels, its uptake, accumulation, and excretion etc., and its plausible mechanistic toxicity with risk assessment approaches. Existing scientific evidence shows that microplastics exposure triggers a wide variety of toxic insult from feeding disruption to reproductive performance, physical ingestion, disturbances in energy metabolism, changes in liver physiology, synergistic and/ or antagonistic action of other hydrophobic organic contaminants etc. from lower to higher trophics. Thus, microplastic accumulation and its associated adverse effects make it mandatory to go in for risk assessment and legislative action. Subsequent research priorities, agenda, and key issues to be addressed are also acknowledged in the present review.

Anda, K. S. D., et al. (2011). "Analysis of the expression of interferon regulatory factors on dendritic cells from systemic lupus erythematosus patients." Arthritis and Rheumatism. Conference: Annual Scientific Meeting of the American College of Rheumatology and Association of Rheumatology Health Professionals **63**(10 SUPPL. 1).

Background/Purpose: Dendritic cells (DC) are a key element between the innate and the adaptative immune responses, they are considered professional antigen presenting cells, and the main source (plasmacytoid DC) of type-I interferon (IFN-I). Elevated levels of IFN- I have been detected in many autoinmune diseases in humans. The genomic and proteomic studies have shown that elevated serum levels of IFN-I and the interferon related genes overexpression are the molecular signature of systemic lupus erythematosus (SLE). The interferon regulatory factors (IRF) are among these upregulated genes. These transcription factors are induced by many different receptors, mainly toll-like receptors and interferon receptors. Diverse genetic association studies have found relationship between many IRF-5 polymorphisms and increased susceptibility to SLE in different ethnic groups. However these studies have been done with total mononuclear cells, which may not reflect specific DC alterations. It is not known if there are alterations in the expression of IRF on DC from SLE patients. The aim of this study was to evaluate the expression of IRF-3 and IRF-5 on DC from SLE patients. Method(s): We included 10 SLE patients (4 with SLEDAI=0, 6 with SLEDAI>6) as well as 10 healthy controls. Peripheral blood mononuclear cells were isolated by Ficoll-Hypaque centrifugation. Monocytes were purified by positive selection with anti-CD14 mAb coated microbeads. DC were generated by culturing monocytes for 6 days in presence of GM-CSF, IL-4 and for 2 additional days in presence of LPS to induce maturation. In vitro generated DC as well as peripheral blood DC defined by the following phenotype, Lin-HLA-DR+CD11c-BDCA-4+, were analyzed for HLA-DR, CD40, IRF3, and IRF5 expression by flow cytometry and Western Blot. Result(s): We found that immature DC from SLE patients shown significantly diminished levels of the CD40 molecule (percentage of CD40+ DC:

control median= 48.8, SLE median= 28, p=0.03). In addition, we observed that expression of IRF-3 and IRF-5 on mature DC from SLE tended to be higher compared with controls (IRF3 MFI mean= 17.7 in controls versus 32.5 in SLE; IRF5 MFI mean=22.1 in controls versus 30.01 in SLE). Furthermore, we found that the expression of these molecules was increased in peripheral blood Lin-HLA-DR+CD11c-BDCA-4+ DC from SLE patients compared with healthy controls (percentage of IRF3 positive cells= 29 in controls versus 76 in SLE; percentage of IRF5 positive cells= 3.6 in controls versus 34.6 in SLE). We found no differences on IRF expression on DC from active SLE and those with inactive disease. Conclusion(s): Our results suggest that the previously reported elevated levels of IFN-I observed in SLE might be explained by the altered expression of IRF on DC from SLE patients. Furthermore, the impaired expression of these factors might be considered as an intrinsic defect in SLE.

Anderson, A. G., et al. (2016). "Microplastics in personal care products: Exploring perceptions of environmentalists, beauticians and students." Marine Pollution Bulletin **113**(1-2): 454-460.

Microplastics enter the environment as a result of larger plastic items breaking down ('secondary') and from particles originally manufactured at that size ('primary'). Personal care products are an important contributor of secondary microplastics (typically referred to as 'microbeads'), for example in toothpaste, facial scrubs and soaps. Consumers play an important role in influencing the demand for these products and therefore any associated environmental consequences. Hence we need to understand public perceptions in order to help reduce emissions of microplastics. This study explored awareness of plastic microbeads in personal care products in three groups: environmental activists, trainee beauticians and university students in South West England. Focus groups were run, where participants were shown the quantity of microbeads found in individual high-street personal care products. Qualitative analysis showed that while the environmentalists were originally aware of the issue, it lacked visibility and immediacy for the beauticians and students. Yet when shown the amount of plastic in a range of familiar everyday personal care products, all participants expressed considerable surprise and concern at the quantities and potential impact. Regardless of any perceived level of harm in the environment, the consensus was that their use was unnatural and unnecessary. This research could inform future communications with the public and industry as well as policy initiatives to phase out the use of microbeads.

Anderson, E. C., et al. (2010). "Investigations of Redox Magnetohydrodynamic Fluid Flow At Microelectrode Arrays Using Microbeads." Analytical Chemistry **82**(7): 2643.

Microbeads are used to track fluid flow over microband electrode arrays to investigate fundamentals of redox magnetohydrodynamics (redox-MHD) in a confined solution. The results may lead toward the design of micro total analysis systems with microfluidics based on the redox-MHD concept. Ion flux was generated by reduction and oxidation of electroactive potassium ferri- and ferrocyanide at selected individually addressable microelectrodes in the array. An external magnetic field was produced by a small, permanent magnet (0.38 T) placed directly below the array with its field perpendicular to the plane of the array. The cross product of ion flux and magnetic field produces a magnetic force (a portion of the Lorentz force equation) that causes the fluid to rotate around the active electrodes. Velocities up to 1.4 mm/s are demonstrated here. The effects on velocities were obtained for different concentrations of redox species, widths of electrodes, gaps between electrodes, and combinations of anodically- and cathodically polarized electrodes. The microbeads allowed mapping of flow patterns and velocities, both parallel and perpendicular to the array chip. The influence of counteracting shear forces, drag along the walls, and reinforcing flow are discussed. A significant result is the

fairly flat flow profile across 650 ...m, attained between electrodes that are oppositely biased. (ProQuest: ... denotes formulae/symbols omitted.)

Anderson, J. A. and A. B. Alford (2014). "Ghost fishing activity in derelict blue crab traps in Louisiana." Marine Pollution Bulletin **79**(1-2): 261-267.

Derelict crab traps impact the coastal ecosystem through continued catch of target species and species of conservation, economic, or recreational importance. During volunteer-supported crab trap cleanups in 2012 and 2013, we quantified ghost fishing activity in derelict crab traps in coastal Louisiana through a citizen scientist program. Volunteers removed 3607 derelict traps during these events, and over 65% of traps analyzed by citizen scientists were actively ghost fishing. Additionally, volunteers identified 19 species enmeshed in derelict traps, including a combination of fresh and saltwater species. We also detected a significant difference in the number of blue crab in actively ghost fishing derelict traps across removal locations with estimated catches varying between 2.4 and 3.5 crabs/trap. Our instantaneous estimates of ghost fishing activity are greater than those previously thought in Louisiana, further justifying current derelict crab trap prevention and removal extension and outreach programs in Louisiana and throughout the Gulf of Mexico. © 2013 Elsevier Ltd.

Anderson, J. C., et al. (2016). "Microplastics in aquatic environments: Implications for Canadian ecosystems." Environmental Pollution **218**: 269-280.

Microplastics have been increasingly detected and quantified in marine and freshwater environments, and there are growing concerns about potential effects in biota. A literature review was conducted to summarize the current state of knowledge of microplastics in Canadian aquatic environments; specifically, the sources, environmental fate, behaviour, abundance, and toxicological effects in aquatic organisms. While we found that research and publications on these topics have increased dramatically since 2010, relatively few studies have assessed the presence, fate, and effects of microplastics in Canadian water bodies. We suggest that efforts to determine aquatic receptors at greatest risk of detrimental effects due to microplastic exposure, and their associated contaminants, are particularly warranted. There is also a need to address the gaps identified, with a particular focus on the species and conditions found in Canadian aquatic systems. These gaps include characterization of the presence of microplastics in Canadian freshwater ecosystems, identifying key sources of microplastics to these systems, and evaluating the presence of microplastics in Arctic waters and biota.

Anderson, P. J., et al. (2017). "Microplastic contamination in Lake Winnipeg, Canada." Environmental Pollution **225**: 223-231.

Microplastics are an emerging contaminant of concern in aquatic ecosystems. To better understand microplastic contamination in North American surface waters, we report for the first time densities of microplastics in Lake Winnipeg, the 11th largest freshwater body in the world. Samples taken 2014 to 2016 revealed similar or significantly greater microplastic densities in Lake Winnipeg compared with those reported in the Laurentian Great Lakes. Plastics in the lake were largely of secondary origin, overwhelmingly identified as fibres. We detected significantly greater densities of microplastics in the north basin compared to the south basin of the lake in 2014, but not in 2015 or 2016. Mean lake-wide densities across all years were comparable and not statistically different. Scanning electron microscopy with energy dispersive X-ray spectroscopy indicated that 23% of isolated particles on average were not plastic. While the ecological impact of microplastics on aquatic ecosystems is still largely unknown, our study contributes to the growing evidence that microplastic contamination is widespread even around sparsely-populated freshwater ecosystems, and provides a baseline for future study and risk assessments.

Anderson, R. V. and D. C. Coleman (1977). "The use of glass microbeads in ecological experiments with bacteriophagic nematodes." Journal of Nematology **9**(4): 319-322.
A system that uses microbeads for the culture of bacteriophgic nematodes is described. Glass-bead culture was found to simulate a soil microcosm more closely than did agar culture i n terms of CO production , number of nematodes produced, and nematode size.

Anderson, T. N. and A. Zarrinpar (2018). "Hepatocyte transplantation: past efforts, current technology, and future expansion of therapeutic potential." Journal of Surgical Research **226**: 48-55.
Hepatic cell transplantation (HCT) continues to garner interest as an alternative to orthotopic liver transplantation and the attendant donor shortage. When compared with solid organ transplantation, advantages of cell transplantation include the potential to treat more patients with a considerably less invasive procedure, the ability to utilize organs otherwise unsuitable for transplant, and leaving the native organ in situ with the potential for regeneration. While studies date back to the early 1960s, advancement of clinical application has been slow due in part to limitations of suitable tissue supplies and reproducible robust techniques. Compared with orthotopic liver transplantation, there are fewer absolute contraindications for donor selection. And, current techniques used to harvest, isolate, store, and even transfuse cells vary little between institutions. Significant variation is seen due to a lack of consensus with maintenance therapy. Although the ideal recipient has not been clearly identified, the most significant results have been demonstrated with correction of congenital metabolic liver disorders, with a few trials examining its utility in cirrhotics and more recently acute liver failure. The most exciting new topic of discussion examines techniques to improve engraftment, with many such as ischemic preconditioning and nonselective partial embolization (microbead therapy), while not yet used in HCT study, showing promise in solid organ research. Advancements in HCT, although slow in progress, have great potential in the ability to alleviate the burden faced in solid organ transplantation and possibly become a long-term viable option, beyond that of a bridge or salvage therapy.

Anderson, Z. T., et al. (2018). "A rapid method for assessing the accumulation of microplastics in the sea surface microlayer (SML) of estuarine systems." Scientific Reports **8**(1): 9428.
Microplastics are an increasingly important contaminant in the marine environment. Depending on their composition and degree of biofouling, many common microplastics are less dense than seawater and so tend to float at or near the ocean surface. As such, they may exhibit high concentrations in the sea surface microlayer (SML - the upper 1-1000 mum of the ocean) relative to deeper water. This paper examines the accumulation of microplastics, in particular microfibres, in the SML in two contrasting estuarine systems - the Hamble estuary and the Beaulieu estuary, southern U.K., via a novel and rapid SML-selective sampling method using a dipped glass plate. Microplastic concentrations (for identified fibres, of 0.05 to 4.5 mm length) were highest in the SML-selective samples (with a mean concentration of 43 +/- 36 fibres/L), compared to <5 fibres/L for surface and sub-surface bulk water samples. Data collected show the usefulness of the dipped glass plate method as a rapid and inexpensive tool for sampling SML-associated microplastics in estuaries, and indicate that microplastics preferentially accumulate at the SML in estuarine conditions (providing a potential transfer mechanism for incorporation into upper intertidal sinks). Fibres are present (and readily sampled) in both developed and more pristine estuarine systems.

Andersson, T. P. M., et al. (2005). "Frog melanophores cultured on fluorescent microbeads: Biomimic-based biosensing." Biosensors and Bioelectronics **21**(1): 111-120.

Melanophores are pigmented cells in lower vertebrates capable of quick color changes and thereby suitable as whole cell biosensors. In the frog dermis skin layer, the large and dark pigmented melanophore surrounds a core of other pigmented cells. Upon hormonal stimulation the black-brown pigment organelles will redistribute within the melanophore, and thereby cover or uncover the core, making complex color changes possible in the dermis. Previously, melanophores have only been cultured on flat surfaces. Here we mimic the three dimensional biological geometry in the frog dermis by culturing melanophores on fluorescent plastic microbeads. To demonstrate biosensing we use the hormones melatonin and alpha-melanocyte stimulating hormone (alpha-MSH) as lightening or darkening stimuli, respectively. Cellular responses were successfully demonstrated on single cell level by fluorescence microscopy, and in cell suspension by a fluorescence microplate reader and a previously demonstrated computer screen photo-assisted technique. The demonstrated principle is the first step towards "single well/multiple read-out" biosensor arrays based on suspensions of different selective-responding melanophores, each cultured on microbeads with distinctive spectral characteristics. By applying small amount of a clinical sample, or a candidate substance in early drug screening, to a single well containing combinations of melanophores on beads, multiple parameter read-outs will be possible. © 2004 Elsevier B.V. Andrade, C. S., et al. (2014). "Biodegradable mulch films performance for autumn-winter strawberry production." Journal of Berry Research **4**(4): 193-202.

An enormous amount of plastic waste resulting from the agricultural activities is produced every year. Part of this plastic remains in the fields, while the other part is sent to recycling or landfill. The use of biodegradable (BD) mulch films can play a key role towards a sustainable development in agricultural sector because they can be plugged in the soil, after its use, together with the crop residues. The aim of this study was to evaluate the performance of white-on-black biodegradable mulch films in contrast to the conventional polyethylene (PE) mulch film in autumn-winter cycle strawberry production, monitoring the variation on soil warming, lifetime of the films in the field as well as the effects on fruit yield. Soil temperatures showed differences among treatments during summer period under open field conditions and autumn-winter season under tunnel. Although the degradation rate of BD mulch films varied along the crop cycle, they provided adequate bed cover and weed suppression until crop end. Plants had similar monthly crop yield distribution, and percentage of commercial and uncommercial fruits between mulch treatments. From the overall results obtained, biodegradable mulch films may be a promising alternative to PE mulching but there should be economic incentives for growers to implement this sustainable practical as its price at present are not yet competitive.

Andrade, J., et al. (2019). "A low-cost system to simulate environmental microplastic weathering." Marine Pollution Bulletin **149 (no pagination)**(110663).

Society concerns about the potential thread of microplastics into the environment call for detailed laboratory and field studies to assess their fate, in particular, their weathering. This can hardly be done in natural conditions and, so, a low-cost system (<EUR 1000) to accelerate photooxidative and hydrolytic weathering is presented in a way that standardizes major marine experimental conditions: incident radiation range, light intensity, temperature and mechanical stress. The system can be valid for many European countries, most US states, and other

intermediate-latitude-countries; otherwise it can be scaled up easily. Validation was done by studying three different polymeric structures: polyamide 6.6, polystyrene and polypropylene. The results agreed nicely with previous reports derived from different working conditions. Therefore, this low-cost system would likely contribute to the standardization of microplastic marine weathering studies by, e.g., improving their intercomparability. Copyright © 2019 Elsevier Ltd

Andrade, M. C., et al. (2019). "First account of plastic pollution impacting freshwater fishes in the Amazon: ingestion of plastic debris by piranhas and other serrasalmids with diverse feeding habits." Environmental Pollution **244**: 766-773.

Reported here is the first evidence of plastic ingestion by freshwater fishes in the Amazon. Plastic bags, bottles, fishing gear, and other products are entering Amazonian water bodies and degrade into meso- and micro-plastic particles that may be ingested, either directly or indirectly via food chains, by fishes. Examination of stomach contents from 172 specimens of 16 serrasalmid species from lower Xingu River Basin revealed consumption of plastic particles by fishes in each of three trophic guilds (herbivores, omnivores, carnivores). Overall, about one quarter of specimens and 80% of species analyzed had ingested plastic particles ranging from 1 to 15 mm in length. Fourier transform infrared spectroscopy indicated 12 polymer types, including 27% identified as polyethylene, 13% polyvinyl chloride, 13% polyamide, 13% polypropylene, 7% poly(methyl methacrylate), 7% rayon, 7% polyethylene terephtalate, and 13% a blend of polyamide and polyethylene terephtalate. Dimensions of ingested plastic particles varied among trophic guilds, even though the frequency and mass of ingested particles were not significantly different among fishes with different feeding habits.

Andrades, R., et al. (2019). "Scavenging as a pathway for plastic ingestion by marine animals." Environmental Pollution **248**: 159-165.

Plastic pollution is prevalent worldwide and affects marine wildlife from urbanized beaches to pristine oceanic islands. However, the ecological basis and mechanisms that result in marine animal ingestion of plastic debris are still relatively unknown, despite recent advances. We investigated the relationship between scavenging behavior and plastic ingestion using green turtles, Chelonia mydas, as a model. Diet analysis of C. mydas showed that sea turtles engaging in scavenging behavior ingested significantly more plastic debris than individuals that did not engage in this foraging strategy. We argue that opportunistic scavenging behavior, an adaptive behavior in most marine ecosystems, may now pose a threat to a variety of marine animals due to the current widespread plastic pollution found in oceans. Scavenging behavior in sea turtles led to high rates and loads of plastic ingestion and may be an important pathway for plastic debris ingestion by marine animals. Copyright © 2019 Elsevier Ltd

Andrades, R., et al. (2016). "Origin of marine debris is related to disposable packs of ultra-processed food." Marine Pollution Bulletin **109**(1): 192-195.

Marine debris is currently distributed worldwide, and the discard and contamination pose hazards to human and wildlife health. One of the gaps in debris science is tracking the source of debris to better evaluate and avoid the pathway of debris from the source to marine environment. For this, we evaluated three beaches of different urbanization levels and environmental influences; a low urbanized beach, a highly urbanized beach and a non-urbanized estuary-associated beach, in order to determine the sources and original use of debris. Plastic was the major material found on beaches, and the urbanized beach recorded the highest debris densities. Marine debris was primarily from land-based sources, and the debris recorded in all beaches was mainly assigned as food-related items. Our results highlight the major presence of disposable and short-lived products comprising the majority of debris that enters the ocean and draw attention to the unsustainable lifestyle of current society.

Andrades, R., et al. (2018). "Marine debris in Trindade Island, a remote island of the South Atlantic." Marine Pollution Bulletin **137**: 180-184.

Marine debris is widespread in oceans worldwide, including the most remote locations. Here, for the first time, we report macro-debris accumulation on beaches of Trindade Island, a remote island 1160km from mainland Brazil. High debris density was recorded on windward, east-coast beaches, which are exposed to wind-driven currents. Small-sized plastic fragments were the most abundant debris. Polyethylene (67%), polypropylene (30%) and polyamide (3%) were the most prevalent polymeric materials identified by ATR-FTIR. Identified debris show that interaction with Trindade fauna, mainly with seabirds and endangered terrestrial crabs, exists and already has some impact. This study provides baseline information on Trindade macro-debris demonstrating that the island, located on the edge of the South Atlantic Gyre, acts as a sink for gyre debris, exposing the island fauna to the threats related to plastic contamination.

Andrady, A. L. (2011). "Microplastics in the marine environment." Marine Pollution Bulletin **62**(8): 1596-1605.

This review discusses the mechanisms of generation and potential impacts of microplastics in the ocean environment. Weathering degradation of plastics on the beaches results in their surface embrittlement and microcracking, yielding microparticles that are carried into water by wind or wave action. Unlike inorganic fines present in sea water, microplastics concentrate persistent organic pollutants (POPs) by partition. The relevant distribution coefficients for common POPs are several orders of magnitude in favour of the plastic medium. Consequently, the microparticles laden with high levels of POPs can be ingested by marine biota. Bioavailability and the efficiency of transfer of the ingested POPs across trophic levels are not known and the potential damage posed by these to the marine ecosystem has yet to be quantified and modelled. Given the increasing levels of plastic pollution of the oceans it is important to better understand the impact of microplastics in the ocean food web. © 2011 Elsevier Ltd.

Andrady, A. L., et al. (2019). "Interactive effects of solar UV radiation and climate change on material damage." Photochemical & Photobiological Sciences **18**(3): 804-825.

Solar UV radiation adversely affects the properties of organic materials used in construction, such as plastics and wood. The outdoor service lifetimes of these materials are influenced by their rates of degradation under solar UV radiation as well as by other climate factors such as temperature, moisture, and atmospheric pollutants. While recovery of the stratospheric ozone layer is expected, local increases in UV radiation are still likely to occur, especially in the tropics, but also elsewhere because of climate change effects. Such increases, when taken together with an increased ambient temperature due to climate change, can significantly shorten the service lifetimes of organic building materials. Several proven technologies, including the use of UV stabilisers, surface treatments or coatings have been developed over the years to mitigate these adverse effects. While these technologies should be able to compensate for any realistic future UV radiation and climate change scenarios, they will also add significantly to the lifetime cost of material in relevant products. Shorter outdoor lifetime of the plastic components in photovoltaic (PV) modules is a serious concern in the solar energy industry. To ensure module durability over the full service-lifetime (of about ~20 years) of the light-harvesting PV components, better stabilisation technologies are being investigated. The present trend towards more environmentally sustainable materials in building, and environmental impact of additives such as stabilisers, need to be considered in addition to their engineering performance. This may require the phasing out of some conventional additives used in plastics as well as substituting wood or other materials in place of plastics in buildings. Depending on the relative costs of mitigation, substituting more UV-stable materials for conventional ones in outdoor products may also be a viable option with some categories of products. Neither the global cost of mitigation of the effects of climate change on materials nor the long-term sustainability of the technologies available for the purpose, have been estimated. Plastic waste and litter exposed outdoors to solar UV radiation over extended periods undergo cracking and fragmentation into small pieces (of micro- and nano-scale size). Release of these fragments into the environment, particularly in the aquatic environment, poses a potential threat to marine biota. Already several hundred of species are known to ingest these fragments that can potentially accumulate additives and pollutants from water. This is a potential threat to humans because 25% of fish marketed for human consumption have been reported to contain microplastics in their digestive systems. The focus of this assessment is on recent advances in understanding the mechanisms of UV-radiation-induced degradation in materials and in assessing emerging technologies for their stabilisation against outdoor UV-degradation. A better understanding of the mechanisms of degradation will allow for innovative stabilisation approaches to be developed. Also assessed is information on the sustainability of the available and emerging UV stabilisation technologies.

Angadi, S. C., et al. (2012). "Novel composite blend microbeads of sodium alginate coated with chitosan for controlled release of amoxicillin." International Journal of Biological Macromolecules **51**(1-2): 45-55.

Composite blend microbeads of sodium alginate (NaAlg) with sodium carboxymethyl cellulose (NaCMC) containing magnesium aluminum silicate (MAS) particles and enteric coated with chitosan have been prepared to achieve controlled release (CR) of amoxicillin in stomach environment. The composite beads have been characterized by X-ray diffraction (XRD) to study drug distribution, DSC for understanding thermal stability and Fourier transform infrared (FTIR) spectroscopy to investigate chemical interactions as well as to assess the structure of the drug-loaded formulations. Surface morphology of the beads was investigated by scanning electron microscopy (SEM). The size distribution of beads loaded with drug as studied by particle size analyzer was in the range of 745-889 mum. The beads exhibited quite widely varying encapsulation efficiencies from 52 to 92%. Equilibrium swelling of the beads measured in water and in vitro release of amoxicillin in pH 1.2 medium suggests that drug release depends on polymer blend composition, concentration of MAS and extent of enteric coating.

Anger, P. M., et al. (2018). "Raman microspectroscopy as a tool for microplastic particle analysis." TrAC - Trends in Analytical Chemistry **109**: 214-226.

This review discusses the identification and quantification of microplastic (MP) using Raman microspectroscopy (RM). It addresses scientists investigating MP in environmental and food samples. We show the benefits and limitations of RM from a technical point of view (sensitivity, smallest particle sizes, speed optimizations, analysis artefacts and background effects) and provide an assessment of the relevance of lab analyses and their interpretation (sample sizes for the analysis, uncertainty of the analysis). All parts are complimented by extensive literature data and a theoretical derivation of the concepts. We conclude with suggestions for a feasible and meaningful RM analysis of MP samples. Copyright © 2018 Elsevier B.V.

Angin, M., et al. (2010). "Successful expansion of functional human regulatory T-cells from individuals

with HIV-1 infection." AIDS Research and Human Retroviruses **26 (10)**: A162.

Background: In the context of HIV-1 infection, the exact impact of regulatory T cells (Tregs) on HIV pathogenesis remains poorly understood. Natural CD4+CD25 +Foxp3+Tregs represent 5-7% of CD4+T cells in healthy donors, however in untreated HIV-1 seropositive individuals absolute CD4 +Treg numbers decrease during disease progression with the overall loss of CD4 T cells, making this population remarkably hard to study. In the present study, we describe an approach to expand functional regulatory T cells from HIV-1 positive individuals. Method(s): Peripheral CD4+CD25+ CD127lo natural Tregs and CD4+CD25-CD127+conventional T cells were isolated from the peripheral blood of individuals with chronic untreated HIV-1 infection, Elite controllers and healthy donors using a FacsAria cell sorter. The Tregs were stimulated with anti-CD3/CD28 microbe-ads and cultured in the presence of IL-2. Frequency and phenotype of the expanded Tregs and conventional T cells were measured by flow cytometry. The suppressive function was assessed by standard flow-based proliferation assays using CFSE dilution of microbead-activated PBMCs in the presence or absence of expanded Tregs. Result(s): Our data show that sorted CD4+CD25 + CD127lo Tregs from HIV-1 negative and positive donors can be expanded, with a mean fold change of 43+/- 11.8 at day 7. The expanded Tregs expressed high levels of Foxp3 compared to the conventional T cells. More importantly, the expanded Tregs were able to suppress activated PBMCs in vitro. Detailed analyses on phenotype, HIV-1 infectability and the functional profile of these expanded Tregs are ongoing. Conclusion(s): Our data show that CD4+CD25 + CD127lo Tregs isolated from HIV-1 positive individuals can be successfully isolated and expanded ex vivo, while maintaning high expression of Foxp3 and their suppressive function. This approach holds great potential for more detailed studies on the role of regulatory T cells in the setting of HIV-1 infection, especially in situations where specimen are scarce (e.g infants, tissues).

Angus, S. V., et al. (2012). "Field-deployable and near-real-time optical microfluidic biosensors for single-oocyst-level detection of Cryptosporidium parvum from field water samples." Journal of Environmental Monitoring **14**(12): 3295-3304.

Cryptosporidium spp. is an obligate, parasitic protozoan that is difficult to detect and causes diarrhea in healthy adults while potentially causing death in the immunocompromised and children. Its treatment options are few and treat the symptoms, not the actual parasite. Current methods of detection are inefficient and rely too heavily upon laboratory sample preparations and technician skill, including differential staining, negative staining, and immunofluorescence methods [especially U.S. Environmental Protection Agency (EPA) Method 1623]. These assays can take from hours to days and require a laboratory environment. In this work, we demonstrated the microbead immunoagglutination assay combined with Mie scatter detection in a microfluidic device to provide a field-deployable and near-real-time alternative to the laboratory-based method (especially EPA Method 1623). Two main challenges were the relatively big diameter of Cryptosporidium oocysts (5-6 mum) and the contaminants in field water samples that negatively affected the immunoagglutination and its scatter detection. We used 4 min sonication to liberate Cryptosporidium oocyst wall proteins (COWP), which was previously used to inactivate Cryptosporidium oocysts. As for the contaminants, we optimized the microbead diameter (920 nm) and the wavelength of incident light (375 nm) to find the angle of scatter detection (45degree) where the Mie scatter from immunoagglutinated microbeads was maximum and the background scatter from contaminants was minimum. This enabled the sub-single-oocyst-level detection despite the fact that only a very small volume of water sample (15 muL) was introduced to the microfluidic biosensor. When combined with filtration/concentration, this method is able to detect <=1 oocyst per large volume of water, comparable to or potentially better than the EPA method 1623, while effectively reducing the time and labor necessary for staining and microscopic analysis. For faster, near-real-time assays, filtration/concentration may not be used, where the detection limit was 1-10 oocysts per mL with the total assay time of 10 min including the 4 min sonication time. The linear range of assay was over 5 orders of magnitude. The final device was compact and had the potential to be used in field situations, and required less technical expertise and/or training compared to the other methods.

Angyal, A., et al. (2010). "Production of steam cracking feedstocks by mild cracking of plastic wastes." Fuel Processing Technology **91**(11): 1717-1724.

In this work the utility of new possible petrochemical feedstocks obtained by plastic waste cracking has been studied. The cracking process of polyethylene (PE), polyethylene-polypropylene (PEPP) and polyethylene-polystyrene (PEPS) has been carried out in a pilot scale tubular reactor. In this process mild reaction parameters has been applied, with the temperature of 530 C and the residence time of 15 min. The produced hydrocarbon fractions as light- and middle distillates were tested by using a laboratory steam cracking unit. It was concluded that the products of the mild cracking of plastic wastes could be applied as petrochemical feedstocks. Based on the analytical data it was determined that these liquid products contained in significant concentration (25-50 wt.%) of olefin hydrocarbons. Moreover the cracking of polystyrene containing raw material resulted in liquid products with significant amounts of aromatic hydrocarbons too. The steam cracking experiments proved that the products obtained by PE and PEPP cracking resulted in similar or better ethylene and propylene yields than the reference samples, however the aromatic content of PEPS products reduced the ethylene and propylene yields.

Ankireddy, S. R. and J. Kim (2015). "Quantum Dot-Bead-DNA Probe-Based Hybridization Fluorescence Assays on Microfluidic Chips." Journal of Nanoscience & Nanotechnology **15**(10): 7918-7921.

The development of chip-based, quantum dot (QD)-bead-DNA conjugate probes for hybridization detection is a prime research focus in the field of microfluidics. QD-Bead-DNA probe-based hybridization detection methods are often called "bead-based assays," and their success is substantially influenced by the dispensing and manipulation capabilities of microfluidic technology. Met was identified as a prognostic marker in different cancers including lung, renal, liver, head and neck, stomach, and breast. In this report, the cancer causing Met gene was detected with QDs attached to polystyrene microbeads. We constructed a microfluidic platform using a flexible PDMS polymer. The chip consists of two channels, with two inlets and two outlets. The two channels were integrated with QD-bead-DNA probes for simultaneous detection of wild type target DNA and mutant DNA, containing three nucleotide changes compared to the wild type sequence. The fluorescence quenching ability of QDs within the channels of microfluidic chips were compared for both DNAs.

Anonymous (1970). "An end to plastic pollution?" Marine Poll **Bull. 1**(9): 130.

A new development in the Department of Chemistry of the University of Aston (Birmingham, England) holds out some promise that we may be approaching the time when plastic pollution is brought under control. A research group under the direction of Professor Gerald Scott is patenting several additives which will cause plastic materials to disintegrate first to granules and then to a fine powder when exposed to ultra violet light Discarded plastic containers and packaging materials would disappear after 3-6 months exposure to summer sunlight By suitable adjustment of the additives, it would be possible to arrange that the small amount of ultra violet

radiation penetrating window glass would not be sufficient to cause disintegration of the plastic white it was in normal use indoors. In any case, it would be possible to incorporate indicator dyes in the material so that a colour change could give early warning that disintegration had started. The technique is effective with polythene and polypropylene plastics but not so Car with Polyvinylchloride (PVC).

Anonymous (1971). "Some remarks on the treatment of plastic waste material. [Dutch]." Tokio Nieuws **34**(pp 6-8).

Research is currently being carried out in a number of institutes to find methods for the disposal of various types of plastics waste material. The following methods are being studied: burning (the most promising method at present); mixing with asphalt or concrete (in an experimental stage); disintegration by exposure to u.v. radiation from the solar spectrum (insufficiently worked out as yet); the powder resulting from the disintegration of plastic might also be noxious; dumping at sea (causes undesirable pollution of the water); addition in u finely divided form to garden soil. In this final approach pulverized polystyrene foam is mixed with clay in a proportion of 20-50% which gives a porous garden soil that retains water and fertilizer. Plants allegedly grow very well on this material.

Anonymous (1973). "Utilization of waste plastic materials in Japan. [Dutch]." Metaal Kunststof **11**(21): 30-33.

A survey is made of the Japanese efforts to solve the problem of waste plastic material accumulation. Among the research and development activities reported are: the testing of an installation for the incineration of 5 tons of plastic wastes per day; a model project for the recovery of plastics from domestic wastes; and an experimental factory for thermal cracking of plastic wastes in order to regain petroleum. Industrial activities include the development of methods for shredding and pulverizing plastics; processes for separation of different types of plastics; processes for thermal decomposition, which requires improvement of the thermal conductivity of the plastic particles; a method for removing hydrochloric acid from PVC; processing fuel possessing properties similar to present fuels; incinerators; methods for recovery and reutilization of plastics from wastes; and development of degradable plastics that decompose in sunlight as a result of an increased oxygen content in the plastic molecules.

Anonymous (1974). "Disposal of plastic waste in Japan is tackled in coordinated manner (Dutch). [Dutch]." Ned.Chem.Industr **16**(21): 389.

Japan, as one of the world's largest plastic producers, has a large problem with waste plastic disposal. Plastic accounts for 8 to 10% (by weight) of Japan's household waste production. In 1970, the Plastic Waste Management Institute of Japan was set up to coordinate the efforts to cope with this problem. The institute carries on research, and provides financial help to private concerns which wish to install plastic waste processing equipment. Twenty five plastic recycling plants are now in operation; 15 more are under construction. In Japan, the plastic producing industry is legally responsible for the processing of its own wastes. Household plastic waste, on the other hand, is processed by public installations. Several processing techniques are now in use or are being investigated: incineration, remolding (into flower pots, fencing, etc.), and pyrolysis, which produces sulfurless fuel oil.

Anonymous (2005). "Amended final report on the safety assessment of polyacrylamide and acrylamide residues in cosmetics." International Journal of Toxicology **24 Suppl 2**: 21-50.

Polyacrylamide is a polymer of controllable molecular weight formed by the polymerization of acrylamide monomers available in one of three forms: solid (powder or micro beads), aqueous solution, or inverse emulsions (in water droplets coated with surfactant and suspended in mineral oil). Residual acrylamide monomer is likely an impurity in most Polyacrylamide preparations, ranging from <1 ppm to 600 ppm. Higher levels of acrylamide monomers are present in the solid form compared to the other two forms. Polyacrylamide is reportedly used in 110 cosmetic formulations, at concentrations ranging from 0.05% to 2.8%. Residual levels of acrylamide in Polyacrylamide can range from <.01% to 0.1%, although representative levels were reported at 0.02% to 0.03%. Because of the large sizes of Polyacrylamide polymers, they do not penetrate the skin. Polyacrylamide itself is not significantly toxic. For example, an acute oral toxicity study of Polyacrylamide in rats reported that a single maximum oral dose of 4.0 g/kg body weight was tolerated. In subchronic oral toxicity studies, rats and dogs treated with Polyacrylamide at doses up to 464 mg/kg body weight showed no signs of toxicity. Several 2-year chronic oral toxicity studies in rats and dogs fed diets containing up to 5% Polyacrylamide had no significant adverse effects. Polyacrylamide was not an ocular irritant in animal tests. No compound-related lesions were noted in a three-generation reproductive study in which rats were fed 500 or 2000 ppm Polyacrylamide in their diet. Polyacrylamide was not carcinogenic in several chronic animal studies. Human cutaneous tolerance tests performed to evaluate the irritation of 5% (w/w) Polyacrylamide indicated that the compound was well tolerated. Acrylamide monomer residues do penetrate the skin. Acrylamide tested in a two-generation reproductive study at concentrations up to 5 mg/kg day(- 1) in drinking water, was associated with prenatal lethality at the highest dose, with evidence of parental toxicity. The no adverse effects level was close to the 0.5 mg/kg day(- 1) dose. Acrylamide tested in a National Toxicology Program (NTP) reproductive and neurotoxicity study at 3, 10, and 30 ppm produced no developmental or female reproductive toxicity. However, impaired fertility in males was observed, as well as minimal neurotoxic effects. Acrylamide neurotoxicity occurs in both the central and peripheral nervous systems, likely through microtubule disruption, which has been suggested as a possible mechanism for genotoxic effects of acrylamide in mammalian systems. Acrylamide was genotoxic in mammalian in vitro and in vivo assays. Acrylamide was a tumor initiator, but not an initiator/promoter, in two different mouse strains at a total dose of 300 mg/kg (6 doses over 2 weeks) resulting in increased lung adenomas and carcinomas without promotion. Acrylamide was tested in two chronic bioassays using rats. In one study, increased incidence of mammary gland tumors, glial cell tumors, thyroid gland follicular tumors, oral tissue tumors, uterine tumors and clitoral gland tumors were noted in female rats. In male rats, the number of tumors in the central nervous system (CNS), thyroid gland, and scrotum were increased with acrylamide exposure. In the second study, using higher doses and a larger number of female rats, glial cell tumors were not increased, nor was there an increase in mammary gland, oral tissue, clitoral gland, or uterine tumors. Tumors of the scrotum in male rats were confirmed, as were the thyroid gland follicular tumors in males and females. Taken together, there was a dose-dependent, but not statistically significant, increase in the number of astrocytomas. Different human lifetime cancer risk predictions have resulted, varying over three orders of magnitude from 2 x 10(- 3) to 1.9 x 10(- 6). In the European Union, acrylamide has been limited to 0.1 ppm for leave-on cosmetic products and 0.5 ppm for other cosmetic products. An Australian risk assessment suggested negligible health risks from acrylamide in cosmetics. The Cosmetic

Anonymous (2008). "Loofah and plastic waste make low-cost housing." Appropriate Technology **35**(4):

15-18.

Elsa Zaldivar has found a way to mix loofah -- a cucumber-like vegetable that is dried to yield a scratchy sponge for use as an abrasive skin scrubber -- with other vegetable matter like husks from corn and caranday palm trees, along with recycled plastic, to form strong, lightweight panels. These can be used to create furniture and construct houses, insulating them from temperature and noise. Determined to find a market for the loofah waste, Zaldivar teamed up with Pedro Padros, an industrial engineer, to search for a way to use the vegetable material to construct inexpensive panels for walls and roofing for building houses. Then Padros got the idea of using plastic waste with the loofah. He invented a machine that melted a mixture of three types of recycled plastic and combined the resulting liquid with loofah and other vegetable fibres, such as cotton netting and chopped corn husks.

Anonymous (2015). "Great Barrier Reef corals eat plastic." Ocean News & Technology **21**(4): 22-23.

Researchers in Australia have found that corals commonly found on the Great Barrier Reef will eat micro-plastic pollution. Microplastics are tiny fragments of plastic in the environment and are a widespread contaminant in marine ecosystems, particularly in inshore coral reefs. As part of the study the researchers put corals collected from the Great Barrier Reef into plastic contaminated water. After 2 nights they found that the corals had eaten plastic particles. The team also sampled the waters adjacent to inshore coral reefs on the Great Barrier Reef.

Anonymous (2015). "Restricting Landfill Must be the Priority." Food Packaging Bulletin **24**(4): 4.

Following PlasticsEurope's call for landfill restrictions issued June 17, the organization presented its recommendations June 22 for the European Union's upcoming Circular Economy Package and called for a landfill ban on recyclable and other recoverable post-consumer waste by 2025 as the priority to improve resource efficiency in Europe. With regards to future packaging recycling targets, PlasticsEurope advocates a life cycle driven approach, based on a cost-benefit analysis. Between 2006 and 2012, the amount of post-consumer plastic waste going to landfills was reduced by 26% and, as a result, plastics recycling rose by as much as 40% and energy recovery increased by 27%." A recent study shows that with today's technology there is an optimum level for plastics packaging recycling. This optimum lies between 35% and 50% depending on the specific situation in the country.

Anonymous (2015). "Sea turtles in plastic pollution peril." Ocean News & Technology: 22.

A new global review led by the University of Exeter that set out to investigate the hazards of marine plastic pollution has warned that all seven species of marine turtles can ingest or become entangled in the discarded debris that currently litters the oceans. Annual global plastic production has grown from 1.5 million tonnes to 299 million tonnes in the last 65 years and as a result plastic pollution is increasing, both on land and at sea.

Anonymous (2016). BEAT THE MICROBEAD. Environmental Engineering. London, Professional Engineering Publishing Ltd. **29:** 56.

Greenpeace is currently running a campaign to get the UK to join America and Canada in their ban of plastic microbeads. They bypass wastewater filtration systems and have a serious, detrimental impact on the flora and fauna of the oceans. Microplastic concentrations in lakes and other closed bodies of water may be even higher than in oceans, where at least the water flows freely.

In the following sentence, the amount of plastics produced in 1950 was incorrectly cited as "approximately 1.9 tons": "World plastics production has experienced almost constant growth for more than half a century, rising from approximately 1.9 tons in 1950..." The correct number should have been 1.9 million tons. EHP regrets the error. Copyright © EPA/National Geographic Channel/Alamy.

Anonymous (2016). "Microplastics and Nanoplastics in Food - an Emerging Issue." World Food Regulation Review **26**(2): 15.

There is global interest in the impact of plastic waste in seas and waterways on natural habitats and wildlife. The European Food Safety Authority (EFSA) says it has "taken a first step" towards a future assessment of the potential risks to consumers from microplastics and nanoplastics in food, especially seafood. Dr Peter Hollman was a member of the working group that helped EFSA's Panel on Contaminants in the Food Chain (CONTAM) to draft its Statement on microplastic and nanoplastic particles in food. Dr Hollman is senior researcher at RIKILT research institute and associate professor for Nutrition and Health, both atWageningen University in The Netherlands. His research includes work on the occurrence, analysis and toxicity of micro- and nanoplastics. EFSA defines microplastics as ranging in size from 0.1 to 5000 micrometres (mu m), or 5 millimetres to give an idea. Nanoplastics measure from 0.001 to 0.1 mu m (i.e. 1 to 100 nanometres).

Anonymous (2016). "Microplastics discovered in the deep, open ocean." Ocean News & Technology: 21.

A unique study by scientists at the National Oceanography Centre (NOC) will provide valuable new insights into the concentrations of microplastics in the open ocean from surface to the seabed. Preliminary findings already show microplastic presence in the top 1,000 m of the water column at the Porcupine Abyssal Plain sustained ocean observatory in the North Atlantic. They will also analyse unique samples from sediment traps stationed in the central North and South Atlantic subtropical gyres, which are giant swirls in the ocean where microplastics tend to accumulate.

Anonymous (2016). "Three Quarters of the Population Believe that Food in Germany is Safe." World Food Regulation Review **26**(1): 20.

When it comes to food, the German population's risk perception is contradictory. This is one of the findings of the third Federal Institute of Risk Assessment (BfR) consumer monitor. On the one hand, almost three quarters of the representatively selected participants interviewed in February 2016 believe that foods offered in the market are safe. On the other hand, more than half of the respondents are concerned about topics such as pesticide residue and microplastics in food, and genetically modified foods, all of which are closely associated with the general issue of food safety. As regards awareness levels in relation to topics of consumer health protection, there were major differences compared to 2015.

Anonymous (2017). "Corals Seem to Like The Taste of Microplastics." Sea Technology **58**(12): 30.

A new Duke University study of plastic ingestion by corals suggests that visual cues, such as a resemblance to prey, don't factor into the appeal of microplastics as food because corals have no eyes. Instead, corals go by taste. Corals in the experiments ate all types of plastics but preferred unfouled microplastics by a threefold difference over microplastics covered in bacteria.

Anonymous (2017). "Larvaceans, microplastics and deep-sea food webs." Marine Pollution Bulletin **123**(1/2): 4.

Over the last decade, scientists have discovered tiny pieces of plastic in many ocean waters, and even in deep-sea mud. However, they know very little about how microplastics are transported within the ocean. A new paper by the Monterey Bay Aquarium Research Institute (MBARI) researchers in the journal Science Advances shows that filter-feeding giant larvaceans can collect and consume microplastic particles in the deep sea. The particles accumulate in larvaceans' cast-off filters and are passed into the animals' faecal pellets, which sink rapidly through the ocean, potentially carrying microplastics to the deep seafloor.

Anonymous (2017). "UK: Minister Visits North America to "Turn Tide on Marine Plastic"." Food Packaging Bulletin **26**(10): 10-11.

United Kingdom Environment Minister, Thérèse Coffey, said 16 February that she has "joined forces with Canada and the USA" in the fight against marine plastic. During a visit to Washington DC and Ottawa in February, the Minister met her international counterparts to discuss the UK's priorities for the marine environment ahead of the G7 Environment meetings to be held later this year. Like the UK, Canada has already banned microbeads in rinse-off cosmetics, and the Minister met the country's Environment and Climate Change Minister, Catherine McKenna, and Dominic LeBlanc, Minister of Fisheries, Oceans and the Canadian Coast Guard, to look at how the two countries can unite in further tackling the threats facing our oceans.

Anonymous (2018). "Ban on Straws Does Not Solve the Marine Litter Problem." Food Packaging Bulletin **27**(3): 8-9.

The German Association for Plastics Packaging and Films (IK Industrievereinigung Kunststoffverpackungen e. V). has rejected a proposed ban on selected plastic products announced 28 May by the European Commission. When it is a question of raising public awareness for the careful use of various resources, and changing behavior in the long term, bans are hardly the right option, according to IK. They do not bring about a genuine understanding of sustainable consumption and environmentally conscious behavior. Roughly 80% of global plastic waste in the oceans is generated by Asian countries, approximately 0.02% comes from Germany and about 1% from Europe. The IK takes the view that the EU Commission should concentrate on the consistent implementation of existing waste legislation in all EU member states and on an EU-wide landfill ban for plastic waste.

In September 2018, Dutch company, Ioniqa Technologies, announced the launch of what it described as "the first PET plastic up-cycling plant". The intention is to convert PET plastic waste into high-grade pure PET raw material, by summer 2019, for use in new food packaging. On 13 December, the Coca-Cola Company announced a new agreement extending a loan to Ioniqa Technologies, to facilitate the development of Ioniqa's proprietary technology to produce high-grade, recycled PET content from hard-to-recycle PET waste. The agreement is designed to accelerate the development and deployment of high-grade recycled content PET for use in bottles used by Coca-Cola.

Anonymous (2018). "Corrections to: Combined effects of UV exposure duration and mechanical abrasion on microplastic fragmentation by polymer type (Environmental Science and Technology (2017) 51 (4368-4376) DOI: 10.1021/acs.est.6b06155)." Environmental Science and Technology **52**(6): 3831-3832.

In our paper, the total volume of the fragmented particles according to UV exposure was miscalculated in Figure 5 and Supporting Information Figure S7. The volume of the fragmented particles was described as 10 pellets; the remaining volume of the parent pellet was correct. In addition, the void volume of EPS pellet and the laminar shape of fragmented EPS particles were considered in recalculation of EPS volume. The corrected Figure 5 is given below. The corrected Figure S7 is provided in the Supporting Information, and the y-axis has been corrected in Figure S7. In addition, the following corrections should be made in the main text. Page 4372. The second paragraph should read, "The volume of the remaining parent pellets was calculated from the measured mean diameters, and the volume of produced particles was calculated on the assumption that all particles were spherical with a diameter at the midpoint of each size category (e.g., 150 mum for 100-200 mum). In case of EPS pellet, it consists of 98% gas and 2% polystyrene on a volume basis. The remaining EPS pellet contained void volume of gas while the fragments in very laminar shape did not have any void gas volume, which was confirmed by scanning electron microscope (data not shown). Thus, in EPS volume calculation, the volume of remaining EPS pellet included 98% of gas, but the volume of EPS fragments was calculated as laminar-shaped polystyrene itself without the void gas volume. While the volume of parent PE pellets remained almost intact (>90%) in all exposure groups, the missing portion of PE volume after weathering increased from 0% to 9.9% according to the UV exposure duration (Figure 5a). In addition, 98% and 96% of PP parent pellets remained after exposure to UV for 0 and 2 months, respectively, with corresponding proportions of 1.6% and 4.2% unaccounted for. After 6 and 12 months, the parent PP pellet volume decreased to 81% and 81%, respectively, while fragmented particles accounted for 1.2% and 2.1%, respectively (Figure 5b). After exposure to UV for 0 and 2 months, parent EPS pellets accounted for 78% and 35% of the original volume, respectively, while 5.4% and 12% of the pellets were fragmented. After 6 and 12 months, no visible parent pellets were apparent, but the volume of fragmented particles accounted for only 21% and 12% of the original parent pellet volume, respectively. The proportion of EPS pellets unaccounted for increased gradually with UV exposure duration, accounting for 17, 53, 79, and 88% in the UV0, UV2, UV6, and UV12 groups, respectively (Figure 5C)." Researchers who conducted studies on the effects of contact lenses presented their results during the 256th National Meeting and Exposition of the American Chemical Society (ACS). Disposal of the contact lenses in various ways according to scientists contributes to microplastic pollution in waterways.

Anonymous (2018). "High levels of hazardous chemicals found in plastics collected from Lake Geneva." Marine Pollution Bulletin **130**: 349.
The first-ever chemical analysis of plastic collected from beaches around Lake Geneva detected cadmium, mercury and lead, sometimes in very high concentrations that exceed the maximum permitted under EU law. The abundance of toxic chemicals that are now restricted or banned in plastic production reflects how old the plastic litter could be. The report, one of very few to examine plastics in freshwater lakes is published in Frontiers in Environmental Science and shows that, like oceans, freshwater habitats are also affected by plastic pollution. Plastic debris in freshwater lakes are likely to pose the same problems to wildlife as marine plastics. In this respect, entanglement and ingestion are of greatest concern states Dr. Montserrat Filella, lead author of this research, based at the Department F.-A. Forel, University of Geneva Switzerland.

Anonymous (2018). "Increase in plastics waste reaching remote South Atlantic islands." Marine Pollution Bulletin **137**: 728.
Scientists investigating plastics in seas surrounding the remote British Overseas Territories discovered they are invading these unique biologically-rich regions. This includes areas that are established or proposed Marine Protected Areas. Plastic causes many problems including entanglement, poisoning and starving through ingestion. The study highlights that the impacts of plastic pollution are not only affecting industrialized regions but also remote biodiverse areas.

Anonymous (2018). "KAYTECH SOLVES CHARLESTOWN WASTEWATER TREATMENT PROBLEM." Civil Engineering : Magazine of the South African Institution of Civil Engineering **26**(9): 48.
By supplying over 3 000 Quick4 Infiltrator Chambers for the new Charlestown Housing Project in Newcastle, KwaZulu- Natal, Kaytech was able to completely eliminate the need for a conventional French drain soakaway system. Manufactured from recycled plastic waste, Kaytech's eco-friendly Infiltrator Chambers deliver a high level of performance on every front -- from ease of transportation, handling and installation, to system reliability. Infiltrator Chamber Systems promote effluent infiltration into the soil with 100% efficiency, while requiring as little as 50% less space compared to French drain systems. With a proven track record exceeding thirty years, tried and tested Infiltrator Chambers provide numerous benefits, including quick and easy installation, flexibility, as well as chemical resistance and UV stability.

Anonymous (2018). "Land-based pollution with microplastics." Marine Pollution Bulletin **128**: 609.

It is now widely accepted that microplastics contaminate oceans and are harmful to coastal and marine habitats. But tiny plastic particles have also been found to present a threat to creatures on land and may have damaging effects similar or even more problematic than in the oceans. Researchers from the Leibniz-Institute of Freshwater Ecology and Inland Fisheries (IGB) in partnership with Freie Universitat Berlin warn that the impact of microplastics in soils, sediments and the freshwaters could have a long-term negative effect on terrestrial ecosystems throughout the world.

A small pilot study presented in October at the United European Gastroenterology Conference measured low concentrations of microplastics in human stool samples from eight individuals who reside in the European Union, Japan and Russia. The study was conducted by researchers from the Medical University of Vienna and Environment Agency Austria. The American Chemistry Council issued the presented statement October 24.

Anonymous (2018). "UK BANS PLASTIC MICROBEADS." BioCycle **59**(2): 9.

Plastic microbeads can no longer be used in cosmetics and personal care products in the United Kingdom, after a long-promised ban went into effect in January. "Microbeads are entirely unnecessary when there are so many natural alternatives available, and I am delighted that from today cosmetics manufacturers will no longer be able to add this harmful plastic to their rinse-off products," said UK Environment Minister Therese Coffey.

Anonymous (2018). "UK: WRAP Adds Momentum to Plastic Waste Fight with New Recycle Now Campaign." Food Packaging Bulletin **27**(1/2): 18.

Called 'Plastic Planet' to demonstrate the sheer volume of plastic in the environment; Recycle Now will call upon consumers to close the 'plastic gap' which sees only 58% of plastic bottles currently recycled in the UK--despite 99% of local authorities collecting bottles at kerbside and an increased public appetite to generally recycle more. The campaign comes as part of the Waste and Resources Action Plan's overarching ambition" to tackle the problem of plastic waste.

Anonymous (2019). "Global Alliance on Plastic Waste Launches." Sea Technology **60**(3): 28.

Energy company Total is participating in the creation of a global alliance of companies from the plastics and consumer goods value chain to help end plastic waste in the environment, especially in the ocean. The Alliance to End Plastic Waste, made up of nearly 30 member companies, has committed more than $1 billion, with the goal of investing $1.5 billion over the next five years.

Anonymous (2019). "It's not just fish, plastic pollution harms the bacteria that help us breathe." Marine Pollution Bulletin **144**: 358.

Anonymous (2019). "Peru takes aim at single-use plastic." EcoAmericas **21**(3): 11.

Peru took a major step toward reducing plastic waste with a new law that will outlaw many throwaway plastic items by the end of 2021. The measure, signed into law Dec. 18, will phase in with different timing for various provisions. The ban will affect single use plastic bags and other non-reusable plastics, drinking straws, and disposable food and drink containers made of plastic or polystyrene foam. The law requires that polyethyleneterephthalate (PET) bottles manufactured in or imported to Peru include at least 15% recycled PET plastic.

Anonymous (2019). "A steady diet of plastic particles." Nature **570**(7761): 279.

Anonymous (2019). "UK Students Conduct Microplastics Survey." Sea Technology **60**(10): 36.

The planet's use of plastics has come under much scrutiny in recent years, and particular attention is being paid to the damage caused in the marine environment by microplastics, defined as all forms of plastics less than 5 mm in size. They can enter the oceans as primary microplastics such as beads from personal-care products and microfibers from clothes, or as secondary microplastics derived from larger plastic items such as drink bottles, which slowly get broken into smaller pieces. The project, managed by the Norfolk Rivers Trust education team, measured the amount of microplastic pollution on the beaches of North Norfolk and included beach litter picking and plastic sorting. Beach samples were sent to Just One Ocean for analysis.

Ansari, S., et al. (2015). "Effects of the orientation of anti-BMP2 monoclonal antibody immobilized on scaffold in antibody-mediated osseous regeneration." Journal of Biomaterials Applications **30**(5): 558-567.

Recently, we have shown that anti-BMP2 monoclonal antibodies (mAbs) can trap endogenous osteogenic BMP ligands, which can in turn mediate osteodifferentiation of progenitor cells. The effectiveness of this strategy requires the availability of the anti-BMP-2 monoclonal antibodies antigen-binding sites for anti-BMP-2 monoclonal antibodies to bind to the scaffold through a domain that will leave its antigen-binding region exposed and available for binding to an osteogenic ligand. We examined whether antibodies bound to a scaffold by passive adsorption versus through Protein G as a linker will exhibit differences in mediating bone formation. In vitro anti-BMP-2 monoclonal antibodies was immobilized on absorbable collagen sponge (ACS) with Protein G as a linker to bind the antibody through its Fc region and implanted into rat calvarial defects. The biomechanical strength of bone regenerated by absorbable collagen sponge/Protein G/anti-BMP-2 monoclonal antibodies immune complex was compared to ACS/anti-BMP-2 monoclonal antibodies or ACS/Protein G/isotype mAb control group. Results demonstrated higher binding of anti-BMP-2 monoclonal antibodies/BMPs to C2C12 cells, when the mAb was initially attached to recombinant Protein G or Protein G-coupled microbeads. After eight weeks, micro-CT and histomorphometric analyses revealed increased bone formation within defects implanted with absorbable collagen sponge/Protein G/anti-BMP-2 monoclonal antibodies compared with defects implanted with absorbable collagen sponge/anti-BMP-2 monoclonal antibodies ($p < 0.05$). Confocal laser scanning microscopy (CLSM) confirmed increased BMP-2, -4, and -7 detection in sites implanted with absorbable collagen sponge/Protein G/anti-BMP-2 monoclonal antibodies in vivo . Biomechanical analysis revealed the regenerated bone in sites with Protein G/anti-BMP-2 monoclonal antibodies had higher mechanical strength in comparison to anti-BMP-2 monoclonal antibodies. The negative control group, Protein G/isotype mAb, did not promote bone regeneration and exhibited significantly lower mechanical properties ($p < 0.05$). Altogether, our results demonstrated that application of Protein G as a linker to adsorb anti-BMP-2 monoclonal antibodies onto the scaffold was accompanied by increased in vitro binding of the anti-BMP-2 mAb/BMP immune complex to BMP-receptor positive cell, as well as increased volume and strength of de novo bone formation in vivo .

Anshita, S., et al. (2013). "Biomedical Waste Management practices at King George's Medical University, Lucknow, Uttar Pradesh, India - a 3000-bed tertiary care hospital." Annals of Environmental Science **7**: 93-100.

Biomedical Waste Management (BMWM) is an integral part of infection control and hygiene programs in healthcare settings. Biomedical waste poses serious threats to environmental health and requires specific treatment and management prior to its final disposal. This study investigated the status of BMWM practices (segregation, collection, transportation, storage and final disposal) and quantification of wastes generated in King George's Medical University (KGMU), a 100 year-old, tertiary care institute in Lucknow, North India. The results of this study revealed that biomedical waste is segregated at the point of generation, which reduces the quantity of incinerable waste. Infectious waste generated in the hospital is about 19-20% of total waste generated of which only 4-5% waste is disposed off by incineration. The remaining percentage of infectious wastes (plastic, glass and sharps) is first treated in the hospital waste treatment facility. All infectious plastic waste is treated by autoclaving to make them noninfectious, than shredded into small pieces and finally sent to an authorized recycler. KGMU establishes a foolproof BMWM setup that ensures its proper collection, transportation, storage and disposal as per norms.

Anthony, R. S., et al. (1998). "Fas antigen (CD95) expression in peripheral blood progenitor cells from patients with leukaemia and lymphoma." Leukemia & Lymphoma **30**(5-6): 449-458.

Fas antigen (CD95) is a cell surface receptor belonging to the tumour necrosis factor/nerve growth factor superfamily and is able to induce apoptosis when triggered by its' natural ligand or an anti-Fas antibody. Fas expression is low on CD34+ bone marrow (BM) progenitor cells, but is increased by various cytokines in vitro. We investigated Fas expression on CD34+ cells from 39 peripheral blood progenitor cell (PBPC) harvests and from 5 normal BM harvests by dual colour flow cytometry to determine if Fas expression was altered during mobilisation. By including calibrated microbeads during flow cytometry, we quantified the number of Fas antigen molecules per cell. A low percentage of PBPC (22%) and normal BM (23%) CD34+ cells expressed Fas antigen. Fas expression varied on CD34+ cells from different diseases and the highest

expression was found in ALL (52%). There was a significant three fold increase in the number of Fas molecules/cell expressed on CD34+ cells (PBPC 6,230 molecules/cell, BM 2,236; p = 0.0003). This level of expression was considerably less than that for CD3/CD19 lymphocytes (33,095 molecules/cell) and CD14 monocytes (47,467 molecules/cell) in the PBPC harvest. In conclusion, mobilisation including the use of growth of factors, has minimal effect on CD34 progenitor cell Fas expression.

Antonsson, A. B. and S. Runmark (1987). "Airborne fibrous glass and dust originating from worked reinforced plastics." American Industrial Hygiene Association Journal **48**(8): 684-687.

The presence of respirable glass fibers in the dust from grinding, drilling and cutting of reinforced polyester plastics was investigated. The results show that 10% of the Swedish Threshold Limit Value (TLV) for synthetic inorganic fibers (3 fibers/mL) seldom will be exceeded. On the other hand, the results indicate that the Swedish TLV for thermosetting plastic dust (3 mg/m³) will be exceeded quite often. The authors examined the possibility of longitudinal glass fiber division during the working of reinforced polyester plastic and whether respirable glass fibers were produced. The results show that such a division does not occur for glass fibers embedded in polyester plastic and that the respirable fibers are related to fiber-shaped plastic particles or organic fiber particles.

Antosiak-Iwanska, M., et al. (2011). "If the parameters of encapsulation of langerhans islets influence insulin secretion?" International Journal of Artificial Organs **34 (8)**: 633.

Objectives: Diabetes remains a devastating disease, with tremendous cost in terms of human suffering and healthcare expenditures. A bioartificial pancreas has the potential as a promising approach to preventing or reversing complications associated with this disease. The immunoisolation of Langerhans islets have been developed as a method of normalization of the carbohydrate metabolism for diabetes. In this study we investigated the production of small diameter alginate microbeads (i.e.<0.3 mm) using electrostatic droplet generation. The aim of our study was to evaluate whether parameters of electrostatic droplet formation could influence the viability and secretory functions of Langerhans islets. Method(s): To investigate how the parameters of droplet generator have an influence on insulin secretion, hormone concentration was estimated during the encapsulated islets culture. Free, encapsulated islets were cultured for up to 10 days. The medium was changed every second day and the samples were taken and tested for insulin content. The islets in all tested groups were stained with dithizone and trypan blue before and after the culture. Result(s): In all groups we observed that 100% islets exhibited insulin production (red dye). In one of the tested group the islets were stained with PI in 30% after 10-day culture. In the same group a decline of insulin secretion was observed to compare with control. Conclusion(s): The viability and insulin secretion by encapsulated islets depend on the process parameters of their encapsulation.

Antunes, J., et al. (2018). "Microplastics on the Portuguese coast." Marine Pollution Bulletin **131**(Pt A): 294-302.

Marine anthropogenic litter was analysed in eleven beaches along the Portuguese coast, over a two-year period (2011-2013). Of all collected items, 99% were plastic and 68% were microplastics (MP; 1-5mm in diameter). Higher MP concentrations were found in winter/autumn, near industrial areas and/or port facilities and in beaches exposed to dominant winds. Resin pellets (79%) were the dominant category close to industrial areas and high concentrations of fragments and polymeric foams were found near fishing ports. The most frequent pellet size classes were 4 and 5mm (respectively 47% and 42%).

Apeh, C. C. (2018). "Survey of Sachet Water Waste Disposal in Liberia." Journal of Health & Pollution **8**(20): 181211.

Background: Five hundred milliliter bags of water, referred to as 'sachet water,' are widely used in Liberia, as they are low cost, safe sources of clean drinking water for the population.

Objectives: This study aims to determine sources of drinking water in the study area, the rate of sachet water use, empty sachet water disposal methods and environmental problems associated with sachet water waste disposal.

Methods: Using a simple random sampling technique, 257 respondents were interviewed between April and June 2018 using structured questionnaires. On a five-point Likert scale with a mean score of 3 as the cutoff point, data were analyzed using descriptive statistics.

Results: The paper found that sachet water (mean (M)=4.37) is an essential source of drinking water in Liberia with a daily consumption rate of at least 6 bags of sachet water per individual. Affordability, availability, and safety were named by respondents as reasons for their consumption of sachet water. Improper disposal methods practiced by the residents of Liberia included ground littering (M=3.42) and burning (M=3.03).

Conclusions: Sachet water consumption has contributed to environmental issues such as drainage system clogs, littering of the environment, the death of terrestrial and aquatic animals due to plastic waste consumption, reduction of oxygen for aquatic life and soil infertility. We recommend the creation of policies and enforcement of sachet water production to include reuse and recycling of sachet water by-products as a requirement for licensing of producers, provision of adequate waste bins and the use of public education campaigns to educate residents on environmental best practices.

Ethics Approval: This study was approved by the Institute for Population Studies, University of Liberia, Monrovia, Liberia.

Appel, A. A., et al. (2015). "X-ray phase contrast imaging of calcified tissue and biomaterial structure in bioreactor engineered tissues." Biotechnology & Bioengineering **112**(3): 612-620.

Tissues engineered in bioreactor systems have been used clinically to replace damaged tissues and organs. In addition, these systems are under continued development for many tissue engineering applications. The ability to quantitatively assess material structure and tissue formation is critical for evaluating bioreactor efficacy and for preimplantation assessment of tissue quality. Techniques that allow for the nondestructive and longitudinal monitoring of large engineered tissues within the bioreactor systems will be essential for the translation of these strategies to viable clinical therapies. X-ray Phase Contrast (XPC) imaging techniques have shown tremendous promise for a number of biomedical applications owing to their ability to provide image contrast based on multiple X-ray properties, including absorption, refraction, and scatter. In this research, mesenchymal stem cell-seeded alginate hydrogels were prepared and cultured under osteogenic conditions in a perfusion bioreactor. The constructs were imaged at various time points using XPC microcomputed tomography (micro CT). Imaging was performed with systems using both synchrotron- and tube-based X-ray sources. XPC micro CT allowed for simultaneous three-dimensional (3D) quantification of hydrogel size and mineralization, as well as spatial information on hydrogel structure and mineralization. Samples were processed for histological evaluation and XPC showed similar features to histology and quantitative analysis consistent with the histomorphometry. These results provide evidence of the significant potential of techniques based on XPC for noninvasive 3D imaging engineered tissues grown in

bioreactors.

Appleby, T., et al. (2016). "The marine biology of law and human health." Journal of the Marine Biological Association of the United Kingdom **96**(1): 19-27.

This review uses a multidisciplinary approach to investigate legal issues concerning the oceans and human health. It firstly seeks to define the boundaries of oceans and human health research. We use three case studies as examples: biomedical research, marine litter and human well-being. Biomedical research raises complex issues relating to coastal states' sovereign rights to exploit their marine resources and the patenting processes. Coastal states have differing degrees of control over research at sea. There are differences in EU and US law over the status of genetic discoveries, with the US having stricter criteria to qualify for patent protection. International law sets the standard for bioprospecting in developing countries under the Nagoya Protocol. The cost and complexity of marine biomedical research mean that it cannot be left to commercial exploration and needs some public funding. The second case study highlights the rise in marine plastics pollution using Marine Conservation Society beachwatch data. It details the need to alter product design to avoid marine pollution and records an unsuccessful attempt by academics and an NGO to make contact with the manufacturers of one polluting product. It also introduces the concept that faulty design could amount to a public nuisance. The third case study highlights the potential health benefits from access to the coast and the statutory responsibility which sits with the US and UK authorities in the provision of well-being. It posits that there needs to be greater inter-agency coordination to promote access to the coast for human well-being. © Marine Biological Association of the United Kingdom 2015.

Aqai, P. (2013). "Bioaffinity mass spectrometry for screening and identification of contaminants." Bioaffinity mass spectrometry for screening and identification of contaminants **199**.

Our environment is constantly threatened by large amounts and variations of manmade chemicals and natural substances. Parts of these substances accumulate and contaminate soil and surface water, affecting the organisms living in it and eventually contaminate the food chain. The European Union (EU) has imposed regulations and obliged EU member states to monitor for possible contaminants in the environment and food. For this, highly sophisticated mass spectrometry (MS) techniques, which can nowadays screen >100 contaminants in a single run, are applied. For rapid and inexpensive screening of contaminants, bioactivity-based screening assays are applied, however, identification of compounds based on their chemical-physical properties is not possible. As both methods cannot identify emerging and unknown bioactive contaminants, there is a need for new tools and concepts. In this thesis, new bioaffinity MS (BioMS) concepts, using an antibody, transport proteins and a receptor, are presented for the screening and identification of contaminants. In the first concept, monoclonal antibodies (Mabs) against ochratoxins were coupled to fluorescent labeled paramagnetic microbeads for high-throughput flow cytometric screening of ochratoxins in wheat and cereal. The identification of ochratoxins with nano-ultra performance liquid chromatography-quadrupole-time-of-flight-MS (nano-UPLC-Q-ToF-MS) was achieved in full scan accurate mass mode. In the second BioMS approach, the flow cytometer was replaced by UPLC-triple quadruple (QqQ)-MS for rapid screening of thyroid transporter ligands. For this, thyroid transport protein transthyretin (TTR) was immobilized onto inexpensive non-colored paramagnetic microbeads and a stable isotopic thyroid hormone was used as label in the competitive inhibition format. For the identification of TTR-binding endocrine disrupting chemicals (EDCs) in process water and urine, nano-UPLC-Q-ToF-MS was used. In order to perform high-throughput screening, a microtiter plate-based high-throughput BioMS approach

was developed with the same beads but coupled with recombinant human sex hormone-binding globulin (rhSHBG) for the detection of designer steroids in dietary supplements. Following the screening with rhSHBG-based BioMS using LC-QqQ-MS, the rhSHBG bioaffinity extracts were injected onto chip-UPLC-Q-ToF-MS operated in full scan mode and a wide range of steroids were identified. The same approach was applied with the estrogen receptor alpha (ER alpha) in which LC-QqQ-MS, instead of the commonly applied GC-MS, was used for the screening of estrogens with a suitable LC-MS-compatible label. The identification of estrogens in ERa-purified supplement extracts was achieved with UPLC-ion mobility (IM)-Q-ToF-MS. These new BioMS concepts present new tools for the screening and identification of emerging yet unknown food and environmental contaminants to ensure consumer's health and fair play in sports.

Aqai, P., et al. (2013). "Receptor-based high-throughput screening and identification of estrogens in dietary supplements using bioaffinity liquid-chromatography ion mobility mass spectrometry." Analytical & Bioanalytical Chemistry **405**(29): 9427-9436.

A high-throughput bioaffinity liquid chromatography-mass spectrometry (BioMS) approach was developed and applied for the screening and identification of recombinant human estrogen receptor alpha (ERalpha) ligands in dietary supplements. For screening, a semi-automated mass spectrometric ligand binding assay was developed applying (13)C2, (15) N-tamoxifen as non-radioactive label and fast ultra-high-performance-liquid chromatography-electrospray ionisation-triple-quadrupole-MS (UPLC-QqQ-MS), operated in the single reaction monitoring mode, as a readout system. Binding of the label to ERalpha-coated paramagnetic microbeads was inhibited by competing estrogens in the sample extract yielding decreased levels of the label in UPLC-QqQ-MS. The label showed high ionisation efficiency in positive electrospray ionisation (ESI) mode, so the developed BioMS approach is able to screen for estrogens in dietary supplements despite their poor ionisation efficiency in both positive and negative ESI modes. The assay was performed in a 96-well plate, and all these wells could be measured within 3 h. Estrogens in suspect extracts were identified by full-scan accurate mass and collision-cross section (CCS) values from a UPLC-ion mobility-Q-time-of-flight-MS (UPLC-IM-Q-ToF-MS) equipped with a novel atmospheric pressure ionisation source. Thanks to the novel ion source, this instrument provided picogram sensitivity for estrogens in the negative ion mode and an additional identification point (experimental CCS values) next to retention time, accurate mass and tandem mass spectrometry data. The developed combination of bioaffinity screening with UPLC-QqQ-MS and identification with UPLC-IM-Q-ToF-MS provides an extremely powerful analytical tool for early warning of ERalpha bioactive compounds in dietary supplements as demonstrated by analysis of selected dietary supplements in which different estrogens were identified.

Aqai, P., et al. (2013). "High-throughput bioaffinity mass spectrometry for screening and identification of designer anabolic steroids in dietary supplements." Analytical Chemistry **85**(6): 3255-3262.

A generic high-throughput bioaffinity liquid chromatography-mass spectrometry (BioMS) approach was developed and applied for the screening and identification of known and unknown recombinant human sex hormone-binding globulin (rhSHBG)-binding designer steroids in dietary supplements. For screening, a semi-automated competitive inhibition binding assay was combined with fast ultrahigh-performance-LC-electrospray ionization-triple-quadrupole-MS (UPLC-QqQ-MS). 17beta-Testosterone-D3 was used as the stable isotope label of which the binding to rhSHBG-coated paramagnetic microbeads was inhibited by any other binding (designer) steroid. The assay was performed in a 96-well plate and combined with the fast LC-MS, 96 measurements could be performed within 4 h. The concentration-dependent

inhibition of the label by steroids in buffer and dietary supplements was demonstrated. Following an adjusted bioaffinity isolation procedure, suspect extracts were injected into a chip-UPLC(NanoTile)-Q-time-of-flight-MS system for full-scan accurate mass identification. Next to known steroids, 1-testosterone was identified in three of the supplements studied and the designer steroid tetrahydrogestrinone was identified in a spiked supplement. The generic steroid-binding assay can be used for high-throughput screening of androgens, estrogens, and gestagens in dietary supplements to fight doping. When combined with chip-UPLC-MS, it is a powerful tool for early warning of unknown emerging rhSHBG bioactive designer steroids in dietary supplements.

Aqai, P., et al. (2012). "Triple bioaffinity mass spectrometry concept for thyroid transporter ligands." Analytical Chemistry **84**(15): 6488-6493.

For the analysis of thyroid transporter ligands, a triple bioaffinity mass spectrometry (BioMS) concept was developed, with the aim at three different analytical objectives: rapid screening of any ligand, confirmation of known ligands in accordance with legislative requirements, and identification of emerging yet unknown ligands. These three purposes share the same biorecognition element, recombinant thyroid transport protein transthyretin (rTTR), and dedicated modes of liquid chromatography-mass spectrometry (LC-MS). For screening, a rapid and radiolabel-free competitive inhibition MS binding assay was developed with fast ultrahigh performance-liquid chromatography-electrospray ionization-triple-quadrupole-MS (UPLC-QqQ-MS) as the readout system. It uses the nonradioactive stable isotopic thyroid hormone (13)C(6)-L-thyroxine as the label of which the binding to rTTR is inhibited by any ligand such as thyroid drugs and thyroid endocrine disrupting chemicals (EDCs). To this end, rTTR is either used in solution or immobilized on paramagnetic microbeads. The concentration-dependent inhibition of the label by the natural thyroid hormone l-thyroxine (T4), as a model analyte, is demonstrated in water at part-per-trillion and in urine at part-per-billion level. For confirmation of identity of known ligands, rTTR was used for bioaffinity purification for confirmation of naturally present free T4 in urine. As a demonstrator for identification of unknown ligands, the same rTTR was used again but in combination with nano-UPLC-quadrupole time-of-flight-MS (nLC-Q-TOF-MS) and urine samples spiked with the model "unknown" EDCs triclosan and tetrabromobisphenol-A. This study highlights the potential of BioMS using one affinity system, both for rapid screening and for confirmation and identification of known and unknown emerging thyroid EDCs.

Aqai, P., et al. (2011). "Immunomagnetic microbeads for screening with flow cytometry and identification with nano-liquid chromatography mass spectrometry of ochratoxins in wheat and cereal." Analytical and bioanalytical chemistry **400**(9): 3085-3096.

Multi-analyte binding assays for rapid screening of food contaminants require mass spectrometric identification of compound(s) in suspect samples. An optimal combination is obtained when the same bioreagents are used in both methods; moreover, miniaturisation is important because of the high costs of bioreagents. A concept is demonstrated using superparamagnetic microbeads coated with monoclonal antibodies (Mabs) in a novel direct inhibition flow cytometric immunoassay (FCIA) plus immunoaffinity isolation prior to identification by nano-liquid chromatography-quadrupole time-of-flight-mass spectrometry (nano-LC-Q-ToF-MS). As a model system, the mycotoxin ochratoxin A (OTA) and cross-reacting mycotoxin analogues were analysed in wheat and cereal samples, after a simple extraction, using the FCIA with anti-OTA Mabs. The limit of detection for OTA was 0.15 ng/g, which is far below the lowest maximum level of 3 ng/g established by the European Union. In the immunomagnetic isolation method, a 350-times-higher amount of beads was used to trap ochratoxins from sample extracts. Following a wash step, bound ochratoxins were dissociated from the Mabs using a small volume of acidified acetonitrile/water (2/8v/v) prior to separation plus identification with nano-LC-Q-ToF-MS. In screened suspect naturally contaminated samples, OTA and its non-chlorinated analogue ochratoxin B were successfully identified by full scan accurate mass spectrometry as a proof of concept for identification of unknown but cross-reacting emerging mycotoxins. Due to the miniaturisation and bioaffinity isolation, this concept might be applicable for the use of other and more expensive bioreagents such as transport proteins and receptors for screening and identification of known and unknown (or masked) emerging food contaminants.

Arango, C., et al. (2014). "Effect of virgin heterophasic PP copolymer content on moisture absorption, thermal and mechanical properties of recycled polyethylene wood flour composites." Journal of the Chilean Chemical Society **59**(1): 2374-2377.

The effect of virgin heterophasic PP copolymer (vPP) content on moisture absorption, as well as on thermal and mechanical properties of recycled polyethylene/wood flour composites was investigated. The polymer matrix of recycled post-consumed plastic waste (rPE) was composed of a matrix of LDPE and a part of PP. Wood flour of Pinus radiata was used as filler at a constant loading of 45 wt.%. rPE/vPP blends and their composites were manufactured by melt blending, and then by injection molding. The morphology of the blends and composites was analyzed by means of scanning electron microscopy. The addition of vPP improved tensile and flexural moduli and flexural strength of wood plastic composites (WPC). The highest increase of these properties was observed for a WPC sample with a rPE/vPP ratio of 19. WPC made with higher virgin PP content (rPE/vPP ratio=9 and 5.7) showed lower increase of mechanical properties compared to polymer matrix and WrPE samples. The moisture uptake of WPC made of rPE/vPP blend was higher than those of rPE, and their mechanical properties were more adversely affected by immersion in water. TGA results indicate that rPE are thermally more stable than rPE/vPP blends. The incorporation of heterophasic PP copolymer into the recycled polymer matrix of WPC delays the starting of wood flour degradation.

Araujo, A., et al. (2019). "Hepatotoxicity of pristine polyethylene microplastics in neotropical physalaemus cuvieri tadpoles (Fitzinger, 1826)." Journal of Hazardous Materials **386**: 121992.

Plastic waste disposal in the environment is a major issue worldwide, whose effects on different biotas are the object of several investigations. The toxicity caused by microplastics (MPs) in organisms living in freshwater environments remains little explored. Little is known about the consequences of the exposure to these pollutants on the health of amphibians. Thus, we tested the hypothesis that the exposure of Physalaemus cuvieri tadpoles to microplastic polyethylene (PE MP) causes histopathological damage to their liver. Data collected after seven days of exposure to MPs (60mg/L) have shown that pollutant bioaccumulation in tadpoles' liver was correlated to different histopathological changes (blood vessel dilation, infiltration, congestion, hydropic degeneration, hypertrophy and hyperplasia), which showed the histopathotoxicity of MPs. Furthermore, we observed changes in hepatocyte nuclei size (area and diameter), volume and shape induced by the exposure to PE MPs, a fact that evidenced the cytotoxic effect of these pollutants. To the best of our knowledge, the current study is the first to report the histopathotoxicity of PE MPs in representatives of the amphibian group, and it contributes to improving knowledge about these pollutants and how they may affect the health of these animals.

Araujo, M. C. B. and M. F. Costa (2019). "From Plant to Waste: The Long and Diverse Impact Chain Caused by Tobacco Smoking." International Journal of Environmental Research & Public Health [Electronic Resource] **16**(15): 28.

Smoking is a social phenomenon of global scope. The impacts start from the cultivation of the plant to the disposal of cigarette butts in the most diverse places. These aspects go beyond economic and public health issues, also affecting natural environments and their biota in a serious and indistinct way. Of the six trillion cigarettes consumed globally each year, four and a half trillion are disposed somewhere in the environment. Cigarette butts are predominantly plastic, non-biodegradable waste, prevalent in coastal environments in various parts of the world, and with high potential for generating impacts on a wide range of socioeconomic and environmental aspects. Among the 5000 compounds found in a cigarette, those with higher toxic potential are mainly concentrated in the filter and in tobacco remnants, which are items found in discarded cigarette butts. After surveying published studies on this topic, the present study addressed the interaction between the impacts related to tobacco smoking, highlighting the problem as an important and emerging issue that demands joint efforts, and actions especially focused on the reduction of environmental impacts, an aspect that has not yet been assessed.

Araz, M. K., et al. (2013). "Microfluidic Multiplexing in Bioanalyses." Journal of Laboratory Automation **18**(5): 350-366.

The importance of biological assays spans from clinical diagnostics to environmental monitoring. Simultaneous detection of multiple analytes enhances the efficacy of bioassays by providing more data per assay under standardized conditions. Nevertheless, simultaneous handling and assaying of multiple samples, targets, and experimental conditions can be laborious, reagent consuming, and time intensive. Given these demands, microfluidic platforms have emerged over the past two decades as well-suited approaches for multiplexed assays. Microfluidic design supports integration of assay steps and reproducible sample manipulation across large sets of conditions-all relevant to multiplexed assays. Taken together, reduced reagent consumption, faster assay times, and potential for automation stemming from microfluidic assay design are attractive and needed multiplexed assay performance attributes. This review highlights recent advances in multiplexed bioanalyses benefitting from microfluidic integration. © 2013 Society for Laboratory Automation and Screening.

Arca-Ramos, A., et al. (2016). "Recyclable cross-linked laccase aggregates coupled to magnetic silica microbeads for elimination of pharmaceuticals from municipal wastewater." Environmental Science & Pollution Research **23**(9): 8929-8939.

In the present work, the use of magnetic mesoporous silica microbeads (MMSMB) as supports was proposed to produce magnetically-separable cross-linked enzyme aggregates (MCLEAs). The effects of cross linking time, addition of bovine serum albumin as protein feeder, pH, glutaraldehyde concentration, and laccase:MMSMB mass ratio on the immobilization yield and enzyme load were investigated. The best conditions allowed the rapid preparation of MCLEAs with high enzyme load, i.e., 1.53 U laccase/mg MCLEAs. The stability of MCLEAs was improved with regard to low pH, presence of chemical denaturants, and real wastewater matrix, compared to free laccase. In addition, the novel biocatalyst exhibited good operational stability, maintaining up to 70 % of its initial activity after 10 successive batch reactions. Finally, MCLEAs demonstrated its catalytic potential to transform acetaminophen and various non-phenolic pharmaceutical active compounds as mefenamic acid, fenofibrate, and indomethacin from biologically treated wastewater effluent, with similar or even higher efficiency than free laccase.

Archer, M. J., et al. (2008). "Development and Characterization of a Solid Phase for Single-Step Enrichment of Pathogenic Targets." Open Analytical Chemistry Journal **2**: 47-54.

The identification of low abundance target nucleic acids in a complex matrix can be challenging due to the abundance background material. Current methods use two-step processes which are time consuming, prone to contamination and usually limited to one pathogen. In this study we describe a single-step target-capture approach using magnetic microbeads with capture probes covalently attached through a phosphorus dendrimer linker. This approach was also used successfully for simultaneous capturing of two low abundance pathogenic nucleic acids present in a complex matrix (800- fold excess of background nucleic acids) by using a multi-pathogen solid phase. The thermal stability of the solid phase allows denaturation and capture to proceed sequentially and the recovery of the targets to be performed by heat denaturation without the risk of probe shedding. The critical variables involved in the development of the solid phase and the steps required for further optimization are discussed.

Arciero, R. A., et al. (2015). "The effect of a combined glenoid and Hill-Sachs defect on glenohumeral stability: a biomechanical cadaveric study using 3-dimensional modeling of 142 patients." American Journal of Sports Medicine **43**(6): 1422-1429.

BACKGROUND: Bone loss in anterior glenohumeral instability occurs on both the glenoid and the humerus; however, existing biomechanical studies have evaluated glenoid and humeral head defects in isolation. Thus, little is known about the combined effect of these bony lesions in a clinically relevant model on glenohumeral stability.

HYPOTHESIS/PURPOSE: The purpose of this study was to determine the biomechanical efficacy of a Bankart repair in the setting of bipolar (glenoid and humeral head) bone defects determined via computer-generated 3-dimensional (3D) modeling of 142 patients with recurrent anterior shoulder instability. The null hypothesis was that adding a bipolar bone defect will have no effect on glenohumeral stability after soft tissue Bankart repair.

STUDY DESIGN: Controlled laboratory study.

METHODS: A total of 142 consecutive patients with recurrent anterior instability were analyzed with 3D computed tomography scans. Two Hill-Sachs lesions were selected on the basis of volumetric size representing the 25th percentile (0.87 cm(3); small) and 50th percentile (1.47 cm(3); medium) and printed in plastic resin with a 3D printer. A total of 21 cadaveric shoulders were evaluated on a custom shoulder-testing device permitting 6 degrees of freedom, and the force required to translate the humeral head anteriorly 10 mm at a rate of 2.0 mm/s with a compressive load of 50 N was determined at 60degree of glenohumeral abduction and 60degree of external rotation. All Bankart lesions were made sharply from the 2- to 6-o'clock positions for a right shoulder. Subsequent Bankart repair with transosseous tunnels using high-strength suture was performed. Hill-Sachs lesions were made in the cadaver utilizing a plastic mold from the exact replica off the 3D printer. Testing was conducted in the following sequence for each specimen: (1) intact, (2) posterior capsulotomy, (3) Bankart lesion, (4) Bankart repair, (5) Bankart lesion with 2-mm glenoid defect, (6) Bankart repair, (7) Bankart lesion with 2-mm glenoid defect and Hill-Sachs lesion, (8) Bankart repair, (9) Bankart lesion with 4-mm glenoid defect and Hill-Sachs lesion, (10) Bankart repair, (11) Bankart lesion with 6-mm glenoid defect and Hill-Sachs lesion, and (12) Bankart repair. All sequences were used first for a medium Hill-Sachs lesion (10 specimens) and then repeated for a small Hill-Sachs lesion (11 specimens). Three trials were performed in each condition, and the mean value was used for data analysis.

RESULTS: A statistically significant and progressive reduction in load to translation was observed after a Bankart lesion was created and with the addition of progressive glenoid defects for each

humeral head defect. For medium (50th percentile) Hill-Sachs lesions, there was a 22%, 43%, and 58% reduction in stability with a 2-, 4-, and 6-mm glenoid defect, respectively. For small (25th percentile) Hill-Sachs lesions, there was an 18%, 27%, and 42% reduction in stability with a 2-, 4-, and 6-mm glenoid defect, respectively. With a >=2-mm glenoid defect, the medium Hill-Sachs group demonstrated significant reduction in translation force after Bankart repair (P < .01), and for the small Hill-Sachs group, a >=4-mm glenoid defect was required to produce a statistical decrease (P < .01) in reduction force after repair.

CONCLUSION: Combined glenoid and humeral head defects have an additive and negative effect on glenohumeral stability. As little as a 2-mm glenoid defect with a medium-sized Hill-Sachs lesion demonstrated a compromise in soft tissue Bankart repair, while small-sized Hill-Sachs lesions showed compromise of soft tissue repair with >=4-mm glenoid bone loss.

CLINICAL RELEVANCE: Bipolar bony lesions of the glenoid and humeral head occur frequently together in clinical practice. Surgeons should be aware that the combined defects and glenoid bone loss of 2 to 4 mm or approximately 8% to 15% of the glenoid could compromise Bankart repair and thus may require surgical strategies in addition to traditional Bankart repair alone to optimize stability.

Ardente, F., et al. (2010). "Life Cycle Assessment-Driven Selection of Industrial Ecology Strategies." <u>Integrated Environmental Assessment & Management</u> **6**(1): 52-60.

The paper presents an application of the Life-Cycle Assessment (LCA) to the planning and environmental management of an "eco-industrial cluster." A feasibility study of industrial symbiosis in southern Italy is carried out, where interlinked companies share subproducts and scraps, services, structures, and plants to reduce the related environmental impact. In particular, the research focuses on new recycling solutions to create open recycling loops in which plastic subproducts and scraps are transferred to external production systems. The main environmental benefits are the reduction of resource depletion, air emissions, and landfilled wastes. The proposed strategies are also economically viable and they suggest cost abatement for the involved companies. This research shows the need for a multidisciplinary approach to data processing and to complexity managing of the investigated systems. In this context, life-cycle thinking is required to be promoted throughout the economy, as well to be as a part of all decisions on products and other criteria such as functionality, health, and safety. The Life-Cycle Assessment approach can be assumed as a methodology for influencing decision makers to make sustainable choices. [ABSTRACT FROM AUTHOR]

Arena, U., et al. (2011). "A techno-economic comparison of fluidized bed gasification of two mixed plastic wastes." <u>Waste Management</u> **31**(7): 1494-1504.

A comparison between the most promising design configurations for the industrial application of gasification based, plastics-to-energy cogenerators in the 2-6. MWe range is presented. A pilot scale bubbling fluidized bed air gasifier, having a feeding capacity of 100 kg/h, provided experimental data: the syngas complete composition, the characterization of the bed material, the entrained fines collected at the cyclone and the purge material from the scrubber. Mass and energy balances and material and substance flow analyses have been therefore drawn to assess

and compare design solutions utilizing two mixed plastic wastes (MPW) obtained from separate collection of plastic packaging, after different levels of pre-treatments. The related techno-economic performances have been finally estimated on the basis of the manufacturer's specifications. The study concludes that the MPW obtained after a very simple pre-treatment and fed to a gasifier coupled with a steam turbine is the solution that currently offers the higher reliability and provides the higher internal rate of return for the investigated range of electrical energy production. © 2011.

Arena, U., et al. (2009). "Tar removal during the fluidized bed gasification of plastic waste." Waste Management **29**(2): 783-791.

A recycled polyethylene was fed in a pilot plant bubbling fluidized bed gasifier, having an internal diameter of 0.381 m and a maximum feeding capacity of 90 kg/h. The experimental runs were carried out under various operating conditions: the bed temperature was kept at about 850 degrees C, the equivalence ratio varied between 0.2 and 0.35, the amount of bed material was between 131 and 215 kg, the fluidizing velocity was between 0.5 and 0.7 m/s, quartz sand and olivine were used as bed material, and air and steam were used as fluidizing reactants. The results confirm that the tar removal treatments applied inside the gasifier (primary methods) can eliminate or strongly reduce the need for a further downstream cleanup of the syngas. In particular, the utilization of a natural olivine as an in situ tar reduction agent remarkably improves the quality of the product gas, in terms of both high hydrogen volumetric fraction and larger syngas yield.

Arias, A. H., et al. (2019). "Evidence of microplastic ingestion by fish from the Bahia Blanca Estuary in Argentina, South America." Bulletin of environmental contamination and toxicology **102**(6): 750-756.

The aim of this study was to assess - for the first time - the occurrence and distribution of microplastics (MPs) in the gastrointestinal tracts (GITs) of a marine commercial fish species (Micropogonias furnieri) from the Bahia Blanca Estuary (BBE) in Argentina, and to evaluate fish potential associated stress. In order to do this, juveniles were sampled using artisanal fishing arts at two sampling locations. Basic measurements of individual fish were taken (total length, total weight, weight of the liver) and GITs were subsequently removed, digested with 30% H₂O₂ for 5 days at 60 degrees C, filtered on Whatman paper and then dried. Samples were observed with a stereomicroscope, and it was demonstrated that 100% of the individuals contained microplastic particles in their GITs. In total, 241 microplastic particles were removed from the GITs of all fish. They were categorized as fibers (60.8%), pellets (28.9%), fragments (8.6%) and laminas (1.4%), and they ranged in size from 0.98 to >5 mm. The average number of particles per fish was higher than that reported in previous global marine studies. Moreover, a positive correlation between the number of MPs per fish and hepatosomatic index was found, suggesting a probable stress in their health condition. These findings provide the first and southernmost evidence of microplastic contamination in biota from the Argentinean sea, which is found in the South Atlantic sea.

Arias-Andres, M., et al. (2018). "Microplastics: New substrates for heterotrophic activity contribute to altering organic matter cycles in aquatic ecosystems." Science of the Total Environment **635**: 1152-1159.

Heterotrophic microbes with the capability to process considerable amounts of organic matter can colonize microplastic particles (MP) in aquatic ecosystems. Weather colonization of microorganisms on MP will alter ecological niche and functioning of microbial communities remains still unanswered. Therefore, we compared the functional diversity of biofilms on microplastics when incubated in three lakes in northeastern Germany differing in trophy and limnological features. For all lakes, we compared heterotrophic activities of MP biofilms with those of microorganisms in the surrounding water by using Biolog EcoPlates and assessed their oxygen consumption in microcosm assays with and without MP. The present study found that the total biofilm biomass was higher in the oligo-mesotrophic and dystrophic lakes than in the eutrophic lake. In all lakes, functional diversity profiles of MP biofilms consistently differed from those in the surrounding water. However, solely in the oligo-mesotrophic lake MP biofilms had a higher functional richness compared to the ambient water. These results demonstrate that the functionality and hence the ecological role of MP-associated microbial communities are context-dependent, i.e. different environments lead to substantial changes in biomass build up and heterotrophic activities of MP biofilms. We propose that MP surfaces act as new niches for aquatic microorganisms and that the constantly increasing MP pollution has the potential to globally impact carbon dynamics of pelagic environments by altering heterotrophic activities.

Arias-Andres, M., et al. (2018). "Microplastic pollution increases gene exchange in aquatic ecosystems." Environmental Pollution **237**: 253-261.

Pollution by microplastics in aquatic ecosystems is accumulating at an unprecedented scale, emerging as a new surface for biofilm formation and gene exchange. In this study, we determined the permissiveness of aquatic bacteria towards a model antibiotic resistance plasmid, comparing communities that form biofilms on microplastics vs. those that are free-living. We used an exogenous and red-fluorescent E. coli donor strain to introduce the green-fluorescent broad-host-range plasmid pKJK5 which encodes for trimethoprim resistance. We demonstrate an increased frequency of plasmid transfer in bacteria associated with microplastics compared to bacteria that are free-living or in natural aggregates. Moreover, comparison of communities grown on polycarbonate filters showed that increased gene exchange occurs in a broad range of phylogenetically-diverse bacteria. Our results indicate horizontal gene transfer in this habitat could distinctly affect the ecology of aquatic microbial communities on a global scale. The spread of antibiotic resistance through microplastics could also have profound consequences for the evolution of aquatic bacteria and poses a neglected hazard for human health.

Arias-Andres, M., et al. (2019). "Collateral effects of microplastic pollution on aquatic microorganisms: An ecological perspective." TrAC - Trends in Analytical Chemistry **112**: 234-240.

Microplastics (MP) provide a unique and extensive surface for microbial colonization in aquatic ecosystems. The formation of microorganism-microplastic complexes, such as biofilms, maximizes the degradation of organic matter and horizontal gene transfer. In this context, MP affect the structure and function of microbial communities, which in turn render the physical and chemical fate of MP. This new paradigm generates challenges for microbiology, ecology, and ecotoxicology. Dispersal of MP is concomitant with that of their associated microorganisms and their mobile genetic elements, including antibiotic resistance genes, islands of pathogenicity, and diverse metabolic pathways. Functional changes in aquatic microbiomes can alter carbon metabolism and food webs, with unknown consequences on higher organisms or human microbiomes and hence health. Here, we examine a variety of effects of MP pollution from the microbial ecology perspective, whose repercussions on aquatic ecosystems begin to be unraveled. Copyright © 2018 Elsevier B.V.

Arjomand Fard, N., et al. (2017). "Efficacy and Safety of G2013 as a Novel Immunosuppressive Agent on Differentiation, Maturation and Function of Human Dendritic Cells." Iranian Journal of Public Health **46**(2): 216-221.

BACKGROUND: The expanse of dendritic cells (DC) differentiation plays an important role in determining immune response. DC-based immunosuppressive drugs have notable side effects in increasing the risk of infectious diseases and cancers. G2013, as a novel anti-inflammatory and immunosuppressive agent, has been tested in experimental model of multiple sclerosis. The aim of this study was to conduct the safety property of G2013 on dendritic cells biology.
METHODS: The effect of G2013 on differentiation, maturation, and function of dendritic cells was examined at Tehran University in 2014. To investigate how G2013 affects human dendritic cells (DC) in a defined inflammatory environment, human peripheral blood mononuclear cells (PBMC) were isolated from healthy blood. Monocytes were then purified using anti-CD14 microbeads. Monocytes were treated with G2013 in two different doses (6 and 12 mug/well) along with adding granulocyte-macrophage colony-stimulating factor (GM-CSF) and interleukin-4 for inducing monocytes to immature DC and adding lipopolysaccharide for running DC maturation. Differentiation, maturation, and function of dendritic cells were examined with flow cytometry and ELISA.
RESULTS: G2013 therapy had no significant effect on CD83, CD86 and DR expression, as well as IL-10 and IL-12 cytokine levels and it, has no remarkable side on differentiation, maturation and function of dendritic cells in immature DC and mature DC process in vitro.
CONCLUSION: G2013 is a safe agent with no adverse effect on differentiation, maturation, and function of dendritic cells. It may be recommended as a novel immunosuppressive agent with no or little side effect in increasing the risk of infectious diseases and cancers.

Arndt, G. (2019). "Trace substances and microplastic in drinking and wastewater. Review of the Wastewater Conferences of Hach Lange GmbH." Flussiges Obst **86**(6): 198-201.

Arnold, J. C. (2004). Chapter 13: Reprocessing**:** 272-299.
This article presents chapter thirteen of the book "Green Composites: Polymer Composites and the Environment," edited by Caroline Baillie. The chapter is entitled "Reprocessing". It deals with management of waste plastics and composites, methods of recycling plastics, methods of sorting and separating polymers and plastics, and future trends. The bulk polymers of polyvinyl chloride, polyethylene, polypropylene, and polystyrene comprise 70 percent of the plastics used worldwide. There are multiple problems in dealing with waste plastics and composites.

Arnold, M. L., et al. (2017). "A normalization factor for an increased comparability within antibody results, tested by bead-based single antigen assays." Hla **89 (6)**: 393-394.
The Implementation of bead based techniques (Luminex) for anti-HLA antibody (Ab) detection has increased the complexity of Ab identification and specification. MFI values in Luminex Single Ag assays do not automatically mirror a predictable Ab concentration. The mean fluorescence intensity (MFI) of Abs is used for the definition of "unacceptable antigens", even though there are considerable inter- and intra-HLA locus differences in the MFI readout of the Luminex assays. The aim of our study was to compare reaction patterns of Ab positive sera with respect to the various HLA class I and II Ab targets. MFI values of HLA specificities were measured and calculated in 278 anti HLA class I Ab positive and 281 anti HLA class II Ab positive sera from patients on the local waiting list in Erlangen, Germany using Luminex Single Ag assays. Anti HLA-C Abs reacted with a lower mean MFI level compared to anti- HLA-A and anti-HLA-B Abs. In contrast, anti HLA-DQ Abs showed higher MFI values than HLA-DR and HLA-DP Abs. In order to define a comparable MFI cutoff for all HLA Ab specificities, two normalization factors were calculated, based on a "positive" assumed cut-off of 3000 MFI: one for anti HLA-C Ab MFI (MFI x 2.11) and one for HLA-DQ Ab (MFI x 0.64) MFI. Due to the various Ag loading densities on the

surface of the microbeads, MFI values of different HLA specificities are not comparable. Furthermore, HLA inter-specific differences in Ab binding cannot be ruled out. In the interest of treating all Ab MFI values equally, independent of the various HLA targets, a unique Ab MFI cutoff within a single patient's serum should be calculated using a normalization factor for - at least - HLA-C and HLA-DQ Abs. In order to perform a "virtual crossmatch", the definition of unacceptable antigens, based on MFI value without taking into account the inter-HLA locus variability should be discussed intensively. A comprehensive concept for the evaluation of this normalization factor would appear to be sensible.

Arnold, R., et al. (1998). "Use of plastic waste for innovative knitted fabrics for agriculture and horticulture." Plasticulture **116**: 43-55.

The recycling of plastic wastes (PES, PP and PE) into woven textiles suitable for use in agriculture and horticulture is discussed. Such textiles can be used for storing, distributing and draining water, for shielding crops from solar radiation, and for protecting crops from the wind, birds and insects. Other topics covered include the manufacture and use of textiles for irrigation, ventilation and oxygenation, for soilless culture, and for heat transfer in greenhouses.

Arnold, W. A. and A. L. Roberts (2000). "Inter- and intraspecies competitive effects in reactions of chlorinated ethylenes with zero-valent iron in column reactors." Environmental Engineering Science **17**(5): 291-302.

Reaction kinetics are a key component of process models used to design Fe(0) permeable barriers employed to treat groundwater contaminated with chlorinated solvents. In this work, columns packed with a mixture of zero-valent iron and glass microbeads were used to assess whether the competitive effects observed in batch systems also occur in column reactors. As with the batch studies previously conducted, both inter- and intraspecies competition were observed, in qualitative agreement with predictions obtained from a modified Langmuir-Hinshelwood-Hougen-Watson (LHHW) kinetic model in which species compete for a limited number of reactive sites. The observed changes in pseudo first-order rate 'constant' at different initial concentrations or in the presence of competitors could not be attributed to alterations in the transport properties of the column packing or to 'aging' of the iron. Numerical simulations were used to explore the consequences of applying a pseudo first-order kinetic model instead of the LHHW model. The results demonstrate that intraspecies competitive effects are sufficiently important to merit explicit consideration in permeable barrier design.

Arouche-Delaperche, L., et al. (2015). "Effects of auto-antibodies anti-signal recognition particle (SRP) and anti-hydroxymethylglutaryl-CoA reductase (HMGCR) on muscle cells." Neuromuscular Disorders **2)**: S250.

Necrotizing myopathies (NM) might be acquired auto-immune muscle diseases, in which muscle biopsy demonstrates marked muscle necrosis with regeneration, little or absence of inflammatory infiltrates and a particular pattern of complement C5b-9 deposition on muscle fibers. NM can be seropositive for some auto-antibodies (aAbs) such as anti-SRP as well as anti-HMGCR. The titer of those Abs is correlated with the creatine kinase levels, but their role remains unclear. In the current study, we investigated the effect of the aAbs anti-SRP and anti-HMGCR on in vitro primary human myoblasts/myotubes. Primary human myoblasts were isolated from human muscle biopsies of nonmyopathic patients. Myoblasts were sorted by CD56 immune-magnetic microbead Abs. To study the effect of the auto-Abs on muscle cells, confluent myoblasts and 3 day myotubes were incubated with anti-SRP or anti-HMGCR positive human IgG for 72 hours or with IVIg as a control. We demonstrate that the addition of the aAbs onto

differentiated myotubes leads to atrophy, as measured by the reduction of the size of myotubes (anti-SRP 66.5 +/- 2.6 mum², anti-HMGCR 66.5 +/- 4.8 mum² vs control 118.8 +/- 6.1 mum², p < 0.001). The expression of atrophic genes as Atrogin and Murf-1 was measured by qPCR; the culture with anti-SRP Abs shows an increase of Atrogin expression and the anti-HMGCR shows an increase of Murf1 compared to the control. Furthermore, addition of the aAbs to a confluent myoblasts significantly reduced the capacity of myoblasts to differentiate (anti-SRP 44.2 +/- 7.7 mum², anti-HMGCR 53.6 +/- 7.7 mum² vs control 147.8 +/- 5.4 mum², p < 0.001). These findings suggest that anti-SRP and anti- HMGCR aAbs have a pathogenic effect on muscle cells in vitro by both inhibiting cell fusion and triggering atrophy on fully differentiated myotubes.

Arp, H. P. H., et al. (2011). "Presence and partitioning properties of the flame retardants pentabromotoluene, pentabromoethylbenzene and hexabromobenzene near suspected source zones in Norway." Journal of Environmental Monitoring **13**(3): 505-513.

The brominated flame retardants (BFRs), pentabromotoluene (PBT), pentabromoethylbenzene (PBEB) and hexabromobenzene (HBB), exhibit physical-chemical properties similar to other persistent organic pollutants, and have been in use as flame retardants for several decades. Data on these BFRs in diverse environmental samples can be found in studies from the 1970s and 1980s, as well as in recent years, though very little in the years in between. Due to a lack of data, the cause for the apparent re-emergence of these BFRs in recent studies is unclear, and could reflect changes in production volumes, accumulation of transformation products from BFR precursors, improved analytical techniques or simply a re-emergence in concern. Very little data are available on their environmentally relevant partitioning properties, which could help to explain the occurrence and fate of these BFRs. In this study we analysed for the presence of HBB, PBT, and PBEB in diverse environmental samples from potential Norwegian BFR source zones. Additionally, environmental partitioning properties of these BFRs as well as brominated benzenes were estimated and validated using experimental data for brominated benzenes. Of the three BFRs, HBB was identified in detectable quantities at most source zones, PBEB only near a metal recycling factory, and PBT only in a few additional locations from where PBEB was detected. Data from this study show that HBB is likely widely distributed, as verified both by chemical analysis and estimated properties. Measured HBB levels in wastewater treatment plants indicate that the treatment practices used in the study locations are not effective at lowering HBB levels, perhaps due to association with low density suspended solids (e.g. microplastics). © 2011 The Royal Society of Chemistry.

Arrieta-Bolanos, E., et al. (2019). "Relative contribution of naive and memory T cells to alloreactivity in hematopoietic cell transplantation." Blood. Conference: 61st Annual Meeting of the American Society of Hematology, ASH **134**(Supplement 1).

Introduction: Graft-versus-host disease (GvHD) is a major impediment to the cure of blood disorders by hematopoietic cell transplantation (HCT). GvHD is mediated by alloreactive T cells recognizing histocompatibility antigen (HAg) mismatches between patient and donor. Naive T cells are thought to be the main mediators of alloreactive responses since, theoretically, memory T cells would have never been exposed to and selected by alloantigens, except in multiparous women or transfused individuals. Accordingly, clinical trials using naive T cell-depleted allografts are being conducted with the aim to reduce GvHD after human leukocyte antigen (HLA)-matched HCT. However, several groups have shown that memory T cells can also mediate alloreactive responses, in particular against mismatched HLA. We hypothesized that the relative importance of naive vs. memory T cell alloreactivity depends on the matching status of the patient-donor pair. Specifically, we reasoned that naive-depletion strategies will be most efficient in HLA-identical sibling HCT, where minor (m)HAg presented by self-HLA are the only targets of T cell alloreactivity, but less so in HLA-matched unrelated HCT, where HLA-DPB1 mismatches (mmDPB1) are frequent and potentially recognized through molecular mimicry by both naive and memory T cells. Method(s): In order to model T cell alloreactivity to mHAg and to major HLA mismatches post HCT, we used a quantitative in vitro assay based on co-culture of responder and stimulating cells. Naive (CD45RA⁺CD45RO-) and memory (CD45RA-CD45RO⁺) CD4⁺ T cells were enriched from peripheral blood mononuclear cells from healthy individuals using microbead technology to >95% purity and used as responders. Irradiated transduced HeLa cells engineered to express single HLA-DP antigens and the necessary machinery for HLA class II antigen presentation were used to stimulate CD4⁺ T cells. HeLa transductants expressing the autologous (i.e. DP-matched, response restricted to mHAg) or an allogeneic (mmDPB1) DP antigen were used to challenge naive and memory CD4⁺ cells from each responder. After 14 days of culture, T cells were restimulated overnight and the levels of T cell response were quantified by cell surface expression of the activation marker CD137. Result(s): In 36 independent T cell cultures from 8 different individuals, the overall levels of alloreactivity against mHAg were significantly lower than those against mmDPB1 (mean 50.3% vs 20.7%, p<0.0001) (Figure 1A). Consistent with current concepts, alloreactivity to mHAg was significantly higher in the naive than in the memory subset (mean 27.7% vs 10.5%, p=0.015) (Figure 1B). This was most evident in 5/8 responders (mean 38.4% vs 13.3%, p=0.016), in particular in females under 40 years of age. In 3 of the 8 responders, mHAg alloreactivity was generally low and not significantly different between the naive and the memory subsets (mean 10.3% vs 12.9%, p=0.73). In contrast, alloreactivity against mmDPB1 was evenly distributed between the naive and the memory subset (mean 52.1% vs 48.5%, p=0.62) in all responders, independent of age, sex or cytomegalovirus serostatus of the responder (Figure 1C). Interestingly, naive DPB1*04:01-restricted mHAg alloreactive CD4⁺ T cells were able to cross-recognize the structurally similar (i.e. permissive) DPB1*04:02 (mean 43.3%) but not the dissimilar (i.e. non-permissive) DPB1*09:01 (mean 14.1%) (Figure 1D). Moreover, when purified CD4⁺ cells from self-DPB1*04:01 homozygous donors were challenged with DPB1*04:02 or DPB1*09:01, naive CD4⁺ T cells were the main source of alloreactive responses against the permissive mmDPB1 (mean 25.0% vs 7.4% for naive and memory cells, respectively), while both memory (mean 50.0%) and naive (mean 46.0%) CD4⁺ cells elicited strong alloresponses against the non-permissive mmDPB1. Conclusion(s): Our data provide the first direct experimental evidence that alloreactivity against mmDPB1 is stronger than against mHAg, and importantly that it is mediated equally by naive and memory CD4⁺ T cells while the mHAg response is mediated mainly by the naive subset. However, our data also suggests that some mmDPB1 involving structurally (and hence functionally) similar alleles (in general permissive) might behave similarly to DPB1 matches. These observations should be taken into account in clinical trials aimed at improving the outcome of unrelated HCT by selective depletion of naive T cells. (Figure Presented).

Artiga, P., et al. (2005). "An innovative biofilm-suspended biomass hybrid membrane bioreactor for wastewater treatment." Desalination **179**(1-3): 171-179.

An innovative membrane-assisted hybrid bioreactor for wastewater treatment was developed in our laboratory. This system was composed by a hybrid circulating bed reactor coupled in series to an ultrafiltration membrane module. Biomass was maintained growing both in suspension and in biofilms onto small rough plastic particles. The growth of nitrifiers in the hybrid system was promoted into biofilms while heterotrophs were in suspension. This made it feasible to operate the unit at higher SRT for nitrifiers than for heterotrophs, which resulted in the presence of a higher fraction of nitrifiers in the reactor. The hybrid bioreactor was used to treat two industrial wastewaters - from a tannery and a fish-canning factory - with high nitrogen and organic matter content. COD removals of around 99% were obtained at an organic loading rate (OLR) of 6.5 kg COD/m super(3)[sup].d and an NLR of 1.8 kg N- NH super(+) sub(4)/m super(3)[sup].d during the treatment of the fish canning wastewater. Between 50-60% of the nitrifying capacity of the reactor was located in the biofilm. During the treatment of the tannery wastewater, OLR and ALR were stepwise increased up to 4.5 kg COD/m super(3)[sup].d and 1.2 kg N- NH super(+) sub(4)/m super(3)[sup].d, respectively. COD removal efficiency was 95%, while up to 97% of ammonia removal was obtained, the concentration of ammonia in the effluent being low, 10 mg N-NH super(+) sub(4)/L. For both industrial wastewaters, the biofilm nitrifying activity was not affected by the variations in the organic loading rates, COD concentration in the influent or characteristics of the influent. Most of the dissolved COD was consumed by suspended biomass in the reactor, avoiding the competition between nitrifiers and heterothophs in the biofilm. Moreover, the membrane filtration unit made it feasible to operate the reactor at high OLR without problems related to either the settling properties of the sludge or the drop in the nitrogen conversion, which usually occurs in other hybrid biological reactors operated at high OLR or NLR.

Artimani, T., et al. (2015). "Estrogen and progesterone receptor subtype expression in granulosa cells from women with polycystic ovary syndrome." Gynecological Endocrinology **31**(5): 379-383.

We evaluated gene expression of estrogen and progesterone nuclear receptors in granulosa cells (GCs) of polycystic ovary syndrome (PCOS) women compared to women with normal cycling ovaries (control group) to achieve a better understanding of ovarian steroid status in patients with PCOS. In this prospective study, 40 patients with PCOS and 40 women with normal ovulatory function who underwent in vitro fertilization (IVF) for treatment of tubal and/or male infertility were recruited. Follicular fluid was collected from patients and GCs were isolated from follicular fluid and then were purified with Micro Beads conjugated to monoclonal anti-human CD45 antibodies. RNA was extracted and reverse transcription was performed. Gene expression of estrogen and progesterone receptors was determined by quantitative real time PCR (qRT-PCR). Estrogen receptor beta (ERbeta) expression was significantly higher than ERalpha expression in both groups ($p < 0.002$). ERalpha and ERbeta mRNA expression in PCOS was significantly lower than control group ($p < 0.002$). The expression levels of PRA and PRB in PCOS was significantly lower than control group ($p < 0.002$). In conclusion, a significant reduction of these genes in GCs from follicles of women with PCOS could be considered as a sign for maturation defect or follicular arrest in GCs. Artimani, T., et al. (2015). "Association between nuclear receptors of estrogen and progesterone with adiponectin receptors in granulosa cells of patients with poly cystic ovary syndrome." Iranian Journal of Reproductive Medicine **1)**: 18-19.

Introduction: The poly cystic ovary syndrome (PCOS), one of the most common endocrine disorders in reproductive age women, is associated with obesity and insulin resistance predisposing to diabetes mellitus type 2 and atherosclerosis. Adiponectin is a recently discovered adipocytokine with insulin -sensitizing and putative anti atherosclerotic properties. Several studies have illustrated that adiponectin can regulate granulosa cell stroidogenesis and

the expression of genes associated with ovulation. Therefore, the aim of this study was to investigate a relationship between gene expression of estrogen and progesterone nuclear receptors and adiponectin receptors in granulosa cells (GCs) of PCOS women compared to women with normal cycling ovaries in order to achieve a better understanding of ovarian steroid status in patients with PCOS. Material(s) and Method(s): In this prospective study, 40 patients with PCOS and 40 women with normal ovulatory function who underwent IVF for treatment of tubal and/or male infertility were recruited. Follicular fluid was collected from patients and. GCs were isolated from follicular fluid by centrifugation and then were purified with Micro Beads conjugated to monoclonal anti-human CD45 antibodies. RNA was extracted and Reverse transcription was performed. Gene expression of AdipoR1, AdipoR2, estrogen and progesterone receptors was determined by quantitative real time PCR (q-PCR). All statistical procedures were run on SPSS 16. P<=0.05 was considered significant. Result(s): By considering all subjects with and without PCOS undergoing controlled ovarian hyperstimulation, we observed ERalpha and ERbeta mRNA expression correlated positively with the mRNA expression of AdipoR1 (r=0.85, p=0.0001 and r=0.92, p=0.0001, respectively) and AdipoR2 (r=0.87, p=0.0001 and r=0.88, p=0.0001, respectively). Estrogen receptor beta (ERbeta) expression was significantly higher compared to ERalpha expression in both groups (p<0.002). Moreover, progesterone receptor A (PRA) and PRB were both expressed in human GCs. However, the expression level of nuclear PRB was very low in both groups (p<0.008). There was a significant correlation between progesterone receptors and adiponectin receptors (r=0.8, p=0.0001 and r=0.88, p=0.0001). In our present results, increased ratio of PRA/PRB in women with PCOS has been revealed. Conclusion(s): This research provides more evidence about expression profiles of genes involved in metabolism, steroidogenesis and ovulation in PCOS and supports the hypothesis that abnormal hormone activity, by different receptor expressions, may be an important factor in the generation of ovarian disorder.

Arunachalam, C. and R. Rajasekaran (2009). "Studies on the productivity of poly-beta-hydroxybutyrate by Alcaligenes eutrophus and Rhizobium meliloti using waste substrate." Journal of Pure and Applied Microbiology **3**(2): 685-689.

Poly-beta-hydroxybutyrate (PHB) is polymer from microbial origin are considered good substitute for plastics and isomers. Since in properties they are similar to petrochemical plastics, yet are truly biodegradable. The two potential bacteria Alcaligenes eutrophus and Rhizobium meliloti PHB production ability were analyzed using molasses as substrate at various concentrations in the fermentative medium (10%, 20%, 30% and 40%). Among this study maximum PHB was noted in high concentration of molasses (40%) in both bacteria, compared with Rhizobium meliloti and Alcaligenes eutrophus produce high amount of PHB in 40%. Alcaligenes eutrophus were optimized for two different carbon source (Sucrose and Maltose), nitrogen source (Ammonium chloride and Sodium nitrate) and various pH (5, 6, 7, 8 and 9). Among this maximum PHB was accumulated in maltose as carbon source, ammonium chloride as nitrogen source and 7 as pH. Thus the use of petroleum derived plastics can be minimized and by which we can live in a plastic pollution free earth.

Arya, C., et al. (2016). ""Killer" Microcapsules That Can Selectively Destroy Target Microparticles in Their Vicinity." Acs Applied Materials & Interfaces **8**(43): 29688-29695.

We have developed microscale polymer capsules that are able to chemically degrade a certain type of polymeric microbead in their immediate vicinity. The inspiration here is from the body's immune system, where killer T cells selectively destroy cancerous cells or cells infected by pathogens while leaving healthy cells alone. The "killer" capsules are made from the cationic biopolymer chitosan by a combination of ionic cross-linking (using multivalent tripolyposphate anions) and subsequent covalent cross-linking (using glutaraldehyde). During capsule formation, the enzyme glucose oxidase (GOx) is encapsulated in these capsules. The target beads are made by ionic cross-linking of the biopolymer alginate using copper (Cu²⁺) cations. The killer capsules harvest glucose from their surroundings, which is then enzymatically converted by GOx into gluconate ions. These ions are known for their ability to chelate Cu²⁺ cations. Thus, when a killer capsule is next to a target alginate bead, the gluconate ions diffuse into the bead and extract the Cu²⁺ cross-links, causing the disintegration of the target bead. Such destruction is visualized in real-time using optical microscopy. The destruction is specific, i.e., other microparticles that do not contain Cu²⁺ are left undisturbed. Moreover, the destruction is localized, i.e., the targets destroyed in the short term are the ones right next to the killer beads. The time scale for destruction depends on the concentration of encapsulated enzyme in the capsules.

Asadi, M. A., et al. (2019). "Microplastics in the sediment of intertidal areas of Lamongan, Indonesia." AACL Bioflux **12**(4): 1065-1073.

Microplastics are small plastic pieces which pose a great threat to marine ecosystems. Indonesia is among the world's largest contributors to microplastics pollution. This research aimed to identify and measure the abundance of microplastics in the intertidal areas of Lamongan, Indonesia. The sediment characteristics in the study areas were also examined for correlation between soil type and microplastics abundance. Microplastics characterization of the sediments were carried out using a modified flotation method. Sediment types were determined using sieve shaker analysis and hydrometer analysis. On average, there were 206 items kg⁻¹ dry weight of microplastics in which fibers shared more than 85% of all microplastics found in the research areas, with an average abundance of 178 items kg⁻¹ dry weight. Fragments constituted 12%, with an average concentration of 25 items kg⁻¹ dry weight. There was no significant difference between microplastics abundance at depths of 0-5 cm and 5-10 cm. However, the sediment texture may contribute to a higher concentration of microplastics. On average, clayey silts held significantly higher concentrations of microplastics than sand and gravelly sand. The high concentration of microplastics in the intertidal areas of Lamongan could have a negative impact on intertidal organisms and therefore may affect humans through the food chain.

Asamoah, B. O., et al. (2019). "A prototype of a portable optical sensor for the detection of transparent and translucent microplastics in freshwater." Chemosphere **231**: 161-167.

Microplastic pollution in water bodies is an alarming problem which needs to be addressed. However, issues such as size, shape and their appearance to light (transparent or translucent) make it difficult to be optically detected. Here, a feasibility study of a portable prototype optical sensor with the capability of measuring simultaneously specular laser light reflection and transmission from microplastic particles is presented. The specular reflection signal and the transmitted interference pattern were recorded with a photodiode and a CCD camera, respectively. With the combination of these two modes of detection, it is possible to screen the type, size, and nonplanarity of two microplastics types, i.e., transparent polyethylene terephthalate (PET) and translucent low-density polyethylene (LDPE), in a volume of freshwater, with high confidence. In principle, the prototype could be used for the detection of both floating microplastics as well as microplastics experiencing sedimentation in natural water bodies, and in water filtration in water treatment plants. Image 1034309 • Development of a prototype optical sensor for microplastics detection. • Detection of transparent and translucent plastic particles in

water bodies. • Monitoring of light-microplastic interactions in water. [ABSTRACT FROM AUTHOR]

Asano, T. (1995). "Sediment transport under sheet-flow conditions." Journal of Waterway, Port, Coastal and Ocean Engineering **121**(5): 239-246.

Experiments on sediment transport under sheet-flow conditions were conducted by tracing individual and grouped light plastic particles. The measurements based on individual particles yielded the vertical and temporal variations of the instantaneous sediment concentration and transport velocity from which the sediment-transport rate per unit width was obtained. In addition, moving areas of painted particle groups were measured to estimate instantaneous sediment transport rates per unit width directly. Measured local sediment-transport rates were the largest at one or two particle diameters above the initial bed surface. Instantaneous sediment-transport rates per unit width exhibited a pi /6 phase lead relative to the free-stream velocity. The measured sediment-transport rates averaged over a half-cycle were compared with forcing functions Shields and mobility parameters. The present data as well as most available existing data in terms of the normalized transport rate without the settling velocity were well arranged by the mobility number to the power of 1.5.

Asanuma, T., et al. (2010). "Super paramagnetic iron oxide MRI shows defective Kupffer cell uptake function in non-alcoholic fatty liver disease." Gut **59**(2): 258-266.

BACKGROUND: The pathogenesis of non-alcoholic fatty liver disease (NAFLD) is incompletely understood. Kupffer cells (KCs), phagocytic liver-resident macrophages, provide a protective barrier against egress of endotoxin from the portal to the systemic circulation. It is not known if KC phagocytic function is impaired in NAFLD. Super-paramagnetic iron oxide (SPIO) magnetic resonance imaging is a comparative technology dependent on KC phagocytic function.

OBJECTIVE: To evaluate KC uptake function, in patients and experimental animals with NAFLD, using SPIO.

METHODS: Abdominal CT and histological examination of liver biopsy specimens were used to estimate the degree of steatosis in patients with NAFLD and controls with chronic hepatitis C. SPIO-MRI was then performed in all patients. Normal rats fed a methionine-choline-deficient diet to induce non-alcoholic steatohepatitis (NASH), the more severe stage of NAFLD, and obese, insulin resistant, Zucker fa/fa rats with steatohepatitis, were also studied with SPIO-MRI and analysed for hepatic uptake of fluorescent microbeads. Immunohistochemical analysis evaluated the numbers of KCs in patients and rat livers.

RESULTS: Relative signal enhancement (RSE), inversely proportional to KC function, was higher in patients with NAFLD than in controls and with the degree of steatosis on CT. RSE also positively correlated with the degree of steatosis on histology and was similarly higher in rats with induced severe NAFLD (NASH). On immunohistochemistry, defective phagocytic function was the result of reduced phagocytic uptake and not due to reduced KC numbers in rats or patients with NAFLD.

CONCLUSIONS: KC uptake function is significantly impaired in patients with NAFLD and experimental animals with NASH, worsens with the degree of steatosis and is not due to a reduction of KC

numbers.

Asari, M., et al. (2019). "Analysis of mismanaged plastic waste in Samoa to suggest proper waste management in Pacific island countries." Waste Management & Research **37**(12): 1207-1216.

Pacific island countries are facing critical challenges in managing the growing amount of increasingly diverse wastes because of changing lifestyles and the concentration of populations in urban areas. Although marine plastic waste is an issue in the Pacific region, there have been almost no studies of the estimation and impacts of ocean plastic waste, and measures to control such waste, in these countries. Here, first we conducted a questionnaire survey about consumption and disposal of plastic products at households in Samoa as one of the examples of Pacific island countries to grasp the flow of plastic materials and awareness or behaviour for plastic waste. Then we quantified ocean plastic waste and discussed the effective and needed countermeasures in Pacific island countries. The total amount of mismanaged plastic waste was estimated to be 327,000 or 156,000 t y⁻¹ (depending on the scenario) in Pacific island countries. The regional Pacific island countries contribution to the global total mismanaged plastic waste was estimated to range from 1.3% to 2.7%. The amount of mismanaged plastic waste per capita in some Pacific island countries, such as Solomon Islands and Micronesia, was also ranked highly globally. The main reasons seem to be that waste collection rates are relatively low in rural areas and rates of plastic waste generation are high. To implement solutions, including improving municipal solid waste collection, reducing plastic waste, improving the collection and recycling of plastics, and the integration of a number of policies is essential.

Ashish and W. C. Wimley (2001). "Visual detection of specific, native interactions between soluble and microbead-tethered alpha-helices from membrane proteins." Biochemistry **40**(46): 13753-13759.

Using peptides tethered to polymer microbeads, we have developed a technique for measuring the interactions between the transmembrane alpha-helices of membrane proteins and for screening combinatorial libraries of peptides for members that interact with specific helices from membrane proteins. The method was developed using the well-characterized homodimerization sequence of the membrane-spanning alpha-helix from the erythrocyte membrane protein glycophorin A (GPA). As a control, we also tested a variant with a dimer-disrupting alteration of a critical glycine residue to leucine. To test for detectable, native interactions between detergent-solubilized and microbead-tethered alpha-helices, we incubated fluorescent dye-labeled GPA analogues in sodium dodecyl sulfate solution with microbeads that contained covalently attached GPA analogues. When the dye-labeled peptide in solution and the bead-tethered peptide both contained the native glycophorin A sequence, the microbeads readily accumulated the dye through lateral peptide-peptide interactions and were visibly fluorescent under UV light. When either the peptide in solution or the peptide attached to the beads contained the glycine to leucine change, the beads did not accumulate any dye. The usefulness of this method for screening tethered peptide libraries was tested by incubating dye-labeled, native sequence peptides in detergent solution with a few native sequence beads plus an excess of beads containing the variant glycine to leucine sequence. When the dye-labeled peptide in solution was present at a concentration of > or =2 microM, the few native sequence beads were visually distinguishable from the others because of their bright fluorescence. Using this model system, we have shown that it is possible to visually detect specific, native interactions between alpha-helices from membrane proteins using peptides tethered to polymer microbeads. It will thus be possible to use this method to measure the specific lateral interactions that drive the folding and organization of membrane proteins and to screen combinatorial libraries of peptides for members that interact with them.

Ashish, Y., et al. (2016). "Removal of phenol from water by catalytic wet air oxidation using carbon bead - supported iron nanoparticle - containing carbon nanofibers in an especially configured reactor." Journal of Environmental Chemical Engineering **4**(2): 1504-1513.

Catalytic wet air oxidation (CWAO) is extensively used for the destruction of organic contaminants in wastewater. The present study describes the removal of phenol from water, used as a model organic contaminant, by CWAO with iron (Fe) metal nanoparticles (NPs)-doped carbon microbeads (~0.6 mm) as the catalyst. The Fe-carbon composite was prepared by the carbonization and activation of the phenolic precursor-based polymeric beads in which the Fe NPs were in-situ added during the polymerization stage. Carbon nanofibers (CNFs) were grown on the carbon microbead substrate by catalytic chemical vapor deposition with acetylene as the carbon source. Oxidation reactions were carried out under different operating conditions in a high pressure-stirred reactor, viz., temperature, catalyst loading, and speed of the stirrer. The reactor was fitted with an especially configured impeller cum catalyst basket which held the prepared CNF-decorated Fe-doped carbon beads. The data showed an efficient remediation of the phenol-laden water, indicating the potential scale-up of the proposed CWAO catalyst and impellor cum catalyst holder-assembly in this study.

Askun, H., et al. (2008). "Preconcentration and matrix elimination for the determination of Pb(II), Cd(II), Ni(II), and Co(II)by 8-hydroxyquinoline anchored poly(styrene-divinylbenzene) microbeads." Journal of Applied Polymer Science **107**(4): 2714-2722.

Poly(styrene-divinylbenzene), PS-DVB, microbeads were modified with 8-hydroxyquinoline (8-HQ) following nitration, reduction of NO2 to NH2, and conversion of NH2 to diazonium salt. Characterization of pristine, NO2, NH2, NN+Cl-, and 8-QH functional groups modified microbeads was made by Fourier transform-infrared spectrometry (FTIR) and porosimetry. Total reflectron-X-ray florescence spectrometer (TXRF) was used to test the affinity of the 8-HQ modified microbeads to toxic metal ions. 8-HQ-modified microbeads were used to examine the adsorption capacity, recovery, preconcentration, and the matrix elimination efficiency for Pb(II), Cd(II), Ni(II), and Co(II) ions as a function of changing pH, initial metal-ion concentrations, and also equilibrium adsorption time of the studied metal ions. Preconcentration factors for the studied toxic metal ions were found to be more than 500-fold and recovery between 93.8% and 100.6%. Ultratrace toxic metal-ion concentrations in sea water were determined easily by using modified microbeads. Reference sea-water sample was used for the validation of the method, and it was found that recovery, preconcentration, and the matrix elimination were performed perfectly. For the desorption of the toxic metal ions, 3M of HNO3 was used and desorption ratio shown to be more than 96%.

Aslam, H., et al. (2020). "Evaluation of microplastics in beach sediments along the coast of Dubai, UAE." Marine Pollution Bulletin **150**: 110739.

Microplastic contamination in beach sediments along coast of Dubai is un-documented. In this study, microplastic contamination in beach sediments collected from the wrack lines of 16 beaches in Dubai was evaluated. Five samples were collected from each beach along a 100 m stretch using a 0.5 m by 0.5 m, quadrant. The number, color, and shape of microplastics were documented. The polymer types of large fibers and strings were identified through FT-IR analysis. 480 microplastics from each of the 16 beaches were selected to detect heavy metals using XRF analysis. The results showed that the average weight of microplastic is 0.33 mg per gram of dry sediment (or 953 mg.m⁻²) and the number of microplastic is 59.71

items per kg of dry sediment (or 165 items.m⁻²). Blue and fibrous microplastics were dominant. Polyethylene strings and fibers were abundantly found. 13 heavy metals were identified of which five are priority pollutants.

Asma, S., et al. (2011). "Survivability of probiotics encapsulated in alginate gel microbeads using a novel impinging aerosols method." International Journal of Food Microbiology **145**(1): 162-168.

Encapsulation of probiotic bacteria in cross-linked alginate beads is of major interest for improving the survivability in harsh acid and bile environment and also in food matrices. Alginate micro beads (10-40 micro m) containing the probiotics Lactobacillus rhamnosus GG and Lactobacillus acidophilus NCFM were produced by a novel technique based on dual aerosols of alginate solution and CaCl₂ cross linking solution. Extruded macro beads (approximately 2 mm diameter) produced by the conventional method and micro beads produced by novel aerosols technique offered comparable protection to L. rhamnosus in high acid and bile environment. Chitosan coating of micro beads resulted in a significant increase in survival time of L. rhamnosus from 40 to 120 min in acid condition and the reduction in cell numbers was confined to 0.94 log over this time. Alginate macro beads are more effective than micro beads in protecting L. acidophilus against high acid and bile. Chitosan coating of micro beads resulted in similar protection to L. acidophilus in macro beads in acid and extended the survival time from 90 to at least 120 min. Viability of this organism in micro beads was 3.5 log after 120 min. The continuous processing capability and scale-up potential of the dual aerosol technique offers potential for an efficient encapsulation of probiotics in very small alginate micro beads below sensorial detection limits while still being able to confer effective protection in acid and bile environment.

Asmonaite, G., et al. (2018). "Size matters: ingestion of relatively large microplastics contaminated with environmental pollutants posed little risk for fish health and fillet quality." Environmental Science & Technology **52**(24): 14381-14391.

In this study, we investigated biological effects associated with ingestion of polystyrene (PS) microplastic (MPs) in fish. We examined whether ingestion of contaminated PS MPs (100-400 micro m) results in chemical stress in rainbow trout (Oncorhynchus mykiss) liver and we explored whether this exposure can affect the oxidative stability of the fillet during ice storage. Juvenile rainbow trout were fed for 4 weeks with four different experimental diets: control (1) and feeds containing virgin PS MPs (2) or PS MPs exposed to sewage (3) or harbor (4) effluent. A suite of ecotoxicological biomarkers for oxidative stress and xenobiotic-related pathways was investigated in the hepatic tissue, and included gene expression analyses and enzymatic measurements. The potential impact of MPs exposure on fillet quality was investigated in a storage trial where lipid hydroperoxides, loss of redness and development of rancid odor were assessed as indications of lipid peroxidation. Although, chemical analysis of PS MPs revealed that particles sorb environmental contaminants (e.g., PAHs, nonylphenol and alcohol ethoxylates and others), the ingestion of relatively high doses of these PS MPs did not induce adverse hepatic stress in fish liver. Apart from small effect on redness loss in fillets of fish exposed to PS MPs, the ingestion of these particles did not affect lipid peroxidation or rancid odor development, thus did not affect fillet's quality.

Ašmonaitė, G., et al. (2018). "Rainbow Trout Maintain Intestinal Transport and Barrier Functions Following Exposure to Polystyrene Microplastics." Environmental Science & Technology **52**(24): 14392.

Ingestion has been proposed as a prominent exposure route for plastic debris in aquatic organisms, including fish. While the consequences of ingestion of large plastic litter are mostly understood, the impacts resulting from ingestion of microplastics (MPs) are largely unknown. We designed a study that aimed to assess impacts of MPs on fish intestinal physiology and examined integrity of extrinsic, physical and immunological barriers. Rainbow trout were exposed to polystyrene (PS) MPs (100–400 µm) via feed for a period of 4 weeks. Fish were fed four types of diets: control, diets containing virgin PS particles, or particles exposed to two different environmental matrices (sewage or harbor effluent). Extrinsic barrier disturbance in intestinal tissue was evaluated via histology. The paracellular permeability toward ions and molecules was examined using Ussing chambers and mRNA expression analysis of tight junction proteins. Active transport was monitored as transepithelial potential difference, short-circuits current and uptake rate of amino acid 3H-lysine. Immune status parameters were measured through mRNA expression level of cytokines, lysozyme activity, and hematological analysis of immune cells. We could not show that PS MPs induced inflammatory responses or acted as physical or chemical hazards upon ingestion. No measurable effects were exerted on fish intestinal permeability, active transport or electrophysiology.

Asokan, P., et al. (2009). "Assessing the recycling potential of glass fibre reinforced plastic waste in concrete and cement composites." Journal of Cleaner Production **17**(9): 821-829.

Abstract: At present glass fibre reinforced plastic (GRP) waste recycling worldwide is very limited due to its intrinsic thermoset properties, lack of characterisation data and non availability of viable recycling and recovery routes. In the present study, efforts were made to recycle GRP waste powder and fibre in concrete and cement composites and assess its quality to comply with the British standards for use in construction applications. Results revealed that the mean compressive strength of concrete composites using 5%–50% GRP waste powder under water curing varied from 37N/mm2 to 19N/mm2. Increase in the concentration of GRP waste decreased the compressive strength. However, increase in curing duration (14–180 days) resulted in improving the compressive strength of concrete with 5% GRP application to 45.75N/mm2. Moreover, the density of concrete with 50% GRP waste was reduced by about 12% as compared to the control sample. The bending strength in terms of modules of rupture (MOR) of 12mm thickness cement composites developed using 5% GRP waste fibre attained 16.5N/mm2. The findings of this work pave the way for further GRP waste recycling in precast construction products for use in various applications. [Copyright &y& Elsevier]

Asokan, P., et al. (2010). "Improvement of the mechanical properties of glass fibre reinforced plastic waste powder filled concrete." Construction & Building Materials **24**(4): 448-460.

Abstract: A comprehensive laboratory experiments were conducted to improve the mechanical properties of glass fibre reinforced plastic (GRP) waste powder filled concrete using superplasticiser for widening the scope for GRP waste recycling for different applications. It is imperative to note that the 28days mean compressive strength of concrete specimens developed with 5–15% GRP waste powder using 2% superplasticiser resulted 70.25±1.43–65.21±0.6N/mm2 which is about 45% higher than that of without the addition of superplasticiser (with GRP waste) and about 11% higher than that of the control concrete (without GRP waste) with 2% superplasticiser. The tensile splitting strength of the concrete

showed 4.12±0.05–4.22±0.03N/mm2 with 5–15% GRP waste powder which is also higher than that of the control concrete (3.85±0.02N/mm2). The drying shrinkage, initial surface absorption and density of GRP waste filled concrete were evaluated and found better than the desirable quality for use in structural and non-structural applications. [Copyright &y& Elsevier]

Asselt, E. D. v., et al. (2017). "Overview of food safety hazards in the European dairy supply chain." Comprehensive Reviews in Food Science and Food Safety **16**(1): 59-75.

Monitoring of dairy products should preferably focus on the most relevant food safety hazards in the dairy supply chain. For this purpose, the possible presence of microbiological, chemical, and physical hazards as well as trends in the dairy supply chain that may affect their presence were assessed. A literature review was combined with available data from EFSA, RASFF, and the Dutch monitoring program on chemical hazards as well as expert information. This study revealed that microbiological hazards are encountered more frequently in dairy products than chemical and physical hazards. Listeria monocytogenes, Staphylococcus aureus, Salmonella, and human pathogenic Escherichia coli were identified as the most important microbiological hazards in dairy products. Soft and semisoft cheeses are most frequently associated with L. monocytogenes and S. aureus enterotoxins, whereas raw milk is most frequently associated with human pathogenic E. coli and Campylobacter spp., Cronobacter spp., and Salmonella spp. are the microbiological hazards of most concern in powdered infant formula. Based on literature, monitoring, and RASFF data, the most relevant chemical hazards in dairy products are aflatoxin M₁, dioxins, and dioxin-like compounds and residues of veterinary drugs. Chemical hazards primarily occur at the dairy farm and may accumulate during further processing. The most relevant physical hazards are metal, glass, and plastic particles introduced during processing. Analysis of trends in the near future revealed that increased milk production is seen as most relevant in relation to food safety. Other trends affecting food safety are climate change and changes at the farm level, which aim to improve animal welfare and environmental sustainability.

Assumpcao, L. C. F. N., et al. (2011). "Co-pyrolysis of polypropylene waste with Brazilian heavy oil." Journal of Environmental Science & Health, Part A: Toxic/Hazardous Substances & Environmental Engineering **46**(5): 461-464.

To evaluate the chemical recycling of plastic residues, co-pyrolysis of polypropylene (PP) waste with Brazilian crude oil was evaluated varying the temperature (400°C to 500°C) and the amount of PP fed to the reactor. The co-pyrolysis of plastic waste in an inert atmosphere provided around 80% of oil pyrolytic, and of these, half represent the fraction of diesel oil. This study can be used as a reference in chemical recycling of plastics, specially associated with plastics co-pyrolysis. [ABSTRACT FROM AUTHOR]

Astner, A. F., et al. (2019). "Mechanical formation of micro- and nano-plastic materials for environmental studies in agricultural ecosystems." Science of the Total Environment **685**: 1097-1106.

Release of microplastics (MPs) and nanoplastics (NPs) into agricultural fields is of great concern due to their reported ecotoxicity to organisms that provide beneficial service to the soil such as earthworms, and the potential ability of MPs and NPs to enter the food chain. Most fundamental studies of the fate and transport of plastic particulates in terrestrial environments employ idealized MP materials as models, such as monodisperse polystyrene spheres. In contrast, plastics that reside in agricultural soils consist of polydisperse fragments resulting from degraded films employed in agriculture. There exists a need for more representative materials in fundamental studies of the fate, transport, and ecotoxicity of MPs and NPs in soil ecosystems. The objective of this study was therefore to develop a procedure to produce MPs and NPs from agricultural plastics (a mulch film prepared biodegradable polymer polybutyrate adipate-co-terephthalate (PBAT) and low-density PE [LDPE]), and to characterize the resultant materials. Soaking of PBAT films under cryogenic conditions promoted embrittlement, similar to what occurs through environmental weathering. LDPE and cryogenically-treated PBAT underwent mechanical milling followed by sieve fractionation into MP fractions of 840mum, 250mum, 106mum, and 45mum. The 106mum fraction was subjected to wet grinding to produce NPs of average particle size 366.0nm and 389.4nm for PBAT and LDPE, respectively. A two-parameter Weibull model described the MPs' particle size distributions, while NPs possessed bimodal distributions. Size reduction did not produce any changes in the chemical properties of the plastics, except for slight depolymerization and an increase of crystallinity resulting from cryogenic treatment. This study suggests that MPs form from cutting and high-impact mechanical degradation as would occur during the tillage into soil, and that NPs form from the MP fragments in regions of relative weakness that possess lower molecular weight polymers and crystallinity.

Aston, L. S., et al. (1996). "Organophosphate Flame Retardants in Needles of Pinus ponderosa in the Sierra Nevada Foothills." Bulletin of environmental contamination and toxicology **57**(6): 859.

Ponderosa pine needle samples were collected in 1993 from foothill sites used as ozone-monitoring stations in the Sierra Nevada and analyzed for concentrations of three organophosphate flame retardants: tris(2-chloroethyl)phosphate, tris(1,3-dichloroisopropyl)phosphate, and tris(2-chloropropyl)phosphate. All three compounds were found on the pine needles at orders of magnitude 13 times larger than those reported for aqueous matrices in other studies. One cause was attributed to volatilization from another location, possibly a near-by plastic-waste incineration plant, and transport to the Sierra Nevada.

Astrup, T., et al. (2009). "Recycling of plastic: accounting of greenhouse gases and global warming contributions." Waste Management & Research **27**(8): 763-772.

Major greenhouse gas (GHG) emissions related to plastic waste recycling were evaluated with respect to three management alternatives: recycling of clean, single-type plastic, recycling of mixed/contaminated plastic, and use of plastic waste as fuel in industrial processes. Source-separated plastic waste was received at a material recovery facility (MRF) and processed for granulation and subsequent downstream use. In the three alternatives, plastic was assumed to be substituting virgin plastic in new products, wood in low-strength products (outdoor furniture, fences, etc.), and coal or fuel oil in the case of energy utilization. GHG accounting was organized in terms of indirect upstream emissions (e.g. provision of energy, fuels, and materials), direct emissions at the MRF (e.g. fuel combustion), and indirect downstream emissions (e.g. avoided emissions from production of virgin plastic, wood, or coal/oil). Combined, upstream and direct emissions were estimated to be roughly between 5 and 600 kg CO(2)-eq. tonne(-1) of plastic waste depending on treatment at the MRF and CO(2) emissions from electricity production. Potential downstream savings arising from substitution of virgin plastic, wood, and energy fuels were estimated to be around 60- 1600 kg CO(2)-eq. tonne(-1) of plastic waste depending on substitution ratios and CO(2) emissions from electricity production. Based on the reviewed data, it was concluded that substitution of virgin plastic should be preferred. If this is not viable due to a mixture of different plastic types and/or contamination, the plastic should be used for energy utilization. Recycling of plastic waste for substitution of other materials such as wood provided no savings with respect to global warming.

Attia, M., et al. (2014). "In vitro characterization of satellite cells from myasthenic patients." Journal of Neuromuscular Diseases **1 (Supplement 1)**: S275.

Myasthenia gravis (MG) is a relatively uncommon neuromuscular disease caused by circulating autoantibodies against proteins of the neuromuscular junction that lead to impaired neuromuscular transmission (NMT). MG is characterized by fatigability and fluctuating muscle weakness as well as muscle atrophy. The regeneration of atrophied muscle is carried out by local stem cells called satellite cells (SC), however, molecular and cellular mechanisms of myogenesis in MG disease are still unknown. Muscle biopsies from 6 MG patients and 6 healthy age-matched controls were collected. SCs were isolated from these muscle biopsies using explant method and positive selection of CD56+ cells using magnetic microbeads. Proliferation and differentiation of SC in vitro was measured respectively by cell counting (flow cytometer) and MF-20 immunolabelling in a kinetics study (from day 0 to day 4). We observed that SCs from MG biopsies proliferate as well as differentiate more actively than SCs from healthy ones. This could be due to the known role of growth factors (IL-6, IGF-1, SDF-1) and myogenic factors (Myf5, MyoD, MRF4, MyoG) in myogenesis. Using real time qPCR, we observed that during SCs proliferation, Myf5, MyoD and Myogenin were more expressed in MG SCs compared to controls. Using immunoloabeling and western blot analyses, we observed that MF-20 and TnT, which are the specific markers of the differentiation, were more expressed in MG SCs compared to controls. In parallel, the number of SCs in muscle biopsies (using anti-Pax7 antibody) was significantly increased in the MG muscle compared to controls. These findings demonstrate the activation of SCs in MG muscle as well as functional differences between SC properties from healthy and MG muscles. The autoimmune attack in MG might lead to important changes in the number and function of SC that could represent a mechanism of compensation to regenerate muscle fibres that have been damaged by the autoantibodies.

Atwood, E. C., et al. (2019). "Coastal accumulation of microplastic particles emitted from the Po River, Northern Italy: Comparing remote sensing and hydrodynamic modelling with in situ sample collections." Marine Pollution Bulletin **138**: 561.

Microplastic research has mainly concentrated on open seas, while riverine plumes remain largely unexplored despite their hypothesized importance as a microplastic source to coastal waters. This work aimed to model coastal accumulation of microplastic particles (1–5 mm) emitted by the Po River over 1.5 years. We posit that river-induced microplastic accumulation on adjacent coasts can be predicted using (1) hydrodynamic-based and (2) remote sensing-based modelling. Model accumulation maps were validated against sampling at nine beaches, with sediment microplastic concentrations up to 78 particles/kg (dry weight).

Hydrodynamic modelling revealed that discharged particle amount is only semi-coupled to beaching rates, which are strongly mouth dependent and occur within the first ten days. Remote sensing modelling was found to better capture river mouth relative strength, and accumulation patterns were found consistent with hydrodynamic modelling. This methodology lays groundwork for developing an operational monitoring system to assess microplastic pollution emitted by a major river.

Atzori, C., et al. (1998). "Current in vitro culture systems for Pneumocystis." FEMS Immunology & Medical Microbiology **22**(1-2): 169-172.

Although Pneumocystis continuous culture systems have not yet been developed, efficient short-term in vitro methods allowing the production of infectious forms of Pneumocystis can now be employed. The quality of the inoculum will influence the in vitro development of P. carinii. For this reason, efficient extraction and cryopreservation techniques are considered in this section. In vitro growth and limited passage were obtained by inoculating freshly extracted parasites onto fibroblast- or epithelial-like cell monolayers cultivated in ordinary tissue culture flasks, culture plates, microcarrier beads or other culture devices. Cultures were usually maintained in an atmosphere of 5% CO2 at 35-37 degrees C. The results obtained in these different systems were surprisingly similar: the number of parasites increased about 6-10 times within the first 3-4 days post-inoculation, then remained stationary until day 7-14 and decreased rapidly. If passages were attempted, the growth decreased gradually and no growth was recorded after 2-3 passages. Proof of the in vitro Pneumocystis attachment to feeder cells has been furnished by electron microscopy. Two currently used feeder cell culture systems were selected in this subchapter. The first system is a co-culture of monolayer lung epithelial-like cells with Pneumocystis. After trypsin treatment and passage of cells with attached parasites to culture bottles containing fresh medium, 3 or more new culture bottles can be plated. A 2-4-fold increase in parasite number can be obtained but, interestingly, cultured parasites were more infectious to the nude rat than freshly extracted lung parasites. In the second system, the spinner flask culture method, Pneumocystis is cultivated on cell coated microbeads in slow stirring vessels, in order to exploit the beads' huge surface where microorganisms can transiently adhere and grow and from where they can be easily detached by simply leaving the beads to settle down. This culture system has ensured 10(8)-10(9) viable trophozoites in each harvest after 7-10 days of slow stirring incubation. [References: 17]

Atzori, C., et al. (1998). "XXI. Current in vitro culture systems for <i>Pneumocystis</i>." Pathogens and Disease **22**(1-2): 169-172.

This culture system has ensured 108–109 viable trophozoites in each harvest after 7–10 days of slow stirring incubation.

Au, S. Y., et al. (2015). "Responses of Hyalella azteca to acute and chronic microplastic exposures." Environmental Toxicology & Chemistry **34**(11): 2564-2572.

Limited information is available on the presence of microplastics in freshwater systems, and even less is known about the toxicological implications of the exposure of aquatic organisms to plastic particles. The present study was conducted to evaluate the effects of microplastic ingestion on the freshwater amphipod, Hyalella azteca. Hyalella azteca was exposed to fluorescent polyethylene microplastic particles and polypropylene microplastic fibers in individual 250-mL chambers to determine 10-d mortality. In acute bioassays, polypropylene microplastic fibers were significantly more toxic than polyethylene microplastic particles; 10-d lethal concentration 50% values for polyethylene microplastic particles and polypropylene microplastic fibers were 4.64 × 104 microplastics/mL and 71.43 microplastics/mL, respectively. A 42-d chronic bioassay using polyethylene microplastic particles was conducted to quantify effects on reproduction, growth, and egestion. Chronic exposure to polyethylene microplastic particles significantly decreased growth and reproduction at the low and intermediate exposure concentrations. During acute exposures to polyethylene microplastic particles, the egestion times did not significantly differ from the egestion of normal food materials in the control; egestion times for polypropylene microplastic fibers were significantly slower than the egestion of food materials in the control. Amphipods exposed to polypropylene microplastic fibers also had significantly less growth. The greater toxicity of microplastic fibers than microplastic particles corresponded with longer residence times for the fibers in the gut. The difference in residence time might have affected the ability to process food, resulting in an energetic effect reflected in sublethal endpoints. Au, S. Y., et al. (2017). "Trophic transfer of microplastics in aquatic ecosystems: Identifying critical research needs." Integrated Environmental Assessment & Management **13**(3): 505-509.

To evaluate the process of trophic transfer of microplastics, it is important to consider various abiotic and biotic factors involved in their ingestion, egestion, bioaccumulation, and biomagnification. Toward this end, a review of the literature on microplastics has been conducted to identify factors influencing their uptake and absorption; their residence times in organisms and bioaccumulation; the physical effects of their aggregation in gastrointestinal tracts; and their potential to act as vectors for the transfer of other contaminants. Limited field evidence from higher trophic level organisms in a variety of habitats suggests that trophic transfer of microplastics may be a common phenomenon and occurs concurrently with direct ingestion. Critical research needs include standardizing methods of field characterization of microplastics, quantifying uptake and depuration rates in organisms at different trophic levels, quantifying the influence that microplastics have on the uptake and/or depuration of environmental contaminants among different trophic levels, and investigating the potential for biomagnification of microplastic-associated chemicals. More integrated approaches involving computational modeling are required to fully assess trophic transfer of microplastics. Integr Environ Assess Manag 2017;13:505-509. © 2017 SETAC.

Aucouturier, J., et al. (2001). "Assessment of efficacy and safety of various adjuvant formulations with a total soluble extract of Trichinella spiralis." Parasite **8**(2 Suppl): S126-132.

Trichinellosis, a re-emerging zoonosis in several countries and pig, is the main species responsible for its transmission to human. Vaccination of swine could be an alternative to prevent the risk of human contamination. In order to develop an efficient and safe inactivate vaccine, the choice of the adjuvant is an important issue. The aim of this study was to develop and select potent and safe adjuvants by screening them in an experimental model with a crude soluble antigen from L1 muscular larvae (ML) of Trichinella spiralis (Ts). The efficacy was checked by the quantification of specific antibody levels. Specific and non-specific IgE antibody levels were also assessed. Safety was checked by the assessment of the local reaction at the injection site. Various Montanide ISA adjuvant formulations including water in oil, oil in water and multiphasic emulsions, but also nanoparticles or microbeads were tested. The results clearly showed differences between the antibody responses induced by the adjuvants and demonstrated the necessity to use an adjuvant to obtain a specific IgG (IgG1 or IgG2a) response directed against the total soluble extract of Ts. All the formulations enhanced the humoral immune response. The origin of the oil contained in the emulsions played an important role on the efficacy. Indeed emulsions based on mineral oils were more efficient than those based on metabolisable oils. However it was linked with stronger local reactions. Multiphasic and oil in water emulsions but also nanoparticles failed to induce IgG2a antibody levels. Microbeads and water in oil formulations based on mineral oils were more efficient. This experimentation allowed then the selection of several adjuvants which efficacy will be further investigated by a challenge test and an analysis of the cellular populations involved in the mechanism of the immune response.

Auge, A. A. (2017). "Anthropogenic debris in the diet of turkey vultures (Cathartes aura) in a remote and low-populated South Atlantic island." Polar Biology **40**(4): 799-805.

Plastic pollution is becoming an increasing issue for wildlife throughout the world. Even remote areas with relatively little human activity are affected. The Falkland Islands are a South Atlantic archipelago with a small human population (<3000), mostly concentrated in one town, Stanley. One hundred regurgitated pellets from turkey vultures (Cathartes aura) were collected in Stanley in July and August 2015 to investigate the diet and amount of anthropogenic debris (human-made artificial products) ingested. The frequency of occurrence of anthropogenic debris was 58 % of pellets for plastic, 25 % for glass, 23 % for paper, 21 % for aluminium and 3 % for fabric. Aside from anthropogenic debris, the majority of pellets were made of sheep wool (on average 29 % of the volume), feathers (19 %) and vegetation (18 %). On average, when present, anthropogenic debris corresponded to 16.1 % of the mass of each pellet, equivalent to 1.6 g. The turkey vultures are known to feed in the open-air rubbish dump near the town. This study highlights that they ingest significant amounts of anthropogenic debris. Further investigations should be undertaken to monitor and identify potential health effects. Other birds also use the dump and may be affected. Even in such remote sparsely populated islands, pollution may be a significant issue. Rubbish management could be put in place to limit birds from feeding at the dumps. A low human population density may not indicate low pollution impacts on wildlife and the environment and should be investigated further in the Falkland Islands and at other remote islands.

Augustsson, P., et al. (2009). "Decomplexing biofluids using microchip based acoustophoresis." Lab on a Chip **9**(6): 810-818.

Highly efficient washing and extraction of microbeads to decomplex analytes ranging from small peptides to large viruses was realised in a microscaled continuous flow format. The bead washing principle reported herein is based on acoustophoresis, i.e. the primary acoustic radiation force in an ultrasonic standing wave and laminar flow properties are utilised to translate bioanalytes trapped on functionalised microbeads from one carrier fluid to another. The carry-over of non-specific material ranges from 1 to 50 ppm relative to input levels depending on application, making acoustophoresis suitable for extraction of rare species from complex environments. Selective extraction of a phosphopeptide relative to its unphosphorylated counterpart is demonstrated using metal oxide affinity capture (MOAC) beads and MALDI-TOF MS readout. Acoustophoresis of microbeads activated with specific binders could be used to capture phage viral particles. The efficiency of the acoustophoretic washing principle was demonstrated by an unspecific phage cross contamination level of only 10(-6) of that in the input bead/phage mixture. The continuous flow format makes acoustophoretic washing flexible regarding sample volume and also allows for easy integration into a sequence of particle handling and analytical unit operations.

Auta, H. S., et al. (2017). "Distribution and importance of microplastics in the marine environment: A review of the sources, fate, effects, and potential solutions." Environment International **102**: 165-176.

The presence of microplastics in the marine environment poses a great threat to the entire ecosystem and has received much attention lately as the presence has greatly impacted oceans, lakes, seas, rivers, coastal areas and even the Polar Regions. Microplastics are found in most commonly utilized products (primary microplastics), or may originate from the fragmentation of larger plastic debris (secondary microplastics). The material enters the marine environment through terrestrial and land-based activities, especially via runoffs and is known to have great impact on marine organisms as studies have shown that large numbers of marine organisms have been affected by microplastics. Microplastic particles have been found distributed in large numbers in Africa, Asia, Southeast Asia, India, South Africa, North America, and in Europe. This review describes the sources and global distribution of microplastics in the environment, the fate and impact on marine biota, especially the food chain. Furthermore, the control measures discussed are those mapped out by both national and international environmental organizations for combating the impact from microplastics. Identifying the main sources of microplastic pollution in the environment and creating awareness through education at the public, private, and government sectors will go a long way in reducing the entry of microplastics into the environment. Also, knowing the associated behavioral mechanisms will enable better understanding of the impacts for the marine environment. However, a more promising and environmentally safe approach could be provided by exploiting the potentials of microorganisms, especially those of marine origin that can degrade microplastics.

CAPSULE: The concentration, distribution sources and fate of microplastics in the global marine environment were discussed, so also was the impact of microplastics on a wide range of marine biota.

Auta, H. S., et al. (2018). "Growth kinetics and biodeterioration of polypropylene microplastics by Bacillus sp. and Rhodococcus sp. isolated from mangrove sediment." Marine Pollution Bulletin **127**: 15-21.

Interest in the biodegradation of microplastics is due to their ubiquitous distribution, availability, high persistence in the environment and deleterious impact on marine biota. The present study evaluates the growth response and mechanism of polypropylene (PP) degradation by Bacillus sp. strain 27 and Rhodococcus sp. strain 36 isolated from mangrove sediments upon exposure to PP microplastics. Both bacteria strains were able to utilise PP microplastic for growth as confirmed by the reduction of the polymer mass. The weight loss was 6.4% by Rhodococcus sp. strain 36 and 4.0% by Bacillus sp. strain 27 after 40days of incubation. PP biodegradation was further confirmed using Fourier-transform infrared spectroscopy and scanning electron microscopy analyses, which revealed structural and morphological changes in the PP microplastics with microbial treatment. These analyses showed that the isolates can colonise, modify and utilise PP microplastics as carbon source.

Auxilio, A. R., et al. (2017). "An experimental study on thermo-catalytic pyrolysis of plastic waste using a continuous pyrolyser." Waste Management **67**: 143-154.

A bench scale, two-stage, thermo-catalytic reactor equipped with a continuous feeding system was used to pyrolyse pure and waste plastics. Experiments using five zeolitic and clay-based catalysts of different forms (pellet and powders) and different plastic feedstocks - virgin HDPE, HDPE w1aste and mixed plastic waste (MPW) were compared to the control experiments - pyrolysis without catalyst. Results indicated that the two pelletized catalysts were the most promising for the conditions employed. Of these two, one with higher acidity and surface area was highly selective for the gasoline fraction (C<inf>5</inf>-C<inf>11</inf>) giving 80% from the total medium distillate conversion using virgin HDPE as feedstock. It also produced the least amount of olefins (17% for virgin HDPE, 4% for HDPE waste and 2% for MPW) and coke (<1% for virgin HDPE, 3% for HDPE waste and 5% for MPW), and the highest aromatics content (22% for virgin HDPE from un-distilled medium distillate, 5% for HDPE and 13% for MPW both from distilled medium distillate). The second pelletized catalyst exhibited high selectivity for the diesel fraction (C<inf>12</inf>-C<inf>25</inf>) giving 63% from the total medium distillate conversion using virgin HDPE as feedstock. The amount of coke deposited on the catalyst surface depended mainly on the mesopore volume, with less coke deposited as the mesopore volume increased. The variation in catalyst selectivity with acidity strength due to Lewis sites on the catalyst surface controls selectivity towards carbon chain length. Copyright © 2017 Elsevier Ltd

Avci, E., et al. (2015). "Piezo-actuated parallel mechanism for biological cell release at high speed." Biomedical Microdevices **17**(5): 1-10.

In this paper, a dynamic releasing approach is proposed for high-speed biological cell manipulation. A compact parallel mechanism for grasping and releasing microobjects is used to generate controllable vibration to overcome the strong adhesion forces between the end effector and the manipulated object. To reach the required acceleration of the end effector, which is necessary for the detachment of the target object by overcoming adhesion forces, vibration in the end effector is generated by applying sinusoidal voltage to the PZT actuator of the parallel mechanism. For the necessary acceleration, we focus on the possible range of the frequency of the PZT-actuator-induced vibration, while minimizing the amplitude of the vibration (14 nm) to achieve precise positioning. The effect of the air and liquid environments on the required vibration frequency for successful release is investigated. For the first time, release results of microbeads and biological cells are compared. Release of the biological cells with 100 % success rate suggests that the proposed active release method is an appropriate solution for adhered biological cells during the release task.

Avci-Adali, M., et al. (2010). "Pitfalls of cell-systematic evolution of ligands by exponential enrichment (SELEX): existing dead cells during in vitro selection anticipate the enrichment of specific aptamers." Oligonucleotides **20**(6): 317-323.

Aptamers represent auspicious ligands for recognition of target molecules on the surface of a specific cell population, such as stem or cancer cells. These ligands are able to capture and enrich desired cells from a cell mixture, and can be used for identification of new biomarkers, development of cell-specific therapeutics, and stem cell therapy. In this study, we investigated the influence of dead cells on single-stranded DNA (ssDNA) binding and established a method to eliminate dead cells from a cell suspension. Flow cytometry analyses demonstrated that all dead cells were stained with fluorescein-labeled ssDNA molecules. The increasing of the proportion of dead cells led to an increased number of cells that were positive for ssDNA staining. Using dead cell removal microbeads, the proportion of dead cells was significantly reduced. The studies demonstrated that dead cells lead to unspecific uptake/binding of ssDNA molecules during cell-Systematic Evolution of Ligands by Exponential enrichment (SELEX) and can cause failure of the selection process. Thus, the elimination of dead cell population before incubation with ssDNA molecules will reduce the loss of target binding sequences and the contamination of the enriched aptamer pool with unspecific ssDNA molecules caused by unspecific binding to dead cells.

Avci-Camur, C., et al. (2018). "Aqueous production of spherical Zr-MOF beads <i>via</i> continuous-flow spray-drying." Green Chemistry **20**(4): 873-878.

Porous metal–organic frameworks (MOFs) are attracting great attention from industry, thanks to their myriad potential applications in areas such as catalysis and gas storage. Zr-MOFs (also known as UiO-type MOFs) are especially promising, owing to their large surface areas, high chemical versatility and remarkable hydrothermal, chemical and thermal stabilities. However, among the challenges currently precluding the industrial exploitation of MOFs is the lack of green methods for their synthesis. Herein we describe a continuous-flow spray-drying method for the simultaneous synthesis and shaping of spherical MOF microbeads in a mixture of water and acetic acid. We used this approach to build two archetypical Zr-MOFs: UiO-66-NH2 and Zr-fumarate. By tuning the concentration of acetic acid in water, we were able to produce, by a scalable process, UiO-66-NH2 and Zr-fumarate beads with SBET and water-sorption values comparable to the literature values obtained with other methods.

Avecilla, S. T., et al. (2016). "How do I perform hematopoietic progenitor cell selection?" Transfusion **56**(5): 1008-1012.

Graft-versus-host disease remains the most important source of morbidity and mortality associated with allogeneic stem cell transplantation. The implementation of hematopoietic progenitor cell (HPC) selection is employed by some stem cell processing facilities to mitigate this complication. Current cell selection methods include reducing the number of unwanted T cells (negative selection) and/or enriching CD34+ hematopoietic stem/progenitors (positive selection) using immunomagnetic beads subjected to magnetic fields within columns to separate out targeted cells. Unwanted side effects of cell selection as a result of T-cell reduction are primary graft failure, increased infection rates, delayed immune reconstitution, possible disease relapse, and posttransplant lymphoproliferative disease. The Miltenyi CliniMACS cell isolation system is the only device currently approved for clinical use by the Food and Drug Administration. It uses magnetic microbeads conjugated with a high-affinity anti-CD34 monoclonal antibody capable of binding to HPCs in marrow, peripheral blood, or umbilical cord blood products. The system results in significantly improved CD34+ cell recoveries (50%-100%) and consistent 3-log CD3+ T-cell reductions compared to previous generations of CD34+ cell selection procedures. In this article, the CliniMACS procedure is described in greater detail and the authors provide useful insight into modifications of the system. Successful implementation of cell selection procedures can have a significant positive clinical effect by greatly increasing the pool of donors for recipients requiring transplants. However, before a program implements cell selection techniques, it is important to consider the time and financial resources required to properly and safely perform these procedures.

Avendano, C., et al. (2015). "Staticmagnetic fields on humansperm. A side effect of magnetic-activated cell sorting?" Fertility and Sterility **1)**: e247.

OBJECTIVE: Non-damaged sperm DNA is one of the prerequisites for achieving successful fertilization and embryo development in assisted reproductive technologies. Magnetic-activated cell sorting (MACS) using paramagnetic annexin V-conjugated microbeads has been proposed as a safe method to select non-apoptotic and viable sperm. The procedure involves the magnetic labeling of sperm with damaged DNA and the passage through a high power static magnetic field (SMF). Intact living spermatozoa without DNA fragmentation pass through the column and are collected for later use, while the fragmented cells are selectively retained. Although there are some concerns about the possible selection and use of sperm with paramegnetic beads, the potential impact of SMF has never been mentioned. Therefore, the objective of this work was to evaluate the possible effect of SMF on human sperm during in vitro manipulation. DESIGN: Prospective study. MATERIALS AND METHODS: Motile sperm from healthy men (n=5) were selected by swim up. Each sperm suspension was separated in 4 fractions (F1, F2, F3 and C). F1, F2, F3 were exposed to a SMF (1.2 Tesla) during 1, 2 and 10 minutes, respectively. Fraction C was kept as control without SMF exposure. Sperm parameters were evaluated immediately after SMF exposure on each fraction and then incubated in capacitating conditions for 3 hours at 37degreeC. Progressive sperm motility (PG, %), curvilinear velocity (VCL, mm/s) and rectilinear velocity (VSL, mm/s) were evaluated using videomicroscopy with computerized image analysis. Spontaneous (sRA) and induced (iRA) acrosomal reaction were evaluated using Coomassie brilliant blue staining. Sperm DNA fragmentation was assessed by TUNEL assay. RESULT(S): PG was increased immediately after exposure to SMF in F1 compared with C (93.5 +/- 2.9 vs. 86.9 +/- 3.9, p<0.05). Also, VSL and VCL increased after capacitation in F1 compared with C (146 +/- 35 vs. 94 +/- 19, p< 0.05 y 192 +/- 23 vs 130 +/- 16, p<0.05; respectively). sRA increased at least 3 times in all groups compared with C (p<0.05), nevertheless iRA did not show differences between groups (p>0.05). There are no differences on sperm DNA fragmentation between groups pre and post capacitation (p>0.05). CONCLUSION(S): We report for the first time the effect of SMF on human sperm. MACS have been proposed to be effective and innocuous to select ''healthy'' sperm after filtration through a high power SMF. However, in this work we have shown that sperm physiological patterns can be modified after exposure to 1.2 Tesla. Further research is needed to assess the beneficial or detrimental effect of SMF on human sperm.

Avery, S. V., et al. (1993). "Salt-stimulation of caesium accumulation in the euryhaline green microalga

Chlorella salina: Potential relevance to the development of a biological Cs-removal process." Journal of General Microbiology **139**(9): 2239-2244.

Accumulation of Cs⁺ by Chlorella salina was 28-fold greater in cells incubated in the presence than in the absence of 0.5 M-NaCl. An approximate 70% removal of external Cs⁺ resulted after 15 h incubation of cells with 50 muM-CsCl and 0.5 M-NaCl. LiCl also had a stimulatory effect on Cs⁺ uptake, although mannitol did not. Cs⁺ influx increased with increasing external NaCl concentration and was maximal between 25-500 mM-NaCl at approximately 4 nmol Cs⁺ h⁻¹ (10⁶ cells)⁻¹. Little effect on Cs⁺ uptake resulted from the presence of Mg²⁺ or Ca²⁺ or from varying the external pH, and Cs⁺ was relatively non-toxic towards C. salina. At increasing cell densities (from 4 x 10⁵ to 1 x 10⁷ cells ml⁻¹), decreasing amounts of Cs⁺ were accumulated per cell although the rate of Cs⁺ removal from the external medium was still greatest at the higher cell densities examined. Freely suspended C. salina and cell-loaded alginate microbeads accumulated similar levels of Cs⁺, however, 46% of total Cs⁺ uptake was attributable to the calcium-alginate matrix in the latter case. When Cs⁺-loaded cells were subjected to hypoosmotic shock, loss of cellular Cs⁺ occurred allowing easy Cs⁺ recovery. This loss exceeded 90% of cellular Cs⁺ when cells were washed with solutions containing <= 50 mM-NaCl between consecutive Cs⁺ uptake periods; these cells subsequently lost their ability to accumulate large amounts of Cs⁺. Maximal Cs⁺ uptake (approximately 85.1% removal after three 15 h incubations) occurred when cells were washed with a solution containing 500 mMNaCl and 200 mM-KCl between incubations. The relevance of these results to the possible use of C. salina in a salt-dependent biological Cs-removal process is discussed.

Avery, S. V., et al. (1995). "Quantification and Characterization of Phagocytosis in the Soil Amoeba Acanthamoeba castellanii by Flow Cytometry." Applied & Environmental Microbiology **61**(3): 1124-1132.

Phagocytosis in the common grazing soil amoeba Acanthamoeba castellanii was characterized by flow cytometry. Uptake of fluorescently labelled latex microbeads by cells was quantified by appropriate setting of thresholds on light scatter channels and, subsequently, on fluorescence histograms. Confocal laser scanning microscopy was used to verify the effectiveness of sodium azide as a control for distinguishing between cell surface binding and internalization of beads. It was found that binding of beads at the cell surface was complete within 5 min and 80% of cells had beads associated with them after 10 min. However, the total number of phagocytosed beads continued to rise up to 2 h. The prolonged increase in numbers of beads phagocytosed was due to cell populations containing increasing numbers of beads peaking at increasing time intervals from the onset of phagocytosis. Fine adjustment of thresholds on light scatter channels was used to fractionate cells according to cell volume (cell cycle stage). Phagocytotic activity was approximately threefold higher in the largest (oldest) than in the smallest (newly divided) cells of A. castellanii and showed some evidence of periodicity. At no stage in the cell cycle did phagocytosis cease. Binding and phagocytosis of beads were also markedly influenced by culture age and rate of rotary agitation of cell suspensions. Saturation of phagocytosis (per cell) at increasing bead or decreasing cell concentrations occurred at bead/cell ratios exceeding 10:1. This was probably a result of a limitation of the vacuolar uptake system of A. castellanii, as no saturation of bead binding was evident. The advantages of flow cytometry for characterization of phagocytosis at the single-cell level in heterogeneous protozoal populations and the significance of the present results are discussed.

Avery-Gomm, S., et al. (2018). "Linking plastic ingestion research with marine wildlife conservation." Science of the Total Environment **637-638**: 1492-1495.

Plastic is an increasingly pervasive marine pollutant. Concomitantly, the number of studies documenting plastic ingestion in wildlife is accelerating. Many of these studies aim to provide a baseline against which future levels of plastic ingestion can be compared, and are motivated by an underlying interest in the conservation of their study species and ecosystems. Although this research has helped to raise the profile of plastic as a pollutant of emerging concern, there is a disconnect between research examining plastic pollution and wildlife conservation. We present ideas to further discussion about how plastic ingestion research could benefit wildlife conservation by prioritising studies that elucidates the significance of plastic pollution as a population-level threat, identifies vulnerable populations, and evaluates strategies for mitigating impacts. The benefit of plastic ingestion research to marine wildlife can be improved by establishing a clearer understanding of how discoveries will be integrated into conservation and policy actions. Copyright © 2018

Avery-Gomm, S., et al. (2012). "Northern fulmars as biological monitors of trends of plastic pollution in the eastern North Pacific." Marine Pollution Bulletin **64**(9): 1776-1781.

Marine plastic debris is a global issue, which highlights the need for internationally standardized methods of monitoring plastic pollution. The stomach contents of beached northern fulmar (Fulmarus glacialis) have proven a cost-effective biomonitor in Europe. However, recent information on northern fulmar plastic ingestion is lacking in the North Pacific. We quantified the stomach contents of 67 fulmars from beaches in the eastern North Pacific in 2009-2010 and found that 92.5% of fulmars had ingested an average of 36.8 pieces, or 0.385 g of plastic. Plastic ingestion in these fulmars is among the highest recorded globally. Compared to earlier studies in the North Pacific, our findings indicate an increase in plastic ingestion over the past 40 years. This study substantiates the use of northern fulmar as biomonitors of plastic pollution in the North Pacific and suggests that the high levels of plastic pollution in this region warrant further monitoring.

Avery-Gomm, S., et al. (2018). "Plastic pollution in the Labrador Sea: an assessment using the seabird northern fulmar Fulmarus glacialis as a biological monitoring species." Marine Pollution Bulletin **127**: 817-822.

Plastic is now one among one of the most pervasive pollutants on the planet, and ocean circulation models predict that the Arctic will become another accumulation zone. As solutions to address marine plastic emerge, is essential that baselines are available to monitor progress towards targets. The northern fulmar (Fulmarus glacialis), a widely-distributed seabird species, has been used as a biological monitor for plastic pollution in the North Sea, and could be a useful monitoring species elsewhere. We quantified plastic ingested by northern fulmars from the southeastern Canadian waters of the Labrador Sea with the objective of establishing a standardized baseline for future comparisons. Over two years we sampled 70 fulmars and found that 79% had ingested plastic, with an average of 11.6 pieces or 0.151 g per bird. Overall, 34% of all fulmars exceeded the Ecological Quality Objective for marine litter, having ingested >0.1 g of plastic.

Avery-Gomm, S., et al. (2013). "Plastic ingestion in marine-associated bird species from the eastern North Pacific." Marine Pollution Bulletin **72**(1): 257-259.

In addition to monitoring trends in plastic pollution, multi-species surveys are needed to fully understand the pervasiveness of plastic ingestion. We examined the stomach contents of 20 bird species collected from the coastal waters of the eastern North Pacific, a region known to have high levels of plastic pollution. We observed no evidence of plastic ingestion in Rhinoceros Auklet, Marbled Murrelet, Ancient Murrelet or Pigeon Guillemot, and low levels in Common Murre (2.7% incidence rate). Small sample sizes limit our ability to draw conclusions about population level trends for the remaining fifteen species, though evidence of plastic ingestion was found in Glaucous-Winged Gull and Sooty Shearwater. Documenting levels of plastic ingestion in a wide array of species is necessary to gain a comprehensive understanding about the impacts of plastic pollution. We propose that those working with bird carcasses follow standard protocols to assess the levels of plastic ingestion whenever possible. © 2013 Elsevier Ltd.

Avio, C. G., et al. (2017). "Microplastics pollution after the removal of the Costa Concordia wreck: first evidences from a biomonitoring case study." Environmental Pollution **227**: 207-214.

Microplastics (MPs) represent a matter of growing concern for the marine environment. Their ingestion has been documented in several species worldwide, but the impact of specific anthropogenic activities remains largely unexplored. In this study, MPs were characterized in different benthic fish sampled after 2.5 years of huge engineering operations for the parbuckling project on the Costa Concordia wreck at Giglio Island. Fish collected in proximity of the wreck showed a high ingestion of microplastics compared to both fish from a control area and values reported worldwide. Also the elevated percentage of nylon, polypropylene lines and the presence of polystyrene are quite unusual for marine organisms sampled in natural field conditions, thus supporting the possible relationship of ingested microplastics with maritime operations during wreck removal. On the other hand, the use of transplanted mussels revealed a lower frequency of ingested MPs, and did not discriminate differences between the wreck and the control area. Some variations were observed in terms of typology and size of particles between surface- and bottom-caged mussels highlighting the influence of a different distribution of MPs along the water column. In conclusion, this study demonstrated that MPs pollution in the area of Costa Concordia was more evident on benthonic environment than on seawater column, providing novel insights on the possibility of using appropriate sentinel organisms for monitoring specific anthropogenic sources of MPs pollution in the marine environment.

Avio, C. G., et al. (2015). "Pollutants bioavailability and toxicological risk from microplastics to marine mussels." Environmental Pollution **198**: 211-222.

Microplastics represent a growing environmental concern for the oceans due to their potential of adsorbing chemical pollutants, thus representing a still unexplored source of exposure for aquatic organisms. In this study polyethylene (PE) and polystyrene (PS) microplastics were shown to adsorb pyrene with a time and dose-dependent relationship. Results also indicated a marked capability of contaminated microplastics to transfer this model PAH to exposed mussels Mytilus galloprovincialis; tissue localization of microplastics occurred in haemolymph, gills and especially digestive tissues where a marked accumulation of pyrene was also observed. Cellular effects included alterations of immunological responses, lysosomal compartment, peroxisomal proliferation, antioxidant system, neurotoxic effects, onset of genotoxicity; changes in gene expression profile was also demonstrated through a new DNA microarray platform. The study provided the evidence that microplastics adsorb PAHs, emphasizing an elevated bioavailability of these chemicals after the ingestion, and the toxicological implications due to responsiveness of several molecular and cellular pathways to microplastics.

Avio, C. G., et al. (2015). "Experimental development of a new protocol for extraction and characterization of microplastics in fish tissues: first observations in commercial species from Adriatic Sea." Marine Environmental Research **111**: 18-26.

The presence of microplastics in the marine environment has raised scientific interest during the last decade. Several organisms can ingest microplastics with potentially adverse effects on the digestive tract, respiratory system and locomotory appendages. However, a clear evidence of tissue accumulation and transfer of such microparticles in wild organisms is still lacking, partially hampered by technical difficulties in isolation and characterization protocols from biological samples. In this work, we compared the efficacy of some existing approaches and we optimized a new protocol allowing an extraction yield of microplastics from fish tissues ranging between 78% and 98%, depending on the polymer size. FT-IR analyses confirmed that the extraction procedure did not affect the particles characteristics. The method was further validated on the fish mullet, Mugil cephalus, exposed under laboratory conditions to polystyrene and polyethylene; the particles were isolated and quantified in stomach and liver, and their presence in the hepatic tissue was confirmed also by histological analyses. A preliminary characterization revealed the presence and distribution of microplastics in various fish species collected along the Adriatic Sea. FT-IR analyses indicated polyethylene as the predominant polymer (65%) in the stomach of fish. The overall results confirmed the newly developed method as a reliable approach to detect and quantify microplastics in the marine biota.

Avio, C. G., et al. (2017). "Plastics and microplastics in the oceans: From emerging pollutants to emerged threat." Marine Environmental Research **128**: 2-11.

Plastic production has increased dramatically worldwide over the last 60 years and it is nowadays recognized as a serious threat to the marine environment. Plastic pollution is ubiquitous, but quantitative estimates on the global abundance and weight of floating plastics are still limited, particularly for the Southern Hemisphere and the more remote regions. Some large-scale convergence zones of plastic debris have been identified, but there is the urgency to standardize common methodologies to measure and quantify plastics in seawater and sediments. Investigations on temporal trends, geographical distribution and global cycle of plastics have management implications when defining the origin, possible drifting tracks and ecological consequences of such pollution. An elevated number of marine species is known to be affected by plastic contamination, and a more integrated ecological risk assessment of these materials has become a research priority. Beside entanglement and ingestion of macro debris by large vertebrates, microplastics are accumulated by planktonic and invertebrate organisms, being transferred along food chains. Negative consequences include loss of nutritional value of diet, physical damages, exposure to pathogens and transport of alien species. In addition, plastics contain chemical additives and efficiently adsorb several environmental contaminants, thus representing a potential source of exposure to such compounds after ingestion. Complex ecotoxicological effects are increasingly reported, but the fate and impact of microplastics in the marine environment are still far to be fully clarified.

Avio, C. G., et al. (2019). "Distribution and characterization of microplastic particles and textile microfibers in Adriatic food webs: General insights for biomonitoring strategies." Environmental Pollution **258**: 113766.

This study provided a comprehensive characterization on ingestion of different typologies of microplastics in several fish and invertebrate species from the Adriatic Sea, considered as a preferential area of plastic accumulation in the Mediterranean. Almost 500 organisms were

sampled in the three sectors of Northern, Central and Southern Adriatic, testing the hypothesis that area of collection, habitat and feeding strategy might influence the occurrence of plastic particles in biota. In this study, the overall characterization considered separately plastic microparticles (MPs) from textile microfibers (MFs) which also included natural and semi-synthetic ones. Ingestion of MPs was a widespread phenomenon, but their number (typically 1 or 2) did not reveal any significant relationship with biometric values, geographical areas or ecological features of the species. Conversely, the frequency of ingestion, ranging from 13 to 35% of organisms containing MPs, appeared a more reliable index to highlight such differences, revealing higher values in species from Central and Southern basins compared to the Northern one, as well as in benthopelagic compared to benthic or pelagic organisms. Geographical differences also occurred in terms of size and typology of ingested particles, suggesting the importance of local river runoffs and surface currents dynamics. Textile microfibers (MFs) were also abundant in Adriatic food webs occurring in all the analyzed species with average numbers (3-10) and frequencies (40-70%) higher than those reported for MPs; further, an elevated percentage of MFs (>80%) was of natural or semi-synthetic origin. Overall, this study provided general insights toward the harmonization of a common biomonitoring strategy, as in the context of MSFD, including the suggestion of a frequency-based index and of a multi-species approach to increase the ecological relevance of assessment, as well as the comparability between different areas and trophic webs.

Awan, I. N., et al. (2012). "Expression and Purification of Mycobacterium tuberculosis Antigens for Use in Immunoassays for Serodetection of M. tuberculosis Infection in TB Patients." Pakistan Journal of Zoology **44**(1).

Tuberculosis (TB) is a fatal and contagious disease. The annual death toll occurring from TB is approximately 2 million according to World Health Organization (WHO). The removal of disease from global face needs immediate treatment for which early diagnosis is pre-requisite. Existing tests for the diagnosis of TB are not efficient and robust. In the present study Mycobacterium tuberculosis specific six antigens namely cfp-10, esat-6 and hspx, along with three antigens which are components of immunodominant mycolyl transferases ag85a, ag85b, ag85c were expressed and purified to evaluate their potential use in immunoassays like Western blotting and multiplex microbead immunoassay. Protein expression of all six antigenic genes was optimized for time and different concentrations of inducer isopropyl beta -D-1-thiogalactopyranoside. Protein products were confirmed by Western blotting and purified through immobilized metal affinity chromatography (IMAC) technique using columns having affinity for His-tag. Each fluorescently labeled set of microbeads were coated with one of the M. tuberculosis specific antigenic proteins and later on human plasma samples of reactivated TB patients along with healthy BCG as well as tuberculin skin test negative controls were tested for presence of antibodies against these antigenic proteins individually in a multiplex format. The results were generated in median fluorescence intensity form which detected antibodies against M. tuberculosis specific antigenic proteins only in reactivated TB patients. This system detected antibodies against four antigenic proteins in 100% of reactivated TB patients. Thus, M. tuberculosis antigens described in this study seem to have purified at the level to be used in the development of immunoassays for the detection of M. tuberculosis infection in TB patients of different categories like active and latent TB.

Awasthi, A. K. and M. Shivashankar (2017). "Study and findings of post-consumer waste PET (polyethylene terephthalate) plastic solubility in amines." Research Journal of Pharmaceutical, Biological and Chemical Sciences **8**(3): 2104-2114.

Polyethylene terephthalate plastic material consumption is increasing across the world day by day and it is used in packaging of drinking water and soft drinks. It has lot of advantages such as light weight and more durable. Post usage plastic waste management and handling is a difficult task. But there are various types of technologies available to manage the plastic waste after post usage. Reuse of plastic waste via recycling technique is effective way to manage the plastic waste. Mechanical recycling is a good technique for single polymer waste recycling while chemical recycling which convert waste plastic into small molecules. Pyrolysis is another technique to degrade the plastic waste in the absence of air. Open dumping of plastic waste is creates the severe environmental issues but it supports the biodegradation of plastic waste by microorganism. Waste to energy and other chemical recycling technologies are also good solution to manage the plastic waste. These technologies supports the manage the plastic waste. But there are still some challenges exist with current technologies. Waste PET plastic solubility with amine is an unique approach to manage the waste. In this paper we have discussed the observation and findings of solubility of PET plastic in amines at room temperature.

Awasthi, A. K., et al. (2017). Plastic solid waste utilization technologies: A Review. 14th International Conference on Science, Engineering and Technology, ICSET 2017, May 2, 2017 - May 3, 2017, Vellore, Tamil Nadu, India, Institute of Physics Publishing.

Plastics are used in more number of applications in worldwide and it becomes essential part of our daily life. In Indian cities and villages people use the plastics in buying vegetable as a carry bag, drinking water bottle, use of plastic furniture in home, plastics objects uses in kitchen, plastic drums in packing and storage of the different chemicals for industrial use, use plastic utensils in home and many more uses. After usage of plastics it will become part of waste garbage and create pollution due to presence of toxic chemicals and it will be spread diseases and give birth to uncontrolled issues in social society. In current scenario consumption of plastic waste increasing day by day and it is very difficult to manage the plastic waste. There are limited methodologies available for reutilization of plastic waste again. Such examples are recycling, landfill, incineration, gasification and hydrogenation. In this paper we will review the existing methodologies of utilization of plastic waste in current scenario. Published under licence by IOP Publishing Ltd.

Awet, T. T., et al. (2018). "Effects of polystyrene nanoparticles on the microbiota and functional diversity of enzymes in soil." Environmental Sciences Europe **30**(1): 11.

Background: The increasing production of nanoplastics and the fragmentation of microplastics into smaller particles suggest a plausible yet unclear hazard in the natural environment, such as soil. We investigated the short-term effects (28 days) of polystyrene nanoparticles (PS-NPs) on the activity and biomass of soil microbiota, and the functional diversity of soil enzymes at environmental relevant low levels in an incubation experiment.

Results: Our results showed a significant decrease in microbial biomass in treatments of 100 and 1000 ng PS-NP g⁻¹ DM throughout the incubation period. Dehydrogenase activity and activities of enzymes involved in N-(leucine-aminopeptidase), P-(alkaline-phosphatase), and C-(beta-glucosidase and cellobiohydrolase) cycles in the soil were significantly reduced at day 28 suggesting a broad and detrimental impact of PS-NPs on soil microbiota and enzymes. Leucine-aminopeptidase and alkaline-phosphatase activities tended to decrease consistently, while beta-glucosidase and cellobiohydrolase activities increased at high concentrations (e.g., PS-NP-1000) in the beginning of the incubation period, e.g., at day 1. On the other hand, basal respiration and metabolic quotient increased with increasing PS-NP application rate throughout

the incubation period possibly due to increased cell death that caused substrate-induced respiration (cryptic growth).
Conclusions: We herewith demonstrated for the first time the potential antimicrobial activity of PS-NPs in soil, and this may serve as an important resource in environmental risk assessment of PS-NPs in the soil environment.

Axworthy, J. B. and J. L. Padilla-Gamino (2019). "Microplastics ingestion and heterotrophy in thermally stressed corals." Scientific Reports **9**(1): 18193.

Rising sea temperatures and increasing pollution threaten the fate of coral reefs and millions of people who depend on them. Some reef-building corals respond to thermal stress and subsequent bleaching with increases in heterotrophy, which may increase the risk of ingesting microplastics. Whether this heterotrophic plasticity affects microplastics ingestion or whether ingesting microplastics affects heterotrophic feeding in corals is unknown. To determine this, two coral species, Montipora capitata and Pocillopora damicornis, were exposed to ambient (~27 degreeC) and increased (~30 degreeC) temperature and then fed microplastics, Artemia nauplii, or both. Following thermal stress, both species significantly reduced feeding on Artemia but no significant decrease in microplastics ingestion was observed. Interestingly, P. damicornis only ingested microplastics when Artemia were also present, providing evidence that microplastics are not selectively ingested by this species and are only incidentally ingested when food is available. As the first study to examine microplastics ingestion following thermal stress in corals, our results highlight the variability in the risk of microplastics ingestion among species and the importance of considering multiple drivers to project how corals will be affected by global change.

Ayari, M. G., et al. (2019). "Synthesis of imprinted hydrogel microbeads by inverse Pickering emulsion to controlled release of adenosine 5'-monophosphate." Materials Science & Engineering. C, Materials for Biological Applications **101**: 254-263.

Herein, we propose the synthesis of a microspherical imprinted hydrogel meant for the controlled release of a nucleotide, adenosine 5'-monophosphate (5'-AMP). Indeed, molecularly imprinted polymers-based (MIPs) materials possess remarkable selective molecular recognition ability that mimicks biological systems. MIPs have been used in numerous applications and hold great promise for the vectorization and/or controlled release of therapeutics and cosmetics. But, the conception of imprinted hydrogels-based drug delivery systems that are able to release polar bioactive compounds is explored weakly. Herein, the synthesis of imprinted hydrogel microbeads by inverse Pickering emulsion is detailed. Microspheres showed a large 5'-AMP loading capacity, around 300mg.g⁻¹, and a high binding capacity comparatively to the non-imprinted counterpart. The MIP had a thermo-responsive release behavior providing sustained release of adenosine 5'-monophosphate in an aqueous buffer simulating both human skin pH and temperature.

Aydn, M. (2017). "Determination of Salmonella spp. prevalence by a recently developed biotinyl-tyramide signal amplification from retailed poultry meat in Adyaman province." Harran Tarm ve Gda Bilimleri Dergisi / Harran Journal of Agricultural and Food Science **21**(4): 412-419.

Worldwide, species belonging to the genus Salmonella are pathogenic bacteria and are the second most food poisoning causative agents after noroviruses. More than 2600 serovar of Salmonella have been defined, and their primary reservoir is poultry. Therefore, salmonellae serovars are most frequently associated with consumption of poultry meat and poultry products, which leads to Salmonella-related foodborne illnesses. The main purpose of this study

was to determine the prevalence of Salmonella spp. by use of biotinyl-tyramide signal amplification from retail poultry (chicken) meat in Adyaman province. For this purpose, magnetic micro-beads which can specifically bind to Salmonella spp., was used for isolation by applying Immunomagnetic Separation (IMS), and Tyramide Amplification (TA) was used for detection of the bacteria in order to determine the presence (by ratio) of Salmonella spp. in poultry meat. In this study, 124 samples of poultry meat were studied and 35 (28.23%) of them were Salmonella positive.

Ayhan, F. (2003). "Surface modification and covalent coupling of Concanavalin A onto Poly(EGDMA/HEMA) microbeads for cell affinity applications." <u>Journal of Bioactive and Compatible Polymers</u> **18**(4): 297-310.

The surfaces of nonporous and porous Poly(EGDMA/HEMA) microbeads were modified by the reaction of sodium periodate, hexamethylenediamine and glutaraldehyde. Covalent immobilization of Concanavalin A (Con A) was optimized for maximum loading at various Con A concentrations, pH, temperatures, and ionic strengths. The optimal Con A immobilized concentration was determined as 0.37 and 0.75 mg/g microbeads for the nonporous and porous microbeads, respectively. Covalent coupling was achieved at 37degreeC, with 0.5 mg/mL of Con A at pH 7.4 and ionic strength of 0.01. The specific activity of Con A immobilized microbeads to carbohydrate structure was tested for affinity for myeloma HeLa cells. The data indicates that Con A may play a role in myeloma cell adhesion.

Ayhan, F., et al. (2002). "Optimization of urease immobilization onto non-porous HEMA incorporated poly(EGDMA) microbeads and estimation of kinetic parameters." <u>Bioresource Technology</u> **81**(2): 131-140.

Jack bean urease (urea aminohydrolase, EC 3.5.1.5) was immobilized onto modified non-porous poly(ethylene glycol dimethacrylate/2-hydroxy ethylene methacrylate), (poly(EGDMA/HEMA)), microbeads prepared by suspension copolymerization for the potential use in hemoperfusion columns, not previously reported. The conditions of immobilization; enzyme concentration, medium pH, substrate and ethylene diamine tetra acetic acid (EDTA) presence in the immobilization medium in different concentrations, enzyme loading ratio, processing time and immobilization temperature were investigated for highest apparent activity. Immobilized enzyme retained 73% of its original activity for 75 days of repeated use with a deactivation constant kd = 3.72 x 10(-3) day(-1). A canned non-linear regression program was used to estimate the intrinsic kinetic parameters of immobilized enzyme with a low value of observable Thiele modulus (phi < 0.3) and these parameters were compared with those of free urease. The best-fit kinetic parameters of a Michaelis-Menten model were estimated as Vm = 3.318 x 10(-4) micromol/s mg bound enzyme protein, Km = 15.94 mM for immobilized, and Vm = 1.074 micromol NH3/s mg enzyme protein, Km = 14.49 mM for free urease. The drastic decrease in Vm value was attributed to steric effects, conformational changes in enzyme structure or denaturation of the enzyme during immobilization. Nevertheless, the change in Km value was insignificant for the unchanged affinity of the substrate with immobilization. For higher immobilized urease activity, smaller particle size and concentrated urease with higher specific activity could be used in the immobilization process.

Ayhan, H. (2002). "Model protein BSA adsorption and covalent coupling onto methyl methacrylate based latex particles with different surface properties." <u>Journal of Bioactive and Compatible Polymers</u> **17**(4): 271-283.

The adsorption and covalent coupling of bovine serum albumin (BSA) onto methylmethacrylate

(MMA) based monodisperse latex particles with different hydrophylic surfaces were investigated. P(MMA) and P(MMA/HEMA) microbeads in the size range of 1.5-2.0 mum were prepared by a dispersion homopolymerization method in the presence of poly(vinylpyrrolidone) (PVP) and poly(vinyl alcohol) (PVA) as steric stabilizer and by copolymerization of MMA and 2-hydroxethyl methacrylate (HEMA) where PVP was used as steric stabilizers. Surface properties of these particles were characterized in terms of contact angle measurements and FTIR-DRS spectra. Additionally, hydroxyl groups of PMMA<inf>PVA</inf> and P(MMA/HEMA) particles were activated to provide aldehyde groups on surfaces. Adsorption of the BSA onto these five types of latex particles was examined as a function of initial albumin concentration, pH and ionic strength of the various cations (Na⁺, Ca⁺ and Mg⁺²) and anions (Cl⁻ and SCN⁻). The maximum adsorption capacities for all latex particles were obtained in solutions with 0.01 mu ionic strength and 1 mg/mL BSA concentration. When using PMMA<inf>PVP</inf>, P(MMA/HEMA) and PMMA<inf>PVP</inf>, the adsorption increased as hydrophobicity increased. Aldehyde activation of the two most hydrophobic particles elevated the coupling (immobilization) significantly in ionic strength of 0.01 mu. The adsorption and/or immobilization were maximum in the presence of monovalent cation, Na⁺ or anion, Cl⁻ for all types of latex particles.

Ayhan, H., et al. (1999). "Protein a immobilized poly(methylmethacrylate-co- hydroxyethylmethacrylate) microbeads for IgG adsorption." Journal of Bioactive and Compatible Polymers **14**(6): 490-503.

Poly (methylmethacrylate-co-2-hydroxyethylmethacrylate) microbeads in the size range of 1.5-2.0 mum were prepared by a phase inversion polymerization. The hydroxyl groups were activated by periodate oxidation, and the active ligand, i.e., protein A was immobilized via a spacer-arm, i.e., hexamethylene diamine (HDMA) by using a cross-linker, i.e., glutaraldehyde and protein A. The optimal concentration obtained for modifications are as follows: sodium periodate concentration: 0.407 x 10⁻² mmol/mL; HMDA concentration: 3.5 x 10⁻² mmol/mL; and glutaraldehyde concentration: 0.7 x 10⁻⁶ mmol/mL. Yields of immobilization of protein A onto the plain and periodate oxidized microbeads were found very dose, and were in the range of 0.01-0.02 mg protein A/g microbeads. The optimal conditions for immobilization are as follows: the initial protein A concentration: 0.1 mg/mL; temperature: 25degreeC; pH: 9.5; and immobilization time:120 min. Incorporation of protein A at these conditions resulted in 0.825 mg protein A/g microbeads. The HIgG adsorption onto these protein A incorporated microbeads was 41 mg HIgG/g microbeads.

Ayhan, H., et al. (2000). "Protein A immobilization and HIgG adsorption onto porous/nonporous and swellable HEMA-incorporated polyEGDMA microspheres." Journal of Biomaterials Science, Polymer Edition **11**(1): 13-25.

Both non swellable and swellable poly(EGDMA/HEMA) microbeads were produced by suspension copolymerization. These microbeads were modified by immobilization of a spacer-arm (hexamethylene diamine (HMDA)) and protein A. The optimal values for modifications were as follows: sodium periodate concentration, 1.0 mgml(-1); HMDA concentration, 4 mgml(-1); and glutaraldehyde concentration, 0.070 microgml(-1). Adsorption of protein A onto the plain and periodate oxidized poly(EGDMA/HEMA) microbeads were very close to each other, and were 0.01-0.02 mg protein A on the 1-g Microbeads I and II, respectively. Protein A immobilization on poly(EGDMA/HEMA) microbeads were studied at different temperatures, times, and pHs using single protein solution containing different amounts of proteins. The optimal values for immobilization were as follows: the initial protein A concentration, 0.1 mgml(-1); temperature, 25 degrees C; pH, 9.5; and immobilization time, 120

min. Incorporation of protein A resulted in 1.420 and 1.825 mg protein A on the 1-g Microbeads I and II, respectively. HIgG adsorption capacity on the protein A-incorporated poly(EGDMA/HEMA) microbeads is 27 and 35 mg HIgGg(-1) polymer for Microbeads I and II, respectively.

Ayhan, H. and E. Piskin (2000). "Collagen immobilization onto P(EGDMA/HEMA) microbeads for cell affinity systems." Journal of Bioactive and Compatible Polymers **15**(1): 27-42.

Both nonswellable and swellable poly(EGDMA/HEMA) microbeads were produced by suspension copolymerization. These microbeads were modified by immobilization of a spacer-arm (hexamethylene diamine, HMDA) and collagen. The optimal values for modifications were as follows: sodium periodate concentration: 0.467 x 10⁻² mmol/mL; HMDA concentration: 3.5 x 10⁻² mmol/mL; and glutaraldehyde concentration: 0.70 x 10⁻⁶ mmol/mL. Adsorption of collagen onto plain and periodate oxidized poly(EGDMA/HEMA) microbeads were similar, 0.25 and 0.50 mg collagen/g polymer, respectively. Collagen immobilization on poly(EGDMA/HEMA) microbeads was studied at various temperatures, times, and pH by using protein solution containing various amounts of proteins. The optimal values for immobilizations were as follows: the initial collagen concentration: 0.25 mg/mL; temperature: 4degreeC; pH 7; and the immobilization time; 120 min. Both fibroblastic 3T3 and epithelial MDBK cells were attached to these unmodified and modified microbeads. The attachments of 3T3 and MDBK cells, especially to the collagen immobilized swellable microbeads were very high. Almost 96% of the 3T3 cells available in the cell culture medium became attached to these microbeads (2297 +/- 122 cells per mg of polymer). There was no significant effect by swelling on cell attachment.

Aylor, B. (2011). "FUELING A FLEET." Recycling Today **49**(6): 102-136.

The article reports on the plan of European solid waste and recycling company Sita to power its Great Britain collection fleet with a fuel made from mixed post-consumer plastics. The company will be converting mixed plastic scrap collected from residential and commercial customers into diesel power to be used by a fleet of solid waste and recycling collection trucks in Great Britain. Sita signed an agreement with Cynar which will provide a solution to the environmental challenge of treating waste plastic that cannot be recycled.

Aytan, U., et al. (2016). "First evaluation of neustonic microplastics in Black Sea waters." Marine Environmental Research **119**: 22-30.

The Black Sea has a high risk of plastic pollution given the high river discharge of several industrialized countries into this semi-enclosed sea. Here, for the first time, the occurrence and distribution of microplastics are reported for the Black Sea. Microplastics were assessed from zooplankton samples taken during two cruises along the south eastern coast of the Black Sea in the November of 2014 and February of 2015. In each cruise neuston samples were collected at 12 stations using a WP2 net with 200 mu m mesh. Microplastics (0.2-5 mm) were found in 92% of the samples. The primary shapes were fibres (49.4%) followed by plastic films (30.6%) and fragments (20%), and no micro beads were found. Average microplastic concentration in November (1.2 plus or minus 1.1 103 p ar. m-3) was higher than in February (0.6 plus or minus 0.55 103 par. m-3). Reduced concentrations in February were possibly caused by increased mixing. The highest concentrations of microplastics were observed in offshore stations during November sampling. The heterogeneous spatial distribution (0.2 103-3.3 1 03 par. m-3 for all samples) and accumulation in some stations could be associated to transport and retention mechanisms linked with wind and the dynamics of the rim current, as well by different sources

of plastic. There were no statistically significant differences in MP concentration between sampling stations and sampling periods (t-test, p < 0.05).The relatively high microplastic concentrations suggest that Black Sea is a hotspot for microplastic pollution and there is an urgency to understand their origins, transportation and effects on marine life.

Azari, B. M., et al. (2009). "Junctional adhesion molecule-a/ F11 receptor (JAM-a/ F11R) expression in multiple myeloma (MM): A Candidate Biomarker of Aggressive Disease." Blood. Conference: 51st Annual Meeting of the American Society of Hematology, ASH. New Orleans, LA United States. Conference Publication: **114**(22).

Background: Multiple myeloma (MM) is an incurable disease of clonal plasma cells that accumulate in the bone marrow (BM), causing monoclonal IG production, bone marrow failure, osteolytic lesions and kidney disease. Although initially treatable, MM ultimately becomes refractory to treatment, and is invariably fatal, when tumor cells that harbor genetic mutations expand without regulation. Therefore novel treatment targets need to be identified. A key mechanism in MM pathogenesis is regulation of tumor growth by the bone marrow (BM) microenvironment, particularly by bone marrow neo-vascularization and adhesion of tumor cells to the marrow stroma. Aberrantly expressed genes that regulate angiogenesis by MM cells enhance MM progression and constitute targets in its treatment. JAM-A/F11R is an endothelial cell (EC) adhesion molecule of the immunoglobulin superfamily which is a multifunctional cell membrane protein that mediates intracellular signaling events that alter EC migration and paracellular permeability. For example, in breast cancer, attenuation of JAM-A increases tumor invasion and metastasis through a decrease in tumor adhesion (Ulas Naik Cell Adh Migr. 2008 Oct;2(4):249-51.). In this study we explored the JAM-A/F11R expression in MM tumor cells and in patients to determine the potential role of this molecule in the pathogenesis and progression of MM. Method(s): The MM cell lines examined were RPMI-8266, U266, and NCI-H929. Human umbilical vein endothelial cells (HUVECs) served as controls. Informed consent was obtained from patients and control subjects. Primary BM tumor cells were enriched to > 95% CD138+ cells by positive selection using anti-CD138 MACS MicroBeads. The CD138-negative fraction was used for outgrowth of confluent EPCs (> 98% vWF/CD133/KDR+). JAM-A mRNA expression was assessed using an microarray gene expression profile, JAM-A probe based real-time PCR, and JAM-A levels in each sample were measure using a standard curve and normalized to GADPH. JAM-A protein levels in MM cell lines and primary tumor cells were measured by flow cytometry and immunofluorescence. For serum studies, peripheral blood was obtained from 25 newly diagnosed MM patients and 8 healthy, age- and sex-matched controls, and JAM-A levels were measured using an ELISA. Statistical analysis was performed using Student's t-test, two-tailed, with P ' .05 considered significant. Result(s): JAM-A mRNA levels were significantly increased in MM cell lines RPMI-8266, U266, and NCI-H929 compared to HUVECs (U266, P = 3x10-5; RPM1-8266, P = 1x10-6; NC1-H929, P= 5x10-4). The JAM-A mRNA levels were significantly greater in RPMI-8226; P < .04 compared to TNFalpha-activated HUVECs for 24 hours which is a proangiogenic switch for HUVEC gene expression. The elevated mRNA expression of the JAM-A in MM cell lines was confirmed by immunofluorescence and flow cytometry which showed the presence of both membrane and cytoplasmic JAM-A protein. Microarray analysis of gene expression profiles from 20 patients' corresponding tumor cells and microenvironmental EPCs showed that JAM-A had a higher level of expression in tumor cells versus MM EPC by 12.62 fold, (P=.0000642). Furthermore, JAM-A had a higher level of expression in MM EPC versus normal control EPC by 2.41 fold, (P=.00113) reflecting a complex regulatory role of F11 signaling in MM, similar to breast cancer (Naik, U. et al 2008). JAM-A was also found to be 12.6 fold greater in tumor cells compared to EPCS (P=.0000642). In addition, circulating levels of soluble JAM-A were found to be significantly greater in the serum of MM patients compared to controls (P < .005), with an average 2-fold increase. Serum levels of JAM-A in MM patients also decreased 71% with treatment n=5, P<.05. Conclusion(s): We show for the first time that JAM-A expression is highly elevated in MM tumor cells and its levels respond to treatment. In addition, MM patients have higher circulating JAM-A levels compared to healthy individuals and circulating JAM-A levels were reduced following treatment, suggesting that JAM-A may serve as a novel biomarker in MM. Current studies in the lab are aimed at correlating these levels with clinical parameters to determine whether JAM-A levels reflect disease severity and response to treatment. Results of these analyses, as well as results of ongoing experiments using JAM-A siRNA and antibody-inhibition approaches to target JAM-A in myeloma tumor and ECs will be presented.

Aziz, F., et al. (2016). "Microbead array based technology for detection and quantitation of viral respiratory pathogens associated with pneumonia among children." International Journal of Infectious Diseases **1)**: 431.

Background: Viruses play an important role in causing respiratory infections in children worldwide. The burden of viruses in respiratory infections among children in Pakistan is unknown, largely due to absence of good quality diagnostic facilities. Common viruses associated with respiratory infections included respiratory syncytial virus (RSV), influenza A/B, along with novel viruses like human metapneumovirus, human coronavirus NL63 and HKU1, and human bocavirus, which have the potential to cause pandemics. Therefore, it is, important to delimit the burden of viral pathogens in respiratory infections among children with viral pneumonia. Advanced molecular biology techniques offer great advantage as they are more sensitive and have fast turnaround time for the identification of respiratory pathogens. Magpix platform is used to detect respiratory targets in multiplex assay based on the principle of magnetic bead which allows multiplexing of up to 50 unique assays in a single microplate well. Methods & Materials: Nasopharyngeal swabs of children with acute respiratory infections were collected in viral transport medium and spiked with Bacteriophage MS2 extrinsic control to check the efficacy of nucleic acid amplification. An automated nucleic acid extraction was done using MagNa Pure instrument. xTAG Respiratory Viral Panel fast assay was used for the detection of wide range of viruses and subtypes. Data were analysed using TDAS RVP Fast software (ver. 2.21) and reported as median fluorescent intensity. Result(s): Upon testing 734 nasopharyngeal swabs 362(49%) were positive for entero/rhinovirus, followed by 48(6.5%) positive for parainfluenza type III, 46(6.2%) RSV, 38 (5.1%) parainfluenza type IV, 35(4.7%) metapneumovirus, 25 (3.4%) bocavirus, 22 (3%) adenovirus, 19(2.6%) parainfluenza type I, 17 (2.3%) coronavirus OC43, 16(2%) influenza A/B, 7(1%) parainfluenza type II and 5 (0.68%) were positive for other coronaviruses 229E/ NL63/ HKU1. Conclusion(s): Multiplex PCR- assay is rapid and sensitive tool for the detection of major respiratory pathogens and helpful in future for vaccine development. The advantage of this system is it has shortened time to perform a wide variety of bioassays, costeffectively and accurately.

Azizan, A., et al. (2009). "Profile of time-dependent VEGF upregulation in human pulmonary endothelial cells, HPMEC-ST1.6R infected with DENV-1, -2, -3, and -4 viruses." Virology Journal **6 (no pagination)**(49).

In this study, the upregulated expression level of vascular endothelial growth factor (VEGF) in a pulmonary endothelial cell line (HPMEC-ST1.6R) infected with dengue virus serotypes 1, 2, 3, and 4 (DENV-1, -2, -3 and -4), was investigated. This cell line exhibits the major constitutive and inducible endothelial cell characteristics, as well as angiogenic response. Infection by all four

DENV serotypes was confirmed by an observed cytopathic effect (CPE), as well as RT-PCR (reverse-transcription polymerase chain reaction) assays. As we had previously reported, the DENV-infected HPMEC-ST1.6R cells exhibited an elongated cytoplasmic morphology, possibly representing a response to VEGF and activation of angiogenesis. In this study, increase in VEGF expression level at designated time points of 0, 8, 24, 96 and 192 hours post-infection was investigated, using a microbead-based Bio-Plex immunoassay. Increased level of VEGF expression in infected-HPMEC-ST1.6R was detected at 8 hours post-infection. Interestingly, VEGF expression level began to decrease up to 96 hours post-infection, after which an upsurge of increased VEGF expression was detected at 192 hours post-infection. This profile of VEGF upregulated expression pattern associated with DENV infection appeared to be consistent among all four DENV-serotypes, and was not observed in mock-infected cells. In this study, the expression level of VEGF, a well-established vascular permeabilizing agent was shown to be elevated in a time-dependent manner, and exhibited a unique dual-response profile, in a DENV-infected endothelial cell. The experimental observation described here provided additional insights into potential mechanism for VEGF-mediated vascular leakage associated with DENV, and support the idea that there are potential applications of anti-VEGF therapeutic interventions for prevention of severe DENV infections.

Azizan, A., et al. (2006). "Differential proinflammatory and angiogenesis-specific cytokine production in human pulmonary endothelial cells, HPMEC-ST1.6R infected with dengue-2 and dengue-3 virus." Journal of Virological Methods **138**(1-2): 211-217.

In this study, the ability of dengue virus serotypes 2 (DENV-2) and 3 (DENV-3) to infect and induce increased production of proinflammatory cytokines in a pulmonary endothelial cell line (HPMEC-ST1.6R) was investigated. This cell line exhibits the major constitutive and inducible endothelial cell characteristics, as well as angiogenic response. DENV-2 and DENV-3 infection was confirmed by an observed cytopathic effect (CPE), as well as RT-PCR and immunofluorescence assays. Increases in Th-1 and Th-2 cytokines IL-4, IL-8, IL-6, IL-10, GM-CSF, INF-gamma, and tumor necrosis factor (TNF-alpha) within DENV-2- and DENV-3-infected cells were demonstrated using a microbead-based Bio-plex assay. Proinflammatory cytokine increases and the expression of a potent angiogenic inducer protein, VEGF were confirmed by dot-blot analysis using the TranSignal Human Angiogenesis Antibody Array. Dengue virus-infected HPMEC-ST1.6R cells exhibited an elongated cytoplasmic morphology, possibly representing a response to VEGF and activation of angiogenesis. The increased levels of Th-1 cytokines and VEGF in DENV-2 virus infected-HPMEC-ST1.6R could be distinguished from those infected by DENV-3. This suggests that cytokine patterns associated with DENV infections may be serotype and strain-specific. The experimental approaches described here could be developed further into a useful diagnostic tool for the characterization of dengue hemorrhagic fever cases, leading to enhancement of treatment therapy.

Azmeera, V., et al. (2017). "Solution and microwave assisted synthesis of beta-Cyclodextrin grafted polyacrylamide: Water treatment and In-vitro drug release study." International Journal of Biological Macromolecules **104**(Pt A): 1204-1211.

The present article reports the application of beta-cyclodextrin grafted polyacrylamides synthesized through solution and microwave assisted polymerization techniques as flocculants and then the employment of partially hydrolyzed products of best grade of each technique in-vitro drug release study of diclofenac sodium. Five different grades of beta-cyclodextrin grafted polyacrylamides by each of solution and microwave assisted polymerization techniques have been synthesized, by varying the monomer concentration. The synthesized polymers have been well characterized and their flocculation performances have been evaluated in kaolin suspension through settling and jar test methods Then the best performing grades of both the techniques have been partially hydrolyzed to prepare three different grades each technique by varying the concentration aqueous NaOH solution. Flocculation efficiencies of these polymers have been investigated in kaolin suspension. Thus best grades of partially hydrolyzed grafted polymers of each technique have been chosen for further study of drug delivery. In-vitro drug release study has been done using diclofenac sodium loaded microbeads prepared by ionic gelation method with two partially hydrolyzed grafted polymers (one from each technique) in phosphate buffer solution (PBS) at 37+/-0.5 C and pH 7.4. The drug load and release have been analyzed by UV-vis spectroscopy.

Azubuike Francis, A., et al. (2018). "Experimental Study of Thermal and Catalytic Pyrolysis of Plastic Waste Components." Sustainability **10**(11).

The advantages of catalytic pyrolysis are degradation at a lower temperature (lower energy consumption), increased selectivity, faster-cracking reactions, shorter residence time, inhibition of the formation of undesirable products, increased product yield and production of liquid products with a lower boiling point [13,14]. [...]a product may be considered an alternative to conventional, non-renewable fuels. 4. [...]a higher proportion of PP increases the gasoline range fraction. Azukizawa, H., et al. (2018). "Comparison among three methods of interferon-gamma enzyme-linked immunospot assay for identifying hypersensitivity-inducing drug culprits." Clinical and Translational Allergy. Conference: 8th Drug Hypersensitivity Meeting, DHM **8**(Supplement 3).

Background Drug-induced Interferon-gamma (IFN-g) enzyme-linked immunoSpot (ELISpot) is an useful in vitro test for identifying culprit drugs in cutaneous adverse drug reactions (cADR) cases. Recent report suggested that the measurement of oxypurinol-inducing IFN-g-releasing cells yields a high diagnostic value in distinguishing between allopurinolallergic and control subjects, when anti-programmed death ligand 1(PD-L1) antibodies were added (anti PD-L1 IFN-g ELISpot). More recently, we reported that drug-induced IFN-g ELISpot using Peripheral blood mononuclear cells (PBMCs), which were stimulated with anti-CD3/CD28 antibody-coated microbeads and IL-2 for 7 days before exposure to the culprit drugs (modified IFN-g ELISpot), was more sensitive than the conventional IFN-g ELISpot. The aim of this study was to clarify the utility of conventional IFN-g ELISpot, anti PD-L1 IFN-g ELISpot, and modified IFN-g ELISpot. Methods Seventeen patients with cADR, caused by clinically convincing culprit drugs, were enrolled in this study. In some cases, the blood samples were obtained at two or three different time points. PBMCs from total 21 samples were analyzed using conventional IFN-g ELISpot, anti PD-L1 IFN-g ELISpot, and modified IFN-g ELISpot. Results Among the culprit drugs tested in each patient, both conventional IFN-g ELISpot and modified IFN-g ELISpot were positive in six

samples, while anti PD-L1 IFN-g ELISpot were positive in four samples. Conclusion Since enrolled cases were limited, more samples are needed for clarifying the enhancement of drug induced IFN-g production by anti PD-L1 antibody. Combination of modified IFN-g ELISpot and conventional IFN-g ELISpot may increase the sensitivity for detecting IFN-g production by drug culprits.

Azzam, M. O. J., et al. (2003). "The role of particle size on the deposition efficiency of ink on plastic spheres." Colloids and Surfaces A: Physicochemical and Engineering Aspects **230**(1-3): 207-216.

Experimental investigation of the effect of carbon particle size on its deposition efficiency on the surface of plastic particles has been performed in stirred vessel. A model based on Langmuir kinetics was used, and it provided a good fit for the experimental results. The effect of de-inking conditions such as, carbon particle size, calcium chloride concentration, and carbon concentration has been investigated. Different sizes of carbon particles were tested. It was found that the deposition rate and the deposition efficiency were generally higher for the larger carbon particles. The effect of CaCl <inf>2</inf> concentration on the deposition efficiency was investigated. Results showed that the deposition rate increased when the concentration of CaCl<inf>2</inf> increased from 0.05 to 0.10g/l (the stochiometric ratio needed to react with sodium stearate). Moreover, the deposition efficiency was higher at this concentration. Concentrations above the stochiometric ratio did not show a systematic behavior for the deposition rate and the deposition efficiency. Finally, the effect of carbon concentration was examined. Carbon concentration of 0.25, 0.30, and 0.40g/l were used. Results showed that the concentration of carbon did not affect the deposition efficiency nor the rate of deposition. This study confirmed the applicability of the method of ink removal from recycled waste paper using plastic particles, proposed by previous investigators. © 2003 Elsevier B.V. All rights reserved.

Baalkhuyur, F. M., et al. (2019). "Corrigendum to "Microplastic in the gastrointestinal tract of fishes along the Saudi Arabian Red Sea coast" (Marine Pollution Bulletin (2018) 131(PA) (407-415), (S0025326X18302625) (10.1016/j.marpolbul.2018.04.040))." Marine Pollution Bulletin: 470.

Baalkhuyur, F. M., et al. (2018). "Microplastic in the gastrointestinal tract of fishes along the Saudi Arabian Red Sea coast." Marine Pollution Bulletin **131**: 407-415.

This study assesses the presence of microplastic litter in the contents of the gastrointestinal tract of 26 commercial and non-commercial fish species from four difference habitats sampled along the Saudi Arabian coast of the Red Sea. A total of 178 individual were examined for microplastics. In total, 26 microplastic fragments were found. Of these, 16 being films (61.5%) and 10 being fishing thread (38.5%). FTIR analysis revealed that the most abundant polymers were polypropylene and polyethylene. Parascolosps eriomma species sampled at Jazan registered the highest number of ingested microplastic. This fish species is benthic and feeds on benthic invertebrates. Although differences in the abundance of microplastic ingestion among species were not statistically significant, a significant change was observed when the level of ingestion of microplastics particles was compared among the habitats. The higher abundance of microplastics particles may be related to the habitats of fish and the presence of microplastics debris near the seabed. The results of this study represent a first evidence that microplastic pollution represents an emerging threat to Red Sea fishes, their food web and human consumers.

Baba, M., et al. (2016). "Removal of extracellular Toxoplasma gondii tachyzoites from suspended cell culture." Parasitology International **65**(5 Pt B): 536-538.

Tachyzoites of Toxoplasma gondii, an obligate intracellular parasite, actively invade a broad spectrum of cell types. T. gondii infects leukocytes and spreads to distant organs such as the brain, lungs and muscles. However, the mechanism of T. gondii transmission from infected leukocytes to peripheral organs is unknown. To show the dynamics of infected leukocytes and intracellular parasites in vivo, previous studies have prepared T. gondii-infected leukocytes and injected them into circulation in experimental animals. However, when the infected leukocytes are prepared in vitro, some extracellular tachyzoites remain in the leukocyte cell culture because it is almost impossible to wash out these extracellular tachyzoites. These extracellular tachyzoites may distort experimental results. In this study, we report a method for removing extracellular tachyzoites from leukocyte culture suspension using antibody-conjugated magnetic beads. Using this method, extracellular tachyzoites in suspension cell culture can be effectively eliminated.

Babu, G. L. and S. K. Chouksey (2011). "Stress-strain response of plastic waste mixed soil." Waste Management **31**(3): 481-488.

Recycling plastic waste from water bottles has become one of the major challenges worldwide. The present study provides an approach for the use plastic waste as reinforcement material in soil. The experimental results in the form of stress-strain-pore water pressure response are presented. Based on experimental test results, it is observed that the strength of soil is improved and compressibility reduced significantly with addition of a small percentage of plastic waste to the soil. The use of the improvement in strength and compressibility response due to

inclusion of plastic waste can be advantageously used in bearing capacity improvement and settlement reduction in the design of shallow foundations.

Babu, G. L. S. and S. K. Chouksey (2012). "Analytical model for stress-strain response of plastic waste mixed soil." Journal of Hazardous, Toxic, and Radioactive Waste **16**(3): 219-228.

Recycling plastic water bottles has become one of the major challenges world wide. The present study provides an approach for the use of plastic waste as reinforcement material in soil, which can be used for ground improvement, subbases, and subgrade preparation in road construction. The experimental results are presented in the form of stress-strain-pore water pressure response and compression paths. On the basis of experimental test results, it is observed that the strength of soil is improved and compressibility reduced significantly with the addition of a small percentage of plastic waste to the soil. In this paper, an analytical model is proposed to evaluate the response of plastic waste mixed soil. It is noted that the model captures the stress-strain and pore water pressure response of all percentages of plastic waste adequately. The paper also provides a comparative study of failure stress obtained from different published models and the proposed model, which are compared with experimental results. The improvement in strength attributable to the inclusion of plastic waste can be advantageously used in ground improvement projects.

Babusikova, O., et al. (1996). "Leukemia-associated phenotypes: their characteristics and incidence in acute leukemia." Neoplasma **43**(6): 367-372.

Leukemia-associated phenotypes have been suggested to be a valuable tool for the detection of minimal residual disease in acute leukemia patients, as they allow to distinguish leukemic blasts from normal hematopoietic progenitor cells. The aim of the present study was to analyze the proportion of acute leukemia patients (both with lymphoid and myeloid leukemias) in which the immunological detection of leukemia-associated phenotypes was convenient for the distinction of leukemic and normal cells. For this purpose we have studied the blast cells from 186 acute leukemia patients at diagnosis with a large panel of monoclonal antibodies by flow cytometry using double staining combinations. From aberrant phenotypes on blast cells we followed lineage infidelity (coexpression of myeloid markers in lymphoid leukemia cells and vice versa, as well as the simultaneous expression of both, T and B cell markers in one lymphoid blast cell) and asynchronous marker expression (simultaneous expression of early and late markers in one cell). One hundred and five of the 186 acute leukemia cases analyzed (56%) showed the presence of leukemia-associated phenotypes. In 41 of the 90 ALL cases followed (46%) and in 40 of the 96 AML cases studied (42%) lineage infidelity was observed. Asynchronous antigen expression was detected in 24 followed cases (13%). Evaluation of the cell marker density by means of calibration microbeads demonstrated abnormal mean channel immunofluorescence and molecules of equivalent soluble fluorescein for CD8 in two patients with T cell malignancies at diagnosis. Abnormal CD8 density might thus represent a characteristic feature of malignant CD8-positive T cell clone. Quantitative marker evaluation therefore seems to be another important mean for the detection of aberrant phenotypes on leukemia cells suitable for the detection of minimal residual disease.

Babusikova, O., et al. (1997). "Quantitative immunocytofluorometry--new parameters for the definition of leukemia cells." Neoplasma **44**(6): 348-355.

In our study we used for definition of leukemia/lymphoma cells a new parameter which allows the enumeration of mean fluorescence intensity expressed by the number of antigen molecules per cell. Quantitative immunofluorescence using calibration microbeads was performed in 36

patients with different acute and chronic lymphoid and myeloid leukemia and in 19 healthy volunteers. We showed that quantitative immunophenotyping allowed the definition of aberrant marker densities on neoplastic cells. We demonstrated under- and overexpression of CD8 marker in CD3/CD4/CD8 complex in T acute lymphatic leukemia and T non-Hodgkin's lymphoma and T leukemia of large granular lymphocytes as compared to normal counterparts. We pointed out that certain antigens (e. g. CD10, CD4, CD24) were expressed at different levels on different cell subsets (CD10 in early B-acute lymphatic leukemia and coexpressed in T-acute lymphatic leukemia, CD4 on T cells and monocytes, CD24 on B cells and granulocytes in chronic myeloid leukemia). We showed that quantitative immune fluorescence could provide new data contributing to a more precise definition of cell differentiation. We documented the significant difference between antigen density of early and late markers in B-cell and myeloid malignancies. Further, we demonstrated that quantitative immune phenotyping could help in determination of exact definition of pathologic clone in morphologically immature leukemia population and showed that parameters of this method are also convenient for cytoplasmic marker evaluation. In our study we were able to demonstrate that CD45 quantitative expression appeared to be a more informative parameter than its percentage of antigen-positive cells as a measure of antigen expression only and we pointed out that low and high CD45 densities enabled to differentiate between pathological clone and residual healthy population in examined sample. We showed that quantitative immune phenotyping could be another important parameter for definition of leukemia phenotype suitable for detection of minimal residual disease.

Babusikova, O. and A. Tomova (2003). "Hairy cell leukemia: early immunophenotypical detection and quantitative analysis by flow cytometry." Neoplasma **50**(5): 350-356.

UNLABELLED: The abnormal coexpression of the so-called 'HCL-restricted' markers (CD22+CD11c, CD25 and CD103) identified on monotypic, slightly large B-lymphocytes in the large cell-gate of dot-plots has previously been shown to be highly characteristic of hairy cell leukemia (HCL). The main aim of our present study was to determine if patterns with low levels of neoplastic cells in bone marrow (BM) or peripheral blood (PB) are of a value the early diagnosis and/or detection of minimal residual disease (MRD) in HCL. Next we wished to determine if quantitative immunophenotyping given by molecules of equivalent soluble fluoresceine (MESF) could help to distinguish pathologic B-lymphocytic pool from that of normal residual B-cells also in patients with low numbers of HCL cells. The abnormal immunophenotypes were studied in 174 specimens from 19 patients with suspect HCL or during follow-up of already treated patients. For evaluation of marker density fluorescent calibration microbeads were used. In 12 HCL patients (67%) permanent complete remission was observed after treatment. In 6 patients (33%) transient MRD+ phenotype was identified but the clinical manifestation of relapse was followed till now in only three patients. One patient was phenotyped just only at diagnosis. The pathological cells in low levels were found in 5 patients at diagnosis (in the range from 2 to 12%) and in patients with MRD+ phenotype they were recognized repeatedly in the range from 2 to 8%. Furthermore, we observed in hairy cells significantly higher values of molecule numbers of some B-cell markers, comparing to that of residual B-cells in nonleukemic lymphocyte gate of the same sample. We found profound and persistent CD4+ lymphopenia in all but one studied patients after CdA treatment.

CONCLUSIONS: Flow cytometric immunophenotyping of PB and BM is highly sensitive and specific method and is capable to detect low levels of malignant cells in HCL. Quantitative analysis of MESF values of pathological B-cells comparing to normal residual B-cells seems to be another new marker of HCL in common, which is reliable detecting also small cell numbers in examined sample. A long-term decline of CD4+ T-cells correlated with the relatively low incidence of clinical progression of HCL.

Badarinath, A. V., et al. (2010). "Formulation and characterization of alginate microbeads of flurbiprofen by ionotropic gelation technique." International Journal of ChemTech Research **2**(1): 361-367.

Flurbiprofen is a non-steroidal anti-inflammatory drug that can used for rheumatoid arthritis, osteoarthritis, ankylosing spondylitis, tendinitis etc. its shorter biological half life (3-4.5 hrs) necessitates that it to be administered in frequent doses of 50-100mg. The main objective of this study was to develop suitable microparticulate system of Flurbiprofen for controlled release delivery system by varying the alginate, CaCl² and HPMC concentrations. In the present work Flubriprofen microbeads were formulated being sodium alginate by ionotropic gelation technique. Prepared beads were evaluated for granulometric studies, micromeretic, scanning electron microscopy, drug entrapment efficiency and in-vitro dissolution studies etc. The prepared beads were free flowing and white in colour. The drug loaded beads showed 83.6-98.2% drug entrapment, which was found to increase with increase in sodium alginate concentration. Scanning electron microscopy revealed that the beads were spherical and rough in structure. The flow property of the all the batches of prepared microbeads were estimated by angle of repose in the range of 22degree30-32degree20. In vitro drug release study of these microbeads indicated controlled release for Flurbiprofen 84.54-97.74% release at the end of 10 h. Hence the observation of all results of the different batches fifth and sixth showed controlled release action and improved drug availability. The release of Flurbiprofen was found to be affected by both concentration of polymers such as sodium alginate and HPMC. By the observation of accelerated stability studies sixth batch formulation was found to be best formulation. From this study, it could be concluded that the spherical and free flowing microbeads of Flurbiprofen could be successfully prepared by ionotropic gelation technique with high entrapment efficiency and prolonged release characteristics.

Badawy, S. Z., et al. (1987). "Immune rosettes of T and B lymphocytes in infertile women with endometriosis." Journal of Reproductive Medicine **32**(3): 194-197.

We examined the cell-mediated immune response in women with pelvic endometriosis by quantitating their T and B lymphocytes. The study was conducted on heparinized peripheral blood and peritoneal fluid. The results were compared with those in a control group of women without evidence of endometriosis. Each patient underwent laparoscopy as part of her infertility evaluation. The ability of T cells to form rosettes with sheep erythrocytes was used to estimate the percentage of total and active T cells. B lymphocytes were quantitated by erythrocyte antibody complement binding capacity. In addition, T and B lymphocytes were assayed with the Immunobead technique using specific monoclonal antibodies. The helper T cell (T4) and suppressor T cell (T8) subsets of lymphocytes were evaluated with specific monoclonal antibodies coupled to microbeads. The results demonstrated an increased number of T and B cells in peritoneal fluid and peripheral blood from patients with endometriosis as compared with controls. Furthermore, the ratio T4:T8 was significantly increased in patients with endometriosis. These results suggest a cell-mediated immune response in the presence of endometriosis.

Badida, M. P., et al. (2013). CHANGE OF SELECTED MECHANICAL PROPERTIES OF RECYCLED PET ON THE TEMPERATURE CONDITIONS. Sofia, Surveying Geology & Mining Ecology Management (SGEM). **1:** 161-168.

The plastic bottles have wide using as one of the most used custom packing materials in market. They are used mainly by food industry also by chemical industry. This paper deals about the

analysis of changes of mechanical properties changed by influence of temperature of selected PET bottles as incoming plastic waste. This material was tested in two temperature conditions. First was low temperature for simulating the cold weather in winter and the second one was the high temperature simulating the hot weather in summer. To find out the changed mechanical properties of PET bottles was made the tensile test where were defined certain parameters. Achieved values of selected mechanical properties - yield strength, tensile strength and relative elongation were compared with the measured values in natural environment. To comparing the material composition of both materials was made the Raman spectroscopy. [PUBLICATION ABSTRACT]

Bae, S. B., et al. (2019). "Electrospraying of environmentally sustainable alginate microbeads for cosmetic additives." International Journal of Biological Macromolecules **133**: 278-283.

Polymer microbeads (MBs) for scrubbing additives have generally been prepared from non-biodegradable synthetic polymers. The worldwide pollution of the marine ecosystem by microplastics urgently demands novel environment-friendly MBs. In this study, Ca-alginate MBs were fabricated by electrospraying an aqueous alginate solution into distilled water containing calcium ions. The size and shape of the Ca-alginate MBs were controlled by electrospraying parameters, such as nozzle diameter and solution concentration. As the alginate concentration and needle diameter were increased, the size of alginate MBs was gradually increased, because of the higher mass flow rate. In addition, the adsorption and degradation behavior of alginate MBs were examined using model contaminants and sea water, respectively. In particular, alginate MBs rapidly degraded in sea water, due to the reversible ion-exchange reaction between Ca²⁺ in MBs and Na⁺ in sea water. Therefore, the electrosprayed Ca-alginate MBs offer a promising alternative for environment-friendly cosmetic additives.

Baek, C., et al. (2018). "Elimination of Humic Acid from Aqueous Sample Using Zinc Oxide/Graphene Oxide-Coated Microbeads." Journal of Nanoscience & Nanotechnology **18**(9): 6360-6363.

Natural organic matter (NOM) is known to cause major problems with drinking water quality management, such as sedimentation of disinfectants during the purification process, microbial growth of water pipes, and corrosion of pipes. For efficient and continuous removal of NOM from drinking water, a packed bed-type platform containing microbeads based on nanostructured zinc oxide (ZnO) was developed. ZnO was synthesized on graphene oxide (GO)-coated microbeads by optimizing the ZnO concentration and reaction time. The morphology of the synthesized ZnO-coated microbeads was confirmed by scanning electron microscopy, and an adsorption test was conducted using a cationic dye. The ZnO/GO microbeads were packed in a microtube. A humic acid contaminated aqueous solution was allowed to flow through the microbeads, and its removal rate was measured by UV-vis spectroscopy. This study confirmed that the purification platform containing ZnO removed more than 90% of humic acid of about 1,000 ppm.

Bagaev, A., et al. (2018). "Anthropogenic microlitter in the Baltic Sea water column." Marine Pollution Bulletin **129**(2): 918-923.

Microlitter (0.5-5mm) concentrations in water column (depth range from 0 to 217.5m) of the main Baltic Proper basins are reported. In total, 95 water samples collected in 6 research cruises in 2015-2016 in the Bornholm, Gdansk, and Gotland basins were analysed. Water from 10- and 30-litre Niskin bathometers was filtered through the 174mum filters, and the filtrate was examined under optical microscope (40x). The bulk mean concentration was 0.40+/-0.58 items per litre, with fibres making 77% of them. Other types of particles are the paint flakes (19%) and fragments (4%); no microbeads or pellets. The highest concentrations are found in the near-bottom samples from the coastal zone (2.2-2.7 items per litre max) and from near-surface waters (0.5m) in the Bornholm basin (5 samples, 1.6-2.5 items per litre). Distribution of particles over depths, types, and geographical regions is presented.

Bagaev, A., et al. (2017). "Anthropogenic fibres in the Baltic Sea water column: Field data, laboratory and numerical testing of their motion." Science of the Total Environment **599**: 560-571.
Distribution of microplastics particles (MPs) in the water column is investigated on the base of 95 water samples collected from various depths in the Baltic Sea Proper in 2015–2016. Fibres are the prevalent type of MPs: 7% of the samples contained small films; about 40% had (presumably) paint flakes, while 63% contained coloured fibres in concentrations from 0.07 to 2.6 items per litre. Near-surface and near-bottom layers (defined as one tenth of the local depth) have 3–5 times larger fibre concentrations than intermediate layers. Laboratory tests demonstrated that sinking behaviour of a small and flexible fibre can be complicated, with 4-fold difference in sinking velocity for various random fibres' curvature during its free fall. Numerical tests on transport of fibres in the Baltic Sea Proper were performed using HIROMB reanalysis data (2007) for the horizontal velocity field and laboratory order-of-magnitude estimates for the sinking velocity of fibres. The model takes into account (i) motion of fibres together with currents, (ii) their very slow sinking, and (iii) their low re-suspension threshold. Sensitivity of the final distribution of fibres to variations of those parameters is examined. These experiments are the first step towards modelling of transport of fibres in marine environment and they seem to reproduce the main features of fibres distribution quite well. [ABSTRACT FROM AUTHOR]

Bagheri, M., et al. (2020). "Towards a circular economy: A comprehensive study of higher heat values and emission potential of various municipal solid wastes." Waste Management **101**: 210-221.
Maximizing resource recovery from waste streams (e.g., energy) is a critical challenge for municipalities. Utilizing the ultimate analysis and high heat value (HHV), we investigated the energy recovery and emission characteristics for 252 solid wastes of a diverse range of geographical origins classifications (e.g., 30 paper, 12 textile, 12 rubber and leather, 29 MSW mixture, 34 plastic, 61 wood, 20 sewage sludge and 53 other wastes) under the thermal waste-to-energy operation. Given the significance of wastes' HHV data, we proposed a rapid and cost-effective methodology for filling the gaps in the experimental data by prediction of the missing or uncertain wastes' HHV. We further employed wastes' nitrogen and sulphur contents to assess their atmospheric emissions. The results from this analysis show the highest energy content belonged to plastic waste, but higher levels of air pollution (mainly due to nitrogen and sulfur) could be emitted during thermal energy recovery of sewage sludge, rubber, and textile wastes. Also, we demonstrated more significant potential for recovering energy from plastic, wood, and paper wastes, while emitting less nitrogen and sulphur compounds to the atmosphere. Finally, our presented HHV models outperform concerning generalizability, validity, and accuracy when comparing the obtained results to those of previously published models. The

results from this present study are particularly advantageous in designing sustainable thermal waste-to-energy systems to facilitate cities' transition into a circular economy.

Bai, B., et al. (2019). "Experimental investigation on liquefaction of plastic waste to oil in supercritical water." Waste Management **89**: 247-253.

In order to solve the problem of low thermal conductivity and high viscous molten liquid reaction product in the process of plastic liquefaction, the experiments of high impact polystyrene (HIPS) plastic liquefaction were carried out in supercritical water. In this paper, the effects of different operating conditions (temperature, time, feedstock concentration and pressure) on liquid products were studied. It is found that the novel phenomenon that the liquid products of HIPS plastic were mainly toluene and ethylbenzene rather than styrene, which was a product of polystyrene. The experimental results showed that plastic first depolymerized to form styrene and 1,3-diphenylpropane, which were then converted to toluene and ethylbenzene. The increase in temperature promoted this transformation process and some traces of polycyclic aromatic hydrocarbons also produced. At 490degreeC, the maximum carbon liquefaction rate of 77.0wt% was obtained, which was 6 times higher than the conventional pyrolysis, and the content of toluene and ethylbenzene were 14wt% and 51.3wt%, respectively. Increasing the reaction pressure and prolonging the reaction time all promoted the progress of the plastic liquefaction reaction, while increasing the feedstock concentration caused the carbon liquefaction rate to increase first and then slightly decrease.

Bai, M., et al. (2018). "Occurrence, characteristics of microplastic during urban sewage treatment process." China Environmental Science **38**(5): 1734-1743.

By extracting microplastics (MPs) in the water and sludge samples, the occurrence of MPs in a coastal municipal sewage plant in Shanghai was studied. This study firstly investigated the characteristics and emissions of MPs in the coastal WWTP of China. Fiber was the most common shape. Rayon was the most common polymer type in the influents. In the effluents, synthetic leather accounted for the largest porpotion followed by rayon, polyester and polyethylene. The abundances of MPs in the influents, mixed water, effluent and sludge stages were 117n/L, 90n/L, 52n/L and 180n/50 g (wet weight), respectively. The removal efficiency of microplastics in the WWTP was 55.6%. Cursory calculations estimated the abundance of MPs in the waters decrease from 3.276 trillion in the influents to 1.456 trillion in the effluents, and the excess sludge contain approximately 54 million MPs. Moreover, a miscalculation of personal care product MP discharge from the mainland China to the ocean was also be discussed.

Baig, T., et al. (2015). "Preparation and evaluation of multi particulates drug delivery system using natural polymers." Current Drug Delivery **12**(3): 314-322.

Simvastatin potassium is a hypolipidemic drug used with exercise, diet, and weight-loss to control elevated cholesterol, or hypercholesterolemia. It is a member of the statin class of pharmaceuticals. Okra mucilage is used to reduce the cholesterol level since microspheres has formulated by using okra mucilage to developed a synergistic effect. Calcium chloride act as a cross linking agent, when react with sodium alginate form a calcium alginate, since develope a gel like microbeads (microspheres). The half life of simvastatin is 2h for simvastatin acid. Simvastatin microspheres were prepared by using sodium alginate in combination with Abelmoschus esculentus (Okra), as drug release modifiers in various proportions to overcome the drug related adverse effects. The drug entrapment efficiency increased progressively with increasing concentration of both sodium alginate and okra mucilage resulting in the formation of larger microspheres entrapping greater amounts of the drug. The prepared microspheres were subjected to various evaluation and in vitro release studies. The particle sizes of the prepared microspheres were determined by optical microscopy and Scanning Electron Microscopy (SEM) analysis. The prepared microspheres had good spherical geometry with smooth surface as evidence by SEM. Study the capability of the formulation to withstand the physiological environment of the stomach and small intestine.

Bailey, K. (2018). "Who's Really to Blame for the Plastics Recycling Crisis? (Hint: It's Not China)." Waste360: 2-2.

The article explores the global crisis of plastic waste and the response to the crisis. It blames the plastic industry for ever-increasing production of plastics and admits to the inability of recyclers to keep pace with the explosion of plastics on the market. The role of plastics in many advancements in medicine, technology and transportation is recognized. The environmental, health and climate impact of the explosion of plastics is also discussed.

Bailey, S. (2012). "SME delivers pots of solutions." Materials Recycling World **200**(7): 99-100.

The article reports on a partnership formed by Müller Dairy and Summit Systems to construct a recycling line intended specifically for plastic waste from yogurt production. The discussions between the companies were centered on several issues, such as production waste of polystyrene with a heat-sealed metallised paper layer. The recycling operation was dubbed Boomerang Plastics.

Baillie, C., et al. (2011). "Waste-based composites - Poverty reducing solutions to environmental problems." Resources, Conservation and Recycling **55**(11): 973-978.

This paper highlights an innovative model of waste management combined with poverty reduction, which has been developed by the organisation Waste for Life (wasteforlife.org) - a network of academics, students, practitioners and on the ground cooperative partners in low income communities. The Waste for Life teams work with local cooperatives to create waste-based composites, which may be sold in local markets, thereby creating an income stream. The application of this model to the context of cartoneros (waste picker) cooperatives in Buenos Aires, Argentina, reveals that viable products can be made from paper and plastic waste, with low-impact material preparation that circumvents the need for chemically intensive, polluting and mechanically degrading procedures, preserving recycled fibre integrity. Tests on material samples indicate mechanical properties comparable to products made with more complex processing. The production model is based on the philosophy that not only the waste materials, but also the production equipment should be locally sourced and manufactured and products created to suit local markets. A simple reproducible model has been developed for the local manufacture of composites from waste, which can provide an income source for waste pickers as well as providing an innovative waste management solution. © 2011 Elsevier B.V. Baini, M., et al. (2018). "Abundance and characterization of microplastics in the coastal waters of Tuscany (Italy): The application of the MSFD monitoring protocol in the Mediterranean Sea." Marine Pollution Bulletin **133**: 543-552.

Monitoring efforts are required to understand the sources, distribution and abundance of microplastic pollution. To verify the abundance of microplastics along the Tuscan coastal waters (Italy), water-column and surface samples were collected in two seasons across four transects at different distances to the coast (0.5, 5, 10 and 20km), within the implementation of the European Marine Strategy Framework Directive. The results show an average concentration of

0.26items/m³ in the water-column samples and 41.1g/km² and 69,161.3items/km² of floating microplastics, with an increase with the distance to the coast The seasonality and the sampling area do not affect the abundance of microplastics. The most abundant size class is 1-2.5mm as fragments and sheets suggesting that fragmentation of larger polyethylene and polypropylene items could be the main source of microplastics. These data represent the application of a harmonized protocol to make the data on microplastics comparable and reliable.

Bair, R. J., et al. (2014). "Radiopaque polymer hydrogel used as a fiducial marker in gynecologic brachytherapy." Brachytherapy **1)**: S73.

Purpose: Implantable fiducial markers are radiopaque materials used to aid in the clinical and radiographic localization of tumors and normal tissues. We assessed a novel FDA-approved hydrogel synthesized as microbeads impregnated with iodine contrast material (TRACE-IT, Augmenix, Waltham, MA) not previously used as a marker in patients undergoing gynecologic brachytherapy. Material(s) and Method(s): Fifteen patients underwent brachytherapy for recurrent endometrial cancer at the vaginal cuff (3, 20%), recurrent cervical cancer (1, 6%) or primary cervical cancer (11, 73%). Patients underwent 3-D image-based brachytherapy that was CT-planned tandem and ring (5), MR-planned tandem and ring (2), CT-planned interstitial (4) or MR-planned interstitial (4). Pretreatment CT scans were obtained for all 15 patients, and 6/15 also underwent MRI prior to hydrogel injection. The hydrogel material was injected using an 18-gauge spinal needle into the target as determined by the physician using a transvaginal approach with direct visualization of the injection site. The injected amount ranged from 0.1-0.4 ml. A total of 62 injections were placed; locations included the primary tumor within the cervix (32) or endometrium (3), right fornix (4), left fornix (5), non-cancerous endometrium (1), non-cancerous cervix (4), vaginal wall/cuff (7) and parametrial tissue (6). Eight target areas received 0.1 cc, 26 had 0.2 cc, 26 had 0.3 cc and 2 had 0.4 cc. To assess the unadjusted effect of baseline parameters on hydrogel visibility, we modeled each outcome using the linear mixed effect model for continuous outcomes. Post-implantation imaging using CT (15) and MRI (6) with T2-weighted images was performed. Two physicians separately scored the visibility of the tracer on CT and on MR using a 5-point scoring scale: 1-not visualized; 2-faint or trace visibility (shadow or haze); 3-visible but indistinct borders (definable entity, not just haze); 4- partially distinct border, partial haze; and 5-clearly visualized, unequivocal. A Cohen's Kappa statistic was calculated to assess interobserver agreement. Result(s): Injection of the radiopaque gel was accomplished without significant bleeding or other complication. The weighted Cohen's Kappa Statistic was 0.75 (95% confidence interval, 0.65-0.86). Post-implantation analysis included mean, median and range of fiducial marker visibility according to disease site and amount of volume injected (see table). The volume of hydrogel injected was significantly associated with visibility on both CT (p=0.047) and MRI (p=0.023). In some situations, accurate characterization of the injectable marker was limited by diffusion of the gel into adjacent tissues and needle tracks with residual marker leading to distortion of the implantation site. When hydrogel implantation was effective, the T2 MRI demonstrated a well-delineated hyperintense focus in the target injection site; a corresponding hyperdense focus was also seen on the post-implantation CT. Conclusion(s): This is the first reported series of the use of an injectable radiopaque hydrogel (TRACE-IT) to visualized targets on 3D imaging during brachytherapy for endometrial or cervical cancer. Our experience demonstrates the technical feasibility and the variation in radiographic visibility of this novel fiducial marker implant. Its effectiveness varied between primary and recurrent malignancies and between imaging modalities. Injection of 0.4 cc or greater is required for unequivocal visibility on CT or MR. (Table Presented).

Baird, G. S. and T. J. Montine (2008). "Multiplex immunoassay analysis of cytokines in idiopathic inflammatory myopathy." Archives of Pathology & Laboratory Medicine **132**(2): 232-238.
CONTEXT: Idiopathic inflammatory myopathies (IIMs), including dermatomyositis, polymyositis, and inclusion-body myositis, can be difficult to diagnose.
OBJECTIVE: To determine if a multiplex immunoassay for markers of inflammation in muscle homogenates correlates with a diagnosis of IIM.
DESIGN: Frozen archived muscle biopsy specimens from 30 patients with IIM and 34 patients without IIM were homogenized and analyzed for cytokine content with a multiplex microbead-based immunoassay system. Analyte concentrations were normalized to total lysate protein concentration prior to comparison.
RESULTS: Two cytokines, interleukin 1ra and monocyte chemoattractant protein 1, and 1 soluble adhesion molecule, intracellular adhesion molecule 1, were found at significantly greater concentrations in muscle samples from patients with IIM. Intracellular adhesion molecule 1 levels alone were 83% sensitive and 91% specific for IIM at a cutoff of 1240 pg/mg muscle protein.
CONCLUSIONS: Immunoassays for selected inflammatory markers can serve in conjunction with histopathologic analysis as sensitive and specific tools for the diagnosis of IIM.

Bajek, A., et al. (2011). "Prostate epithelial stem cells are resistant to apoptosis after alpha1-antagonist treatment. The impact for BPH patients." Central European Journal of Urology **64**(4): 256-257.
INTRODUCTION: Induction of apoptosis in prostatic epithelial cells by doxazosin, terazosin and prazosin has been well documented. However, the biochemical pathways of doxazosin action is still unclear. Aforementioned drugs should lead to decrease of prostate volume, although this effect was never observed in patients suffering from BPH after treatment with alpha1-antagonists. Probably, it is connected with cancer stem cells' resistance on chemotherapeutic agents. The aim of this study was to compare incidence of apoptosis induced by doxazosin in progenitor and differentiated cells isolated from human prostate epithelium.
MATERIAL AND METHODS: For this purpose tissue specimens were obtained from 10 patients suffering from BPH, the primary cultures of prostate epithelium were established and CD133 MicroBeads sorting was prepared. Both, CD133(+)/CD133(-) co-cultures and CD133(+) cells were incubated with different concentration of doxazosin for 12 h. Cell viability and apoptosis was estimated with Annexin V-FITC.
RESULTS: 12 h incubation of CD133(+)/CD133(-) co-cultures with doxazosin resulted in increase of apoptotic cells, while in CD133(+) cultures no changes were observed. Correlation between apoptotic cell number and doxazosin concentration in CD133(+)/ CD133(-) co-cultures group was high (R = 0.99).
CONCLUSION: Doxazosin induced apoptosis in co-cultures of progenitor and differentiated epithelial cells. However, progenitor cells were not susceptible to apoptosis, what can be a reason of treatment failure in BPH patients.

Baker, J. (2010). "Polymer processing has it all mixed up." Materials Recycling Week **195**(2): 18-19.
The article focuses on the recycle of plastic packaging film waste through polythene film reprocessors in Great Britain. It says that plastic recycling requires careful collection of wastes because recycling of mixed plastics is not permissible due to their different physical characteristics. It mentions offshore recycling as a way to deal with the loss of connection between waste handling at source and an end processor wherein collected materials are delivered abroad. However, the Department for Environment, Food and Rural Affairs (Defra) still

favors more with the existing system than with offshore recycling especially for recycling commercial polythene packaging.

Bakir, A., et al. (2016). "Relative importance of microplastics as a pathway for the transfer of hydrophobic organic chemicals to marine life." Environmental Pollution **219**: 56-65.

It has been hypothesised that, if ingested, plastic debris could act as vector for the transfer of chemical contaminants from seawater to organisms, yet modelling suggest that, in the natural environment, chemical transfer would be negligible compared to other routes of uptake. However, to date, the models have not incorporated consideration of the role of gut surfactants, or the influence of pH or temperature on desorption, whilst experimental work has shown that these factors can enhance desorption of sorbed contaminants several fold. Here, we modelled the transfer of sorbed organic contaminants dichlorodiphenyltrichloroethane (DDT), phenanthrene (Phe) and bis-2-ethylhexyl phthalate (DEHP) from microscopic particles of polyvinylchloride (PVC) and polyethylene (PE) to a benthic invertebrate, a fish and a seabird using a one-compartment model OMEGA (Optimal Modelling for EcotoxicoloGical Applications) with different conditions of pH, temperature and gut surfactants. Environmental concentrations of contaminants at the bottom and the top of published ranges were considered, in combination with ingestion of either 1 or 5% by weight of plastic. For all organisms, the combined intake from food and water was the main route of exposure for Phe, DEHP and DDT with a negligible input from plastic. For the benthic invertebrate, predictions including the presence of contaminated plastic resulted in very small increases in the internal concentrations of DDT and DEHP, while the net change in the transfer of Phe was negligible. While there may be scenarios in which the presence of plastic makes a more important contribution, our modelling study suggests that ingestion of microplastic does not provide a quantitatively important additional pathway for the transfer of adsorbed chemicals from seawater to biota via the gut.

Bakir, A., et al. (2012). "Competitive sorption of persistent organic pollutants onto microplastics in the marine environment." Marine Pollution Bulletin **64**(12): 2782-2789.

Plastics are known to sorb persistent organic pollutants from seawater. However, studies to quantify sorption rates have only considered the affinity of chemicals in isolation, unlike the conditions in the environment where contaminants are present as complex mixtures. Here we examine whether phenanthrene and 4,4'-DDT, in a mixture, compete for sorption sites onto PVC with no added additives (unplasticised PVC or uPVC) and Ultra-High Molecular Weight polyethylene. Interactions were investigated by exposing particles of uPVC and UHMW PE to mixtures of 3H and 14C radiolabelled Phe and DDT. Changes in sorption capacity were modelled by applying a Freundlich binding sorption isotherms. An Extended Langmuir Model and an Interaction Factor Model were also applied to predict equilibrium concentrations of pollutants onto plastic. This study showed that in a bi-solute system, DDT exhibited no significantly different sorption behaviour than in single solute systems. However, DDT did appear to interfere with the sorption of Phe onto plastic, indicating an antagonistic effect.

Balakrishnan, G., et al. (2019). "Towards more realistic reference microplastics and nanoplastics: preparation of polyethylene micro/nanoparticles with a biosurfactant (Electronic supplementary information (ESI) available. See DOI: 10.1039/c8en01005f)." Environmental Science: Nano **6**(1): 315-324.

Microplastics are ubiquitous in the aquatic environment and polyethylene (PE) fragments are commonly identified in field samples. Studies are needed to evaluate the toxicity of microplastics, especially for the smallest ones that can be ingested by a wide range of organisms. However, due to a lack of preparation methods, small PE microplastics are not often used in laboratory studies. Here, a simple method was developed for the preparation of PE microparticles using dissolution of PE in toluene followed by emulsification in water. After complete evaporation of water and toluene, a powder of PE microparticles was obtained with radii between 0.2 to 0.80 µm. The protocol could be optimized by adding surfactants like Tween 60 or Tween 80, and the possible use of a solution of microalgae exudates as a biosurfactant was also demonstrated. Planktonic crustaceans were exposed to different types of microparticles to evaluate their bioavailability depending on the surfactant.

Balanc, B., et al. (2016). "Calcium-Alginate-Inulin Microbeads as Carriers for Aqueous Carqueja Extract." Journal of Food Science **81**(1): E65-E75.

Carqueja (Pterospartum tridentatum) is an endemic species and various bioactive compounds have been identified in its aqueous extract. The aim of this study was to protect the natural antioxidants from the aqueous extract of carqueja by encapsulation in Ca-alginate microbeads and Ca-alginate microbeads containing 10% and 20% (w/v) of inulin. The microbeads produced by electrostatic extrusion technique had an average diameter from 625 µm to 830 µm depending on the portion of inulin. The sphericity factor of the hydrogel microbeads had values between 0.014 and 0.026, while freeze dried microbeads had irregular shape, especially those with no excipient. The reduction in microbeads size after freeze drying process (expressed as shrinkage factor) ranged from 0.338 (alginate microbeads with 20% (w/v) of inulin) to 0.523 (plain alginate microbeads). The expressed radical scavenging activity against ABTS and DPPH radicals was found to be between 30% and 40% for encapsulated extract, while the fresh extract showed around 47% and 57% of radical scavenging activity for ABTS and DPPH radicals, respectively. The correlation between antioxidant activity and the total phenolic content were found to be positive (in both assay methods, DPPH and ABTS), which indicate that the addition of inulin didn't have influence on antioxidant activity. The presence of inulin reduced stiffness of the hydrogel, and protected bead structure from collapse upon freeze-drying. Alginate-inulin beads are envisaged to be used for delivery of aqueous P. tridentatum extract in functional food products. Practical Application The alginate-inulin formulations are aimed at delivery of bioactive compounds in functional food products. The mechanical properties of the microbeads were assessed as they indicate how the particles will be able to withstand stress (for example, during process of incorporation into food). In addition, freeze-dried forms of the microbeads were also considered, as they are more convenient for long-term applications.

Balasubramanian, M. and S. Raiyani (2014). Biodegradable packaging: Competitor and technology landscape report. Flexible Packaging Conference, FlexPackCon 2014, October 19, 2014 - October 22, 2014, Myrtle Beach, SC, United states, Society of Plastics Engineers.

Biodegradable packaging is a great need as plastic is harmful to people and the environment. Plastic leaches out chemicals called phthalates into the food, food products and water in plastic bottles. Phthalates are oestrogen mimics and they increase the levels of oestrogen in humans and food chains and there is evidence that they cause cancer including breast cancers and lead to low fertility in men. So, replacing plastic would be good for people's health. Biodegradable packaging is made from natural raw materials such as corn starch and sugar cane, both of which are consumed by humans and are not harmful to people's health. Another great thing about biodegradable packaging is that it takes less energy to produce, has less carbon emissions and therefore helps reduce climate change. Biodegradable packaging is entirely compostable in industrial facilities and is therefore less harmful than the incineration of plastic waste which releases harmful chemicals into the atmosphere. Furthermore, plastics take a long time to degrade and fill up landfill sites so biodegradable packaging is better for the environment and sustainable living. Many companies are switching to bio-packing for their products. Considering numerous advantages that biodegradable packaging offer over Synthetic plastics, it can be anticipated that it has a great future in the different areas of packaging. Research and Development efforts are required to develop biodegradable packaging having good packaging performance besides being economical. Dolcera report focuses on finding the relevant patents encompassing the Biodegradable packaging for Liquids. Patents cover various types of films and laminates, containers, methods of producing containers etc are described mostly in relevant patents. The keywords used in the search were obtained after an extensive study of relevant patents. The class codes for the search were obtained from the control patents and more class codes with manual search of classification index. The report highlights year-wise patent activity (trend line) along with the key industrial players in the field. Patents are categorized on the basis of patent focus-Biodegradable containers for liquid products. The categorized patents were further analyzed to determine the key players under each category. A comprehensible result in the form of Dolcera dashboard has been given. Dashboard links the companies in each category to their patents, hence making an interactive platform for analysis. Furthermore, patents have been mapped to commercially available products produced by the respective assignees and other licensees. Balasubramanian, V., et al. (2010). "High-density polyethylene (HDPE)-degrading potential bacteria from marine ecosystem of Gulf of Mannar, India." Letters in Applied Microbiology **51**(2): 205-211.

AIMS: Assessment of high-density polyethylene (HDPE)-degrading bacteria isolated from plastic waste dumpsites of Gulf of Mannar.

METHODS AND RESULTS: Rationally, 15 bacteria (GMB1-GMB15) were isolated by enrichment technique. GMB5 and GMB7 were selected for further studies based on their efficiency to degrade the HDPE and identified as Arthrobacter sp. and Pseudomonas sp., respectively. Assessed weight loss of HDPE after 30 days of incubation was nearly 12% for Arthrobacter sp. and 15% for Pseudomonas sp. The bacterial adhesion to hydrocarbon (BATH) assay showed that the cell surface hydrophobicity of Pseudomonas sp. was higher than Arthrobacter sp. Both fluorescein diacetate hydrolysis and protein content of the biofilm were used to test the viability and protein density of the biomass. Acute peak elevation was observed between 2 and 5 days of inoculation for both bacteria. Fourier transform infrared (FT-IR) spectrum showed that keto carbonyl bond index (KCBI), Ester carbonyl bond index (ECBI) and Vinyl bond index (VBI) were increased indicating changes in functional group(s) and/or side chain modification confirming the biodegradation.

CONCLUSION: The results pose us to suggest that both Pseudomonas sp. and Arthrobacter sp. were proven efficient to degrade HDPE, albeit the former was more efficacious, yet the ability of latter cannot be neglected.

SIGNIFICANCE AND IMPACT OF THE STUDY: Recent alarm on ecological threats to marine system is dumping plastic waste in the marine ecosystem and coastal arena by anthropogenic activity. In maintenance phase of the plastic-derived polyethylene waste, the microbial degradation plays a major role; the information accomplished in this work will be the initiating point for the degradation of polyethylene by indigenous bacterial population in the marine ecosystem and provides a novel eco-friendly solution in eco-management.

Balasubramanian, V., et al. (2014). "Enhancement of in vitro high-density polyethylene (HDPE) degradation by physical, chemical, and biological treatments." Environmental Science & Pollution Research **21**(21): 12549-12562.

Partially degraded high-density polyethylene (HDPE) was collected from plastic waste dump yard for biodegradation using fungi. Of various fungi screened, strain MF12 was found efficient in degrading HDPE by weight loss and Fourier transform infrared (FT-IR) spectrophotometric analysis. Strain MF12 was selected as efficient HDPE degraders for further studies, and their growth medium composition was optimized. Among those different media used, basal minimal medium (BMM) was suitable for the HDPE degradation by strain MF12. Strain MF12 was subjected to 28S rRNA sequence analysis and identified as Aspergillus terreus MF12. HDPE degradation was carried out using combinatorial physical and chemical treatments in conjunction to biological treatment. The high level of HDPE degradation was observed in ultraviolet (UV) and KMnO4/HCl with A. terreus MF12 treatment, i.e., FT10. The abiotic physical and chemical factors enhance the biodegradation of HDPE using A. terreus MF12.

Balbi, C., et al. (2019). "Flow Cytometric Analysis of Extracellular Vesicles from Cell-conditioned Media." Journal of Visualized Experiments **144**(02): 12.

Flow cytometry (FC) is the method of choice for semi-quantitative measurement of cell-surface antigen markers. Recently, this technique has been used for phenotypic analyses of extracellular vesicles (EV) including exosomes (Exo) in the peripheral blood and other body fluids. The small size of EV mandates the use of dedicated instruments having a detection threshold around 50-100 nm. Alternatively, EV can be bound to latex microbeads that can be detected by FC. Microbeads, conjugated with antibodies that recognize EV-associated markers/Cluster of Differentiation CD63, CD9, and CD81 can be used for EV capture. Exo isolated from CM can be analyzed with or without pre-enrichment by ultracentrifugation. This approach is suitable for EV analyses using conventional FC instruments. Our results demonstrate a linear correlation between Mean Fluorescence Intensity (MFI) values and EV concentration. Disrupting EV through sonication dramatically decreased MFI, indicating that the method does not detect membrane debris. We report an accurate and reliable method for the analysis of EV surface antigens, which can be easily implemented in any laboratory.

Balcom, P. and P. C. Van (2019). Exergy-based sustainability analysis for tile production from waste plastics in Uganda. ASME 2019 13th International Conference on Energy Sustainability, ES 2019, collocated with the ASME 2019 Heat Transfer Summer Conference, July 14, 2019 - July 17, 2019, Bellevue, WA, United states, American Society of Mechanical Engineers (ASME).

This paper presents an exergy-based sustainability analysis of manufacturing roof tiles from plastic waste in Uganda. Exergy analyses measure the sustainability of industrial processes. This work focuses specifically on the developing country context and on utilizing waste material. A summary of the current plastic waste situation in Uganda, the environmental and health issues associated with plastic waste, current means of recycling plastic waste into new products, and an analysis of the Ugandan roofing market are presented. The motivation for this study is to examine the resources utilized to improve overall exergy efficiency, reduce production costs, and reduce negative environmental impacts. The company, Resintile, is the only manufacturer of roof tiles from plastic waste in Uganda. Their tiles comprised mainly of sand and plastic waste are manufactured in an industrialized process involving drying, extrusion, and pressing. The exergy consumed at each stage including transportation is presented. The extruder consumes the majority of the exergy, but wrapping insulation around the barrel could save over 3 MJ, and a heat engine could provide over 7.5 MJ of usable exergy. The total exergy consumed to produce one batch of seventy-five tiles is over 122 MJ, the potentially recoverable exergy is over 5 MJ (4.3% of consumed exergy), and the realistic recoverable exergy is nearly 10.7 MJ (8.7% of consumed exergy). The realistic can be greater than the potential by adding a heat engine to the sand drying process to generate usable exergy rather than merely recover consumed exergy.

Resintile's plastic roof tiles save a net 86.3 kg of CO2 from entering the atmosphere per batch of tiles and adoption of the suggested improvements to the manufacturing process would save an additional 3.8 kg of CO2 per batch. Copyright 2019 ASME

Baldissera, L., et al. (2012). "Soluble guanylyl cyclase activation inhibits human eosinophil chemotaxis and reduces murine allergic inflammation." Annals of Allergy, Asthma and Immunology **5)**: A126.

Eosinophil recruitment to inflamed lung is a hallmark of allergic asthma, where the chemokine eotaxin acts as selective eosinophil chemoattractant released upon allergen challenge (Holgate, 2008). Increased cGMP intracellular levels inhibit eosinophil chemotaxis (Thomazzi et al., 2004). Therefore, this study aimed to investigate the inhibitory effects of BAY 60-2770 (NOand haem-independent sGC activator) in eotaxin-induced human eosinophil chemotaxis and pulmonary allergic inflammation in mice. Human blood eosinophils (4x106 cells/mL) were isolated from healthy volunteers by negative immunomagnetic anti-CD16 microbeads separation, after approval from National Committee for Ethics in Human Research - CONEP (number 44347) and written informed consent from subjects. Cells were incubated with BAY 60-2770 (1-10 muM; 30 min, 37degreeC) and allowed to migrate toward eotaxin (300 etag/ml; 1 h, 37degreeC) in chemotaxis chamber. Our data showed that human eosinophil migration to eotaxin was significantly inhibited (p<0.001) by BAY 60-2770 (10 muM: 17+/-5 eosinophil/HPF) compared with vehicle (0.1% DMSO)- treated cells (113+/-13 eosinophil/HPF). In separate experiments, C57BL6 mice were subjected to immunization and challenge with ovalbumin (OVA), after approval of by The Ethical Principles in Animal Research (number 2622-1). After 48 h post-OVA challenge, total and differential cell counts in bronchoalveolar lavage (BAL) fluids and bone marrow cells were obtained. Chronic oral treatment with BAY 60-2770 (1 mg/kg/gavage; 14 days) significantly reduced (p<0.001) the eosinophil counts in BAL fluid (1.7+/-0.4 x 106/mL) compared with untreated mice (6.0+/-0.7 x 106/mL). The bone marrow eosinophilopoiesis was also reduced by BAY 60-2770 treatment (1.4+/-0.15 vs 0.7+/-0.14 x106/mL for untreated and treated groups, respectively; p<0.001). Our findings that BAY 60-2770 inhibits human eosinophils chemotaxis and allergic pulmonary eosinophilic inflammation suggest that this sGC activator may be of therapeutic value in the treatment of asthma.

Baldwin, A. K., et al. (2016). "Plastic Debris in 29 Great Lakes Tributaries: Relations to Watershed Attributes and Hydrology." Environmental Science & Technology **50**(19): 10377-10385.

Plastic debris is a growing contaminant of concern in freshwater environments, yet sources, transport, and fate remain unclear. This study characterized the quantity and morphology of floating micro- and macroplastics in 29 Great Lakes tributaries in six states under different land covers, wastewater effluent contributions, population densities, and hydrologic conditions. Tributaries were sampled three or four times each using a 333 mum mesh neuston net. Plastic particles were sorted by size, counted, and categorized as fibers/lines, pellets/beads, foams, films, and fragments. Plastics were found in all 107 samples, with a maximum concentration of 32 particles/m³ and a median of 1.9 particles/m³. Ninety-eight percent of sampled plastic particles were less than 4.75 mm in diameter and therefore considered microplastics. Fragments, films, foams, and pellets/beads were positively correlated with urban-related watershed attributes and were found at greater concentrations during runoff-event conditions. Fibers, the most frequently detected particle type, were not associated with urban-related watershed attributes, wastewater effluent contribution, or hydrologic condition.

Balić, K., et al. (2019). THE IMPACT OF PLASTIC ON THE MARINE ENVIRONMENT. Sofia, Surveying Geology & Mining Ecology Management (SGEM). **19:** 557-564.

The harmfulness of plastic waste on marine organisms and species has been demonstrated. Throwing and dumping plastic waste is causing damage to the environment, causing economic damage to activities such as tourism, fisheries, and sea traffic, and can affect people's health through the food chain. The paper will outline ways and measures to prevent the introduction of single-use plastic into the marine environment as well as the possibility of producing biodegradable plastics. Through this paper concept of marine waste and its impact on the environment, as well as the legal regulation of the protection of the sea and the marine environment will be analysed. Reducing the production of single-use plastics reduces its disposal to the marine environment, and the production of plastic that can be composted allows for a permanent reduction in the disposal of plastic waste into the marine environment. If it is desired to achieve a circular life cycle for plastics, measures must be taken to increase the generation of plastic waste and its release into the environment. It is considered that the active support of the recycled plastics market should be encouraged by the use of environmental materials and high quality recycling in order to achieve the ultimate goal of reducing the amount of plastic waste in the environment.

Baljit, S. and S. Nisha (2007). "Optimized synthesis and characterization of polystyrene graft copolymers and preliminary assessment of their biodegradability and application in water pollution alleviation technologies." Polymer Degradation and Stability **92**(5): 876-885.

With more and more plastics being employed in human lives and increasing pressure being placed on capacities available for plastic waste disposal, the need for biodegradable plastics and biodegradation of plastic wastes has assumed increasing importance in the last few years. Keeping in view the environmental pollution caused by the waste polystyrene and to make the waste polystyrene technologically important, we have modified/functionalized the polystyrene with natural polymers and hydrophilic monomer through graft copolymerization. The present paper discusses the optimum conditions for the synthesis of graft copolymers and characterization of these polymers with SEMs and FTIR and thereafter biodegradation studies of these polymers by soil burial method. The present paper also discusses the effect of crosslinker concentration on the swelling and metal ion sorption (As⁺⁵ uptake) through the functionalized polystyrene, with the intention to make use of these polymeric networks in water pollution alleviation technology. It has been observed that percent As⁵⁺ uptake decreases from 80% to 60% as the crosslinker concentration increases from 0.032 mM to 0.162 mM in the polymeric networks. It has also been observed from the degradation studies that the grafting of starch onto polystyrene has induced 37% degradation after 160 days soil burial treatment and no degradation has been observed in case of grafting of acrylic acid onto polystyrene.

Ballent, A., et al. (2016). "Sources and sinks of microplastics in Canadian Lake Ontario nearshore, tributary and beach sediments." Marine Pollution Bulletin **110**(1): 383-395.

Microplastics contamination of Lake Ontario sediments is investigated with the aim of identifying distribution patterns and hotspots in nearshore, tributary and beach depositional environments. Microplastics are concentrated in nearshore sediments in the vicinity of urban and industrial regions. In Humber Bay and Toronto Harbour microplastic concentrations were consistently >500 particles per kg dry sediment. Maximum concentrations of ~28,000 particles per kg dry sediment were determined in Etobicoke Creek. The microplastic particles were primarily fibres and fragments <2mm in size. Both low- and high-density plastics were identified using Raman spectroscopy. We provide a baseline for future monitoring and discuss potential sources of microplastics in terms of how and where to implement preventative measures to reduce the contaminant influx. Although the impacts of microplastics contamination on ecosystem health and functioning is uncertain, understanding, monitoring and preventing further microplastics contamination in Lake Ontario and the other Great Lakes is crucial.

Balter, M. L., et al. (2016). "System Design and Development of a Robotic Device for Automated Venipuncture and Diagnostic Blood Cell Analysis." Proceedings of the IEEE/RSJ International Conference on Intelligent Robots and Systems **2016**: 514-520.

Diagnostic blood testing is the most prevalent medical procedure performed in the world and forms the cornerstone of modern health care delivery. Yet blood tests are still predominantly carried out in centralized labs using large-volume samples acquired by manual venipuncture, and no end-to-end solution from blood draw to sample analysis exists today. Our group is developing a platform device that merges robotic phlebotomy with automated diagnostics to rapidly deliver patient information at the site of the blood draw. The system couples an image-guided venipuncture robot, designed to address the challenges of routine venous access, with a centrifuge-based blood analyzer to obtain quantitative measurements of hematology. In this paper, we first present the system design and architecture of the integrated device. We then perform a series of in vitro experiments to evaluate the cannulation accuracy of the system on blood vessel phantoms. Next, we assess the effects of vessel diameter, needle gauge, flow rate, and viscosity on the rate of sample collection. Finally, we demonstrate proof-of-concept of a white cell assay on the blood analyzer using in vitro human samples spiked with fluorescently labeled microbeads.

Balter, M. L., et al. (2018). "Automated end-to-end blood testing at the point-of-care: Integration of robotic phlebotomy with downstream sample processing." Technology **6**(2): 59-66.

Diagnostic blood testing is the most commonly performed clinical procedure in the world, and influences the majority of medical decisions made in hospital and laboratory settings. However, manual blood draw success rates are dependent on clinician skill and patient physiology, and results are generated almost exclusively in centralized labs from large-volume samples using labor-intensive analytical techniques. This paper presents a medical device that enables end-to-end blood testing by performing blood draws and providing diagnostic results in a fully automated fashion at the point-of-care. The system couples an image-guided venipuncture robot, developed to address the challenges of routine venous access, with a centrifuge-based blood analyzer to obtain quantitative measurements of hematology. We first demonstrate a white blood cell assay on the analyzer, using a blood mimicking fluid spiked with fluorescent microbeads, where the area of the packed bead layer is correlated with the bead concentration. Next we perform experiments to evaluate the pumping efficiency of the sample handling module. Finally, studies are conducted on the integrated device - from blood draw to analysis - using blood vessel phantoms to assess the accuracy and repeatability of the resulting white blood cell assay.

Balzer, K. M., et al. (2004). "Donor-specific sensitization by cadaveric venous allografts used for arterial reconstruction in peripheral arterial occlusive vascular disease." Tissue Antigens **64**(1): 13-17.

The use of allogeneic venous grafts from postmortal organ donors allows for the reconstruction of critically affected arteries in patients with peripheral occlusive vascular disease. We were interested to determine the prevalence and specificity of anti-HLA antibodies in patients after allogeneic vein transplantation. Anti-HLA class I and II alloantibodies were analyzed by

flowcytometric analysis using color-coded microbeads coated with HLA antigens including recombinant single antigens. Nine out of 10 patients involving 12 venous allografts were positive for anti-HLA alloantibodies. All antibody-positive patients carried both anti-HLA class I and II alloantibodies. Anti-donor HLA specificity of the anti-HLA alloantibodies was seen in seven out of nine patients for anti-class I antibodies and in eight out of nine patients for anti-HLA class II antibodies. A high rate of donor-specific allosensitization was seen after allogeneic venous transplantation. In conclusion, allosensitization not only includes a humoral response against the constitutively expressed class I antigens but also extends to class II antigens.

Banaee, M., et al. (2019). "Evaluation of single and combined effects of cadmium and micro-plastic particles on biochemical and immunological parameters of common carp (Cyprinus carpio)." Chemosphere **236**(124335).

The growing accumulation of microplastics (MPs) in aquatic environments is a global concern. MPs are capable to interact with other environmental contaminants, including heavy metals, altering their toxicity. The aim of the study was to investigate the sub-lethal effects of cadmium chloride (Cd) alone and in combination with MPs on common carp (Cyprinus carpio). Multi-biomarkers, including plasma biochemical parameters and intrinsic immunological factors, were measured after 30 days of exposure. Exposure to Cd or NPs reduced the plasma activities of acetylcholinesterase (AChE) and gamma-glutamyl-transferase (GGT) and increased aspartate aminotransferase (AST), alanine aminotransferase (ALT), lactate dehydrogenase (LDH) and alkaline phosphatase (ALP). Exposure to both compounds enhanced the observed effects except for AST activity and ALP at the highest concentrations, whereas evidenced an antagonistic interaction in ALT. Plasma total protein, albumin, and globulin levels were decreased, and the levels of glucose, triglyceride, and cholesterol levels increased mainly in the Cd groups with no additional effects derived from the co-exposure to both stressors. Lysozyme and alternative complement (ACH50) activities and the levels of total immunoglobulins, and complement C3 and C4 in fish exposed to Cd and MPs were lower than those in the control group and this decrease was more significant by the mixture of both compounds. These findings showed that the exposure to Cd or MPs alone is toxic to fish altering the biochemical and immunological parameters. Moreover, these alterations are even greater when the Cd and the MPS are combined suggesting synergistic effects in increasing Cd toxicity and vice versa.

Banati, H., et al. (2017). "Determination of Mycotoxin Production of Fusarium Species in Genetically Modified Maize Varieties by Quantitative Flow Immunocytometry." Toxins **9**(2): 22.

Levels of mycotoxins produced by Fusarium species in genetically modified (GM) and near-isogenic maize, were determined using multi-analyte, microbead-based flow immunocytometry with fluorescence detection, for the parallel quantitative determination of fumonisin B1, deoxynivalenol, zearalenone, T-2, ochratoxin A, and aflatoxin B1. Maize varieties included the genetic events MON 810 and DAS-59122-7, and their isogenic counterparts. Cobs were artificially infested by F. verticillioides and F. proliferatum conidia, and contained F. graminearum and F. sporotrichoides natural infestation. The production of fumonisin B1 and deoxynivalenol was substantially affected in GM maize lines: F. verticillioides, with the addition of F. graminearum and F. sporotrichoides, produced significantly lower levels of fumonisin B1 (~300 mg.kg⁻¹) in DAS-59122-7 than in its isogenic line (~580 mg.kg⁻¹), while F. proliferatum, in addition to F. graminearum and F. sporotrichoides, produced significantly higher levels of deoxynivalenol (~18 mg.kg⁻¹) in MON 810 than in its isogenic line (~5 mg.kg⁻¹). Fusarium verticillioides, with F. graminearum and F. sporotrichoides, produced lower amounts of deoxynivalenol and zearalenone than F.

proliferatum, with F. graminearum and F. sporotrichoides. T-2 toxin production remained unchanged when considering the maize variety. The results demonstrate the utility of the Fungi-PlexTM quantitative flow immunocytometry method, applied for the high throughput parallel determination of the target mycotoxins.

Banchón, C., et al. (2019). "Biostabilization of sewage sludge in the Antarctic." Antarctic Science **31**(4): 216-217.

Antarctica is no longer a pristine environment due to atmospheric pollution, fuel spills, inadequate waste management and wastewater discharges from anthropogenic activities (Harris 1998, Stark et al. 2015). Approximately 37% of the permanent stations and 69% of the summer stations lack any form of sewage treatment (Gröndahl et al. 2009). The characteristics of wastewater from stations are also of concern because they are a complex mix of contaminants containing human waste, cosmetics, viruses, dyes, detergents, medications, chemicals from laboratories and even microplastics (Bhardwaj et al. 2018). In Antarctica, treatment plants discharge treated water into the sea and then sludge is packed and sealed into drums for later shipment to Chile. Nevertheless, sewage sludge (c. 59–88% organic matter) could become a biosolid instead of being a waste if correctly stabilized. The Ecuadorian Antarctic station 'Pedro Vicente Maldonado' produced c. 200 kg of sewage sludge during expeditions in 2017 and 2018. Thus, the aim of the present study was to biostabilize sewage sludge using two methods (one thermal and one biological) at the Ecuadorian Antarctic station. As a result, the stabilization of sewage sludge produced a biosolid that was easier and more cost effective to transport, avoiding odour problems.

Bandow, N., et al. (2017). "Contaminant release from aged microplastic." Environmental Chemistry **14**(6): 394-405.

Recycled plastic granules of high-density polyethylene, polyvinyl chloride and polystyrene the size of microplastics were exposed to artificial aging conditions (2000 h; photooxidative and thermo-oxidative) to simulate their fate outdoors. Their potential to leach into water during the aging process was investigated using column percolation tests. Aging-related changes on the surface of the material were characterised by IR measurements indicating oxidation reactions with the formation of new adsorption bands (C=O, C-O and OH), especially in the case of photooxidative aging. These findings were confirmed by the identification of leachable organic compounds. Leaching of total organic carbon, Cl, Ca, Cu and Zn is clearly affected by changes due to aging, and their release is increased after photooxidative aging. In general, exposure to photooxidative conditions shows a greater influence on aging and thus on leaching and seems to be the more important mechanism for the aging of microplastic in the environment. Comparison with the total content of inorganic species revealed that, for most elements, less than 3% of the total content is released after 2000 h of photooxidative aging.

Bank, M. S. and S. V. Hansson (2019). "The Plastic Cycle: A Novel and Holistic Paradigm for the Anthropocene." Environmental Science and Technology **53**(13): 7177-7179.

Bank, M. S., et al. (2013). Albatross as Sentinels of Heavy Metal Pollution: Local and Global Factors. Les Ulis, EDP Sciences. **1**.

Heavy metal pollution in the Pacific Ocean has garnered significant attention in recent years, especially with regard to rising mercury emissions from Asia. Uncertainty exists over the extent to which mercury in biota may have resulted from increases in anthropogenic emissions over time. Albatrosses, including those inhabiting the North Pacific, are wide-ranging, long-lived, keystone, avian predators. Consequently, they serve as ideal sentinel species for investigating the effects of historical and contemporary pollution as well as local and global factors related to heavy metal exposure, bioaccumulation, and ecotoxicological risk. To date, high levels of mercury and lead have been documented in albatross species throughout the Pacific. To address biotic exposure to these multiple stressors, here we synthesize and conduct meta-analyses of total mercury, methylmercury, and lead exposure data in Black-footed albatross (Phoebastria nigripes) and Laysan albatross (Phoebastria immutabilis). Our approach includes data from the field and literature, and for total mercury and methyl mercury, we use measurements from museum feathers spanning the past 130 years for Black-Footed albatross. We discuss the use and application of stable isotopes (δ15N and δ13C) as a way to control for temporal changes in trophic structure and diet and we demonstrate the importance of conducting speciation analyses for mercury to account for historical, curator-mediated, inorganic mercury contamination of specimens. Our data showed higher levels of inorganic mercury in older specimens of Black-Footed albatross as well as two non-pelagic species (control samples) lacking historical sources of bioavailable mercury exposure, which suggests that studies on bioaccumulation should measure methylmercury rather than total mercury when utilizing museum collections. Changes in methylmercury levels in Black-Footed albatross were consistent with historical global and recent regional increases observed among published estimates and proxies of anthropogenic mercury emissions. At the local scale, previous research has also reported that lead paint exposure from buildings was also an important environmental stressor for Laysan albatross. Thus, albatross species face heavy metal exposure threats at both local (lead) and global scales (mercury, and potentially heavy metals in plastics). Specific types of plastic pollution entering marine environments have been documented to contain heavy metals at levels, which if bio-available, may present a non-localized source of lead exposure in albatross species known to ingest (and regurgitate to their young) large amounts of marine plastic. Heavy metal toxicity along with other stressors may undermine current and future reproductive outcomes in these seabird species, although unraveling effects from specific metals in the context of a complex metal mixture presents some challenges. Collectively, our findings and review of the literature suggest that albatrosses in this region may be an effective marine flagship species and raising the profile of these organisms likely would successfully support broader biodiversity conservation efforts in the North Pacific.

Bano, K., et al. (2019). "A novel, thermotolerant, extracellular PHB depolymerase producer Paenibacillus alvei PHB28 for bioremediation of biodegradable plastics." Turkish Journal of Biochemistry **44**(3): 344-353.

Background: Poly-beta-hydroxybutyrate (PHB) is the most important and versatile class of biodegradable polymers used successfully in the medical, agricultural and industrial field. Idea is to find the novel isolate for degradation of biodegradable plastics that can enhance the bioremediation. Material(s) and Method(s): Thirty-one PHB and PHB depolymerase enzyme producing isolates out of 80 mesophilic bacteria from Lucknow region were further screened for PHB degradation capability by secreting extracellular PHB depolymerase enzyme in minimal salt media supplemented with PHB (0.15%). Various biodegradable plastic films were tested by soil burial method for weight loss determination. Result(s): 37.3% weight loss has been observed in PHB films when buried under the soil for 45 days in the presence of a novel PHB degrader identified as Paenibacillus alvei PHB28 by 16S rRNA sequencing (GenBank accession number KX886342). These Gram-negative, spore-forming, thermotolerant bacteria produce maximum PHB depolymerase (5.03 U/mL) at 45degreeC, pH 8.0, with 0.15% substrate concentration when incubated for 96 h with starch (0.1%) and yeast extract (0.01%) as an additional nutrient

supplements. Conclusion(s): To the best of our knowledge this is the first report of PHB depolymerase production by P. alvei PHB28 which may contribute successfully to combat plastic pollution and to sustain the green environment.

Bar Oz, M., et al. (2016). "Acetylation reduces SOX9 nuclear entry and ACAN gene transactivation in human chondrocytes." Aging Cell **15**(3): 499-508.

Changes in the content of aggrecan, an essential proteoglycan of articular cartilage, have been implicated in the pathophysiology of osteoarthritis (OA), a prevalent age-related, degenerative joint disease. Here, we examined the effect of SOX9 acetylation on ACAN transactivation in the context of osteoarthritis. Primary chondrocytes freshly isolated from degenerated OA cartilage displayed lower levels of ACAN mRNA and higher levels of acetylated SOX9 compared with cells from intact regions of OA cartilage. Degenerated OA cartilage presented chondrocyte clusters bearing diffused immunostaining for SOX9 compared with intact cartilage regions. Primary human chondrocytes freshly isolated from OA knee joints were cultured in monolayer or in three-dimensional alginate microbeads (3D). SOX9 was hypo-acetylated in 3D cultures and displayed enhanced binding to a -10 kb ACAN enhancer, a result consistent with higher ACAN mRNA levels than in monolayer cultures. It also co-immunoprecipitated with SIRT1, a major deacetylase responsible for SOX9 deacetylation. Finally, immunofluorescence assays revealed increased nuclear localization of SOX9 in primary chondrocytes treated with the NAD SIRT1 cofactor, than in cells treated with a SIRT1 inhibitor. Inhibition of importin beta by importazole maintained SOX9 in the cytoplasm, even in the presence of NAD. Based on these data, we conclude that deacetylation promotes SOX9 nuclear translocation and hence its ability to activate ACAN.

Barbakadze, K., et al. (2018). "Separation of metal and plastic wastes from wire and cable manufacturing for effective recycling." Resources, Conservation & Recycling **139**: 251-258.

The trend to recycle materials in industry has increased over the last few years as manufacturers seek ways to decrease material costs and reduce their environmental footprints. In the wire and cable manufacturing industry, excess wire and cable is shredded into a mixture commonly known as fluff. Because fluff is comprised of different metals as well as polymers of varying physical and chemical properties, it cannot be recycled into a usable product until the different components comprising fluff have been separated. Metallic components could possibly be used for recovery of metals from zinc-carbon and alkaline spent batteries. However, the amount of metals in fluff is low from the economical point of view. Polymeric components might be used in the production of aggregate in concrete – considered for this application together with fly ash. We have employed different concentrations and combinations of frothers, wetting agents, and inorganic materials, encouraging the separation of the different components of fluff by taking advantage of each component's physical properties. An essential stage of the operation was separating metals from polymers. Among polymers, the main component of fluff was PVC – that we successfully reclaimed and then verified our results through the use of differential scanning calorimetry (DSC) and thermogravimetric analysis (TGA). Success in this endeavor would spell dramatic reductions in unrecyclable wire and cable waste, increase reclamation of materials, and further improve our understanding of the pros and cons of different density-based separation methods. [ABSTRACT FROM AUTHOR]

Barbee, K. D., et al. (2009). "Electric field directed assembly of high-density microbead arrays." Lab on a Chip **9**(22): 3268-3274.

We report a method for rapid, electric field directed assembly of high-density protein-conjugated microbead arrays. Photolithography is used to fabricate an array of micron to sub-micron-scale wells in an epoxy-based photoresist on a silicon wafer coated with a thin gold film, which serves as the primary electrode. A thin gasket is used to form a microfluidic chamber between the wafer and a glass coverslip coated with indium-tin oxide, which serves as the counter electrode. Streptavidin-conjugated microbeads suspended in a low conductance buffer are introduced into the chamber and directed into the wells via electrophoresis by applying a series of low voltage electrical pulses across the electrodes. Hundreds of millions of microbeads can be permanently assembled on these arrays in as little as 30 seconds and the process can be monitored in real time using epifluorescence microscopy. The binding of the microbeads to the gold film is robust and occurs through electrochemically induced gold-protein interactions, which allows excess beads to be washed away or recycled. The well and bead sizes are chosen such that only one bead can be captured in each well. Filling efficiencies greater than 99.9% have been demonstrated across wafer-scale arrays with densities as high as 69 million beads per cm(2). Potential applications for this technology include the assembly of DNA arrays for high-throughput genome sequencing and antibody arrays for proteomic studies. Following array assembly, this device may also be used to enhance the concentration-dependent processes of various assays through the accelerated transport of molecules using electric fields.

Barbieri, E. (2009). "Occurrence of plastic particles in procellariiforms, south of Sao Paulo State (Brazil)." Brazilian Archives of Biology and Technology **52**(2): 341-348.

Seabirds ingest plastic particles floating on the surface of the world's oceans. The birds can ingest plastic particles that they mistakenly identify as prey items. Alternatively, plastics can be taken up in the stomach contents of prey species. Plastic is often passed from parents to chicks in regurgitated food. In this study, individual petrels and albatrosses brought in by the tide onto Ilha Comprida beach between January 2000 and December 2002 were collected. Ilha Comprida, a barrier island in southern Sao Paulo, Brazil, was traversed by car along a transect of 70 kilometers. A total of 110 birds of 10 species were collected and 64.54% had plastic panicles in their stomach. Frequencies of occurrence were Macronectes giganteus (64.28%), Thalassarche melanophrys (73.07%), Thalassarche chlororhinchos (44.44%), Puffinus puffinus (85.71%), Puffinus gravis (7.41%), Puffinus griseus (63.63%), Fumarus glacialoides (33.33%), Daption capensis (75%), Pachyptila belcheri (33.33%), Procellaria aequinoctialis (25%). These results demonstrated the extent of contamination with plastic and the possible harmful effects on seabirds.

Barboza, L. G. A., et al. (2018). "Marine microplastic debris: An emerging issue for food security, food safety and human health." Marine Pollution Bulletin **133**: 336-348.

Recent studies have demonstrated the negative impacts of microplastics on wildlife. Therefore, the presence of microplastics in marine species for human consumption and the high intake of seafood (fish and shellfish) in some countries cause concern about the potential effects of microplastics on human health. In this brief review, the evidence of seafood contamination by microplastics is reviewed, and the potential consequences of the presence of microplastics in the marine environment for human food security, food safety and health are discussed. Furthermore, challenges and gaps in knowledge are identified. The knowledge on the adverse effects on human health due to the consumption of marine organisms containing microplastics is very limited, difficult to assess and still controversial. Thus, assessment of the risk posed to humans is challenging. Research is urgently needed, especially regarding the potential exposure and associated health risk to micro- and nano-sized plastics.

Barboza, L. G. A., et al. (2019). "Microplastics in wild fish from North East Atlantic Ocean and its potential for causing neurotoxic effects, lipid oxidative damage, and human health risks associated with ingestion exposure." Science of the Total Environment: 134625.

Microplastics (MP) pollution has received increased attention over the last few years. However, while the number of studies documentating the ingestion of microplastics by fish has increased, fewer studies have addressed the toxicological effects derived from the ingestion of these small items in wild conditions. Here, MP contamination and effect biomarkers were investigated in three commercially important fish species from the North East Atlantic Ocean. From the 150 analysed fish (50 per species), 49 % had MP. In fish from the 3 species, MP in the gastrointestinal tract, gills and dorsal muscle were found. Fish with MP had significantly (p <= 0.05) higher lipid peroxidation levels in the brain, gills and dorsal muscle, and increased brain acetylcholinesterase activity than fish where no MP were found. These results suggest lipid oxidative damage in gills and muscle, and neurotoxicity through lipid oxidative damage and acetylcholinesterase induction in relation to MP and/or MP-associated chemicals exposure. From the 150 fish analysed, 32 % had MP in dorsal muscle, with a total mean (+/- SD) of 0.054 +/- 0.099 MP items/g. Based on this mean and on EFSA recommendation for fish consumption by adults or the general population, human consumers of Dicentrachus labrax, Trachurus trachurus, Scomber colias may intake 842 MP items/year from fish consumption only. Based on the mean of MP in fish muscle and data (EUMOFA, NOAA) of fish consumption per capita in selected European and American countries, the estimated intake of microplastics through fish consumption ranged from 518 to 3078 MP items/year/capita. Considering that fish consumption is only one of the routes of human exposure to microplastics, this study and others in the literature emphasize the need for more research, risk assessment and adoption of measures to minimize human exposure to these particles. Thus, MP pollution and its effects should be further investigated and addressed according to the WHO 'One Health' approach.

Barboza, L. G. A., et al. (2018). "Microplastics increase mercury bioconcentration in gills and bioaccumulation in the liver, and cause oxidative stress and damage in Dicentrarchus labrax juveniles." Scientific Reports **8**(1): 15655.

The presence of microplastics and several other pollutants in the marine environment is of growing concern. However, the knowledge on the toxicity of mixtures containing microplastics and other contaminants to marine species is still scarce. The main goals of this study were to investigate the oxidative stress and lipid oxidative damage potentially induced by 96 h of exposure to mercury (0.010 and 0.016 mg/L), microplastics (0.26 and 0.69 mg/L), and mixtures of the two substances (same concentrations, full factorial) in the gills and liver of D. labrax juveniles, and the possible influence of microplastics on mercury bioconcentration (gills) and bioaccumulation (liver). The results indicate that the presence of microplastics in the water increased the concentration of mercury in gills and liver of D. labrax juveniles. Microplastics and mercury, alone and in mixtures, caused oxidative stress in both organs. Based on the total induction of antioxidant enzymatic activity, the type of toxicological interaction in fish exposed to the mixture containing the lowest concentration of the two substances was addition in gills,

and addition or synergism in the liver. These results stress the need to further address the role of microplastics in the bioconcentration, bioaccumulation, and toxicity of other environmental contaminants in different species.

Barboza, L. G. A., et al. (2018). "Microplastics cause neurotoxicity, oxidative damage and energy-related changes and interact with the bioaccumulation of mercury in the European seabass, Dicentrarchus labrax (Linnaeus, 1758)." Aquatic Toxicology **195**: 49-57.

Microplastics pollution is a global paradigm that raises concern in relation to environmental and human health. This study investigated toxic effects of microplastics and mercury in the European seabass (Dicentrarchus labrax), a marine fish widely used as food for humans. A short-term (96h) laboratory bioassay was done by exposing juvenile fish to microplastics (0.26 and 0.69mg/L), mercury (0.010 and 0.016mg/L) and binary mixtures of the two substances using the same concentrations, through test media. Microplastics alone and mercury alone caused neurotoxicity through acetylcholinesterase (AChE) inhibition, increased lipid oxidation (LPO) in brain and muscle, and changed the activities of the energy-related enzymes lactate dehydrogenase (LDH) and isocitrate dehydrogenase (IDH). All the mixtures caused significant inhibition of brain AChE activity (64-76%), and significant increase of LPO levels in brain (2.9-3.4 fold) and muscle (2.2-2.9 fold) but not in a concentration-dependent manner; mixtures containing low and high concentrations of microplastics caused different effects on IDH and LDH activity. Mercury was found to accumulate in the brain and muscle, with bioaccumulation factors of 4-7 and 25-40, respectively. Moreover, in the analysis of mercury concentrations in both tissues, a significant interaction between mercury and microplastics was found. The decay of mercury in the water increased with microplastics concentration, and was higher in the presence of fish than in their absence. Overall, these results indicate that: microplastics influence the bioaccumulation of mercury by D. labrax juveniles; microplastics, mercury and their mixtures (ppb range concentrations) cause neurotoxicity, oxidative stress and damage, and changes in the activities of energy-related enzymes in juveniles of this species; mixtures with the lowest and highest concentrations of their components induced different effects on some biomarkers. These findings and other published in the literature raise concern regarding high level predators and humans consuming fish being exposed to microplastics and heavy metals, and highlight the need of more research on the topic.

Barboza, L. G. A., et al. (2018). "Single and combined effects of microplastics and mercury on juveniles of the European seabass (Dicentrarchus labrax): changes in behavioural responses and reduction of swimming velocity and resistance time." Environmental Pollution **236**: 1014-1019.

Microplastics and mercury are environmental pollutants of great concern. The main goal of the present study was to investigate the effects of these pollutants, both individually and in binary mixtures, on the swimming performance of juvenile European seabass, Dicentrarchus labrax. Microplastics alone, mercury alone and all the mixtures caused significant reduction of the swimming velocity and resistance time of fish. Moreover, changes in behavioural responses including lethargic and erratic swimming behaviour were observed. These results highlight that fish behavioural responses can be used as sensitive endpoint to establish the effects of contamination by microplastics and also emphasizes the need to assess the combined effects of microplastics and other environmental contaminants, with special attention to the effects on behavioural responses in fish and other aquatic species.

Barceló, D. and Y. Picó (2019). "Microplastics in the global aquatic environment: Analysis, effects, remediation and policy solutions." Journal of Environmental Chemical Engineering **7**(5).

This opinion paper reports on Microplastics (MPs) pollution in the aquatic environment. MPs are a global problem being detected everywhere: marine environment, wastewaters, surface waters, soils, sediments, food and air. MPs can also absorb organic contaminants, and can be ingested by organisms and introduced into the food web. MPs can be a vector as well of pathogens whereas airborne fibrous MPs may enter our respiratory system with risk to the environment and humans. Main issues and gaps related to MPs on-going and future research are highlighted: chemical analysis, fate in wastewater and drinking water treatment plants, environmental and human health effects as well as remediation strategies. Policy recommendations towards limiting the amount of plastic waste are being formulated to mitigate MPs pollution. © 2019 Elsevier Ltd.

Barfield, R. C., et al. (2004). "A one-step large-scale method for T- and B-cell depletion of mobilized PBSC for allogeneic transplantation." Cytotherapy **6**(1): 1-6.

BACKGROUND: The presence of T and B cells in allogeneic grafts contributes to GvHD and to EBV-associated lymphoproliferative disease (LPD). Depletion of T and B cells from the graft decreases the risk of these complications.

METHODS: T and B cells were depleted from mobilized peripheral stem cells from volunteer donors (n=5) using anti-CD3 and anti-CD19 Abs conjugated to magnetic microbeads, and the CliniMACS device. The function of the stem cells after depletion was evaluated using colony assays and non-obese diabetic (NOD)/SCID repopulating experiments.

RESULTS: The mean mononuclear cell (MNC) count prior to T- and B-cell depletion was 2.19x10(10) (range 1.48-3.53). After depletion, the mean percentage of contaminating T cells was 0.02% (range 0.01-0.04%) with a mean log(10) depletion of 3.4 (range 3-3.8). The mean percentage of contaminating B cells was 0.1% (range 0.01-0.4%) with a mean log(10) depletion of 2.2 (range 1.4-3). The mean recovery of CD3- and CD19-negative MNCs after depletion was 70% (range 54-88%) and the mean recovery of CD34(+) stem cells was 69% (range 52-98%). The mean number of natural killer (NK) cells after T- and B-cell depletion was 5.2x10(8) (range 2-10x10(8)). In vitro colony assays and in vivo NOD/SCID repopulation assays showed no negative impact of this method on the function of the hematopoietic stem cells.

DISCUSSION: Our results show that the CliniMACS system can be used to efficiently deplete PBSC of T and B cells simultaneously, without adverse effect on the graft.

Bargallo, M. E., et al. (2017). "Utility of Systematic Isolation of immune cell subsets from HIV-infected individuals for miRNA profiling." Journal of Immunological Methods **442**: 12-19.

INTRODUCTION: Peripheral blood mononuclear cells (PBMCs) are frequently used for genomic analyses, but several factors can affect the yield and integrity of nucleic acids, including the methods of cell collection and isolation. The goal of this work was to analyze the utility of systematic isolation of different immune cell subsets by immunomagnetic separation and the RNA integrity after isolated cells from samples of HIV-infected patients.

METHODS: PBMC from Healthy Controls (HC, n=15), Elite Controllers (EC, n=15), Viremic Controllers (VC, n=15), Viremic Progressors (VP, n=15) and HIV-infected patients on therapy (ART, n=15) were isolated by Ficoll-Paque density gradient centrifugation. Subsets were separated with monoclonal antibodies (CD56, CD14, CD4, and CD8) conjugated to microbeads. We evaluated the yield and purity of each subset isolated from PBMCs under resting and activated conditions; LPS, anti-CD3/CD28 and anti-CD16 were used to activate monocytes, PBMC, T cells and NK cells, respectively. The quality of extracted RNA was tested by 2100 Bioanalyzer.

RESULTS: In resting conditions, the average yield of CD14⁺ (monocytes) was decreased (p=0.021) in HIV+ patients compared with healthy controls. CD56⁺ (Natural

Killer-NKs; p=0.03) and CD8⁺ (Cytotoxic T lymphocytes-CTL p=0.001) cells were increased in HIV+ patients after 72h of activation. The purity assay detected significant differences in CD14⁺ (p<=0.001) and CD8⁺ (p=0.034) subpopulations when comparing PBMC isolated either from healthy controls or HIV+ patients. The number of activated cells in HIV+ presented differences in CD8 subset (p=0.003). Finally, similar quantities of high quality RNA were extracted from immune cells subsets obtained by our method. Specifically, we show that Bioanalyzer electrophenograms reveal optimal RIN values in HIV positive and negative patients in resting condition (EC:8;HC:6.5;VC:8.80;VP:8;HAART:7.5) and activated condition (EC:9;HC:6.7;VC:8.2;VP:7.2;HAART:8.6).

CONCLUSION: This method allowed us to obtain a sufficient quantity of different isolated immune cell subsets from HIV-infected individuals at different disease stages. Moreover, the assessed qualities of nucleic acids allow us to perform subsequent molecular studies, such as microRNA profiling.

Barletta, M. and A. R. A. Lima (2019). "Systematic review of fish ecology and anthropogenic impacts in South American estuaries: Setting priorities for ecosystem conservation." Frontiers in Marine Science **6**(May).

Research on estuarine ecology in South America (SA) increased quali-quantitatively since the early 1980 in search of consistent recommendations for estuarine conservation. The most important ecological theory achieved is that the seasonal fluctuation of the salinity gradient creates an ecocline influenced by gradual changes between river-dominated to marine-like waters. Estuarine fish fauna adapts to these changeable abiotic characteristics, including the spatial, and seasonal bioavailability of dissolved oxygen and numerous pollutants. However, studies on the influence of the estuarine ecocline are still missing for key estuarine systems. This study provides an overview of fish ecology and anthropogenic impacts within estuarine systems of SA and discusses priorities for environmental conservation. Research on fish reached important conclusions regarding essential habitats and fish interaction with other biological and abiotic compartments over spatio-temporal settings, including conditions of severe anthropogenic impacts. These impacts are related to unplanned urban settlements, industrial estates, ports, damming of major rivers, dredging activities, and deforestation for extensive farming. Changes in estuarine morphology alter natural flows and lead to habitat losses, disrupting the ecocline and impairing fishes from moving among formerly connected habitats, especially earlier ontogenetic phases. In addition, industrial, urban, and farming activities often result in high loads of metals and persistent organic pollutants, organic enrichment and oxygen depletion. Moreover, plastic debris, a ubiquitous contaminant with sources on every human activity, including fishing, when fragmented into microplastics, become preferably concentrated in semi-enclosed environments, as estuaries. Metals, POPs and microplastics are actually asserted to be persistent. When in high concentrations, they become bioavailable to the estuarine trophic web through bioaccumulation, being biomagnified or biotransfered toward higher trophic level organisms, such as top predator fishes. Therefore, research on environmental quality and fish ecology must be based on robust sampling designs along the whole ecocline using long-term approaches. In addition, basic sanitation, co-management, an improved licensing system and scientifically-based risk assessments/monitoring for all sorts of enterprise are also urgent. These conservation priorities need to be in place before human-driven changes surpass the ecosystem's capacity to produce resources and maintain services. © 2019 Barletta and Lima.

Barletta, M., et al. (2019). "Distribution, sources and consequences of nutrients, persistent organic

pollutants, metals and microplastics in South American estuaries." Science of the Total Environment **651**(Pt 1): 1199-1218.

Estuarine pollution imposes rapid, increasing and lasting environmental modifications. In the present review, especial attention is given to estuaries in South America (SA), where legislation, policies and actions to guarantee environmental quality remain ineffective. There, the majority of estuaries face uncontrolled occupation of its margins by urban and industrial centres, agriculture and aquaculture expansion, water extraction and flow control. The lack of basic sanitation and poor environmental management (including territories within Marine Protected Areas) often lead to hydrological alterations, high nutrient loads, and the presence and dynamics of pollutants (nutrient loads, persistent organic pollutants (POPs), metals and plastic debris) along the entire estuarine ecocline. Organic enrichment has increased dissolved oxygen consumption, with wide spatio-temporal variability along latitudes and estuarine gradients. The toxicity, biogeochemistry and availability of metals and POPs depend on the annual fluctuations of salinity, water renewal, dissolved oxygen levels, suspended particulate loads, sediment mobility, grain size and composition at the sink. Plastic debris from land sources are widespread in estuaries, where they continue to fragment into microplastics. River basins are the main contributors of plastics to estuaries, whose transportation and accumulation are subjected to interannual water flow variations. Although some systems seems to be in a better condition in relation to others around the world (e.g. Goiana and Negro estuaries), many others are among the most modified worldwide (e.g. Guanabara Bay and Estero Salado System). We propose that, estuarine conservation plans should consider year-round fluctuations of the ecocline and the resulting cycles of retention and flush of environmental signals and their influence on trophic webs over the whole extent of estuarine gradients.

Barnaby, R., et al. (2017). "Effectiveness of table top water pitcher filters to remove arsenic from drinking water." Environmental Research **158**: 610-615.

Arsenic contamination of drinking water is a serious threat to the health of hundreds of millions of people worldwide. In the United States ~3 million individuals drink well water that contains arsenic levels above the Environmental Protection Agency (EPA) maximum contaminant level (MCL) of 10mug/L. Several technologies are available to remove arsenic from well water including anion exchange, adsorptive media and reverse osmosis. In addition, bottled water is an alternative to drinking well water contaminated with arsenic. However, there are several drawbacks associated with these approaches including relatively high cost and, in the case of bottled water, the generation of plastic waste. In this study, we tested the ability of five tabletop water pitcher filters to remove arsenic from drinking water. We report that only one tabletop water pitcher filter tested, ZeroWater, reduced the arsenic concentration, both As³⁺ and As⁵⁺, from 1000mug/L to < 3mug/L, well below the MCL. Moreover, the amount of total dissolved solids or competing ions did not affect the ability of the ZeroWater filter to remove arsenic below the MCL. Thus, the ZeroWater pitcher filter is a cost effective and short-term solution to remove arsenic from drinking water and its use reduces plastic waste associated with bottled water.

Barnard, R. T., et al. (2011). "Expecting the unexpected: Nucleic acid-based diagnosis and discovery of emerging viruses." Expert Review of Molecular Diagnostics **11**(4): 409-423.

Extrapolation from recent disease history suggests that changes in the global environment, including virus, vector and human behavior, will continue to influence the spectrum of viruses to which humans are exposed. In this article, these environmental changes will be enumerated, and their potential impact on target-focused, nucleic acid-based diagnostic tests will be

considered, followed by a presentation of some emerging technological responses. © 2011 Expert Reviews Ltd.

Barnes, D. K., et al. (2009). "Accumulation and fragmentation of plastic debris in global environments." Philosophical Transactions of the Royal Society of London - Series B: Biological Sciences **364**(1526): 1985-1998.

One of the most ubiquitous and long-lasting recent changes to the surface of our planet is the accumulation and fragmentation of plastics. Within just a few decades since mass production of plastic products commenced in the 1950s, plastic debris has accumulated in terrestrial environments, in the open ocean, on shorelines of even the most remote islands and in the deep sea. Annual clean-up operations, costing millions of pounds sterling, are now organized in many countries and on every continent. Here we document global plastics production and the accumulation of plastic waste. While plastics typically constitute approximately 10 per cent of discarded waste, they represent a much greater proportion of the debris accumulating on shorelines. Mega- and macro-plastics have accumulated in the highest densities in the Northern Hemisphere, adjacent to urban centres, in enclosed seas and at water convergences (fronts). We report lower densities on remote island shores, on the continental shelf seabed and the lowest densities (but still a documented presence) in the deep sea and Southern Ocean. The longevity of plastic is estimated to be hundreds to thousands of years, but is likely to be far longer in deep sea and non-surface polar environments. Plastic debris poses considerable threat by choking and starving wildlife, distributing non-native and potentially harmful organisms, absorbing toxic chemicals and degrading to micro-plastics that may subsequently be ingested. Well-established annual surveys on coasts and at sea have shown that trends in mega- and macro-plastic accumulation rates are no longer uniformly increasing: rather stable, increasing and decreasing trends have all been reported. The average size of plastic particles in the environment seems to be decreasing, and the abundance and global distribution of micro-plastic fragments have increased over the last few decades. However, the environmental consequences of such microscopic debris are still poorly understood. [References: 96]

Barnes, S. J. (2019). "Out of sight, out of mind: Plastic waste exports, psychological distance and consumer plastic purchasing." Global Environmental Change Part A: Human & Policy Dimensions **58**: N.PAG-N.PAG.

• Exporting plastic waste creates psychological distance from plastic waste pollution. • Exporting plastic waste creates an artificially cleaner local environment. • Artificially cleaner local environments encourage plastics consumption. • Level of plastic waste acts as a mediator in the relationship. • Examines policy aimed at reducing future plastics consumption and pollution. Per capita consumption of plastic continues to increase and remains at high levels in high-income countries, despite obvious contributions to the global problem of plastics pollution. This paper attempts to provide an explanation for this phenomenon based on construal level theory, positing that plastic waste is a problem that is perceived as "out of sight and out of mind" for consumers in high plastic consumption (typically high income) countries and that this is influenced by the export of plastic waste to other (typically lower income and lower consumption) countries for disposal – shifting the burden of mismanaged plastic waste and perceptions of plastics pollution in the countries creating the majority of plastic waste. The apparent lack of plastics pollution in a local environment becomes a mediator, influenced by the export of plastic waste, which may then contribute to further plastics consumption. The theory is tested using structural equation modelling using rare, available matched data for mismanaged plastic waste, plastic waste exports, and plastics consumption at an aggregate country level. All study hypotheses are supported. The paper concludes with recommendations for future research and practice, including potential changes to government policy aimed at reducing future plastics consumption and pollution. [ABSTRACT FROM AUTHOR]

Barnes, S. J. (2019). "Understanding plastics pollution: The role of economic development and technological research." Environmental Pollution **249**: 812-821.

Our world is awash with plastic. The massive increase in plastics production, combined with a shift to single-use, disposable plastics and widespread mismanagement of plastic waste, has created a huge "tragedy of the commons" (Hardin, 1968) in our oceans, seas and waterways. Plastics pollution is now a global externality that damages ecosystems, curtails biodiversity and ultimately has the potential to affect everyone on the planet. Although waste output is often modelled separately from environmental pollution in research, in the case of plastics, the waste problem has become one of global pollution. In this paper, we model the relationship between mismanaged plastic waste 1 and income per capita for 151 countries, and for the first time find empirical support for the environmental Kuznets curve using plastics pollution data. Further, we find support for the hypothesis that a key instrument for reducing plastics pollution is investment in scientific and technological research. The paper concludes with a discussion of the results, limitations, and implications for future research and practice. Image 1 • Models the relationship between mismanaged plastic waste and economic development. • Finds original empirical support for the EKC in the context of mismanaged plastic waste. • Plastics pollution reduced in countries through scientific and technical research. • Examines policy implications of research findings in reducing plastics pollution. Original empirical support for environmental Kuznets curve for plastics pollution and reduction in plastics pollution via research investment, based on data for 151 countries. [ABSTRACT FROM AUTHOR]

Barnsley, L. C., et al. (2017). "Understanding the dynamics of superparamagnetic particles under the influence of high field gradient arrays." Physics in Medicine & Biology **62**(6): 2333-2360.

The aim of this study was to characterize the behaviour of superparamagnetic particles in magnetic drug targeting (MDT) schemes. A 3-dimensional mathematical model was developed, based on the analytical derivation of the trajectory of a magnetized particle suspended inside a fluid channel carrying laminar flow and in the vicinity of an external source of magnetic force. Semi-analytical expressions to quantify the proportion of captured particles, and their relative accumulation (concentration) as a function of distance along the wall of the channel were also derived. These were expressed in terms of a non-dimensional ratio of the relevant physical and physiological parameters corresponding to a given MDT protocol. The ability of the analytical model to assess magnetic targeting schemes was tested against numerical simulations of particle trajectories. The semi-analytical expressions were found to provide good first-order approximations for the performance of MDT systems in which the magnetic force is relatively constant over a large spatial range. The numerical model was then used to test the suitability of a range of different designs of permanent magnet assemblies for MDT. The results indicated that magnetic arrays that emit a strong magnetic force that varies rapidly over a confined spatial range are the most suitable for concentrating magnetic particles in a localized region. By comparison, commonly used magnet geometries such as button magnets and linear Halbach arrays result in distributions of accumulated particles that are less efficient for delivery. The trajectories predicted by the numerical model were verified experimentally by acoustically focusing magnetic microbeads flowing in a glass capillary channel, and optically tracking their path past a high field gradient Halbach array.

Barral, A. M., et al. (2018). "Bacterial colonization and partial degradation of plastic debris in California coastal waters." FASEB Journal. Conference: Experimental Biology **32**(1 Supplement 1).

Several studies have addressed the role of microbes associated with plastic marine debris. However, little is known about the nature of microbes attaching to plastic in coastal areas, and how it could potentially impact humans. The goal of this project is to evaluate the microbial diversity on plastic marine debris, specifically the more abundant types of floating plastic (ex. single-use plastic bags) made of polyethylene (PE) and polypropylene (PP) in coastal waters. Our hypothesis is that microbes will colonize plastic and that the diversity and abundance of microbial communities will be directly influenced by plastic resin type. We are also interested in colonization of plastic by pathogenic species and/or species with potential to degrade plastic. Three plastic resin types (high density polyethylene (HDPE), low density polyethylene (LDPE), and polypropylene (PP)) were placed in stainless steel cages, submerged to approx. 50 cm depth in Southern California coastal waters and retrieved at 4 different time points between 3 and 40 days along with water samples for comparative purposes. Two sample sets were collected between May 2016 and May 2017. DNA was extracted and 16S rRNA metagenomic tag sequencing was used to differentiate the microbial community. Colonies grown parallel on Salt Water Agar and Vibrio-specific media were characterized by 16S amplicon sequencing. In addition, Fourier Transform Infrared Spectroscopy (FTIR) was used to analyze the breakdown of plastic over time and scanning electron microscopy (SEM) to visualize the biofilms attached to plastic on day 40. Our results indicate that over 40% of the sequences obtained are from unclassified organisms. The three plastic resin types exhibited a diverse assemblage of heterotrophic bacterial taxa, while in water samples photosynthetic genera were the most prevalent. There were differences between plastic resin types and the surrounding water, as well as temporal differences. We did not find evidence of Vibrio cholerae either by 16S metagenomic sequencing or by 16S sequencing of colonies isolated on ChromAgar Vibrio. However, other potentially pathogenic genera such as Francisella and Rickettsia were present on plastic at earlier sampling time points. In addition, all three plastic resins showed signs of chemical degradation over time, and SEM revealed a rich biofilm containing diatoms, bacterial, and protist populations. Together, this study indicates that there are differences in the microbial communities growing on coastal marine plastic debris with potential implications for human health and the environment.

Barria, C., et al. (2019). "Effect of nanoplastics on fish health and performance: A review." Marine Pollution Bulletin **(no pagination)**(110791).

Small plastic particles are considered emerging pollutants, and this has motivated a considerable number of studies to establish their environmental consequences. At present, the study of the

effects of nanoplastics (NPs) on aquatic organisms is still scarce, especially in organisms from higher trophic levels such as fish. This review describes the effects reported in different fish species after exposure to plastic particles smaller than 100 nm. Studies show that NPs can adversely affect fish at different stages of development, with reported accumulation in tissues, decreased locomotor and foraging activities, effects on growth and the immune system and alterations on lipid metabolism and neurotoxicity. However, mortality, effects on hatching success or malformations related to NPs have not been reported to this date. Copyright © 2019 Elsevier Ltd

Barrows, A. P. W., et al. (2018). "Marine environment microfiber contamination: Global patterns and the diversity of microparticle origins." Environmental Pollution **237**: 275-284.

Microplastic and microfiber pollution has been documented in all major ocean basins. Microfibers are one of the most common microparticle pollutants along shorelines. Over 9 million tons of fibers are produced annually; 60% are synthetic and ~25% are non-synthetic. Non-synthetic and semi-synthetic microfibers are infrequently documented and not typically included in marine environment impact analyses, resulting in underestimation of a potentially pervasive and harmful pollutant. We present the most extensive worldwide microparticle distribution dataset using 1-liter grab samples (n=1393). Our citizen scientist driven study shows a global microparticle average of 11.8+/-24.0 particles L⁻¹ (mean+/-SD), approximately three orders of magnitude higher than global model predictions. Open ocean samples showed consistently higher densities than coastal samples, with the highest concentrations found in the polar oceans (n=51), confirming previous empirical and theoretical studies. Particles were predominantly microfibers (91%) and 0.1-1.5mm in length (77%), a smaller size than those captured in the majority of surface studies. Using muFT-IR we determined the material types of 113 pieces; 57% were classified as synthetic, 12% as semi-synthetic, and 31% as non-synthetic. Samples were taken globally, including from coastal environments and understudied ocean regions. Some of these sites are emerging as areas of concentrated floating plastic and anthropogenic debris, influenced by distant waste mismanagement and/or deposition of airborne particles. Incorporation of smaller-sized microfibers in oceanographic models, which has been lacking, will help us to better understand the movement and transformation of synthetic, semi-synthetic and non-synthetic microparticles in regional seas and ocean basins.

Barrows, A. P. W., et al. (2018). "A watershed-scale, citizen science approach to quantifying microplastic concentration in a mixed land-use river." Water Research **147**: 382-392.

Microplastic (particles<5mm) pollution dynamics are well documented in oceans and increasingly studied in freshwater. We used a watershed-scale approach to examine spatial and temporal patterns in microplastic concentrations in the Gallatin River watershed (Montana, USA). At 72 sites, trained volunteers collected ~1-L grab samples at 4 seasons per year over 2 years (n=714 samples). Microplastics were found in 57% of the samples (mean=1.2 particles L⁻¹). The majority of particles were fibers (80%), 0.1-1.5mm long. Chemical identification determined 93% of particles measured by muFT-IR were synthetic or semi-synthetic materials. Microplastic concentration differed significantly among dates, but showed no longitudinal pattern or relationship to land-use among subwatersheds. At two sites with gaging stations, microplastic was negatively related to discharge when compared across dates. This suggests stormwater is not a source of microplastic in this watershed, but instead dilutes microplastic inputs from other sources. We conclude that microplastic sources are diverse, and measurements of microplastic deposition, resuspension, and transport may be

needed to clarify the role of land-use patterns on microplastic pollution. This large scale, citizen science based approach provides a model for future analysis which can further expand microplastic collection at the watershed scale.

Barrows, A. P. W., et al. (2017). "Grab vs. neuston tow net: a microplastic sampling performance comparison and possible advances in the field. (Special Issue: Microplastics in the environment.)." Analytical Methods **9**(9): 1446-1453.

With the rapid evolution of microplastic research over several decades, there is an urgent need to compare methodologies for quantifying microplastic in aquatic environments. The most common method for sea surface sampling is a neuston net tow. This method captures microplastic from large water volumes, and although is widely employed, it is specifically designed for studying plankton ecology. Its effectiveness for microplastic research is limited by the net's mesh size as well as the likelihood of contamination. In our study, we compared a 1 L surface grab sampling method to a 335 micro m neuston net tow. Grab sampling collected over three orders of magnitude more microplastic per volume of water as well as a smaller size range and greater proportion of non-fibrous plastic than sampling with a neuston net. Consequently, solely relying on neuston net samples appears to result in an underestimation of the extent of microplastic pollution. For studies aiming to capture and sort larger microplastics without a microscope, the neuston tow method is preferred, since it samples a greater volume of water, increasing the potential of capturing microplastic pieces. Grab sampling can capture plastic at the micro- and nano-scale and in environments where neuston nets are impractical, but the small volume of water sampled may result in high variability among samples. The comparison of these techniques comes at a critical time when sampling methods need standardization for the accurate measurement of the distribution and composition of microplastic in aquatic environments worldwide.

Barry, J., et al. (2009). "Aerosol and spray deposition in a child nasal phantom." Journal of Aerosol Medicine and Pulmonary Drug Delivery **22 (2)**: 186.

The current work is motivated by the need for efficient intranasal delivery of vaccines in a mass campaign scenario for diseases such as influenza. An optimal nasal delivery system seeks to penetrate the nasal valve and efficiently target the mucosal membranes. A child nasal airway phantom was constructed by stere-olithography techniques in five coronal sections based on CT images of an 8-year-old male. The anterior section comprising the nasal airway up to the nasal valve was molded of soft silicone rubber. The other sections were constructed of hard plastic resin. Regional deposition was measured for two classes of devices: a nasal spray device (median aerosol diameter of 80 mum) and a vibrating-mesh nebulizer with orifice size selected for intranasal delivery (median aerosol diameter of 24 mum). Deposition was assessed using the fluorescent tracer technique. Significant differences in deposition were observed between the child phantom and a previously-developed adult nasal airway phantom (53-year-old male constructed of 77 machined acrylic plates). The anatomy of the child phantom placed the device tip in closer proximity to the nasal valve, and the soft nares of the child phantom enabled more realistic placement. Deposition also differed markedly between the spray and the aerosol. The spray deposited mostly as one or more large droplets at or just beyond the nasal valve. The aerosol deposited more broadly to mucosal surfaces in the nasal tract.

Barry, J., et al. (2011). "Intranasal dry powder deposition in a child phantom." Journal of Aerosol Medicine and Pulmonary Drug Delivery **24 (3)**: 45.

Intranasal delivery of vaccines in dry powder form has significant potential as an alternative to vaccination by injection or nasal spray. An optimal nasal delivery system seeks to penetrate the nasal valve and efficiently target the nasal airway mucosal membranes. Iterative evaluation of airway deposition patterns is highly useful for optimization of dry powder delivery system design. Experiments utilized a nasal airway phantom constructed by stereolithography techniques in five sections based on CT images of a 5-year-old child. The anterior section comprising the nasal airway up to the nasal valve was molded of soft silicone rubber to mimic facial flexibility. The other sections were constructed of hard plastic resin. A mucous simulant was applied to the interior surfaces of the model. Dry fluorescein powders sieved to 60 /mum. were introduced into one nares using a prototype intranasal device powered by a breathing simulator. Regional deposition was assessed by visual inspection of the opened airway sections and quantified by eluting powders from sections and measuring fluorescence. Test data show 60% or more of the dry powder loaded into the device deposited in the internal nasal airway sections of the phantom beyond the nasal valve. The deposition rates were not sensitive to the alignment of the intranasal device. These results contrast with lower deposition fractions and much higher sensitivity to alignment for liquid aerosols in similar phantom tests.

Barton, R. (2011). "A very British approach." Local Authority Waste & Recycling **19**(11): 18-18.
The article discusses the disadvantages of offshore recycling for Europe and suggests an alternative to it. The practice of Europe to export plastic waste to the Far East particularly China for recycling is said to contribute to a massive carbon footprint. It is noted that China uses large amounts of fossil and non-renewable fuels and has high levels of pollution. The author suggests to use the services of recycling companies in Great Britain such as recycled products.

Barwicki, J. (2010). "Testing of the disc-, anchor- and paddle-type mixing units by the use of non-invasive method to evaluate the mixing quality." Problemy Inzynierii Rolniczej **18**(1): 97-104.
Investigations were conducted on an experimental stand consisted of: cylindrical steel tank, electric motor of variable rotation rate, energy demand meter, piezoelectric transducer to measure mixture homogeneity and the computer for recording test results. Disc-, anchor- and paddle-type mixing units were investigated. Water and artificial (plastic) particulates, similar in physico-mechanical properties to fruit and vegetable products processed in the food industry, were used as media in the experiment. Energy consumption in mixing process was measured for four rotational speeds of the mixing units: 150, 250, 300 and 400 r.p.m. The effects of mixing unit construction on duration and energy consumption in mixing process were stated. Obtained results may be useful at designing new types, as well as to improving construction of existing mixing units.

Basarova, P., et al. (2005). "The influence of flotation agent concentration on the wettability and flotability of polystyrene." Journal of Colloid & Interface Science **286**(1): 333-338.
The fundamental flotation process is the formation of a flocculant by air bubbles and solid particles in an aqueous solution. The behavior of plastic particles is significantly influenced by the wettability of the plastics. In this article the reciprocal relationship between the flotability and wettability of polystyrene was studied at different concentrations of flotation agents, particularly terpineol, polyethylene glycol dodecyl ether, tannic acid, and calcium lignosulfonate. The conclusions obtained demonstrate the dissimilar action of flotation depressants, what means different adhesion mechanisms on a plastic surface.

Bashan, Y., et al. (2006). "Increase in auxiliary photoprotective photosynthetic pigments in wheat seedlings induced by Azospirillum brasilense." Biology and Fertility of Soils **42**(4): 279-285.

Inoculation of wheat seedlings with the plant growth-promoting bacterium Azospirillum brasilense Cd was immobilized in alginate microbeads and, without applying any stress, significantly increased the quantity of several photosynthetic pigments, such as chlorophyll a, chlorophyll b, and the auxiliary photoprotective pigments violaxanthin, zeaxanthin, antheroxanthin, lutein, neoxanthin, and beta -carotene. This resulted in greener plants with no apparent visible stress. After monitoring the quantity of photosynthetic pigments for 4 weeks, we observed that inoculated plants had higher quantities of pigments in shoot and stem. The greatest difference in the quantity of all pigments between inoculated and noninoculated plants occurred in the first week of growth. Regardless of treatment, the quantity of pigments in stems was three to four times less than the quantity of these pigments in shoots. Application of Azospirillum, either as liquid inoculant or as alginate microbeads, did not alter the positive effect of the bacteria on pigment production or the positive response of the plants towards A. brasilense Cd inoculation.

Bashan, Y., et al. (2002). "Alginate microbeads as inoculant carriers for plant growth-promoting bacteria." Biology and Fertility of Soils **35**(5): 359-368.

A method of inoculating wet and dry seeds with plant growth-promoting bacteria (PGPB) using alginate microbeads as a substrate and Azospirillum brasilense as the model PGPB was developed. The microbeads were produced by low pressure spraying of an alginate solution mixed with liquid bacterial culture suspended in a very rich medium through a small nozzle resulting in small-diameter droplets. These droplets, when sprayed into a slowly stirred solution of CaCl₂, immediately hardened into microbeads at diameters ranging between 100 and 200 micro m. Although the process killed part of the entrapped bacteria, the remaining bacteria residing in the microbeads were sufficient (>10¹¹ colony-forming units (CFU) g⁻¹ inoculant) for seed inoculation. Further, it was found that the bacterial population in the inoculant could be enhanced by secondary multiplication in the same medium for an additional 16 h. It was found that the microbeads could be used either wet or dry. Dry inoculant was produced using dry air at 38 degrees C, creating a powdery substance loaded with >10⁹ CFU g⁻¹ beads. Alternatively, dry microbeads were produced using a standard freeze-drying procedure. This dry preparation was easily attached to dry seed surfaces with the addition of 1% alcohol-diluted lecithin or with 0.5% synthetic paper adhesive (Resistol). The bacteria were slowly released from the microbeads in amounts ranging from 10⁴ to 10⁶ CFU g⁻¹ depending on the type (wet or dry, with or without skim milk) and the time of incubation (the longer the incubation period, the smaller the amount of bacteria released with time). The wet and dry inoculants enhanced the development of wheat and tomato seedlings growing in unfertile soil, and biodegraded within 15 days in moist soil.

Baskin, L. S., et al. (2004). "Anatomical studies of the mouse genital tubercle." Advances in Experimental Medicine & Biology **545**: 103-121.

BACKGROUND: To study the etiology of hypospadias, we propose the use of a mouse model, the embryonic mouse genital tubercle. In this study, we define the development of the mouse genital tubercle with special emphasis on urethral formation demonstrating anatomical similarities to human development.

MATERIALS AND METHODS: Serial sections of genital tubercles from embryonic male and female mice ages 14 to 21 days gestation from timed pregnant animals, newborn and adult mice were immunohistochemical stained with antibodies to E-cadherin, cytokeratins 7, 10, and 14. Patency of the urethral was assessed by india ink injection via the bladder. Urethral lumen morphology was determined by the creation of plastic resin cast. Surface morphology of the genital tubercle was defined by scanning electron microscopy.

RESULTS: India Ink injection into the bladder showed that the urethral lumen was patent from 14 days gestation. Plastic resin casts revealed that the male urethra was characterized by a S shaped curve, the presence of the bulbar urethral gland and a longer length than age matched females. The ontogeny of the genital tubercle development revealed two epithelial edges that subsequently touched and fused into the completed urethra. During development cytokeratin immunohistochemical staining demonstrated that the epithelial cells of the urethral lumen are of bladder origin and the surface cells of skin origin.

CONCLUSION: The functional and developmental anatomy of the mouse genital tubercle provides a useful model to study normal and abnormal human urethral development.

Bassett, D. C., et al. (2014). "Dissolution of copper mineral phases in biological fluids and the controlled release of copper ions from mineralized alginate hydrogels." Biomedical materials (Bristol, England) **10**(1): 015006.

Here we investigate the dissolution behaviour of copper minerals contained within biocompatible alginate hydrogels. Copper has a number of biological effects and has most recently been evaluated as an alternative to expensive and controversial growth factors for applications in tissue engineering. Precise control and sustained release of copper ions are important due to a narrow therapeutic window of this potentially toxic ion, and alginate would appear to be a good material of choice for this purpose. We found that aqueously insoluble copper minerals could be precipitated during gelling within or mixed into alginate hydrogels in the form of microbeads prior to gelling to serve as depots of copper. These minerals were found to be soluble in a variety of biological fluids relevant to in vitro and in vivo investigations, and the alginate carrier served as a barrier to diffusion of these ions and therefore offered control over the rate and duration of release (Cu(2+) release rates observed between 10-750 µMol g(-1) h(-1) and duration for up to 32 d). Copper mineral and copper mineralized alginate microbeads were characterized using powder x-ray diffraction, FTIR, thermogravimetric analysis and scanning electron microscopy. Dissolution kinetics were studied based on measurements of copper ion concentrations using colourimetric methods. In addition we characterized the complexes formed between released copper ions and biological fluids by electron paramagnetic spectroscopy which offers an insight into the behaviour of these materials in the body.

Basto, M. N., et al. (2019). "Plastic ingestion in aquatic birds in Portugal." Marine Pollution Bulletin **138**: 19-24.

In modern society, plastic items have become indispensable. The rapid growth of plastic production has led to an increase in the concentration of plastic waste in the environment and, consequently, wildlife has been severely affected. As wide-ranging foragers and predators, aquatic birds are ideal sentinels for monitoring changes in their environment. Plastic found in stomach contents of stranded aquatic birds collected throughout Portugal was examined. Out of the 288 birds processed, 12.9% ingested plastics. Six of the 16 species assessed showed evidence of plastic ingestion. The Lesser Black-backed Gull (18.7%) had the highest incidence while, among those that did ingest plastics, the Northern Gannet (4.8%) had the lowest. User plastics were the most common type of plastic ingested, while microplastics and off/white-clear were the most common size and colour respectively of plastics found. This study sets a first multispecies baseline for incidence of plastic ingestion by aquatic birds in Portugal. Copyright © 2018 Elsevier Ltd

Batel, A., et al. (2018). "Microplastic accumulation patterns and transfer of benzo[a]pyrene to adult zebrafish (Danio rerio) gills and zebrafish embryos." Environmental Pollution **235**: 918-930.

Since only a few studies have investigated effects of microplastics (MPs) by routes other than ingestion, this study was designed to analyze the accumulation patterns and transfer of toxic substances associated with microplastic exposure by simple attachment to (1) adult zebrafish (Danio rerio) gills and (2) zebrafish embryos. Two sizes of fluorescently labelled polymers (1-5 and 10-20 micro m) loaded with the model polycyclic aromatic hydrocarbon (PAH) benzo[a]pyrene (BaP) were used to analyze fate, accumulation and transfer of microplastic-associated persistent organic pollutants (POPs) on gills and embryos. Results indicate that microplastics did not permanently accumulate at high amounts in adult zebrafish gills after 6 nor 24 h of incubation: Most particles only superficially adhered to the mucus layer on the filaments, which is constantly being excreted. In contrast, the smaller and heavier MPs (1-5 micro m) accumulated in high numbers on the surface of zebrafish egg chorions. In both exposure scenarios, transfer of BaP could be visualized with fluorescence microscopy: A prominent BaP signal was visible both in gill filaments and arches after 6 and 24 h incubation and in zebrafish embryos after exposure to BaP-spiked microplastics. Furthermore, the gill EROD (Ethoxyresorufin-O-deethylase) assay showed a clear trend to CYP 1A (Cytochrom P450 1 A) induction via exposure to BaP-spiked microplastics. However, BaP from spiked microplastics did not reach sufficiently high concentrations to be able to induce morphological effects in the fish embryo toxicity test (FET). In contrast, control exposure to waterborne BaP did induce effects in the FET. As a conclusion, microplastics can also transfer POPs not only via ingestion, but also by simple attachment to epithelia or via the water column. However, further studies are needed to clarify if these interactions are of environmental concern relative to waterborne exposure to toxic substances.

Batel, A., et al. (2016). "Transfer of benzo[a]pyrene from microplastics to Artemia nauplii and further to zebrafish via a trophic food web experiment: CYP1A induction and visual tracking of persistent organic pollutants." Environmental Toxicology & Chemistry **35**(7): 1656-1666.

The uptake of microplastic particles and the transfer of potential harmful substances along with microplastics has been studied in a variety of organisms, especially invertebrates. However, the potential accumulation of very small microplastic particles along food webs ending with vertebrate models has not been investigated so far. Therefore, a simple artificial food chain with Artemia sp. nauplii and zebrafish (Danio rerio) was established to analyze the transfer of microplastic particles and associated persistent organic pollutants (POPs) between different trophic levels. Very small (1-20 µm) microplastic particles accumulated in Artemia nauplii and were subsequently transferred to fish. Virgin particles not loaded with POPs did not cause any observable physical harm in the intestinal tracts of zebrafish, although parts of the particles were retained within the mucus of intestinal villi and might even have been taken up by epithelial cells. The transfer of associated POPs was tested with the polycyclic aromatic hydrocarbon benzo[a]pyrene and an ethoxyresorufin- O-deethylase (EROD) assay for CYP1A induction in zebrafish liver as well as via fluorescence analyses. Whereas a significant induction in the EROD assay could not be shown, because of high individual variation and low sensitivity regarding substance concentration, the fluorescence tracking of benzo[a]pyrene indicates that food-borne microplastic-associated POPs may actually desorb in the intestine of fish and are thus transferred to the intestinal epithelium and liver. Bates, M. C., et al. (2019). "Translational Research and Early Favorable Clinical Results of a Novel Polyphosphazene (Polyzene-F) Nanocoating." Regenerative Engineering and Translational Medicine **5**(4): 341-353.

Abstract: This manuscript is a review of the preclinical and early clinical findings related to a unique fluorinated polyphosphazene nanolayer device surface modification. Polyzene-F (PzF) is a novel, high-molecular weight, highly pure polyphosphazene that was designed to enhance the biologic interface between a medical device surface and human tissue or blood. The polymer also has unique mechanical properties that for the first time allow implants to be paved with a coating that has a nanoscale thickness of < 50 nm. The coating has inherent thrombus resistant properties and takes on biomimetic properties soon after implant due to favorable protein adhesion. Over the last 1.5 decades, PzF has undergone extensive preclinical testing including benchtop endothelial cell migration and platelet adhesion studies followed by increasingly sophisticated evaluation in 16 different animal models. The coating consistently has shown reduced platelet adhesion, decreased clotting, reduced inflammation, and accelerated healing compared with different surfaces as well as uncoated controls. These preclinical findings have translated into early compelling clinical evidence that suggest enhanced healing and reduced thrombosis can be achieved with a PzF-coated implant. There are now two PzF nanocoated products approved by the US Food and Drug Association (FDA), embolic spheres, and a coronary stent. This is the first detailed overview of the history, preclinical findings, and current clinical results attributed to the PzF coating with emphasis on the coronary stent Cobra-PzF. Lay Summary: Over the last few decades, we have seen remarkable advances in medical technology including the development of less invasive surgical alternatives for the treatment of heart and vascular disease. One of the key advances in treating or preventing heart attack, stroke, and limb loss has been the development of stents. Stents are small, metallic, mesh-like devices that can be expanded within blocked vessels via small catheters placed through the groin or wrist. These stents provide structural support while the vessel heals. One of the challenges with stents and other permanent device implants is related to how our bodies react to foreign materials. One of the most feared complications of stents is clotting, which can result in abrupt closure of the treated artery. In the case of heart stents, abrupt closure can cause a heart attack or even sudden death whereas clotting within stents in the neck arteries (carotids) can cause stroke. Additional normal body defense mechanisms include complicated immune responses that trigger inflammation and can cause scarring resulting in early recurrence of the blockage or so-called "restenosis." In an effort to eliminate restenosis, many stents are now coated with drugs that slow or prevent healing. The downside of this approach has been the need for long-term blood-thinning medications like Plavix and aspirin. In this article, we review the history and current clinical findings of a new way to potentially make medical implants invisible to the normal foreign body defense responses that cause subsequent complications. The innovation involves the development of a new compound called Polyzene-F (CeloNova BioSciences, San Antonio, TX) that can be placed on the surface of a device in a layer that is extremely thin. This new coating is so thin it cannot be seen with even the strongest available microscopes and falls into a new category of material science called nanotechnology. Nanotechnology involves materials that are measured on a molecular level rather than the

traditional measurements used in the field of medical devices. We describe many experiments done on the benchtop alongside animal studies and early clinical results that support the hypothesis that an enhanced biologic response can be expected for implants coated with Polyzene-F. The initial types of heart disease patients being studied with this new coated stent (Cobra-PzF) are those at high risk for bleeding since we know these patients are less tolerant of blood thinning medicine. This initial narrow focus was selected based on the experience from our team and others suggesting animal studies do not always predict how humans respond to new treatments coupled with the knowledge that drug-eluting stents are getting better each day. We do see signals in the completed Cobra-PzF clinical trials that clotting and recurrence (restenosis) are low, but these studies do not directly compare this device to alternative stents in a type of study we call a "randomized trial." There is an ongoing large randomized trial comparing the Polyzene-F nanocoated stent (Cobra PzF) with contemporary drug-eluting stents in patients at high risk for bleeding, which should complete enrollment in 2019. At the same time, the US FDA-approved Polyzene-F-coated microbeads (Embozene, Boston Scientific, Marlborough, MA) are being studied for the treatment of tumors and cancer. If an enhanced biologic response is proven in the ongoing randomized trials being conducted on the currently approved Polyzene-F-coated devices, then this new surface enhancement may have broader application for a variety of medical device implants. Batool, S., et al. (2019). "Gastroretentive clarithromycin loaded sodium alginate microbeads: Effect of needle size and drying processes on the swelling and release profile." Latin American Journal of Pharmacy **38**(2): 271-280.

The aim of this study was to investigate the influence of processing parameters such as drying conditions and needle gauges on the size, morphology and drug release from alginate beads using clarithromycin as model drug. The microbeads were prepared by ionotropic gelation method using three needle sizes (18G, 21G, and 23G). The size distribution of prepared beads for air drying, fluidized bed drying and freeze drying was 745, 672, and 1530 micro m, respectively. XRD and DSC depicts that crystallization of drug was suppressed in the beads. Freeze dried beads showed maximum swelling and release in both acidic and alkaline as compared to other two formulations. Fluidized bed dried formulations were relatively robust with predictable swelling and drug release. Copyright © 2018, Colegio de Farmaceuticos de la Provincia de Buenos Aires. All rights reserved.

Battle, R., et al. (2014). "A strategy for the identification of denatured antigen reactive antibodies-a case review reveals a natural antibody capable of generating a positive crossmatch." Tissue Antigens **84 (1)**: 73.

Antibody reactivity to denatured HLA antigens coated onto the surface of microbeads, in HLA antibody (anti-HLA) single antigen bead assays (SAB) is not new, nor is the reported existence of HLA cross reactive 'natural antibodies' in individuals with no history of alloimmunization. This reactivity can make the interpretation of transplant recipients' HLA antibody profiles problematic, and can potentially lead to the listing of clinically irrelevant HLA antibodies.However, dismissing this reactivity in patients known to be non-sensitised (such as non-transfused, non-transplanted males) may not be safe due to the possibility of 'natural antibodies' which may cross-react with HLA antigens. A consequence of this may be an unexpected positive crossmatch (XM) or, if a transplant proceeds, antibody mediated allograft damage. In order to determine between genuine and denatured HLA reactivity we have established a protocol for testing suspected denatured antibody cases, with the aim of maximising patients' opportunity for transplant. Here we report a case of a 41 year old, non-sensitised male, with extensive class I antibody reactivity defined by routine SAB (cPRA 54%). Many of the HLA antibodies were against antigens previously reported as suspected denatured targets. An assessment of the epitopes present within the serum reactivity demonstrated only a single group of antibody targets (HLA-A*23,24) possessed an epitope not present upon antigens determined as negative in the SAB assay. Testing using an in-house denatured antigen assay confirmed this finding as HLA-A*23, 24 reactivity disappeared while all other reactivity remained. Furthermore a SAB assay using HLA targets with a reduced amount of denatured antigen, iBeads (One Lambda), demonstrated reactivity to only HLA-A*23, 24. Finally a flow XM was performed against cells expressing HLA-A*24, producing a positive result (T cell RMF 6.81, B cell RMF 13.24). The use of the methods described above can help to better define unexpected antibody reactivity and reduce the risk of listing antibodies which are not clinically relevant; in this case cPRA was reduced to 21% via the removal of denatured antigen specific antibodies. Further studies are required to better understand the provenance of HLA alloantibodies in patients with no history of exposure to alloHLA.

Bau, D., et al. (2019). "Solid phase-based cross-matching for solid organ allo-grafting using the luminex platform: Rather regression than progress in comparison to the ELISA-based precursor procedure." Hla **93 (5)**: 304.

Donor-specific anti-HLA antibodies (DSA) of a given donor represent the most prominent cause for hyper-acute and acute rejections. In order to select recipients without DSA the complement-dependent cytotoxicity (CDC) crossmatch as the standard procedure was established. As a functional assay it strongly depends on the availability of isolated donor lymphocytes and especially on their vitality. During the last ten years several disadvantages of the CDC-based procedure have increasingly been discussed with respect to this assay's high susceptibility to disruptive factors such as autoimmune diseases of the immune complex type (type III) or pharmacological treatment of a given recipient often leading to unexpected "false-positive" results of the CDC-cross match. As methodical alternatives for anti-HLA antibody specific cross-matching two ELISA-based procedures i) the Antibody Monitoring System (AMS) and ii) the Ab Cross assay had been established in our laboratory. Both systems, however, were later discontinued for commercial reasons in the years 2013 and 2016, respectively. Using the same set of diagnostic antibodies the AMS-ELISA, now named DSA, was again manufactured as a micro bead-based array using the Luminex platform. With a view to establishing the DSAprocedure as the only remaining solid phase-based crossmatch system commercially available, this procedure was systematically evaluated in our laboratory. Primarily but not exclusively, based on drawbacks of the evaluation software, about 44% of the virtually negative and about 19% of the virtually positive cross match results had to be classified as divergent. We provide evidence that for various reasons the outcomes provided by the DSA-assay, in contrast to those of the AMS-ELISA as its precursor system, have to be critically challenged. Thus, modifications are urgently required by the manufacturer in order to lead to a system of sufficient validity again usable for any laboratory's routine diagnostics.

Bau, D., et al. (2019). "Solid phase-based cross-matching using the luminex platform for solid organ allo-grafting: Rather regression than progress in comparison to the ELISA-based precursor procedure." Hla **94 (Supplement 1)**: 22-23.

Many disadvantages of the CDC-based crossmatch (XM) procedure have been discussed in the last few years regarding this assay's high susceptibility to disruptive factors which frequently lead to false positive outcomes. In this context, autoimmune diseases especially of the immune complex type (type III) or pharmacological treatment of a given recipient have been shown to

lead to unexpected "false-positive" outcomes of the CDC-XM. As methodical alternatives for anti-HLA antibody specific cross-matching two ELISA-based procedures i) the AMS-ELISA and ii) the AbCrossELISA had been established in our tissue typing laboratory and those of some other groups. Both systems, however, were discontinued for mere commercial reasons in the years 2013 and 2016, respectively. Using the same set of diagnostic antibodies, the AMS-ELISA, now named Donor-Specific Antibodies/DSA, was afterwards again manufactured as a microbead-based array using the Luminex platform. With a view to establishing the DSA-assay as the only remaining solid phase-based XM-system commercially available, this procedure was systematically evaluated in our laboratory. Primarily but not exclusively based on drawbacks of the evaluation software, however, 69 (32.5%) of the virtually defined XM-results (n = 212 independent anti-HLA class I and II specifications and their corresponding DSA-assays, respectively) were classified as divergent using the DSA-assay whereas only 143 results (67.5%) were classified as accordant by this assay's software. Referring to the chosen cohort of recipients (n = 106) not less than 62 (58.4%) of them were characterized by findings which are not supported by virtual cross-matching. We here provide evidence that the outcomes provided by the DSA-assay, in contrast to those of the AMS-ELISA as its precursor system, have critically to be challenged. Thus, modifications are urgently required by the manufacturer in order to lead again to a system of sufficient validity usable for any laboratory's routine diagnostics.

Bau, D., et al. (2018). "Solid phase-based cross-matching using the luminex platform for solid organ allo-grafting: Regression rather than progress in comparison to the elisa-based precursor procedure." Hla **92 (Supplement 1)**: 18.

In order to select recipients without harmful donor-specific antibodies, the complement-dependent cytotoxicity (CDC) crossmatch (XM) was established as the standard procedure. As a functional assay it strongly depends on the availability of vital donor lymphocytes. Its negative pre-transplant outcome is currently regarded as the most important requirement for a successful kidney graft survival. During the last ten years, however, several disadvantages of the CDC-based procedure have increasingly been discussed due to this assay's high susceptibility to disruptive factors. In this context, several autoimmune diseases of the immune complex type (type III) or pharmacological treatment of a given recipient have been shown to lead to unexpected "false-positive" results of the CDC-XM. As methodical alternatives for anti-HLA antibody specific cross-matching two ELISA-based procedures i) the Antibody Monitoring System-(AMS) and ii) the AbCross-ELISA were established in our tissue typing laboratory and those of some other groups. Both systems, however, were discontinued for mere commercial reasons in the years 2013 and 2016, respectively. Using the same set of diagnostic antibodies the AMS-ELISA was then again manufactured as a microbead-based array using the Luminex platform. With a view to establishing this DSA-named-procedure as the only remaining solid phase-based XM-system commercially available, it was systematically evaluated in our laboratory. Primarily but not exclusively based on drawbacks of the evaluation software, however, more than 40% of the virtually negative crossmatch results were classified as divergent i.e. as false positive. We here provide evidence that the outcome provided by the DSA-assay, in contrast to that of its precursor AMS-ELISA has to be critically challenged. Thus, modifications are urgently required in order to lead to a system of sufficient validity and usability for any laboratory's routine diagnostics again.

Baudrimont, M., et al. (2019). "Ecotoxicity of polyethylene nanoplastics from the North Atlantic oceanic gyre on freshwater and marine organisms (microalgae and filter-feeding bivalves)." Environmental Science & Pollution Research **02**: 02.

Each year, 5 to 10 million tons of plastic waste is dumped in the oceans via freshwaters and accumulated in huge oceanic gyres. Under the effect of several abiotic factors, macro plastic wastes (or plastic wastes with macro sizes) are fractionated into microplastics (MP) and finally reach the nanometric size (nanoplastic NP). To reveal potential toxic impacts of these NPs, two microalgae, Scenedemus subspicatus (freshwater green algae), and Thalassiosira weissiflogii (marine diatom) were exposed for up to 48 h at 1, 10, 100, 1000, and 10,000 mug/L to reference polyethylene NPs (PER) or NPs made from polyethylene collected in the North Atlantic gyre (PEN, 7th continent expedition in 2015). Freshwater filter-feeding bivalves, Corbicula fluminea, were exposed to 1000 mug/L of PER and PEN for 48 h to study a possible modification of their filtration or digestion capacity. The results show that PER and PEN do not influence the cell growth of T. weissiflogii, but the PEN exposure causes growth inhibition of S. subspicatus for all exposure concentrations tested. This growth inhibition is enhanced for a higher concentration of PER or PEN (10,000 mug/L) in S. subspicatus. The marine diatom T. weissiflogii appears to be less impacted by plastic pollution than the green algae S. subspicatus for the exposure time. Exposure to NPs does not lead to any alteration of bivalve filtration; however, fecal and pseudo-fecal production increased after PEN exposure, suggesting the implementation of rejection mechanisms for inedible particles.

Bauernhofer, T., et al. (2005). "Association of disease progression and poor overall survival with detection of circulating tumor cells in peripheral blood of patients with metastatic breast cancer." Oncology Reports **13**(2): 179-184.

The aim of this study was to define the frequency and clinical relevance of cytokeratin positive metastatic tumor cells in the peripheral circulation of patients with stage IV breast cancer. Peripheral blood was collected from 32 consecutive patients with metastatic breast cancer and 23 healthy donors. Tumor cells were enriched using positive selection with anti-HEA125-microbeads and cytospins were prepared of the positive selection eluate. Slides were incubated with a Fab2 fragment of the pancytokeratin antibody A45-B/B3 conjugated with alkaline phosphatase (AKP) and a CAM5.2-AKP monoclonal antibody and developed with an alkaline phosphatase anti-alkaline phosphate reaction (APAAP). All samples were evaluated using light microscopy and an automated image analysis system. In 8/32 (25%) patients cytokeratin positive (CK+) cells could be detected after anti-HEA125 enrichment in the peripheral blood whereas in none out of 23 healthy donors. One to 1000 (median 5) positive cells per patient sample were observed and cluster of tumor cells in one patient. Automated image analysis was as powerful in detecting micrometastases as conventional light microscopy. All patients with CK+ cells in the peripheral circulation (8/8, 100%) showed progressive disease at the time-point of blood draw whilst only 9/24 (37.5%) showed disease progression without detection of positive cells. The median overall survival of CK+ patients was 4+/-2 months compared to 13+/-7 months of CK- patients (p<0.001). CK+ cells are detectable in the peripheral circulation of 25% of patients with metastatic breast cancer after positive selection with anti-HEA125. Detection of tumor cells in the peripheral circulation might be correlated with progression of disease and shorter overall survival.

Bawazer, L. A., et al. (2012). "Evolutionary selection of enzymatically synthesized semiconductors from biomimetic mineralization vesicles." Proceedings of the National Academy of Sciences of the United

States of America **109**(26).

The way nature evolves and sculpts materials using proteins inspires new approaches to materials engineering but is still not completely understood. Here, we present a cell-free synthetic biological platform to advance studies of biologically synthesized solid-state materials. This platform is capable of simultaneously exerting many of the hierarchical levels of control found in natural biomineralization, including genetic, chemical, spatial, structural, and morphological control, while supporting the evolutionary selection of new mineralizing proteins and the corresponding genetically encoded materials that they produce. DNA-directed protein expression and enzymatic mineralization occur on polystyrene microbeads in water-in-oil emulsions, yielding synthetic surrogates of biomineralizing cells that are then screened by flow sorting, with light-scattering signals used to sort the resulting mineralized composites differentially. We demonstrate the utility of this platform by evolutionarily selecting newly identified silicateins, biomineralizing enzymes previously identified from the silica skeleton of a marine sponge, for enzyme variants capable of synthesizing silicon dioxide (silica) or titanium dioxide (titania) composites. Mineral composites of intermediate strength are preferentially selected to remain intact for identification during cell sorting, and then to collapse postsorting to expose the encoding genes for enzymatic DNA amplification. Some of the newly selected silicatein variants catalyze the formation of crystalline silicates, whereas the parent silicateins lack this ability. The demonstrated bioengineered route to previously undescribed materials introduces in vitro enzyme selection as a viable strategy for mimicking genetic evolution of materials as it occurs in nature. Baynham, R. (2015). "Reform would solve confidence crisis." Materials Recycling World **204**(8): 19-19.

The author discusses the issues faced by Closed Loop Recycling Ltd. and many other plastic recycling companies in Great Britain which include the strong demand for unprocessed plastic waste from export markets that has kept prices at level and untenable by recyclers during volatility in prime polymer prices due to lower oil prices. It notes the proposal of British Plastics Federation Recycling Group to amend the packaging recovery note (PRN).

Bayo, J., et al. (2018). "Microplastics as vector for persistent organic pollutants in urban effluents: the role of polychlorinated biphenyls. (Special Issue: Sustainable city.)." International Journal of Sustainable Development and Planning **13**(4): 671-682.

The presence of microplastics in the environment is considered a global threat, not only for the physical damage induced to the organisms that ingest them and leachability of their constituent, but also as a potential carrier of organic and inorganic contaminants, with an interaction poorly described. Microbeads collected from four facial cleansers, with a well-known polymeric and additive composition, were used as an indicator for the sorption of polychlorinated biphenyls (PCBs) in treated urban effluents, in order to study the behavior of microplastics versus these persistent organic pollutants in water. A stock standard solution (EPA 525, 525.1 PCB mix) was used for this purpose, being a certified material produced in accordance with ISO Guide 34:2009 and ISO/IEC 17025:2005. It consists of a mixture of eight congeners: PCB1, PCB5, PCB31, PCB47, PCB91, PCB154, PCB171 and PCB200 in n-hexane (500 micro g/ml of each component). Sorption experiments were carried out in batch mode, previously in bi-distilled water, and finally in treated urban effluents. PCB congeners retained by microplastics and remaining in water were further analyzed by means of gas chromatography, using a protocol previously described with an initial column temperature of 70 degrees C and a ramp of 10 degrees C/min up to 150 degrees C, 3 degrees C/min up to 200 degrees C, and 8 degrees C/min to a final temperature of 280 degrees C. The sorption process proved to be reliable and repeatable both for samples in bi-distilled water and treated urban effluents, showing different interactions between the organic pollutants and the microplastics. PCB congeners with a low-molecular weight proved to be preferentially sorbed by an oxidized polyethylene included in one of the microbeads, although the maximum amount for total PCB sorption was for the facial cleanser with TiO₂ in its composition.

Bayo, J., et al. (2017). "Microbeads in commercial facial cleansers: threatening the environment." CLEAN Soil, Air, Water **45**(7).

The presence of primary microplastics in the environment is considered a major concern because of three main reasons: the physical damage to organisms that ingest them, the leaching of constituent contaminants such as monomers or additives, and the sorption of inorganic and organic chemicals. Microbeads collected from four facial cleansers, a personal care product commonly used by European consumers, have been analyzed in this paper. The variability in size distribution, specific surface area, the oxidation state of the polymer and the presence of whitening agents in one of the cosmetic formulations proved to be related with the ability to sorb heavy metals and polychlorinated biphenyls (PCBs), both in bi-distilled water and treated urban effluents. The sorption process for heavy metals proved to be related to a physical mechanism, without a specific interaction between the adsorbate and the microbead. In the case of PCBs, low molecular weight congeners proved to be preferentially sorbed by oxidized polyethylene (Microbead-B, MB-B), although the maximum amount for total PCBs sorption was for the facial cleanser with TiO₂ in its composition (Microbead-A, MB-A) and a moderate ecotoxicity. Regression models developed for PCBs showed a similar behavior of these pollutants in bi-distilled and real treated urban effluents for microbeads, indicating that the exposed surface area was not the only mechanism responsible for sorption, but also the specific partitioning into the bulk microplastic.

Bayo, J., et al. (2018). "Non-polymeric chemicals or additives associated with microplastic particulate fraction in a treated urban effluent." WIT Transactions on the Built Environment **179**: 303-314.

The presence of microplastics in freshwater environments is of emerging concern, because they have been ubiquitously detected. Different adverse effects have been described in ingesting organisms: physical damage due to the plastic particles themselves, leaching of constituent monomers, the potential transport of organic and inorganic pollutants, and leaching of additives used in the manufacturing and polymerization of plastic products. In this last case, especially when additives are not chemically bound to the polymer structure, may be leached out into the aquatic environment. This paper deals with the role of wastewater treatment plants as sources of additives associated to particulate forms. A 9.0% of particulate fraction was a source of plastic additives, such as antioxidants, lubricants, corrosion inhibitors, plasticizers, adhesives, heat stabilizers or flame retardants, among others. The main plastic additives found in the wastewater samples were Zn/Ca PVC stabilizer, Methyl Tin Mercaptide (MTM), Ethoxylated Tallow Alkyl Amine (ETAA), Methyl Alkyl Imidazoline Sodium Salts (MAISS), Butyl Ricinoleate (BR), Di-o-benzamido diphenyl disulfide (DBD), RTV-730 and Molybdenum-Zinc Oxygen Complex (MZO Complex). There was a statistically significant removal of all of them after the wastewater treatment process, accounting for a 91.14%, although some of them proved to disappear in the biological reactor or even in the primary clarifier.

Bayo, J., et al. (2020). "Microplastics in an urban wastewater treatment plant: The influence of physicochemical parameters and environmental factors." Chemosphere **238**: 124593.

This paper presents the abundance, concentration and variability of microplastics (MP) in an

urban wastewater treatment plant (WWTP), according to different water parameters and environmental factors, their possible sources and removal efficiency. A total of 352.6L of wastewater from four stages of the treatment process were processed following a standardized extraction protocol by density separation, trinocular microscopic identification and polymeric analysis by Fourier transform infrared spectroscopy. MP comprised a 46.6% of total microlitter, with a statistically significant removal of 90.3% in the final effluent of the WWTP. Five different shapes were isolated; i.e. fragment, film, bead, fiber, and foam. The most prominent MP forms in the final effluent were fragments and fibers, with the most common size class being 400-600mum. Seventeen different polymer families were identified, with low-density polyethylene being the most prevalent one (52.4%) in a film form (27.7%), mostly from agriculture greenhouses near the sewage plant and single plastic bags (it is noted that only a year ago consumers are charged for them in Spain). Influent wastewater with high concentrations of suspended solids proved to have a low MP burden with a larger MP size, possibly due to a hetero-aggregation with particulate matter. Agglomeration of polystyrene and polyethylene terephthalate with organic material is also suggested, both with surface energies higher than 25mNm⁻¹ enough for a high biofouling rate. The sewage plant cushions sharp-point microplastic concentrations during the warm season, allowing a stable performance of the WWTP.

Bayo, J., et al. (2016). "Microplastics and microfibers in the sludge of a municipal wastewater treatment plant." International Journal of Sustainable Development and Planning **11**(5): 812-821.

The presence of microplastics and synthetic microfibers in the environment is increasing, causing an accumulation in the food chain because their ingestion by different organisms in the ecological community. This paper deals with the importance of wastewater treatment plants (WWTPs) as a source of microplastics and microfibers from the sludge to the environment. These micropollutants have been monitored in an urban WWTP during 2015, after being separated from the sludge. Micro-pollutants were extracted by flotation, using a concentrated solution of sodium chloride and several stainless steel sieves. After an initial screening performed with a trinocular microscope, the samples were analyzed by Fourier transform infrared spectrometry and a differential scanning calorimeter, this last technique only for the identified subsamples. Significant matches with databases could be observed, identifying different compounds such as polypropylene, Nylon copyright , transparent thermoplastic polyamides, norbornene, and ethyl acrylate, among others. These microplastics and microfibers could be transported with organic matter on fertilizers, being used as compost in the field crops of Campo de Cartagena.

Bayo, J., et al. (2019). "Abundance, morphology and chemical composition of microplastics in sand and sediments from a protected coastal area: The Mar Menor lagoon (SE Spain)." Environmental Pollution **252**: 1357-1366.

This paper presents the abundance and ubiquitous presence of microplastics in a protected coastal zone located in the southeast of Spain: The Mar Menor lagoon, an important tourist destination in this region. Seventeen sampling sites, corresponding to both intertidal and backshore points, were collected during winter 2017 and 2018, being situated in different protected areas according to international, European and Spanish environmental policies. The main objectives of the study were to examine microplastics in both protected and non-protected areas, and to test the importance of local activities on their presence. Northwest samples reported higher average microplastic concentrations than samples collected in the southeastern part of the coastal lagoon, likely due to the extensive use of sludge from wastewater treatment plants besides the fragmentation of low density polyethylene from plastic greenhouses, being microplastic films also higher for northwest than for southeast samples. Moreover, large inter-site differences observed in microplastic concentrations also demonstrated that local activities, mainly tourism and fishery, may play an important role as microplastic sources. The extensive amount of 17 different polymer types identified in this paper, much higher than most reported in similar studies, together with the variety of colors of microplastics most of them in a fragmented form (59.4%) and mainly detected in urban beaches, should be related to the geographical situation of this coastal lagoon, together with enormous environmental passives accumulated over the past 50 years. Only polyvinyl ester resins proved to be statistically higher in non-protected than in protected zones, probably related to their use in manufacturing boat hulls, although sources and pathways for microplastics are always difficult to assess. Measures to avoid microplastic pollution should be taken through educational programs, with also a clear commitment from plastic producers and transformers. Image 1 • Microplastic represented 51.1% of total microlitter. • Microplastic concentrations were highest northwest, consistent with water runoff. • Local activities; i.e., tourism and fishery, also influence microplastic abundance. • Film forms mainly made up of LDPE were present as a consequence of plastic greenhouses degradation. [ABSTRACT FROM AUTHOR]

Bayramoglu, G. and M. Y. Arica (2017). "Polyethylenimine and tris(2-aminoethyl)amine modified p(GA-EGMA) microbeads for sorption of uranium ions: equilibrium, kinetic and thermodynamic studies." Journal of Radioanalytical and Nuclear Chemistry **312**(2): 293-303.

Poly(glycidyl methacrylate-ethyleneglycol dimethacrylate), p(GA-EGMA), microbeads were prepared through suspension polymerization. It was decorated with polyethylene imine (PEIM) and tris(2-aminoethyl)amine (TAEA) ligands to decorate with polyamine groups. These microbeads were used for sorption of uranium ions from aqueous solution. The maximum sorption of uranium ions on the PEIM and TAEA modified microbeads was observed at pH 6.0. The maximum sorption capacity of acid hydrolyzed p(GA-EGMA)-OH, p(GA-EGMA)-PEIM and p(GA-EGMA)-TAEA microbeads was found to be 7.21, 87.8 and 64.3 mg g⁻¹. The sorption process conforms to the pseudo-second order kinetic model and the Langmuir and Temkin isotherm models well. Copyright © 2017, Akademiai Kiado, Budapest, Hungary.

Bayramoglu, G., et al. (2016). "Removal of bisphenol A from aqueous medium using molecularly surface imprinted microbeads." Chemosphere **150**: 275-284.

The aim of this study is to prepare bisphenol A (BPA) imprinted polymers, which can be used for the selective removal of BPA from aqueous medium. The BPA-imprinted (MIP) and non-imprinted (NIP) microbeads were synthesized, and characterized by Zeta-sizer, FTIR, SEM and BET method. Bisphenol A was determined in solutions using liquid chromatography-mass spectroscopy (LC-MS). The effect of initial concentration of BPA, the adsorption rate and the pH of the medium on the capacity of BPA-imprinting polymer were studied. Adsorption capacity of BPA was affected by the amount of the incorporated functional monomer in the polymer network. BPA adsorption capacity of MIP-3 and NIP microbeads from aqueous medium was estimated as 76.7 and 59.9 mg g(-1), respectively. The binding efficiencies of BPA-MIP-3

microbeads for different phenolic compounds (i.e., BPA with p-toluidine, 4-aminophenol or 2-naphthol) were explored at binary solutions, and the binding capacities of BPA-imprinted microbeads were found to be 2.79 x 10(-1), 2.39 x 10(-1), 7.59 x 10(-2) and 5.48 x 10(-2) mmol g(-1) microbeads, respectively. The satisfactory results demonstrated that the obtained BPA-MIP microbeads showed an appreciable binding specificity toward BPA than similar structural compounds in the aqueous medium. Moreover, the reusability of BPA-MIP-3 microbeads was tested for several times and no significant loss in adsorption capacity was observed. Finally, the binary and multi-component systems results show that MIP-3 microbeads have special recognition selectivity and excellent binding affinity for template molecule "BPA".

Bayramoglu, G., et al. (2011). "Immobilization of catalase via adsorption on poly(styrene-d-glycidylmethacrylate) grafted and tetraethyldiethylenetriamine ligand attached microbeads." Bioresource Technology **102**(4): 3653-3661.

Fibrous poly(styrene-d-glycidylmethacrylate) (P(S-GMA)) brushes were grafted on poly(styrene-divinylbenzene) (P(S-DVB)) beads using surface initiated-atom transfer radical polymerization (SI-ATRP). Tetraethyldiethylenetriamine (TEDETA) ligand was incorporated on P(GMA) block. The multi-modal ligand attached beads were used for reversible immobilization of catalase. The influences of pH, ionic strength and initial catalase concentration on the immobilization capacities of the P(S-DVB)-g-P(S-GMA)-TEDETA beads have been investigated. Catalase adsorption capacity of P(S-DVB-g-P(S-GMA)-TEDETA beads was found to be 40.8 +/- 1.7 mg/g beads at pH 6.5 (with an initial catalase concentration 1.0mg/mL). The K(m) value for immobilized catalase on the P(S-DVB-g-P(S-GMA)-TEDETA beads (0.43 +/- 0.02 mM) was found about 1.7-fold higher than that of free enzyme (0.25 +/- 0.03 mM). Optimum operational temperature and pH was increased upon immobilization. The same support was repeatedly used five times for immobilization of catalase after regeneration without significant loss in adsorption capacity or enzyme activity.

Bazilchuk, N. (2006). "High-Seas Garbage Pickup." Conservation in Practice **7**(1): 1.

The article describes an effort to track ocean debris aboard a National Oceanic and Atmospheric Administration hurricane hunter airplane in the Pacific. The crew of the airplane found plastic fishing debris, such as individual floats and great balls of netting. Fishing nets kill fish and marine mammals and harming coral reefs. Abandoned fishing nets in the North Pacific also damage the Hawaiian archipelago.

Baztan, J., et al. (2014). "Protected areas in the Atlantic facing the hazards of micro-plastic pollution: First diagnosis of three islands in the Canary Current." Marine Pollution Bulletin **80**(1-2): 302-311.

Coastal zones and the biosphere as a whole show signs of cumulative degradation due to the use and disposal of plastics. To better understand the manifestation of plastic pollution in the Atlantic Ocean, we partnered with local communities to determine the concentrations of micro-plastics in 125 beaches on three islands in the Canary Current: Lanzarote, La Graciosa, and Fuerteventura. We found that, in spite of being located in highly-protected natural areas, all beaches in our study area are exceedingly vulnerable to micro-plastic pollution, with pollution levels reaching concentrations greater than 100. g of plastic in 1. l of sediment. This paper contributes to ongoing efforts to develop solutions to plastic pollution by addressing the questions: (i) Where does this pollution come from?; (ii) How much plastic pollution is in the world's oceans and coastal zones?; (iii) What are the consequences for the biosphere?; and (iv) What are possible solutions?. © 2014 Elsevier Ltd.

Beato, F., et al. (2012). "Purification and expansion of antigen-specific human tregs for clinical application using a single step CD25 positive selection." Blood. Conference: 54th Annual Meeting of the American Society of Hematology, ASH **120**(21).

Background: Regulatory T cells (Tregs) play a role in maintaining T cell homeostasis and self-tolerance. Tregs immunotherapy has great potential for the prevention of allograft rejection and graft-vs-host disease (GVHD), but GMP reagents and procedures are required for clinical use. We have shown that allo-specific Tregs can be isolated by positive CD25 selection and negative selection of CD127, CD8 and CD19 by Miltenyi immunobeads, and then expanded in amounts sufficient for potential clinical use. Such a number of immunobeads would make a GMP procedure so costly to be clinically unaffordable. Therefore, in this study we tested whether a single step of CD25 positive selection using magnetic micro beads followed by expansion with allogeneic DC, rapamycin, IL-2, and IL-15 for 12 days generates Tregs that retain their phenotype (Foxp3) expression to a high level, are minimally contaminated with non-Tregs, and are highly suppressive. We explored a simplified approach that employs only CD25 positive selection, followed by culture. Concerns still remain on the purity and contamination of the expanded population, in particular contamination with cytotoxic CD8⁺T cells as these cells could have unfavorable outcomes in immunotherapy trials. Method(s): We purified Tregs using the 'clinical grade' CD25 human positive selection magnetic beads from Miltenyi; we then labeled the Tregs with CFSE and cultured with allogeneic monocyte-derived DC as stimulus in the presence of rapamycin, IL-2 and IL-15. At the end of 12 days expanded allo-specific Tregs were analyzed for their phenotype, sorted and tested for alloreactive and suppressive functions. We performed a total of 10 experiments: Results: The purity of CD4⁺CD25⁺CD127dim Foxp3⁺after the initial separation ranged from 20-83%, median-44%. (Table Presented) To assess whether the non-Tregs in the culture were allo-reactive we sorted the expanded Tregs into: CFSE⁺CD25⁺, CFSE-CD25-, CFSE⁺CD25-, CFSE-CD25⁺, we then set up a 3 and 6 days mixed leukocyte reaction (MLR) against the initial stimulator or self. Non-Tregs in the culture did not respond to antigen with or without IL-2, whereas the allo-reactive Tregs, CFSE-CD25⁺, responded to allogeneic DC only in the presence of IL-2. CFSE⁺ Tregs did not respond even in the presence of IL-2. To determine whether the entire expanded population was enriched with antigen specific suppression, we culture the enriched 'Tregs' at various ratios with naive autologous CD4⁺CD25-responder T cells and allogeneic DC from original stimulator, and found that a 50% suppression was achieved with a 1:2000 Treg:Tconv ratio. To analyze fidelity of cytokine secretion profile, we re-stimulated cultured 'Tregs' with allogeneic DC or PMA/Iononycin and compared data to expanded Tconv from the same individual; Tregs had significantly more TGF-beta and less TNF-alpha secretion than Tconv. Conclusion(s): Our data demonstrate that Tregs purified with the GMP-compatible CD25 Miltenyi immunobeads can be expanded, retain high levels of Foxp3 expression, and maintain high suppressive potency. The frequency of contaminating cells after culture was small and we did not observed residual alloreactivity.

Beaumont, N. J., et al. (2019). "Global ecological, social and economic impacts of marine plastic." Marine Pollution Bulletin **142**: 189-195.

This research takes a holistic approach to considering the consequences of marine plastic pollution. A semi-systematic literature review of 1191 data points provides the basis to determine the global ecological, social and economic impacts. An ecosystem impact analysis demonstrates that there is global evidence of impact with medium to high frequency on all subjects, with a medium to high degree of irreversibility. A novel translation of these ecological impacts into ecosystem service impacts provides evidence that all ecosystem services are impacted to some extent by the presence of marine plastic, with a reduction in provision predicted for all except one. This reduction in ecosystem service provision is evidenced to have implications for human health and wellbeing, linked particularly to fisheries, heritage and charismatic species, and recreation.

Becker-Merok, A., et al. (2012). "Interferon-alpha2 protein levels are increased in the majority of patients with systemic lupus erythematosus and associated with disease activity and activation of multiple cytokines." Scandinavian Journal of Rheumatology **126)**: 25.

Background: Associations between systemic lupus erythematosus (SLE) and mutations in interferon (IFN) regulatory factor genes and expression of IFNinducible genes are well known. The impact of circulating IFN-alpha protein in SLE has not yet been studied extensively. Objective(s): To determine the function of circulating IFN-alpha protein in SLE. Method(s): We used a highly sensitive solution-phase multiplex magnetized bead assay to investigate circulating levels of IFN-alpha2 in relation to autoantibody profiles, clinical disease activity, and other inflammatory cytokines in a cross-sectional study of SLE patients (n = 87). Cytokine levels were determined on stored sera aliquots and cut-off levels were determined by the geometric mean + 2 SD in healthy controls (n = 27). Result(s): IFN-alpha2 levels were increased in 64% of SLE patients, who displayed a higher prevalence of ongoing renal disease (nephritis defined as proteinuria > 0.5 g/24 h with active urinary sediment; 0 vs. 11%, p = 0.06), higher disease activity [SLE Disease Activity Index (SLEDAI) score 4 vs. 8, p = 0.07], and had a significantly higher sum of activated cytokines (median 4.5, range 7) compared to patients with normal IFN-alpha2 (median 1, range 3; p < 0.001). Conclusion(s): Solution-phase microbead assay identified increased IFN-alpha2 levels in two-thirds of SLE patients with longstanding disease. These data indicate that IFN-alpha2 not only is a susceptibility factor for SLE but also has a role in disease perpetuation in a large subset of SLE patients. The results are encouraging with respect to potential therapeutic implications.

Becker-Merok, A., et al. (2013). "Circulating interferon-alpha2 levels are increased in the majority of patients with systemic lupus erythematosus and are associated with disease activity and multiple cytokine activation." Lupus **22**(2): 155-163.

Mutations in interferon (IFN) regulatory factor genes and the biological activity of type I IFN on expression of specific genes that are induced by IFN have been associated with various aspects of systemic lupus erythematosus (SLE). Circulating levels of IFN-alpha in SLE has not been extensively studied because of limited sensitivity of available ELISA assays. We performed a cross-sectional case-control study where circulating levels of IFN-alpha2 were measured by a highly sensitive, solution phase multiplex magnetized bead assay and investigated the relation of IFN-alpha2 with autoantibody profiles, clinical disease activity and levels of inflammatory cytokines in SLE patients (n = 87). Cytokine levels were determined on stored sera aliquots with cut-off levels determined by the geometric mean + 2SD in healthy controls (n = 27). IFN-alpha2 levels were increased in 64% of SLE patients, who displayed more renal disease and higher disease activity (p = 0.06) and had a significantly higher sum of activated cytokines (median 4.5, range 7) compared to patients with normal IFN-alpha2 (median one, range 3; p < 0.001). Solution phase micro-bead assay thus identified increased IFN-alpha2 levels in two-thirds of SLE patients with longstanding disease. The association with clinical disease and activation of multiple inflammatory cytokines supports a role for IFN-alpha2 in disease perpetuation in a large subset of SLE patients.

Beckingham, B. and U. Ghosh (2017). "Differential bioavailability of polychlorinated biphenyls associated with environmental particles: Microplastic in comparison to wood, coal and biochar." Environmental Pollution **Part A. 220**: 150-158.

Microplastic particles are increasingly being discovered in diverse habitats and a host of species are found to ingest them. Since plastics are known to sorb hydrophobic organic contaminants (HOCs) there is a question of what risk of chemical exposure is posed to aquatic biota from microplastic-associated contaminants. We investigate bioavailability of polychlorinated biphenyls (PCBs) from polypropylene microplastic by measuring solid-water distribution coefficients, gut fluid solubilization, and bioaccumulation using sediment invertebrate worms as a test system. Microplastic-associated PCBs are placed in a differential bioavailability framework by comparing the results to several other natural and anthrogenic particles, including wood, coal, and biochar. PCB distribution coefficients for polypropylene were higher than natural organic materials like wood, but in the range of lipids and sediment organic carbon, and smaller than black carbons like coal and biochars. Gut fluid solubilization potential increased in the order: coal < polypropylene < biochar < wood. Interestingly, lower gut fluid solubilization for polypropylene than biochar infers that gut fluid micelles may have solubilized part of the biochar matrix while bioaccessibility from plastic can be limited by the solubilizing potential of gut fluids dependent on the solid to liquid ratio or renewal of fluids in the gut. Biouptake in worms was lower by 76% when PCBs were associated with polypropylene compared to sediment. The presence of microplastics in sediments had an overall impact of reducing bioavailability and transfer of HOCs to sediment-ingesting organisms. Since the vast majority of sediment and suspended particles in the environment are natural organic and inorganic materials, pollutant transfer through particle ingestion will be dominated by these particles and not microplastics. Therefore, these results support the conclusion that in most cases the transfer of organic pollutants to aquatic organisms from microplastic in the diet is likely a small contribution compared to other natural pathways of exposure. Beckman, J. A., et al. (2019). "Comparative Transcriptomics of Ex Vivo, Patient-Derived Endothelial Cells Reveals Novel Pathways Associated With Type 2 Diabetes Mellitus." JACC **4**(5): 567-574.

In this study low-input RNA-sequencing was used to annotate the molecular identity of endothelial cells isolated and immunopurified with CD144 microbeads. Using this technique, comparative gene expression profiling from healthy subjects and patients with type 2 diabetes mellitus identified both known and novel pathways linked with EC dysfunction. Modeling of diabetes by treating cultured ECs with high glucose identified shared changes in gene expression in diabetic cells. Overall, the data demonstrate how purified ECs from patients can be used to generate new hypotheses about mechanisms of human vascular disease.

Beckwith, V. K. and M. M. P. B. Fuentes (2018). "Microplastic at nesting grounds used by the northern Gulf of Mexico loggerhead recovery unit." Marine Pollution Bulletin **131**: 32-37.

Microplastics can impact key habitats used by endangered species, such as marine turtles. They impact the environment by transporting toxicants and altering sediment properties affecting temperature and sediment permeability. Our study determined the exposure of the ten most important nesting sites for the Northern Gulf of Mexico Loggerhead Recovery Unit to microplastic. Sand samples were obtained at each nesting site during the 2017 nesting season and analyzed for abundance and characteristics of microplastic. Microplastic was found at all sites, with an average abundance of 61.08+or-34.61 pieces/m², and 59.9% located at the dunes, where turtles primarily nest. A gradual decrease in microplastics abundance was observed from the most western nesting ground to the east. The results from this study indicate that microplastic accumulation on nesting sites for the Northern Gulf of Mexico may be of great concern, and could negatively affect the incubating environment for marine turtles.

Becquart, P., et al. (2006). "Quantitation of HIV-1 RNA in breast milk by real time PCR." Journal of Virological Methods **133**(1): 109-111.

HIV-1 RNA in breast milk is a strong predictor of HIV-1 transmission through breastfeeding. In the present report, breast milk samples from HIV-1 uninfected donors were spiked with dilution of quantified culture supernatant from HIV-1_{NDK} infected PBMC. Two RNA extraction techniques based on silica extraction, NuclisensReg. (BioMerieux) and Triazol (Qiagen), two techniques based on guanidine thiocynanate/chloroforme extraction, TRIzol (Life Technologie) and Amplicor HIV-1 Monitor^{TM} (Roche Diagnostic Systems), and one technique based on electrostatic adsorption on iron oxide micro beads (Promega) were compared. HIV-1 RNA was quantitated by real time PCR (LTR gene) and Amplicor HIV-1 Monitor^{TM}. Combining magnetic micro beads extraction and real time PCR quantitation allowed to correctly quantify breast milk HIV-1 RNA, with a difference between the expected and measured HIV-1 RNA levels always lower than 0.3 log copies/ml. The same combination was confirmed on 25 breast milk samples from HIV-1 infected women collected in Kwazulu-Natal, South Africa, by comparing measurements with those obtained by the Amplicor HIV-1 Monitor^{TM} (r²=0.88). Nucleic acid extraction by magnetic micro beads followed by real time PCR is a reliable, sensitive, rapid and simple procedure to quantify HIV-1 RNA in breast milk and allows for PCR inhibitors found frequently in these samples.

Beer, S., et al. (2018). "No increase in marine microplastic concentration over the last three decades - A case study from the Baltic Sea." Science of the Total Environment **621**: 1272-1279.

Microplastic is considered a potential threat to marine life as it is ingested by a wide variety of species. Most studies on microplastic ingestion are short-term investigations and little is currently known about how this potential threat has developed over the last decades where global plastic production has increased exponentially. Here we present the first long-term study on microplastic in the marine environment, covering three decades from 1987 to 2015, based on a unique sample set originally collected and conserved for food web studies. We investigated the microplastic concentration in plankton samples and in digestive tracts of two economically and ecologically important planktivorous forage fish species, Atlantic herring (Clupea harengus) and European sprat (Sprattus sprattus), in the Baltic Sea, an ecosystem which is under high anthropogenic pressure and has undergone considerable changes over the past decades. Surprisingly, neither the concentration of microplastic in the plankton samples nor in the digestive tracts changed significantly over the investigated time period. Average microplastic concentration in the plankton samples was 0.21+/-0.15particlesm⁻³. Of 814 fish examined, 20% contained plastic particles, of which 95% were characterized as microplastic (<5mm) and of these 93% were fibres. There were no significant differences in the plastic content between species, locations, or time of day the fish were caught. However, fish size and microplastic in the digestive tracts were positively correlated, and the fish contained more plastic during summer than during spring, which may be explained by increased food uptake with size and seasonal differences in feeding activity. This study highlights that even though microplastic has been present in the Baltic environment and the digestive tracts of fishes for decades, the levels have not changed in this period. This underscores the need for greater understanding of how plastic is cycled through marine ecosystems. The stability of plastic concentration and contamination over time observed here indicates that the type and level of

microplastic pollution may be more closely correlated to specific human activities in a region than to global plastic production and utilization as such.

Beiras, R., et al. (2018). "Ingestion and contact with polyethylene microplastics does not cause acute toxicity on marine zooplankton." Journal of Hazardous Materials **360**: 452-460.

Toxicity of polyethylene microplastics (PE-MP) of size ranges similar to their natural food to zooplanktonic organisms representative of the main taxa present in marine plankton, including rotifers, copepods, bivalves, echinoderms and fish, was evaluated. Early life stages (ELS) were prioritized as testing models in order to maximize sensitivity. Treatments included particles spiked with benzophenone-3 (BP-3), a hydrophobic organic chemical used in cosmetics with direct input in coastal areas. Despite documented ingestion of both virgin and BP-3 spiked microplastics no acute toxicity was found at loads orders of magnitude above environmentally relevant concentrations on any of the invertebrate models. In fish tests some effects, including premature or reduced hatching, were observed after 12 d exposure at 10 mg L-1 of BP-3 spiked PE-MP. The results obtained do not support environmentally relevant risk of microplastics on marine zooplankton. Similar approaches testing more hydrophobic chemicals with higher acute toxicity are needed before these conclusions could be extended to other organic pollutants common in marine ecosystems. Therefore, the replacement of these polymers in consumer products must be carefully considered.

Beiras, R., et al. (2019). "Polyethylene microplastics do not increase bioaccumulation or toxicity of nonylphenol and 4-MBC to marine zooplankton." Science of the Total Environment **692**: 1-9.

Global production of synthetic polymers, led by polyethylene (PE), rose steadily in the last decades, and marine ecosystems are considered as a global sink. Although PE is not biodegradable, in coastal areas it fragments into microplastics (MP) readily taken up by biota, and have been postulated as vectors of hydrophobic chemicals to marine organisms. We have tested this hypothesis using two organisms representative of the marine plankton, the holoplanktonic copepod Acartia clausi, and the meroplanktonic larva of the Paracentrotus lividus sea-urchin, and two model chemicals with similar hydrophobic properties, the 4-n-Nonylphenol and the 4-Methylbenzylidene-camphor used as plastic additive and UV filter in cosmetics. Both test species actively ingested the MP particles. However, the presence of MP never increased the bioaccumulation of neither model chemicals, nor their toxicity to the exposed organisms. Bioaccumulation was a linear function of waterborne chemical disregarding the level of MP. Toxicity, assessed by the threshold (EC₁₀) and median (EC₅₀) effect levels, was either independent of the level of MP or even in some instances significantly decreased in the presence of MPs. These consistent results challenge the assumption that MP act as vectors of hydrophobic chemicals to planktonic marine organisms.

Beiras, R. and T. Tato (2019). "Microplastics do not increase toxicity of a hydrophobic organic chemical to marine plankton." Marine Pollution Bulletin **138**: 58-62.

Planktonic sea-urchin larvae actively ingest polyethylene microplastics (MP) that accumulate in the larval stomach and can be distinguished from natural food using polarized light microscopy. MP filtering rates were similar to those of natural particles (microalgae) of the same size range; 0.30 to 0.35 mL min⁻¹. However, the ingestion of MP did not increase the toxicity of a hydrophobic organic chemical, the 4-n-nonylphenol (NP), either in microalgae-fed or starved larvae. The 48 h EC₅₀ of NP was more than two fold higher in fed (158.8 to 190.9 micro g L⁻¹) compared to starved larvae (64.3 to 83.7 micro g L⁻¹), disregarding the presence and amount of MP, which did not significantly affect larval growth. Therefore, MP did not act as vectors of a hydrophobic chemical such as NP to these planktonic organisms. These results challenge the hypothetical role of MP as vectors of organic contaminants to marine food webs.

Beiras, R., et al. (2019). "A 2-Tier standard method to test the toxicity of microplastics in marine water using <i>Paracentrotus lividu</i>s and <i>Acartia clausi</i> larvae." Environmental Toxicology and Chemistry **38**(3): 630-637.

A 2-tier standardized protocol was designed to test the toxicity of microplastics to planktonic organisms. This approach uses sea urchin (Paracentrotus lividus) and copepod (Acartia clausi) larvae because they are common biological models in marine research, and standard methods for toxicity testing with regulatory applications are available. In Tier I, leachates obtained at a 100 to 1 liquid to solid ratio are tested, and toxic units are calculated using a probit dose–response model to quantify the toxicity of the plastics. In Tier II, which is conducted only if significant toxicity (> 1 toxic unit) is found in Tier I, particles less than 20 μm in size are tested at concentrations between 0.1 and 10 mg L−1, and a toxicity threshold suitable for ranking materials according to their toxicity is obtained from the 10% effect concentration (EC10) values. Results point to chemical additives as being responsible for the toxicity found in certain plastic materials. This process is suitable for both a priori identification of the hazard posed by plastic objects in the aquatic environment, and a posteriori assessment of environmental risk caused by microplastic pollution. The method also provides a quantitative procedure appropriate for ranking plastic materials according to their toxicity to aquatic organisms. Environ Toxicol Chem 2019;38:630–637. © 2018 SETAC

Bekhit, M., et al. (2016). "Encapsulation of Lactococcus lactis subsp. lactis on alginate/pectin composite microbeads: effect of matrix composition on bacterial survival and nisin release." Journal of Food Engineering **180**: 1-9.

Alginate/pectin hydrogel microspheres were prepared by extrusion based on a vibrating technology to encapsulate bacteriocin-producing lactic acid bacteria. Effects of both alginate/pectin (A/P) biopolymers ratio and physiological state of Lactococcus lactis subsp. lactis (exponential phase, stationary phase) were examined for nisin release properties, L. lactis survival and beads physico-chemical properties. Results showed that A/P composites were more efficient to increase beads properties than those formulated with pure alginate or pectin. Association of alginate and pectin induces synergistic effect which improves microbeads mechanical properties. FTIR spectroscopy confirms possible interactions between alginate and pectin during inter-penetrating network formation. Physiological state of bacteria during encapsulation process and microbeads composition (A/P ratio, enrichment of internal medium with nutrients) were determining factors for both bacteria viability and bacteriocin release. Of the several matrices tested A/P (75/25) with glucose-enriched M17 gave the best results when L. lactis was encapsulated in exponential state.

Belak-Cvitanovi, A., et al. (2011). Comparative analysis of different alginate-based immobilization systems for encapsulation of polyphenolic antioxidants from red raspberry leaves (Rubus idaeus L.) by electrostatic extrusion. 7th International Congress of Food Technologists, Biotechnologists and Nutritionists, 2011, September 20, 2011 - September 23, 2011, Opatija, Croatia, Croatian Society of Food Technologists, Biotechnologists and Nutritionists.

Traditionally used in folk medicine for its health benefits, leaves of red raspberry (Rubus idaeus L.) present a rich source of bioactive compunds and contributes to an increase of the overall intake of bioactive compounds in the daily diet, so an effective supplementation form containing red raspberry leaves bioactives should be established. Up to date spray drying has been mainly used as a technique for the entrappment of polyphenolic compounds from various plant substrates. Since spray-drying requires complex equipment and high energy inputs, a need arises for development of an effective immobilization system applying a simple technique, such as electrostatic extrusion. The aim of this study was to encapsulate polyphenolic compounds from red raspberry leaves extract in different alginate-based matrices using electrostatic extrusion. For that purpose plain alginate, as well as caseine and chitosan reinforced alginate microbeads were evaluated in terms of encapsulation efficiency and release profiles of polyphenols in water. The release kinetics was determined by following total phenol content and antioxidant capacity during time period of 24h, where antioxidant capacity was measured by ABTS radical scavenging assay. The obtained results revealed the same difussion controlled release patterns for all samples. The majority of polyphenolic compounds are released during 10-15 min, while the encapsulation efficiency varied between 80.5 % for alginate and 84.4 % for chitosan-alginate microbeads. In addition to alginate-based microbeads described above, Ca-alginate microbeads containing dextrose as a filler substance were prepared by absorption of raspberry leaves extract compounds in blank Ca-alginate microbeads. In this case, somewhat lower encapsulation efficiency (77%) was determined, while diffussion rate of polyphenolic compounds was nearly the same. The results suggest the potential of alginate-based microbeads prepared by electrostatic extrusion to be used for delivery of bioactive compounds, and contribute to the development of novel functional food products, as well as antioxidant-containing supplements for pharmaceutical and cosmetic aplications.

Belharet, K., et al. (2014). Study on rotational and unclogging motions of magnetic chain-like microrobot. IEEE International Conference on Intelligent Robots and Systems.

Magnetic microrobotics was nowadays one of the most advanced technique to reach deep locations in human body for future biomedical applications. Different magnetic microrobot designs were proposed, such as bead pulling or microswimmers. In this paper, the use of chain-like of magnetic N-microspheres was investigated to enable new kind of motions and applications. An accurate theoretical model of chain-like magnetic microbeads navigating in viscous fluidic environments is described. Thus, the behavior of such microrobot was analyzed for different number of microspheres (ranging from N = 2 to 5). The efficiency of the proposed technique was demonstrated experimentally in a microfluidic vessel phantom to mimic atherosclerosis disease leading to plaque formation that fully occluded a vasculature. © 2014 IEEE.

Beligaswatte, A., et al. (2013). "The mean fluorescence intensities of anti-HLA antibodies detected using micro-bead flow cytometry predict the risk of platelet transfusion refractoriness." British Journal of Haematology **162**(3): 409-412.

There are no accepted methods to predict the development of platelet transfusion refractoriness (PTR) due to human leucocyte antigen (HLA)-alloimmunization. Hence, matched platelets are usually given only to patients demonstrating PTR, necessarily resulting in some ineffective random donor platelets (RDPLT) transfusions. To assess its utility in predicting PTR, we retrospectively tested samples from 387 patients receiving chemotherapy for acute leukaemia or autologous transplantation using a micro-bead flow cytometry assay. The average of the mean fluorescence intensities (avgMFI) of the class I beads in the screening assay was correlated with outcomes of RDPLT transfusions during a 2 week period. Antibodies were detected in 57 patients; 66 developed PTR, of whom 28 were alloimmunized. avgMFI usefully predicted the development of PTR (area under the receiver operating curve 0.87, 95%

confidence interval: 0.77-0.96). A logistic regression model estimated the probability of PTR to be >90% when avgMFI >5440. These results indicate that micro-bead flow cytometry assays could inform a risk-adapted strategy for managing thrombocytopaenic HLA allo-immunized patients.

Belkaid, Y., et al. (1998). "Analysis of cytokine production by inflammatory mouse macrophages at the single-cell level: selective impairment of IL-12 induction in Leishmania-infected cells." European Journal of Immunology **28**(4): 1389-1400.

Intracellular staining for cytokines and parasites, combined with 2-colour flow cytometric analyses, were used to examine the frequencies of IL-12-, TNF- alpha - and IL-6-producing macrophages in response to Leishmania major infection and/or activation with IFN- gamma /lipopolysaccharide (LPS). Inflammatory macrophages were obtained from nonimmune granulomas, initiated by the injection of polyacrylamide microbeads (Bio-gel P-100) into subcutaneous pouches of 4 mouse strains (BALB/c, C3H/HeN, C57BL/6, CBA). Infection of inflammatory macrophages in vitro using metacyclic promastigotes produced identical effects on cytokine responses regardless of whether cells from genetically resistant or susceptible mouse strains were used: IL-12 was not produced in response to infection itself, virtually every infected cell lost its ability to produce IL-12 in response to IFN- gamma /LPS, and the IL-6 response was partially inhibited, whereas the TNF- alpha response of infected cells was unimpaired. Low-multiplicity infection of inflammatory macrophages in vivo using either metacyclic promastigotes or tissue amastigotes also resulted in the complete and selective inhibition of IL-12 responses in infected cells. These data establish the physiologic relevance of prior observations regarding the selective impairment of IL-12 induction pathways in infected macrophages, and suggest a mechanisms for the delayed onset of cell-mediated control mechanisms that is typical of even self-limiting forms of leishmanial disease.

Bellas, J., et al. (2016). "Ingestion of microplastics by demersal fish from the Spanish Atlantic and Mediterranean coasts." Marine Pollution Bulletin **109**(1): 55-60.

Microplastic pollution has received increased attention over the last few years. This study documents microplastic ingestion in three commercially relevant demersal fish species from the Spanish Atlantic and Mediterranean coasts, the lesser spotted dogfish Scyliorhinus canicula, the European hake Merluccius merluccius and the red mullet Mullus barbatus. Overall 212 fish were examined, 72 dogfish, 12 hakes and 128 red mullets. The percentage of fish with microplastics was 17.5% (15.3% dogfish, 18.8% red mullets and 16.7% hakes), averaging 1.56+or-0.5 items per fish, and the size of the microplastics ranged from 0.38 to 3.1 mm. These fish species are used currently as biomonitors for marine pollution monitoring within the Spanish Marine Pollution Monitoring Programme (SMP), and may be as well suitable candidates for monitoring spatial and temporal trends of ingested litter. The data presented here represent a baseline for the implementation of the Marine Strategy Framework Directive descriptor 10 in Spain.

Belli, B. (2012). "Plastic Seas." E THIS WEEK: 8-8.

The article presents information related to the problem of plastic waste in the oceans around the world. It is stated that a research by the Five Gyres found that much of the plastic waste is distributed vertically due to wind mixing ocean layers. It is mentioned that plastic debris also breaks down fairly rapidly in sea water besides strangling and choking marine life.

Bellingeri, A., et al. (2019). "Combined effects of nanoplastics and copper on the freshwater alga Raphidocelis subcapitata." Aquatic Toxicology **210**: 179-187.

Nanoplastics are recognized as able to interact with other pollutants including heavy metals, and with natural organic matter, with implications for the potential risks to biota. We investigated the interaction of carboxylated polystyrene nanoparticles (PS-COOH NPs) with copper (Cu) and algal exudates (EPS) and how such interaction could affect Cu toxicity towards the freshwater microalga Raphidocelis subcapitata. PS-COOH NPs behavior in the presence of Cu and EPS was determined by dynamic light scattering (DLS), while PS-COOH NPs surface interaction with Cu ions and EPS was investigated by fluorimetric analysis. ICP-MS was used to test Cu ion adsorption to PS-COOH NPs in the presence and absence of algae. The interaction between PS-COOH NPs and the algal cell wall was assessed by fluorescence microscopy. Short- and long-term toxicity tests were carried out in parallel to assess the impact of PS-COOH NPs on algal growth.

Bellofiore, A., et al. (2012). "Impact of acute pulmonary artery stiffening on right ventricular function in a canine model." American Journal of Respiratory and Critical Care Medicine. Conference: American Thoracic Society International Conference, ATS **185**(MeetingAbstracts).

RATIONALE Stiffening of the large pulmonary arteries (PA) is a stronger predictor of mortality in pulmonary arterial hypertension (PAH) than either mean PA pressure (mPAP) or pulmonary vascular resistance (PVR) [1]. However, the determinants of PA stiffening in PAH are not well understood. Pressure alone increases arterial stiffness via stretch/strain (strain-stiffening) [2]; chronic accumulation of extracellular matrix such as collagen [3] also increases stiffness (remodeling). Here we sought to create PA strain-stiffening in the absence of PA remodeling and quantify right ventricular (RV) function and the efficiency of RV-PA hemodynamic interactions (eta<inf>vv</inf>). We hypothesize that PA strain-stiffening impairs RV function but that a healthy RV is able to compensate and maintain adequate efficiency (eta<inf>vv</inf> > 1) [4]. METHODS Acute PAH was induced in six female beagles under isoflurane anesthesia by injecting micro-beads (150-500 mum) into the RV. Right heart catheterization (RHC) was performed to measure RV and mPAP. Cardiac MRI was performed to assess RV function (2D CINE balanced SSFP) and PA relative area change (RAC) over the cardiac cycle (velocity-encoded 2D phase contrast). Both RHC and MRI were performed before (PRE) and after (POST) embolization. RESULTS Hemodynamic, RV function and eta<inf>vv</inf> measures PRE and POST are shown in Table 1. Embolization increased mPAP and PVR, decreased PA compliance (RAC and CPA) and increased PA stiffness (beta). RV volumes (ESV, EDV, SV and EF) did not change significantly, although the increased afterload resulted in a threefold increase in stroke work. The RV-PA hemodynamic coupling efficiency eta<inf>vv</inf> decreased from 3.28+/-1.08 to 1.63+/-0.93 (p<0.05). A novel MRI-only technique for calculating eta<inf>vv</inf> recently proposed by Sanz et al. [5] also decreased but the change was not significant. CONCLUSIONS An acute increase in mPAP dramatically stiffens the main PA, which contributes to increased RV afterload. This increase in afterload decreases the hemodynamic efficiency of RV-PA interactions but does not cause decoupling (eta<inf>vv</inf> < 1). Comparison to a model in which both strain-stiffening and remodeling occur will help clarify the mechanisms by which PA stiffening impairs RV function and thus predicts RV failure in patients with PAH. (Table Presented).

Beloki, L., et al. (2013). "The abrogation of TCR-independent interactions with human serum ensures a selective capture of therapeutic virus-specific CD8+ T-cells by multimer technology in Adoptive Immunotherapy." Journal of Immunological Methods **396**(1-2): 168-172.

Multimers are complexes of recombinant MHC-class I molecules conjugated with antigenic immunodominant peptides and labeled with fluorescent molecules or magnetic microbeads that allow the quantification and selection of virus-specific cytotoxic T-cell subpopulations. Specific

T-cell receptors recognize the immunodominant peptides and bind to the multimers. Although these complexes are only recognized by CD8(+) T cells with specific T-cell receptors for the particular antigen, it has been observed that multimers can also bind non-specifically to CD8- cells, such as B-cells and monocytes. Using PBMCs from CMV-seropositive healthy donors, we analyze the tendency of Pentamer and Streptamer multimers towards non-specific interactions and describe a method to avoid this unwanted event. We find that a notable proportion of multimer-positive cells are likely to represent cross-contamination by cells lacking a TCR specific for pp65. In addition, we demonstrate that this unspecific interaction can be overcome by the pre-incubation of multimer-stained PBMCs with human AB serum, without altering their capacity to bind specifically to the CD8(+) T cell population of interest. In conclusion, in this study we characterize a novel method to abrogate TCR-independent interactions of multimers to ensure a pure and safe therapeutic product for Adoptive Immunotherapy.

Belontz, S. L., et al. (2019). "Embracing an interdisciplinary approach to plastics pollution awareness and action." AMBIO - A Journal of the Human Environment **48**(8): 855-866.

This paper considers how an interdisciplinary approach to the "wicked problem" of plastics pollution offers unique and important collaborative possibilities. Specially, the paper considers the approach of the Synthetic Collective, a group comprising artists, humanities scholars, and scientists. Considering first how artists and scientists might respond differently to tracking, mapping, understanding, and representing plastics pollution, we then look for potential points of commonality across disciplinary difference. In respect to the urgent and multifaceted problem of marine plastics pollution in the Great Lakes region, we ask what are some of the successes and pitfalls of bringing together diverse approaches and interests? The paper concludes with a clear strategy: a set of instructions geared towards building successful interdisciplinary collaborations. Ultimately, we conclude that a strong relationship amongst scientists and artists is possible, fruitful, and indeed warranted when shared goals are the driving principle of the group. [ABSTRACT FROM AUTHOR]

Belscak-Cvitanovic, A., et al. (2017). "Chemometric evaluation of binary mixtures of alginate and polysaccharide biopolymers as carriers for microencapsulation of green tea polyphenols." International Journal of Food Properties **20**(9): 1971-1986.

In this study principal component analysis and artificial neural networks were used to evaluate the potential of using binary mixtures of sodium alginate and other polysaccharide biopolymers as the carriers for microencapsulation of green tea bioactive compounds. Using binary mixtures of alginate and adjunct biopolymers increased the particle size (from 722 to 1344 micro m) and textural parameters of the microbeads. Chemometric techniques revealed the combination of biopolymers and their ratio as the main factors influencing the encapsulation performance. The combination of alginate with hydroxypropyl methylcellulose and locust bean gum enabled to retain the highest (-)-epigallocatechin gallate and caffeine contents, the highest total phenols encapsulation efficiency, and their most retarded release in water, confirming these as the best delivery systems of polyphenol-type active compounds and signifying their potent food applications.

Belscak-Cvitanovic, A., et al. (2017). "Modification of functional quality of beer by using microencapsulated green tea (Camellia sinensis L.) and Ganoderma mushroom (Ganoderma lucidum L.) bioactive compounds." Chemical Industry & Chemical Engineering Quarterly **23**(4): 457-471.

Increasing interest in production of frequently consumed functional food products has focused the present study on implementation of microencapsulated Ganoderma mushroom and green tea bioactive compounds in beer production. Electrostatic extrusion assisted microencapsulation of green tea and Ganoderma extracts enabled production of particles ranging from 490 to 1000 micro m in size, with up to 75% of entrapped total polyphenols. Dried, powdered extracts, as well as microparticles encapsulating Ganoderma and green tea extracts that exhibited the best morphological properties and retarded release of polyphenols (alginate and alginate-chitosan coated, as well as chitosan coated pectin microbeads) were implemented in beer production. The addition of Ganoderma microbeads to pilsner beer did not augment its polyphenolic concentration (TPC), as opposed to the addition of green tea encapsulating microbeads to radler, while adding dried Ganoderma and spray dried green tea extracts enabled to increase the TPC for up to 3-fold higher values. Ganoderma dried extract-enriched pilsner beer and spray dried green tea extract-enriched radler were preferred in terms of sensory properties, due to the lowest bitterness intensity and most pronounced herbal aroma of the added adjuncts. Refrigerated storage of Ganoderma hydrogel microbeads-enriched pilsner beer revealed fluctuations of TPC, while green tea hydrogel microbeads-enriched radler exhibited better stability. The established methodology provides a procedure suitable for microencapsulate-enrichment of drink and food products, thus setting a reliable basis for future functional food production by microencapsulate implementation strategies.

Belscak-Cvitanovic, A., et al. (2011). "Encapsulation of polyphenolic antioxidants from medicinal plant extracts in alginate-chitosan system enhanced with ascorbic acid by electrostatic extrusion." Food Research International **44**(4): 1094-1101.

In this study the encapsulation of raspberry leaf, hawthorn, ground ivy, yarrow, nettle and olive leaf extracts was performed by electrostatic extrusion in alginate-chitosan microbeads, with ascorbic acid being used for the dissolution of chitosan. The original and encapsulated plant extracts were characterized for their polyphenol content and composition, mineral content and antioxidant capacity. Raspberry leaf encapsulating microbeads exhibited the highest total phenol content and antioxidant capacity, followed by hawthorn, while olive leaf microbeads contained the lowest total phenol content. High encapsulation efficiency was obtained for all extract encapsulating microbeads (80-89%). Nettle extract-containing microparticles were characterized with the largest particle size and irregular shape, due to a high content of microelements (copper, strontium, and zinc), which affected the gelling process of alginate. Although the antioxidant stability of hydrogel microcapsules was deteriorated during refrigerated storage, which might be attributed to the instability of ascorbic acid, the obtained microbeads deliver significant biological activity and antioxidant potential which may increase the daily intake of antioxidants when implemented in a food product.

Beltran-Sanahuja, A., et al. (2019). "Monitoring polymer degradation under different conditions in the marine environment." Environmental Pollution **259**: 113836.

The perdurability of plastics in the environment is one of the major concerns of plastic pollution and, as a consequence, oceans are accumulating large amounts of plastic. The degradation of conventional and biobased materials was evaluated through a laboratory experiment for a year simulating four different conditions in the marine environment. The water column

environmental compartment was simulated under euphotic and aphotic (with and without light availability) conditions. The seafloor environmental compartment was simulated with sediment under non-polluted and polluted conditions. By combining weight loss (%), spectroscopic and thermal analyses, the degradation patterns regarding the polymer structure were assessed. The studied biobased materials were polylactic acid (PLA) based materials and showed higher degradability than conventional ones. The weight loss of conventional materials was not influenced by the water column or sediment, while in PLA-based materials, the degradation rates were ca. 5 times greater in the sediment than in the water column. The absorbance (Abs) value at 3400 cm⁻¹ for polyethylene terephthalate (PET), and carbonyl (CO) index for PET and PLA could be useful to detect early signs of degradation. The crystallization index could be a useful parameter to discriminate degradation stages. The obtained results highlight the different degradability rates of materials depending on the specific environmental marine conditions.

Belzagui, F., et al. (2019). "Microplastics' emissions: Microfibers' detachment from textile garments." Environmental Pollution **248**: 1028-1035.

Microplastics (synthetic polymers <5mm) have been recently recognized as a big environmental concern, as their ubiquity is an undeniable fact. Their wide variety regarding shapes, sizes, and materials turn them into an intrinsically risky pollutant capable of causing several environmental impacts. Textile microfibers (MF) are a microplastic sub-group. These are mostly shed when a normal laundry of any garment takes place. Special attention has been put onto them, as high concentrations have been found in products for human consumption as shellfish and tap water. However, as there is no consensus on the methodologies to quantify and report the results of MFs detached from textile garments, the degree of similarity between published studies is very low. Hence, the aim of this research was to evaluate the microfibers' detachment rates of finished garments and to provide a set of comparable units to report the results. These were found to range between 175 and 560MF/g or 30000-465000MF/m² of garment. In addition, there was a high correlation between the MF detachment and the textile article superficial density. Finally, our results were compared with a recent paper that estimated the annual mass flow of MFs to the oceans. This previous publication is 30 times higher when related to the mass but 40 times lower if related to the number of MFs.

Bembridge, G. P., et al. (2000). "Respiratory syncytial virus infection of gene gun vaccinated mice induces Th2-driven pulmonary eosinophilia even in the absence of sensitisation to the fusion (F) or attachment (G) protein." Vaccine **19**(9-10): 1038-1046.

Complete protection against respiratory syncytial virus (RSV) infection was induced in mice vaccinated on two occasions with 2.5 mu g of DNA, encoding the fusion (F) protein of RSV, precipitated onto gold microbeads. In contrast, immunisation with DNA encoding the attachment (G) protein of RSV resulted in a significant reduction in viral load following infection, but did not afford complete protection. Gene gun delivery of DNA-F elicited a T helper-2 (Th2) biased immune response that could not be modulated by the co-delivery of plasmids encoding IL-2, IL-12 or IFN gamma . Similarly gene gun delivery of DNA-G primed a Th2 response. Thus, all gene gun vaccinated mice produced a predominant Th2 biased pulmonary immune response characterised by the production of IL-4 and IL-5 with little IFN gamma following RSV challenge. Analysis of bronchoalveolar lavage (BAL) cells, 5 days post challenge, indicated that there was only a two-fold increase in the number of inflammatory cells in vaccinated compared with control animals. Despite the strong Th2 cytokine bias of lung lymphocytes and the predominant recruitment of CD4 super(+) T cells, following challenge, there was not a marked pulmonary eosinophilic response (range from 2 to 7% of BAL). In contrast, the BAL from mice vaccinated with control plasmid contained significantly more eosinophils than any other group.

Ben Jazia, D., et al. (2011). "Imbibing drops of ethanol/water mixtures in model nanoporous networks with tunable pore structure: Deviation from square root to linear time regime imbibition kinetics." Colloids and Surfaces A: Physicochemical and Engineering Aspects **384**(1-3): 643-652.

In this paper, we report on the imbibition of model hydrophobic nanoporous networks formed by polystyrene (PS) microbead assemblies. Spontaneous imbibition of these structures with sessile drops was achieved using water/ethanol mixtures of higher wettability than pure water. We used the high sensitivity of particle coalescence to tiny temperature variations around T<inf>g</inf> to finely adjust the topographical features, and thereafter the imbibition properties of the porous networks. Reconstructions of the networks led to distinct and quantifiable variations of the free volume, and pore sizes. These model hydrophobic nanoporous systems allowed addressing the important issue of the interplay between the topographical features of a porous medium, and the free-imbibition kinetics of a liquid mixture droplet over a wide range of concentration, surface tension and hence, of driving capillary pressure. Our results show deviations from the expected square root time-dependence characterizing the imbibition in the Darcy's regime. In particular, a linear time-regime was observed above a threshold ethanol concentration (capillary pressure), and below a threshold sintering temperature of the microbead assembly. While the latter arises naturally as a result of the modification of the pore structure (sintering and pore closure), and hence of the pellet's permeability following the annealing, the deviation related to the composition of the liquid mixture is a less trivial and a quite new behaviour. Here we propose a phenomenological picture which allows accounting for this concentration-driven acceleration of the spontaneous imbibition, based on the singular properties of the liquid mixture which dynamically modify the local structure and conditions around the confined imbibition front, especially at high ethanol content. This work may thus contribute understanding imbibition behaviour of liquid mixtures and of complex fluid in general in nanoporous networks, an issue that is of technological relevance in current material science and engineering. © 2011 Elsevier B.V.

Benavides, P. T., et al. (2017). "Life-cycle analysis of fuels from post-use non-recycled plastics." Fuel **203**: 11.

Plastic-to-fuel (PTF) technology uses pyrolysis to convert plastic waste--especially non-recycled plastics (NRP)--into ultra-low sulfur diesel (ULSD) fuel. To assess the potential energy and environmental benefits associated with PTF technology, we calculated the energy, water consumption, and greenhouse gas emissions of NRP-derived ULSD and compared the results to those metrics for conventional ULSD fuel. For these analyses, we used the Greenhouse gases, Regulated Emissions and Energy use in Transportation (GREET®) model. Five companies provided pyrolysis process product yields and material and energy consumption data. Co-products of the process included char and fuel gas. Char can be landfilled, which, per the company responses, is the most common practice for this co-product, or it may be sold as an energy product. Fuel gas can be combusted to internally generate process heat and electricity. Sensitivity analyses investigated the influence of co-product handling methodology, product yield, electric grid composition, and assumed efficiency of char combustion technology on life-cycle greenhouse gas emissions. The sensitivity analysis indicates that the GHG emissions would likely be reduced up to 14% when it is compared to conventional ULSD, depending on the co-product treatment method used. NRP-derived ULSD fuel could therefore be considered at a minimum carbon neutral with the potential to offer a modest GHG reduction. Furthermore, this

waste-derived fuel had 58% lower water consumption and up to 96% lower fossil fuel consumption than conventional ULSD fuel in the base case. In addition to the comparison of PTF fuels with conventional transportation fuels, we also compare the results with alternative scenarios for managing NRP including power generation and landfilling in the United States.

Bencic-Nagale, S., et al. (2006). "Microbead chemical switches: an approach to detection of reactive organophosphate chemical warfare agent vapors." Journal of the American Chemical Society **128**(15): 5041-5048.

In this article, we describe the preparation and application of microbeads that exhibit a "turn on" fluorescence response within seconds of exposure to diethyl chlorophosphate (DCP) vapor. This sensing approach is modeled after the mechanism for acetylcholinesterase enzyme activity inhibition and uses a specific and irreversible reaction between phosphoryl halides and a fluorescent indicator. The microbeads are fabricated by adsorbing fluoresceinamine (FLA) onto carboxylate-functionalized polymer microbeads coated with poly(2-vinylpyridine) (PVP). When the microbeads are subjected to DCP vapor, the conversion of FLA into a phosphoramide causes a rapid and intense fluorescence increase. The PVP layer provides a high density of proton-accepting pyridine nitrogen sites that neutralize the HCl released during the reaction, thereby maintaining high product fluorescence, even after vapor exposure. No significant response is observed when the microbeads are subjected to other nerve agent simulants, a mustard gas simulant, and volatile organics. The size, sensitivity, and subsecond response of these microbeads make them suitable for nerve agent vapor detection and inclusion into microbead sensor arrays.

Bencic-Nagale, S. and D. R. Walt (2005). "Extending the longevity of fluorescence-based sensor arrays using adaptive exposure." Analytical Chemistry **77**(19): 6155-6162.

Fluorescent microbead sensor arrays were prepared to determine sensor array longevity. Sensor longevity is limited by photobleaching of the dyes attached to the microbeads and presents one of the biggest drawbacks of most fluorescent dye-based arrays. Responses of an array of organic vapor sensors were acquired for 2 weeks to evaluate the sensor performance over time. Photobleaching effects were overcome in two ways: (1) by limiting the excitation light power and gradually increasing the power at a rate comparable to the sensor photobleaching rates and (2) by illuminating subsections of the array through an optical slit. Both approaches extended the longevity of a sensor array. During the longevity study, the sensor arrays were employed to test their ability to correctly distinguish between responses to seven vapors. A high classification accuracy (99.8%) was obtained after 17,700 exposures for vapor responses collected over two weeks using only approximately 8% of the array's surface area.

Benez, A., et al. (1999). "Detection of circulating melanoma cells by immunomagnetic cell sorting." Journal of Clinical Laboratory Analysis **13**(5): 229-233.

We developed a cellular approach to the identification of circulating melanoma cells in peripheral blood using immunomagnetic cell sorting. One hundred seventy-eight blood samples from 129 melanoma patients and 30 samples from healthy persons and nonmelanoma patients were examined. After density gradient centrifugation the interphase was incubated with the mAb 9.2.27. Positive cells were labeled with magnetic microbeads and enriched by immunomagnetic cell sorting. Cells were stained using an alkaline phosphatase-antialkaline phosphatase assay and examined by light microscopy. In spiking experiments, melanoma cells seeded at a concentration of one melanoma cell per ml whole blood could be detected reliably with the assay. Circulating melanoma cells were not found in 30 controls examined, nor were

9.2.27-positive cells found in 41 patients with primary malignant melanoma. In patients with regional lymph node metastases and in patients with disseminated disease, circulating 9.2.27-positive cells could be detected in 3 out of 22 patients (13.6%) and 10 out of 66 patients (15.2%) examined. We present a sensitive and specific immunocytological approach to detect circulating melanoma cells in peripheral blood. The method is not suitable for early detection of metastases but is a valuable tool for further investigating biological characteristics of circulating melanoma cells.

Benez, A., et al. (2001). "Morphologically intact melanoma cells may be detected in peripheral blood of melanoma patients." Recent Results in Cancer Research **158**: 113-117.

The detection of circulating melanoma cells has been the subject of numerous investigations in recent years. We developed a cellular approach to identifying circulating melanoma cells in peripheral blood using immunomagnetic cell sorting. The examination covered 205 blood samples from 155 melanoma patients and 30 samples from healthy persons and nonmelanoma patients. After density gradient centrifugation, the interphase was incubated with the 9.2.27 antibody. Positive cells were labeled with magnetic microbeads and enriched by immunomagnetic cell sorting. Cells were stained using an alkaline phosphatase-anti-alkaline phosphatase assay and examined by light microscopy. In spiking experiments, melanoma cells seeded at a concentration of one melanoma cell per milliliter of whole blood could be detected reliably. Circulating melanoma cells were not found in 30 controls, nor were 9.2.27-positive cells found in 41 patients with primary malignant melanoma. In patients with regional lymph node metastases and disseminated disease, circulating 9.2.27-positive cells could be detected in 3 of 29 patients (10%) and 13 of 85 patients (15%) examined, respectively. We conclude that immunomagnetic cell sorting is a promising method with high sensitivity and specificity. The method is not suitable for early detection of metastases but is a valuable tool for further investigating the biological characteristics of circulating melanoma cells.

Benitez-Mateos, A. I., et al. (2019). "Selective Immobilization of Fluorescent Proteins for the Fabrication of Photoactive Materials." Molecules **24**(15): 30.

The immobilization of fluorescent proteins is a key technology enabling to fabricate a new generation of photoactive materials with potential technological applications. Herein we have exploited superfolder green (sGFP) and red (RFP) fluorescent proteins expressed with different polypeptide tags. We fused these fluorescent proteins to His-tags to immobilize them on graphene 3D hydrogels, and Cys-tags to immobilize them on porous microparticles activated with either epoxy or disulfide groups and with Lys-tags to immobilize them on upconverting nanoparticles functionalized with carboxylic groups. Genetically programming sGFP and RFP with Cys-tag and His-tag, respectively, allowed tuning the protein spatial organization either across the porous structure of two microbeads with different functional groups (agarose-based materials activated with metal chelates and epoxy-methacrylate materials) or across the surface of a single microbead functionalized with both metal-chelates and disulfide groups. By using different polypeptide tags, we can control the attachment chemistry but also the localization of the fluorescent proteins across the material surfaces. The resulting photoactive material formed by His-RFP immobilized on graphene hydrogels has been tested as pH indicator to measure pH changes in the alkaline region, although the immobilized fluorescent protein exhibited a narrower dynamic range to measure pH than the soluble fluorescent protein. Likewise, the immobilization of Lys-sGFP on alginate-coated upconverting nanoparticles enabled the infrared excitation of the fluorescent protein to be used as a green light emitter. These novel photoactive biomaterials open new avenues for innovative technological developments towards

the fabrication of biosensors and photonic devices.

Benjamin, D., et al. (2014). "Plastic ingestion by Bigeye Thresher shark Alopias superciliosus off Ratnagiri southwest coast of India." International Journal of Environmental Sciences **5**(2): 277-281.

Marine debris a majority of which is plastic is negatively affecting the survival of aquatic life worldwide. Ingestion of plastic debris by turtles, seabirds, marine mammals, and occasionally fish has been well documented but from sharks are rare from Indian Coast. The specimen obtained measured 346 cm in total length (TL), 190 cm in standard length (SL) and weighed 51 kg. The gut was examined thoroughly and 2 transparent plastic covers weighing 3.48 g and 4.32 g of 40 micron each with an area of 1200 cm² respectively partially in tampered condition was pulled out from the foregut region. Therefore microplastic ingestion is now a common phenomenon not only affecting the lower trophic level animals but also sharks which constitute an important predator group in marine ecosystems and consequently play an essential role on energy exchange within the highest trophic levels.

Benjamin, M. and F. J. Newhook (1982). "Effect of glass microbeads on Phytophthora zoospore motility." Transactions of the British Mycological Society **78**(1): 43-46.

Six P. spp. in the confined environment of glass microbeads were used. Results indicated that different spp. are affected to varying degrees by the 'contact stimulus' phenomenon described by previous workers. P. cinnamomi was the least sensitive to contact stimulus. It is considered that zoospores of even the most sensitive spp., P. megasperma var. megasperma and P. citricola, would retain motility long enough for this attribute to make an effective contribution to dispersal in soil micro-environments.

Bennett, N. (2015). "Our triple crisis opens the door to real change." ENDS (Environmental Data Services)(480): 8-9.

The author shares her thoughts on crises affecting the British economy and environment and how environmentalists can push for change in the 2015 election. Issues raised include the failure of the government's energy savings bill known as the Green Deal, the lack of jobs and affordable housing, and environmental issues that may come up in election campaigns such as wildlife restoration, flooding and plastic waste.

Benson, M., et al. (2011). "A Bruton's tyrosine kinase inhibitor prevents antigen-driven B cell activation in vivo." Arthritis and Rheumatism. Conference: Annual Scientific Meeting of the American College of Rheumatology and Association of Rheumatology Health Professionals **63**(10 SUPPL. 1).

Background/Purpose: Therapeutic targeting of B cells has proven effective for a multitude of human autoimmune indications. Most investigative and approved therapies are injected monoclonal antibodies that either deplete or inactivate B cells by targeting B cell surface moieties directly or by inactivating B cell modulating cytokines, with orally-available B cell modulating treatments currently lacking. Proximal to the intracellular signaling components of the B cell receptor (BCR) resides a network of adaptor proteins and protein tyrosine kinases that include the Tec family kinase Bruton's Tyrosine Kinase (BTK). The kinase activity of BTK is critical for transmitting signals received through the BCR to downstream signaling pathways that direct B cell activation. In this study, we assessed the ability of an orally-accessible BTK inhibitor to prevent antigen-driven B cell activation in vivo. Method(s): C57BL/6 mice were dosed orally with either vehicle alone or vehicle with BTK inhibitor at 10, 3, 1, or 0.3 mgs/kg as indicated. For the anti-IgD model, either 100mg of agonistic anti-CD40 (clone 1C10) or 200ml of goat-anti-mouse anti-IgD antisera (Ebioscience) were injected intraperitoneally (i.p) two hours after dosing. Mice were sacrificed between 4-18 hours later and splenic B cells analyzed. For mRNA transcript analysis, mature B220⁺CD23⁺ B cells were enriched to >93% purity by B cell negative selection followed by CD23 positive selection by antibody-coupled microbeads. Purified RNA was analyzed for mRNA transcript levels. To analyze the induction of B cell surface activation markers, B220⁺ B cells were analyzed by FACS for CD86 expression levels. For the NP-Ficoll model, 100mg of NP-Ficoll were injected i.p. the day after dosing with either vehicle alone or vehicle with BTK inhibitor. BTK inhibitor was dosed daily for the duration of the experiment until day 7, whereupon anti-NP serum IgM and IgG3 titers were quantified by ELISA. Result(s): We report that dosing with a BTK inhibitor suppressed, in a dose dependent manner, both anti-IgD driven B cell activation and NP-Ficoll elicited anti-NP IgM and IgG3 antibody titers in vivo. The suppression of anti-IgD driven B cell activation was manifested by suppression of the surface activation markers CD86 as well as suppression of mRNA transcripts (e.g. c-Myc, Bcl-xL, CCL3, CD98, EBI2, EGR1, EGR2 and IRF4), all markers otherwise rapidly induced upon engagement of the BCR with antigen. BTK inhibition had no impact on agonistic anti-CD40 driven B cell activation, indicating the specificity of the BTK inhibitor used in this study for the BCR signaling pathway. Lastly, inhibition of BTK prevented, in a dose-dependent manner, the generation of anti-NP IgM and IgG3antibodies upon immunization with NP-Ficoll. Conclusion(s): Our results provide mechanistic insight into the role of BTK inhibition in a mouse model of in vivo BCR-driven B cell activation and support the concept that BTK kinase inhibitors represent a promising therapeutic approach for patients with B cell-dependent autoimmune disorders.

Bentley, R. (1994). Evaluation of environmentally acceptable packaging for Navy use.

When man operates at sea, he generates solid waste. Under ideal conditions, all waste would be returned to shore for treatment and disposal. However, when operating periods at sea are prolonged, much of the waste must be disposed in the marine environment. Discarded plastic items pose a special ecological problem because they are buoyant, durable and strong. Sea life is endangered by entanglement or ingestion. Sea lanes can be identified by the concentration of floating debris, much of which is plastics. Shores and beaches are littered with plastic discards that appear on the incoming tide. Public Law 100-220, the U.S. Marine Plastic Pollution Research and Control Act of 1987 not only adopted Annex V of the International Maritime Pollution (MARPOL) Protocol, it extended its application to U.S. Navy vessels. Coordination of the Navy's implementation of the public law is administered by the Plastics Removal In the Marine Environment (PRIME) Program Manager. Responsibility for various aspects of the PRIME Program are shared by the System Commands, primarily the Naval Supply, Naval Sea, and Naval Air Systems Command. Other major agencies of the Federal Government are also heavily involved in the implementation of the PRIME effort, namely the Defense Logistics Agency, the General Services Administration, and the sister services to the Navy. The Naval Supply Systems Command's effort in support of the PRIME Program has been directed at reduction or elimination of plastic consumable commodities going aboard U.S. Navy ships. This involves a comprehensive review of the governing specifications and ordering data as well as investigations of the commercial marketplace for new materials, products, processes, and ideas. One especially notable area of plastic waste generation is packaging materials. Studies of waste generation aboard Navy ships have shown that 7% of the trash is composed of plastic, with 70% of the plastics being packaging and packing materials. This paper presents the results of evaluations of new products and processes that support the plastic waste reduction goal, particularly in the area of packaging and packing applications.

Benyamini, N., et al. (2016). "The effect of lenalidomide on multiple myeloma associated macrophages." Blood. Conference: 58th Annual Meeting of the American Society of Hematology, ASH **128**(22).

Introduction: In multiple myeloma (MM), accessory cells, such as monocytes and macrophages, located in the bone marrow (BM) tumor microenvironment play a crucial role in the fate of malignant cells. Under the influence of the surrounding milieu, monocytes can change their migratory capacity and differentiate into tumor-associated macrophages (TAMs). In the tumor site, TAMs can alter their profile from M1 macrophages with antitumor activities to M2-like macrophages that support tumor growth. Lenalidomide (Len), an immunomodulatory drug, used for MM treatment, is known to target different immune components inducing inflammatory responses; however, its direct influence on monocyte migration, macrophage differentiation and function in the tumor microenvironment is still unclear. The current study has aimed to explore the effect of Len on monocyte recruitment, macrophage polarization and pro-tumor functions. Method(s): Monocytes were isolated from peripheral blood mononuclear cells of healthy donors, using anti-CD14 microbeads. To assess their migration capacity, monocytes were allowed to migrate through transwell insert towards the conditioned medium (CM) obtained from the BM of newly diagnosed MM patients or from MM cell lines (RPMI or U266) in the presence or absence of Len (10muM); the percentage of migrating monocytes was determined by FACS. For macrophage generation, monocytes were cultured with M-CSF followed by incubation with IL-4 to obtain M2 macrophages. To generate TAMs, CM obtained from the BM of MM patients was used. Len was added to the culture every 24 hours. The phenotype and functional properties of the generated macrophages were assessed. Endocytosis was evaluated by an antigen uptake assay. Macrophages were incubated with FITC-dextran at 37degreeC or 4degreeC, as a control, for 60 minutes, and analyzed by FACS. To test T cell proliferation, autologous lymphocytes labeled with CFSE, were stimulated with PHA and co-cultured with macrophages. T cell (CD3+) division was assessed by FACS. For IFN-gamma secretion evaluation, lymphocytes co-cultured with macrophages were stimulated with PMA and ionomycin. The percentage of T cells expressing IFN-gamma was quantified by FACS. Result(s): Monocyte migration towards CM obtained from MM cell lines (RPMI or U266) or from BM of MM patients (80.89%; n=4; p<0.01, 57.17%; n=4; p<0.01 and 42.9%; n=9; p<0.05, respectively) was significantly higher compared to migration towards normal BM CM (25.39%; n=2). Monocytes treated with Len demonstrated significantly decreased migration toward CM of MM cell lines (RPMI or U266) compared to untreated monocytes (45% vs. 80.8%; n=4 and 30.2% vs. 57.1%; n=4, respectively; p<0.01). The effect of Len on monocyte migration toward patientderived CM was diverse. While 4 samples demonstrated decreased migration compared to untreated cells [51.1% vs. 59.6%; n=4; p<0.01], in 5 samples it increased [39.8% vs. 29.7%; n=5; n=5; p<0.01]. To evaluate the effect of Len on macrophage polarization we examined their phenotype and functions. Both M2 macrophages and TAMs treated with Len expressed higher levels of M2 markers CD206, CD163, and cytokine IL-10 compared to untreated macrophages. Functional assays showed that Len increased endocytosis of both M2 macrophages [50% vs. 20%; n=5; P<0.01] and TAMs [47.4% vs. 41.4%; n=6; NS]. Exposure to Len led to suppression of T cell proliferation, when T cells were co-cultured with either autologous M2 macrophages [31% vs. 16%; n=4; p<0.05] or TAMs [39.7% vs. 31.5%; n=3; p<0.01]. In addition, M2 macrophages treated with Len demonstrated a reduction in IFN-gamma secretion from T cells compared to untreated M2 macrophages (10.6% vs. 7.1%; n=4; NS). Conclusion(s): This study has demonstrated that Len has a direct effect on monocyte/macrophage behavior in the microenvironment generated by MM cells. Len is found to reduce monocyte migration, support polarization of macrophages towards the M2 phenotype and promote macrophage immunosuppressive functions, such as endocytosis, reduction of T-cell proliferation and

inhibition of IFN-gamma production. These findings need to be further investigated in in vivo experiments and could support the benefit of using agents targeting specific pathways associated with TAM development in the treatment of MM patients.

Berber, A. A. (2019). "POLYSTYRENE NANOPLASTICS TRIGGER TOXICITY ON TWO DIFFERENT AQUATIC ORGANISMS (BRACHIONUS PLICATILIS, DAPHNIA MAGNA)." Fresenius Environmental Bulletin **28**(8): 6146.

Micro and nano-sized plastic particles are found almost everywhere, especially the aquatic system and because of their size, they can be ingested as food by many organisms and these plastics which enter the food chain, raise a great concern. In this study, the effects of 50 nm diameter of polystyrene nanoplastics (PNPs) on Brachionus plicatilis and Daphnia magna were investigated. The acute toxicity tests were conducted on Brachionus plicatilis. According to the tests LC50 value was determined as 1.22 mg/ mL (0.34-15.13, 95% confidence limits). Three parameters, tail length, tail intensity and tail moment were evaluated to detect genotoxic effect of PNPs on Daphnia magna with single cell gel electrophoresis (Comet). According to the result PNPs were increased three parameters compared to the control. As a result, PNPs have negative effects on both aquatic organisms Brachionus plicatilis and Daphnia magna.

Berber, A. A. and M. Yurtsever (2018). "TOXICOLOGICAL EFFECT OF POLYETHYLENE MICROSPHERE ON BRACHIONUS PLICATILIS AND DAPHNIA MAGNA." Fresenius Environmental Bulletin **27**(7): 4972-4979.

Pollution of the aquatic environment by microplastic could be having a massive impact on marine life. As far as the dimensions of the microplastics decrease, the negative effects are also increasing. In this study, the effects of 10-22 µm diameter fluorescent polyethylene microplastics (PEMs) on Brachiomus plicatilis and Daphnia magna were investigated. The acute toxicity and population growth test were conducted on Brachiomus plicatilis. According to the tests LC50 value was calculated as 0.764 mg/mL (0.4-1.458, 95% confidence limits). Statistically significant differences were found in the 90-hour population growth test compared to the control. According to genotoxic evaluation on Daphnia magna with single cell gel electrophoresis (Comet), tail length, tail intensity and tail moment were increased by PEMs compared to the control. In conclusion, PEMs (10-22 µm) have negative effects on both aquatic organisms Brachiomus plicatilis and Daphnia magna. [ABSTRACT FROM AUTHOR]

Berg, K. (2019). "Sailing to the heart of the plastic wasteland." Recycling International: 52-53.

Bergami, E., et al. (2016). "Nano-sized polystyrene affects feeding, behavior and physiology of brine shrimp Artemia franciscana larvae." Ecotoxicology & Environmental Safety **123**: 18-25.

Nano-sized polymers as polystyrene (PS) constitute one of the main challenges for marine ecosystems, since they can distribute along the whole water column affecting planktonic species and consequently disrupting the energy flow of marine ecosystems. Nowadays very little knowledge is available on the impact of nano-sized plastics on marine organisms. Therefore, the present study aims to evaluate the effects of 40 nm anionic carboxylated (PS-COOH) and 50 nm cationic amino (PS-NH 2) polystyrene nanoparticles (PS NPs) on brine shrimp Artemia

franciscana larvae. No signs of mortality were observed at 48 h of exposure for both PS NPs at naplius stage but several sub-lethal effects were evident. PS-COOH (5–100 µg/ml) resulted massively sequestered inside the gut lumen of larvae (48 h) probably limiting food intake. Some of them were lately excreted as fecal pellets but not a full release was observed. Likewise, PS-NH 2 (5–100 µg/ml) accumulated in larvae (48 h) but also adsorbed at the surface of sensorial antennules and appendages probably hampering larvae motility. In addition, larvae exposed to PS-NH 2 undergo multiple molting events during 48 h of exposure compared to controls. The activation of a defense mechanism based on a physiological process able to release toxic cationic NPs (PS-NH 2) from the body can be hypothesized. The general observed accumulation of PS NPs within the gut during the 48 h of exposure indicates a continuous bioavailability of nano-sized PS for planktonic species as well as a potential transfer along the trophic web. Therefore, nano-sized PS might be able to impair food uptake (feeding), behavior (motility) and physiology (multiple molting) of brine shrimp larvae with consequences not only at organism and population level but on the overall ecosystem based on the key role of zooplankton on marine food webs. [ABSTRACT FROM AUTHOR]

Bergami, E., et al. (2019). "Polystyrene nanoparticles affect the innate immune system of the Antarctic sea urchin <i>Sterechinus neumayeri</i>." Polar Biology **42**(4): 743-757.

Plastic debris has been recognised as a potential stressor for Antarctic marine organisms. In this study, the effects of surface charged polystyrene nanoparticles (PS NPs) on the immune cells (coelomocytes) of the Antarctic sea urchin Sterechinus neumayeri were assessed through in vitro short-term cultures. The behaviour of anionic carboxylated (PS-COOH) and cationic amino-modified (PS-NH2) NPs in filtered natural sea water (NSW) from King George Island (South Shetland Islands) was characterised by dynamic light scattering. Cellular morphology, NP uptake, phagocytic capacity and gene expression were evaluated after 6 and 24 h of exposure to 1 and 5 µg mL−1 PS NPs. Secondary characterisation showed an initial good dispersion of PS NPs in NSW, followed by nano-scale aggregation after 24 h. Both PS NPs affected cellular phagocytosis and generated an inflammatory response against oxidative stress and apoptosis at the molecular level. Fluorescently labelled PS-COOH aggregates were internalised by phagocytes and associated to the modulation of genes related to external challenges, antioxidant responses and cell protection against stress and apoptosis. Exposure to PS-NH2 caused a strong decrease in phagocytic capacity and the formation of cellular debris at 5 µg mL−1 after 24 h, but low gene modulation, suggesting a threshold in coelomocytes defence ability against PS-NH2. This study represents the first attempt to assess the impact of nanoplastics on Antarctic marine organisms. Our findings demonstrate that PS NPs with different surface charges constitute a challenge for S. neumayeri immune cells.

Bergami, E., et al. (2017). "Long-term toxicity of surface-charged polystyrene nanoplastics to marine planktonic species Dunaliella tertiolecta and Artemia franciscana." Aquatic Toxicology **189**: 159-169.

Plastic pollution has been globally recognized as a critical issue for marine ecosystems and nanoplastics constitute one of the last unexplored areas to understand the magnitude of this threat. However, current difficulties in sampling and identifying nano-sized debris make hard to

assess their occurrence in marine environment. Polystyrene nanoparticles (PS NPs) are largely used as nanoplastics in ecotoxicological studies and although acute exposures have been already investigated, long-term toxicity on marine organisms is unknown. Our study aims at evaluating the effects of 40 nm PS anionic carboxylated (PS-COOH) and 50 nm cationic amino-modified (PS-NH₂) NPs in two planktonic species, the green microalga Dunaliella tertiolecta and the brine shrimp Artemia franciscana, respectively prey and predator. PS NP behaviour in exposure media was determined through DLS, while their toxicity to microalgae and brine shrimps evaluated through 72 h growth inhibition test and 14 d long-term toxicity test respectively. Moreover, the expression of target genes (i.e. clap and cstb), having a role in brine shrimp larval growth and molting, was measured in 48 h brine shrimp larvae. A different behaviour of the two PS NPs in exposure media as well as diverse toxicity to the two planktonic species was observed. PS-COOH formed micro-scale aggregates (Z-Average >1 micro m) and did not affect the growth of microalgae up to 50 micro g/ml or that of brine shrimps up to 10 micro g/ml. However, these negatively charged NPs were adsorbed on microalgae and accumulated (and excreted) in brine shrimps, suggesting a potential trophic transfer from prey to predator. On the opposite, PS-NH₂-formed nano-scale aggregates (Z-Average <200 nm), caused inhibition of algal growth (EC₅₀=12.97 micro g/ml) and mortality in brine shrimps at 14 d (LC₅₀=0.83 micro g/ml). Moreover, 1 micro g/ml PS-NH₂ significantly induced clap and cstb genes, explaining the physiological alterations (e.g. increase in molting) previously observed in 48 h larvae, but also suggesting an apoptotic pathway triggered by cathepsin L-like protease in brine shrimps upon PS-NH₂ exposure. These findings provide a first insight into long-term toxicity of nanoplastics to marine plankton, underlining the role of the surface chemistry in determining the behaviour and effects of PS NPs, in terms of adsorption, growth inhibition, accumulation, gene modulation and mortality. The use of long-term end-point has been identified as valuable tool for assessing the impact of nanoplastics on marine planktonic species, being more predictable of real exposure scenarios for risk assessment purposes.

Berger, C., et al. (2003). "CD28 costimulation and immunoaffinity-based selection efficiently generate primary gene-modified T cells for adoptive immunotherapy." Blood **101**(2): 476-484.

The introduction of an inducible suicide gene has been proposed as a strategy to exploit the antitumor reactivity of donor T cells after allogeneic hematopoietic stem cell transplantation but permit control of graft-versus-host disease. However, there are several obstacles to this approach that may impair the ability of T cells to function and survive in vivo. These include the requirement for in vitro activation or long-term culture to introduce the transgene and obtain therapeutic cell numbers, the toxicity of drug selection to enrich transduced cells, and the immunogenicity of the transgene-encoded products. Here we have developed a transduction and selection strategy for generating large numbers of polyclonal T cells transduced with a retroviral vector encoding the human low-affinity nerve growth factor receptor (LNGFR) for selection and a Fas-based suicide construct (LV'VFas). Ligation of CD28 in conjunction with a T-cell receptor signal permitted efficient transduction, substantially promoted T-cell growth, and contributed to the generation of gene-modified T cells that retained clonal diversity, functional properties, and a homing receptor profile similar to untransduced peripheral blood lymphocytes. Microbeads conjugated directly to antibody specific to LNGFR significantly improved the immunomagnetic selection of LV'VFas-modified T cells and assisted in scaling of the selection procedure to therapeutic cell numbers. Thus, these studies identified a strategy that requires only a brief ex vivo culture and does not use drug selection to obtain large numbers of functional gene-modified polyclonal T cells that can be used for adoptive

immunotherapy.

Berglund, E., et al. (2019). "Microplastics in a freshwater mussel (Anodonta anatina) in Northern Europe." Science of the Total Environment **697**: N.PAG-N.PAG.

Unlabelled Image • Plastic fibres and particles could be confirmed in freshwater mussels. • Higher concentrations of microplastics in urban areas compared to a rural location. • Higher concentrations of microplastics in areas with wastewater treatment plants. • All mussels contained microfibers. Alarming amounts of microplastics have recently been shown to accumulate in the environment. Recent focus has been on synthetic material contaminating the marine environment, while effects on freshwater habitats and organisms have received less attention. We here confirm and analyse occurrence of microplastics in the duck mussel, Anodonta anatina, in a Swedish river. All analysed mussels contained microplastics, and the number of microplastic debris found in the mussels increased with mussel size. In addition, we demonstrate higher concentrations of microplastics downstream urban areas with wastewater treatment plants compared to a rural upstream location. Both fibres and particles were found in the mussels, indicating that the emissions of these pollutants may have varying origin. Our study indicates that microplastics can be suspended in the water column in streams and that concentrations are higher downstream anthropogenic activity. We discuss our results in light of potential pathways in rural versus surrounding arable land, and highlight a number of required research directions in the aquatic system. [ABSTRACT FROM AUTHOR]

Bergmann, M., et al. (2017). "Citizen scientists reveal: Marine litter pollutes Arctic beaches and affects wild life." Marine Pollution Bulletin **125**(1-2): 535-540.

Recent data indicate accumulation areas of marine litter in Arctic waters and significant increases over time. Beaches on remote Arctic islands may be sinks for marine litter and reflect pollution levels of the surrounding waters particularly well. We provide the first quantitative data from surveys carried out by citizen scientists on six beaches of Svalbard. Litter quantities recorded by cruise tourists varied from 9-524 g m^{- 2} and were similar to those from densely populated areas. Plastics accounted for > 80% of the overall litter, most of which originated from fisheries. Photographs provided by citizens show deleterious effects of beach litter on Arctic wildlife, which is already under strong pressure from global climate change. Our study highlights the potential of citizen scientists to provide scientifically valuable data on the pollution of sensitive remote ecosystems. The results stress once more that current legislative frameworks are insufficient to tackle the pollution of Arctic ecosystems. Copyright © 2017 The Authors

Bergmann, M., et al. (2019). "White and wonderful? Microplastics prevail in snow from the Alps to the Arctic." Science Advances **5**(8): eaax1157.

Microplastics (MPs) are ubiquitous, and considerable quantities prevail even in the Arctic; however, there are large knowledge gaps regarding pathways to the North. To assess whether atmospheric transport plays a role, we analyzed snow samples from ice floes in Fram Strait. For comparison, we investigated snow samples from remote (Swiss Alps) and populated (Bremen,

Bavaria) European sites. MPs were identified by Fourier transform infrared imaging in 20 of 21 samples. The MP concentration of Arctic snow was significantly lower (0 to 14.4 x 10³ N liter⁻¹) than European snow (0.19 x 10³ to 154 x 10³ N liter⁻¹) but still substantial. Polymer composition varied strongly, but varnish, rubber, polyethylene, and polyamide dominated overall. Most particles were in the smallest size range indicating large numbers of particles below the detection limit of 11 mum. Our data highlight that atmospheric transport and deposition can be notable pathways for MPs meriting more research.

Berman, P. (1991). "McDonald's Caves In." Forbes **147**(3): 73.
McDonald's has ceased plans to recycle its polystyrene packaging. The company was developing a project to build seven polystyrene recycling plants in concert with its suppliers, turning the recycled material into plastic resin pellets to be sold to rubber companies. They had also formed a task force with the Environ Defense Fund to study solid waste, but the environmental group disapproved of the recycling plan for fear of a perception by environmental fringe" groups of consorting with the capitalist" interests. McDonald's has replaced polystyrene packaging with polycoated paper, a material hard to recycle once it has been contaminated with food. In addition, making paperboard uses more energy and generates more pollution than producing polystyrene.

Bernard, K. A., et al. (2016). "Ophthalmic Drug Packaging: Safety Risks and Patient Acceptability Issues." Pharmaceutical Technology **40**(10): 44-51.
The article presents case studies related to ophthalmic drug container closure design flaws and the measures taken by the U.S. Food and Drug Administration in mitigating safety risks and patient acceptability. Topics discussed include the safety risk and patient acceptability issues associated with ophthalmic drug packaging, the tamper-evident ring features of packaging, shedding of plastic particles, and the issues of patient-packaging interface with the overly tight bottle closures.

Bernardini, I., et al. (2018). "First data on plastic ingestion by blue sharks (Prionace glauca) from the Ligurian Sea (North-Western Mediterranean Sea)." Marine Pollution Bulletin **135**: 303-310.
Few studies have focused so far on plastic ingestion by sharks in the Mediterranean Sea. The aim of this paper was to determine, for the first time, the plastic litter ingested by blue sharks (Prionace glauca), categorized as "Critically Endangered" in the Mediterranean Sea by IUCN, caught in the Pelagos Sanctuary SPAMI (North-Western Mediterranean Sea). The analysis of the stomach contents was performed following the MSFD Descriptor 10 standard protocol implemented with FT-IR spectroscopy technique. The results showed that 25.26% of sharks ingested plastic debris of wide scale of sizes from microplastics (<5 mm) to macroplastics (>25 mm). The polyethylene sheetlike user plastics, widely used as packaging material, are the most ingested debris. This research raises a warning alarm on the impact of plastic debris on a threatened species, with a key role in the food web, and adds important information for futures mitigation actions.

Berti, F., et al. (2009). "Microfluidic-based electrochemical genosensor coupled to magnetic beads for hybridization detection." Talanta **77**(3): 971-978.
This paper describes the development of a rapid and sensitive enzyme- linked electrochemical genosensor using a novel microfluidic-based platform. In this work, hybridization was performed on streptavidin-coated paramagnetic micro-beads functionalized with a biotinylated capture

probe. The complementary sequence was then recognized via sandwich hybridization with a capture probe and a biotinylated signaling probe. After labeling the biotinylated hybrid with a streptavidin-alkaline phosphatase conjugate, the beads were introduced in a disposable cartridge composed of eight parallel microchannels etched in a polyimide substrate. The modified beads were trapped with a magnet addressing each microchannel individually. The presence of microelectrodes in each channel allowed direct electrochemical detection of the enzymatic product within the microchannel. Detection was performed in parallel within the eight microchannels, giving rise to the possibility of performing a multiparameter assay. Quantitative determinations of the analyte concentrations were obtained by following the kinetics of the enzymatic reaction in each channel. The chip was regenerated after each assay by removing the magnet and thus releasing the magnetic beads. The system was applied to the analytical detection of PCR amplified samples with a RSD% = 6. A detection limit of 0.2 nM was evaluated.

Berto, D., et al. (2017). "Preliminary study to characterize plastic polymers using elemental analyser/isotope ratio mass spectrometry (EA/IRMS)." Chemosphere **176**: 47-56.

Plastic waste is a growing global environmental problem, particularly in the marine ecosystems, in consideration of its persistence. The monitoring of the plastic waste has become a global issue, as reported by several surveillance guidelines proposed by Regional Sea Conventions (OSPAR, UNEP) and appointed by the EU Marine Strategy Framework Directive. Policy responses to plastic waste vary at many levels, ranging from beach clean-up to bans on the commercialization of plastic bags and to Regional Plans for waste management and recycling. Moreover, in recent years, the production of plant-derived biodegradable plastic polymers has assumed increasing importance. This study reports the first preliminary characterization of carbon stable isotopes (δ 13 C) of different plastic polymers (petroleum- and plant-derived) in order to increase the dataset of isotopic values as a tool for further investigation in different fields of polymers research as well as in the marine environment surveillance. The δ 13 C values determined in different packaging for food uses reflect the plant origin of “BIO” materials, whereas the recycled plastic materials displayed a δ 13 C signatures between plant- and petroleum-derived polymers source. In a preliminary estimation, the different colours of plastic did not affect the variability of δ 13 C values, whereas the abiotic and biotic degradation processes that occurred in the plastic materials collected on beaches and in seawater, showed less negative δ 13 C values. A preliminary experimental field test confirmed these results. The advantages offered by isotope ratio mass spectrometry with respect to other analytical methods used to characterize the composition of plastic polymers are: high sensitivity, small amount of material required, rapidity of analysis, low cost and no limitation in black/dark samples compared with spectroscopic analysis. [ABSTRACT FROM AUTHOR]

Bertoldo, M., et al. (2016). "Emulsion Blending Approach for the Preparation of Gelatin/Poly(butylene succinate-co-adipate) Films." ACS Biomaterials Science and Engineering **2**(4): 677-686.

Emulsion blending as a new method to combine a water-soluble biopolymer, gelatin, with a synthetic biodegradable elastomer, poly(butylene succinate-co-adipate) (PBSA), was investigated. Blending by wet processing a hydrophilic biopolymer with a hydrophobic synthetic polymer aimed at evaluating the potential for improving the mechanical properties of the biopolymer without affecting its biodegradability. The effect of the variation of blend composition, and of the experimental procedure for the emulsification and the subsequent preparation of cast films from the resulting oil-in-water emulsions was analyzed. In particular, processing temperature, concentration of the precursor solutions (aqueous gelatin and PBSA in dichloromethane, respectively), blending method and post treatment conditions (T, P) affect the quality and stability of the aqueous gelatin emulsion containing PBSA in dichloromethane as the dispersed phase. Control of the aqueous phase viscosity is a key parameter for both the emulsion stability and the morphology of the final heterophasic cast films. In fact, viscosity must be sufficiently low to allow high shear emulsification, but high enough to prevent coalescence among the organic phase droplets. The process conditions optimized for a 80/20 blend were extended to the preparation of blends with 5-30 wt % PBSA. It was found that evaporation of the organic phase must be nearly quantitative before casting to allow the formation of uniform films at any investigated composition of the immiscible polymer blend. In fact, when the films are produced by casting, the presence of residual organic solvent along with too high a viscosity of the aqueous gelatin phase promotes the formation of cavities opening up at the lower film surface as a result of the higher density of CH<inf>2</inf>Cl<inf>2</inf>. However, such cavities, internally sheathed with PBSA microbeads precipitated upon evaporation of the organic phase, if smaller than 100 mum turned out to improve the flexibility of the films. Besley, A., et al. (2017). "A standardized method for sampling and extraction methods for quantifying microplastics in beach sand." Marine Pollution Bulletin **114**(1): 77-83.

Microplastics are ubiquitous in the environment, are frequently ingested by organisms, and may potentially cause harm. A range of studies have found significant levels of microplastics in beach sand. However, there is a considerable amount of methodological variability among these studies. Methodological variation currently limits comparisons as there is no standard procedure for sampling or extraction of microplastics. We identify key sampling and extraction procedures across the literature through a detailed review. We find that sampling depth, sampling location, number of repeat extractions, and settling times are the critical parameters of variation. Next, using a case-study we determine whether and to what extent these differences impact study outcomes. By investigating the common practices identified in the literature with the case-study, we provide a standard operating procedure for sampling and extracting microplastics from beach sand.

Bessa, F., et al. (2018). "Occurrence of microplastics in commercial fish from a natural estuarine environment." Marine Pollution Bulletin **128**: 575-584.

Microplastic ingestion has been reported for several marine species, but the level of contamination in transitional systems and associated biota is less known. The aim of this study was to assess the occurrence of microplastic ingestion in three commercial fish species: the sea bass (Dicentrarchus labrax), the seabream (Diplodus vulgaris) and the flounder (Platichthys flesus) from the Mondego estuary (Portugal). Microplastics were extracted from the gastrointestinal tract of 120 individuals by visual inspection and digestion solution. A total of 157 particles were extracted from 38% of total fish (96% fibers), with 1.67+or-0.27 (SD) microplastics per fish. Significantly higher amount of ingested microplastics was recorded for D. vulgaris (73%). The dominant polymers identified by micro -FTIR were polyester, polypropylene and rayon (semi-synthetic fiber). It is reported for the first time the presence of this pollutant in fish populations from the Mondego estuary raising concerns on their potential negative effects.

Bessa, F., et al. (2019). "Microplastics in gentoo penguins from the Antarctic region." Scientific Reports **9**(1): 14191.

There is growing evidence that microplastic pollution (<5 mm in size) is now present in virtually all marine ecosystems, even in remote areas, such as the Arctic and the Antarctic. Microplastics have been found in water and sediments of the Antarctic but little is known of their ingestion by higher predators and mechanisms of their entry into Antarctic marine food webs. The goal of this study was to assess the occurrence of microplastics in a top predator, the gentoo penguin Pygoscelis papua from the Antarctic region (Bird Island, South Georgia and Signy Island, South Orkney Islands) and hence assess the potential for microplastic transfer through Antarctic marine food webs. To achieve this, the presence of microplastics in scats (as a proof of ingestion) was investigated to assess the viability of a non-invasive approach for microplastic analyses in Antarctic penguins. A total of 80 penguin scats were collected and any microplastics they contained were extracted. A total of 20% of penguin scats from both islands contained microplastics, consisting mainly of fibers and fragments with different sizes and polymer composition (mean abundance of microplastics: 0.23 +/- 0.53 items individual⁻¹ scat, comprising seven different polymers), which were lower values than those found for seabirds in other regions worldwide. No significant differences in microplastic numbers in penguin scats between the two regions were detected. These data highlight the need for further assessment of the levels of microplastics in this sensitive region of the planet, specifically studies on temporal trends and potential effects on penguins and other organisms in the Antarctic marine food web.

Besseling, E., et al. (2014). "Nanoplastic Affects Growth of S. obliquus and Reproduction of D. magna." Environmental Science & Technology **48**(20): 12336-12343.

The amount of nano- and microplastic in the aquatic environment rises due to the industrial production of plastic and the degradation of plastic into smaller particles. Concerns have been raised about their incorporation into food webs. Little is known about the fate and effects of nanoplastic, especially for the freshwater environment. In this study, effects of nano-polystyrene (nano-PS) on the growth and photosynthesis of the green alga Scene desmus obliquus and the growth, mortality, neonate production, and malformations of the zoo plankter Daphnia magna were assessed. Nano-PS reduced population growth and reduced chlorophyll concentrations in the algae. Exposed Daphnia showed a reduced body size and severe alterations in reproduction. Numbers and body size of neonates were lower, while the number of neonate malformations among neonates rose to 68% of the individuals. These effects of nano-PS were observed between 0.22 and 103 mg nano-PS/L. Malformations occurred from 30 mg of nano-PS/L onward. Such plastic concentrations are much higher than presently reported for marine waters as well as freshwater, but may eventually occur in sediment pore waters. As far as we know, these results are the first to show that direct life history shifts in algae and Daphnia populations may occur as a result of exposure to nanoplastic. [ABSTRACT FROM AUTHOR]

Besseling, E., et al. (2017). "The Effect of Microplastic on the Uptake of Chemicals by the Lugworm Arenicola marina (L.) under Environmentally Relevant Exposure Conditions." Environmental Science & Technology **51**(15): 8795-8804.

It has been hypothesized that ingestion of microplastic increases exposure of aquatic organisms to hydrophobic contaminants. To date, most laboratory studies investigated chemical transfer from ingested microplastic without taking other exposure pathways into account. Therefore, we studied the effect of polyethylene (PE) microplastic in sediment on PCB uptake by Arenicola marina as a model species, quantifying uptake fluxes from all natural exposure pathways. PCB concentrations in sediment, biota lipids (Clip) and porewater measured with passive samplers were used to derive lipid-normalized bioaccumulation metrics Clip, Biota sediment accumulation factor (BSAF), Bioaccumulation factor (BAF) and the Biota plastic accumulation factor (BPAF). Small effects of PE addition were detected suggesting slightly increased or decreased bioaccumulation. However, the differences decreased in magnitude dependent on the metric used to assess bioaccumulation, in the order: Clip > BSAF > BPAF > BAF, and were nonsignificant for BAF. The fact that BAF, that is, normalization of Clip on porewater concentration, largely removed all effects of PE, shows that PE did not act as a measurable vector of PCBs. Biodynamic model analysis confirmed that PE ingestion contributed marginally to bioaccumulation. This work confirmed model-based predictions on the limited relevance of microplastic for bioaccumulation under environmentally realistic conditions, and illustrated the importance of assessing exposure through all media in microplastic bioaccumulation studies. [ABSTRACT FROM AUTHOR]

Besseling, E., et al. (2015). "Microplastic in a macro filter feeder: Humpback whale Megaptera novaeangliae." Marine Pollution Bulletin **95**(1): 248-252.

Marine filter feeders are exposed to microplastic because of their selection of small particles as food source. Baleen whales feed by filtering small particles from large water volumes. Macroplastic was found in baleen whales before. This study is the first to show the presence of microplastic in intestines of a baleen whale (Megaptera novaeangliae). Contents of its gastrointestinal tract were sieved, dissolved in 10% potassium hydroxide and washed. From the remaining dried material, potential synthetic polymer particles were selected based on density and appearance, and analysed by Fourier transform infrared (FTIR) spectroscopy. Several polymer types (polyethylene, polypropylene, polyvinylchloride, polyethylene terephthalate, nylon) were found, in varying particle shapes: sheets, fragments and threads with a size of 1. mm to 17. cm. This diversity in polymer types and particle shapes, can be interpreted as a representation of the varying characteristics of marine plastic and the unselective way of ingestion by M. novaeangliae. Besseling, E., et al. (2017). "Fate of nano- and microplastic in freshwater systems: A modeling study." Environmental Pollution **220**: 540-548.

Riverine transport to the marine environment is an important pathway for microplastic. However, information on fate and transport of nano- and microplastic in freshwater systems is lacking. Here we present scenario studies on the fate and transport of nano-to millimetre sized spherical particles like microbeads (100 nm–10 mm) with a state of the art spatiotemporally resolved hydrological model. The model accounts for advective transport, homo- and heteroaggregation, sedimentation-resuspension, polymer degradation, presence of biofilm and burial. Literature data were used to parameterize the model and additionally the attachment efficiency for heteroaggregation was determined experimentally. The attachment efficiency ranged from 0.004 to 0.2 for 70 nm and 1050 nm polystyrene particles aggregating with kaolin or bentonite clays in natural freshwater. Modeled effects of polymer density (1–1.5 kg/L) and biofilm formation were not large, due to the fact that variations in polymer density are largely overwhelmed by excess mass of suspended solids that form heteroaggregates with microplastic. Particle size had a dramatic effect on the modeled fate and retention of microplastic and on the positioning of the accumulation hot spots in the sediment along the river. Remarkably, retention was lowest (18–25%) for intermediate sized particles of about 5 µm, which implies that the smaller submicron particles as well as larger micro- and millimetre sized plastic are preferentially retained. Our results suggest that river hydrodynamics affect microplastic size distributions with profound implications for emissions to marine systems. [ABSTRACT FROM AUTHOR]

Besseling, E., et al. (2019). "Quantifying ecological risks of aquatic micro- and nanoplastic." Critical Reviews in Environmental Science and Technology **49**(1): 32-80.

Diverse effects of nano- and microplastic (NMP) have been demonstrated in the laboratory. We provide a broad review of current knowledge on occurrence, measurement, modeling approaches, fate, exposure, effects, and effect thresholds as regard to microplastics in the aquatic environment. Using this information, we perform a 'proof of concept' risk assessment for NMP, accounting for the diversity of the material. New data is included showing how bioturbation affects exposure, and exposure is evaluated based on literature data and model analyses. We review exposure and effect data and provide a worst case risk characterization, by comparing HC<inf>5</inf> effect thresholds from 'all inclusive' Species Sensitivity Distributions (SSDs) with the highest environmental concentrations reported. HC<inf>5</inf> values show wide confidence intervals yet suggest that sensitive aquatic organisms in near-shore surface waters might be at risk. Besseling, E., et al. (2013). "Effects of Microplastic on Fitness and PCB Bioaccumulation by the Lugworm Arenicola marina (L.)." Environmental Science & Technology **47**(1): 593-600.

It has been speculated that marine microplastics may cause negative effects on benthic marine organisms and increase bioaccumulation of persistent organic pollutants (POPs). Here, we provide the first controlled study of plastic effects on benthic organisms including transfer of POPs. The effects of polystyrene (PS) microplastic on survival, activity, and bodyweight, as well as the transfer of 19 polychlorinated biphenyls (PCBs), were assessed in bioassays with Arenicola marina (L.). PS was pre-equilibrated in natively contaminated sediment. A positive relation was observed between microplastic concentration in the sediment and both uptake of plastic particles and weight loss by A. marina. Furthermore, a reduction in feeding activity was observed at a PS dose of 7.4% dry weight. A low PS dose of 0.074% increased bioaccumulation of PCBs by a factor of 1.1–3.6, an effect that was significant for ΣPCBs and several individual congeners. At higher doses, bioaccumulation decreased compared to the low dose, which however, was only significant for PCB105. PS had statistically significant effects on the organisms' fitness and bioaccumulation, but the magnitude of the effects was not high. This may be different for sites with different plastic concentrations, or plastics with a higher affinity for POPs. [ABSTRACT FROM AUTHOR]

Bethge, W. A., et al. (2008). "Haploidentical allogeneic hematopoietic cell transplantation in adults using CD3/CD19 depletion and reduced intensity conditioning: an update." Blood Cells Molecules & Diseases **40**(1): 13-19.

Haploidentical hematopoietic cell transplantation (HHCT) after high dose conditioning with CD34-selected stem cells has been complicated by high regimen related toxicities, slow engraftment and delayed immune reconstitution leading to increased treatment related mortality (TRM). A new regimen using reduced intensity conditioning (RIC) and graft CD3/CD19 depletion with anti-CD3 and anti-CD19 coated microbeads on a CliniMACS device may allow HHCT with lower toxicity and faster engraftment. CD3/CD19 depleted grafts not only contain CD34+ stem cells but also CD34 negative progenitors, natural killer, graft facilitating and dendritic cells. RIC was performed with fludarabine (150-200 mg/m(2)), thiotepa (10 mg/kg), melphalan (120 mg/m(2)) and OKT-3 (5 mg/day, day -5 to +14) and no posttransplant immunosuppression. Twenty nine patients (median age=42 (range, 21-59) years) have been transplanted with this regimen. Diagnosis were AML (n=16), ALL (n=7), NHL (n=3), MM (n=2) and CML (n=1). Patients were "high risk" with refractory disease or relapse after preceding HCT. The CD3/CD19 depleted haploidentical grafts contained a median of 7.6x10(6) (range, 3.4-17x10(6)) CD34+ cells/kg, 4.4x10(4) (range, 0.006-44x10(4)) CD3+ T cells/kg and 7.2x10(7) (range, 0.02-37.3x10(7)) CD56+ cells/kg. Donor-recipient KIR-ligand-mismatch was found in 19 of 29 patients. The regimen was well tolerated with maximum acute toxicity being grade 2-3 mucositis. Because of severe neurotoxicity in 4 patients treated with 200 mg/m(2) fludarabine, the dose was reduced to 150 mg/m(2). Engraftment was rapid with a median time to >500 granulocytes/microL of 12 (range, 10-21) days, >20,000 platelets/microL of 11 (range, 7-38) days and full donor chimerism after 2-4 weeks in all patients. Incidence of grade II-IV degrees GVHD was 48% with grade II degrees =10, III degrees =2 and IV degrees =2. One patient, who received the highest T-cell dose, developed lethal grade IV GVHD. TRM in the first 100 days was 6/29 (20%) with deaths due to idiopathic pneumonia syndrome (n=1), mucormycosis (n=1), pneumonia (n=3) or GVHD (n=1). Overall survival is 9/29 patients (31%) with deaths due to infections (n=7), GVHD (n=1) and relapse (n=12) with a median follow-up of 241 days (range, 112-1271). In conclusion, this regimen is promising in high risk patients lacking a suitable donor, and a prospective phase I/II study is ongoing.

Betts, K. (2008). "Why small plastic particles may pose a big problem in the oceans." Environmental

Science & Technology **42**(24): 8995-8995.

The article focuses on the role that plastic trash fragments play in marine pollutant transport. It states that an international conference sponsored by the U.S. National Oceanic and Atmospheric Administration held in September of 2008 examined the microplastic problem and defined microplastics as plastic fragments smaller than 5 millimeters. It mentions that flame retardants, antimicrobials, and plasticizers can be released into the ocean environment as plastic items break down, and the plastics can behave in a sponge-like fashion to collect hydrophobic persistent organic pollutants. Hideshige Takada of the Tokyo University of Agriculture and Technology is investigating if microplastics expose marine animals to phenolic compounds through ingestion.

Beubler, E., et al. (2016). "Influence of the Surfactant Tyloxapol on Mucociliary Clearance in Human Respiratory Cystic Fibrosis Cells." Pharmacology **98**(1-2): 1-3.

Dehydration of the apical surface of cystic fibrosis (CF) airway epithelia leads to a greatly impaired mucociliary clearance function in CF patients. In an in vitro cell model of human airway epithelia taken from CF patients and cultivated for 60 days, mucociliary clearance was zero. Tyloxapol, a synthetic surfactant, is able to restore the mucociliary clearance of the CF epithelia. The velocity of mucociliary clearance, using polystyrene microbeads as markers, increased within the first minute of tyloxapol treatment from zero to 12 micro m/s and reached a maximum of 22 micro m/s after 120 min. In conclusion, tyloxapol restores mucociliary clearance in a MucilAirTM-CF model and may accordingly be efficient in CF patients to restore mucociliary clearance.

Beycan, A., et al. (2015). "Comparative proteomic analysis of bone marrow plasma cells by using mass spectrometry based bottom up proteomic strategies." Blood **126 (23)**: 5334.

Aim : As all other cancer types, multiple myeloma is a complex disease, yet its molecular mechanism that is not fully understood and needs to be furtherly investigated. Besides, the molecular mechanism responsible from the transition of healthy cells into malignant ones is still under investigation. In such comparative studies, human myeloma cell lines are preferred as positive control, while tonsillar plasma cells are used as negative control. The aim of this study is to perform a comparative proteomic analysis regarding the progression of Multiple Myeloma (MM) by using protein profiles of plasma cells obtained from MGUS, SMM, symptomatic myeloma patients, tonsil plasma cells obtained from healthy individuals and human myeloma cells of cell line origin to elucidate the underlying molecular mechanism involved in myeloma. Material(s) and Method(s): Five groups were adopted in the experiment. Of these groups, MM patients were classified mainly into three groups according to marrow plasma cell content (PCC) validated by flow cytometry: group1: 0-9, group 2: 10-20 and group 3: >20 %. The fourth group consisted of human myeloma cell line (HMCL) RPMI 8226 and was designated as positive control, while tonsil plasma cells were used as negative control and specified as the fifth group. Marrow samples were collected from 30 patients newly diagnosed with Multiple Myeloma (n: 28 symptomatic and n: 1 smoldering (SMM)) and MGUS (n: 1)).Tonsil plasma cells were isolated from healthy tonsil tissue treated with trypsin enzyme and were then confirmed by using Selection Kit microbead specific for EasySep Human CD138 marker. Protein profile maps of groups were obtained via 2D gel electrophoresis and comparative analysis and detection of up/down regulated protein spots was performed by using PDQuest 8.01 software. Proteins from differently expressed protein spots were then identified using Matrix-assisted laser desorption/ionization mass spectroscopy (MALDI) by Peptide Mass Fingerprinting (PMF) analysis Results: By using bottom up strategies, nine of the significantly expressed protein spots were identified with PMF analyses. The identified proteins are as follows:, Calreticulin (ERp60), Endoplasmin/ tumor rejection antigen (ERp99), MZB1(Marginal zone B and B1 cell specific protein/ pERp1), Actin cytoplasmic1 (ACTB), Thioredoxin domain-containing protein 5 (TXNDC5/ERp46), Protein disulfide isomerase (PDI) and HLA class I histocompatibility antigen (MHC class I antigen A*2). According to the results, calreticulin (which functions as chaperones and is responsible for Ca+2regulation and cell proliferation) showed a weak positive correlation with increase in patient PC content. The level was lowest in normal B cells. Endoplasmin/ tumor rejection antigen (which is assigned as chaperones and function in apoptotic process and Ca+2 regulation)declined by increase in PC content in patient samples. Level was lowest in HMCL. Marginal zone B and B1 cell specific protein (which functions as chaperones and is involved in apoptotic process, oxidoreductase activity, regulation of Ca+2, cell proliferation and activates B cell quantiity) correlated with PC percentage and was highest in HCML and lowest in normal B cells. Actin cytoplasmic1 protein (which functions in cell proliferation)synthesis showed a minimum decline in synthesis by increase in PC content .Level was highest in normal B cells. Thioredoxin domain-containing protein 5 which plays role in apoptotic process and shows oxireductase activity within MM/MGUS plasma cells also displayed a positive correlation but we were not able to detect a difference in HMCL and normal B cells which were synthesized less than the patient samples. Protein disulfide isomerase (which acts as chaperones and plays part in apoptotic process and shows oxireductase function) has a weak negative correlation with PC content and synthesis was lowest in HMCL. HLA class I histocompatibility antigen production did not correlate with PC content , it was higher in normal B cells compared to HMCL. Conclusion(s): In conclusion in this study we were able to confirm our previous findings which were presented at ASH 2013 by comparing the results with normal tonsil CD138+ plasma cells and a HMCL. Our study results suggest that the proteins which are involved in Calcium metabolism, chaperone binding and oxidative stress are also associated with low vs. high proliferation profile in myeloma.

Beyer, J., et al. (2017). "Blue mussels (Mytilus edulis spp.) as sentinel organisms in coastal pollution monitoring: A review." Marine Environmental Research **130**: 338.

The blue mussel (Mytilus spp.) is widely used as a bioindicator for monitoring of coastal water pollution (mussel watch programs). Herein we provide a review of this study field with emphasis on: the suitability of Mytilus spp. as environmental sentinels; uptake and bioaccumulation patterns of key pollutant classes; the use of Mytilus spp. in mussel watch programs; recent trends in Norwegian mussel monitoring; environmental quality standards and background concentrations of key contaminants; pollutant effect biomarkers; confounding factors; particulate contaminants (microplastics, engineered nanomaterials); climate change; harmonization of monitoring procedures; and the use of deployed mussels (transplant caging) in pollution monitoring. Lastly, the overall state of the art of blue mussel pollution monitoring is discussed and some important issues for future research and development are highlighted.

Bez, J., et al. (1998). "Waste treatment in product specific life cycle inventories." International Journal of Life Cycle Assessment **3**(2): 100-105.

The model approach described in this paper shows an operationalized concept for the allocation of the environmental effects caused by the landfill process to special input components. The calculation of the landfill emissions in the model is based on the emission spectrum (landfill gas and seepage water) of an average-sized landfill in Germany and the elementary composition of the single waste fraction under consideration. The resulting reactor landfill module comprises an average split for diffuse and captured landfill emissions, the use of captured landfill gases in a

gas engine and a cleaning of captured seepage water in a waste water treatment plant. A short case study demonstrates the calculation of the effects of landfilling of a defined waste fraction (bottle fraction in post-consumer plastic waste).

Bhagat, S., et al. (2016). "Evaluating plastic waste disposal options in Delhi using multi criteria decision analysis." IIOAB Journal **7**(11Specialissue): 25-35.

Continuous rise in the population of India has led to a steep increase in the amount of solid waste generated, particularly from urban areas which ultimately deteriorates soil and water due to unscientific disposal methods. Plastic forms an important constituent in the composition of the urban MSW because of its increasing use in our everyday lives and therefore requires the selection of a sustainable management option which is currently absent in the existing policy framework of India. This study uses the Multi Criteria decision analysis approach (MCDA) in order to evaluate different options for waste disposal for arriving at the most sustainable option for management and disposal of plastic waste in Delhi. A panel of nine members, who were faculty, researchers and students from the Indian Institute of Technology (IIT), Delhi was made and they evaluated seven disposal options against a set of environmental, health, financial and legislative criteria. The seven options included Landfill, Recycling, Incineration, Pyrolysis and a combination of two processes each from the first three mentioned in the study. The panel weighed the criteria and scored the options on them to arrive at an overall aggregate score for the best option. The study reveals that MCDA is a very effective and transparent measure of involving and encouraging public participation in decision making with highly successful results in the context of waste management. The panel suggested that a blend of recycling along with incineration was the best option which was followed by recycling and incineration. The worst method in the panel's consideration was the open landfilling currently practiced in Delhi which is a big source of soil contamination. The paper suggests that MCDA approach for evaluation of waste disposal options can arrest soil contamination to a great extent by providing the best waste management choice. Bhandari, A., et al. (2019). "Early-Stage Ocular Hypertension Alters Retinal Ganglion Cell Synaptic Transmission in the Visual Thalamus." Frontiers in Cellular Neuroscience **13**: 426.

Axonopathy is a hallmark of many neurodegenerative diseases including glaucoma, where elevated intraocular pressure (ocular hypertension, OHT) stresses retinal ganglion cell (RGC) axons as they exit the eye and form the optic nerve. OHT causes early changes in the optic nerve such as axon atrophy, transport inhibition, and gliosis. Importantly, many of these changes appear to occur prior to irreversible neuronal loss, making them promising points for early diagnosis of glaucoma. It is unknown whether OHT has similarly early effects on the function of RGC output to the brain. To test this possibility, we elevated eye pressure in mice by anterior chamber injection of polystyrene microbeads. Five weeks post-injection, bead-injected eyes showed a modest RGC loss in the peripheral retina, as evidenced by RBPMS antibody staining. Additionally, we observed reduced dendritic complexity and lower spontaneous spike rate of On-alphaRGCs, targeted for patch clamp recording and dye filling using a Opn4-Cre reporter mouse line. To determine the influence of OHT on retinal projections to the brain, we expressed Channelrhodopsin-2 (ChR2) in melanopsin-expressing RGCs by crossing the Opn4-Cre mouse line with a ChR2-reporter mouse line and recorded post-synaptic responses in thalamocortical relay neurons in the dorsal lateral geniculate nucleus (dLGN) of the thalamus evoked by stimulation with 460 nm light. The use of a Opn4-Cre reporter system allowed for expression of ChR2 in a narrow subset of RGCs responsible for image-forming vision in mice. Five weeks following OHT induction, paired pulse and high-frequency stimulus train experiments revealed that presynaptic vesicle release probability at retinogeniculate synapses was elevated. Additionally, miniature synaptic current frequency was slightly reduced in brain slices from OHT mice and proximal dendrites of post-synaptic dLGN relay neurons, assessed using a Sholl analysis, showed a reduced complexity. Strikingly, these changes occurred prior to major loss of RGCs labeled with the Opn4-Cre mouse, as indicated by immunofluorescence staining of ChR2-expressing retinal neurons. Thus, OHT leads to pre- and post-synaptic functional and structural changes at retinogeniculate synapses. Along with RGC dendritic remodeling and optic nerve transport changes, these retinogeniculate synaptic changes are among the earliest signs of glaucoma.

Bharadwaj, D. N. (2010). "Use and environment impact of biodegradable plastics - a review." Current Advances in Agricultural Sciences **2**(2): 65-69.

Persistence of chemical compounds in plastic made them non-biodegradable polluting the environment. Disposal of plastic waste in a country like India where municipal waste management systems are already weak becomes a brutal problem. This garbage even had reached onto mountains and the deep oceans. Petroleum plastics with synthetic additives proved carcinogenic and have several harmful effects on animal life. To overcome this problem India needs to use biodegradable plastics in several areas viz., agricultural mulch, industrial packaging, wrapping, milk packets, food service, personal care, pharmaceuticals, surgical implants, medical devices and recreation. In the interest of public health and environmental catastrophes it is now critical to generate alternative resources of biodegradable plastics and avoid the use of petrochemical plastics. Exploitation of cellulose from bagasse, cotton lint and regenerated cellulose from non-edible starch (from waste and spoiled grains) can be converted to lactic acid polymers; plasticized thermoplastic starch is good for making disposables.

Bhardwaj, L., et al. (2019). "Persistent organic pollutants in lakes of Broknes peninsula at Larsemann Hills area, East Antarctica." Ecotoxicology **28**(5): 589-596.

Anthropogenic activity in East Antarctica has increased since the last 2-3 decades because of various scientific expeditions. Additionally, global pollution due to various newly introduced pollutants like pesticides is on use since the past century and many factors contribute to contamination even in Antarctica. During thirty fourth Indian Scientific Expedition to Antarctica (ISEA) in austral summer of 2014-2015, fifteen lake water samples were collected from five different lakes at Broknes peninsula, Larsemann Hills, East Antarctica. Persistent Organic Pollutants (POPs) residue levels found in lake water samples varied from 10.33-70.00 pg/mL in five different lakes. Presence of p,p'-DDT was detected in all different lakes but high concentration found in P4 lake water. After study confirms that Broknes peninsula in the Larsemann Hills area, East Antarctica has a trace amount of POPs which is an alarming situation and needs to be investigated further to maintain the pristine environment in Antarctica. The presence of POPs may be attributed to orographic effects, migratory birds, biomagnification and anthropogenic sources. In the future, new emerging pollutants must be analyzed like microplastics, phthalate, Paraxanthene etc.

Bhattacharya, S. S., et al. (2013). "Tranexamic acid loaded gellan gum-based polymeric microbeads for controlled release: In vitro and in vivo assessment." Colloids and Surfaces B: Biointerfaces **112**: 483-491.

Gellan gum (GG) microbeads containing tranexamic acid (TA), an anti-fibrinolytic drug were prepared by a classic sol-gel transition induced by ionic crosslinking technique using aluminum chloride (AlCl<inf>3</inf>) as cross-linking agent. The influence of different formulation variables on in vitro physico-chemical parameters and drug release studies were performed systematically. The microbeads were evaluated by scanning electron microscopy (SEM), Fourier transform infra-red (FTIR) spectroscopy, X-ray diffraction (XRD), differential scanning calorimetry (DSC) and high performance liquid chromatographic (HPLC) analysis. Particle size and swelling behavior of microbeads were also investigated. Microbeads showed improved drug encapsulation efficiency along with enhanced drug release. The in vivo studies exhibited sustained drug release in rabbits over a prolonged period after oral administration of these newly developed TA loaded GG microbeads. Based on the results of in vitro and in vivo studies in experimental animal model it was concluded that these microbeads provided intestinal specific controlled release of TA. © 2013 Elsevier B.V.

Bhattacharya, S. S., et al. (2013). "A RP-HPLC method for quantification of diclofenac sodium released from biological macromolecules." International Journal of Biological Macromolecules **58**: 354-359.

Interpenetrating network (IPN) microbeads of sodium carboxymethyl locust bean gum (SCMLBG) and sodium carboxymethyl cellulose (SCMC) containing diclofenac sodium (DS), a nonsteroidal anti-inflammatory drug, were prepared by single water-in-water (w/w) emulsion gelation process using AlCl<inf>3</inf> as cross-linking agent in a complete aqueous environment. Pharmacokinetic study of these IPN microbeads was then carried out by a simple and feasible high-performance liquid chromatographic method with UV detection which was developed and validated for the quantification of diclofenac sodium in rabbit plasma. The chromatographic separation was carried out in a Hypersil BDS, C18 column (250mmx4.6mm; 5m). The mobile phase was a mixture of acetonitrile and methanol (70:30, v/v) at a flow rate of 1.0ml/min. The UV detection was set at 276nm. The extraction recovery of diclofenac sodium in plasma of three quality control (QC) samples was ranged from 81.52% to 95.29%. The calibration curve was linear in the concentration range of 20-1000ng/ml with the correlation coefficient (r²) above 0.9951. The method was specific and sensitive with the limit of quantification of 20ng/ml. In stability tests, diclofenac sodium in rabbit plasma was stable during storage and assay procedure. © 2013.

Bhattacharya, S. S., et al. (2012). "Al3+ ion cross-linked interpenetrating polymeric network microbeads from tailored natural polysaccharides." International Journal of Biological Macromolecules **51**(5): 1173-1184.

Interpenetrating network (IPN) microbeads of sodium carboxymethyl locust bean gum (SCMLBG) and sodium carboxymethyl cellulose (SCMC) containing diclofenac sodium (DS), a non steroidal anti-inflammatory drug were prepared by single water-in-water (w/w) emulsion gelation process using AlCl(3) as cross-linking agent in a complete aqueous environment. The influence of different variables like total polymer concentration, gelation time and crosslinker content on in vitro physico-chemical characteristics and drug release rate in different media was investigated. Drug loaded microbeads were evaluated through Fourier transform infra-red (FTIR), X-ray diffraction (XRD) and differential scanning calorimetry (DSC) analyses. Scanning electron microscopy (SEM) micrograph of the beads suggested the formation of spherical particles. FTIR analysis indicated the stable nature of the drug in the blend microbeads. DSC and XRD analysis revealed amorphous state of drug after encapsulation. The drug release profile in acidic medium was considerably less in comparison to alkaline media. Formulations showed non-Fickian type transport mechanism. These tri-valent ion crosslinked beads not only improve drug encapsulation efficiency but also enhance drug release in phosphate buffer.

Bhogayata, A. C. and N. K. Arora (2019). "Utilization of metalized plastic waste of food packaging articles in geopolymer concrete." The Journal of Material Cycles and Waste Management **21**(4): 1014-1026.

The metalized plastics are extensively used by the food packaging industry. The metalized plastic wastes (MPW) are largely unfit for reuse and recycle process and impose harmful impacts to the environment. The MPW may be sustainably utilized in construction materials. The fly ash-based geopolymer concrete (GPC) has emerged as a sustainable construction material in the past few decades. Therefore, a novel combination of MPW and GPC may hold the potential of preparing a greener and sustainable construction material. The objectives were to obtain the optimum dosage of MPW fibers and to evaluate the corresponding response of the fresh and strength properties of the modified GPC. To explore the effectiveness of the addition of MPW into GPC, the life cycle assessment was studied for MPW and the novel composite prepared by combining GPC and MPW. The results exhibited improvement of strength properties of modified GPC specimens due to MPW fibers with a reduced trend of improvement of workability. It was observed that an addition of 1% MPW fibers by volume of the mix showed good performance of the composite for all test conditions. The sustainability assessment of the novel composite demonstrated promising outcomes ensuring the feasibility of usage of MPW into the GPC.

Biagini, R. E., et al. (2002). "Development of multiplexed fluorescence microbead covalent assays (FMCAs) for pesticide biomonitoring." Bulletin of environmental contamination and toxicology **68**(4): 470-477.

Biagini, R. E., et al. (2004). "Comparison of a multiplexed fluorescent covalent microsphere immunoassay and an enzyme-linked immunosorbent assay for measurement of human immunoglobulin G antibodies to anthrax toxins." Clinical & Diagnostic Laboratory Immunology **11**(1): 50-55.

Recently, the Centers for Disease Control and Prevention reported an accurate, sensitive, specific, reproducible, and quantitative enzyme-linked immunosorbent assay (ELISA) for immunoglobulin G (IgG) antibodies to Bacillus anthracis protective antigen (PA) in human serum (C. P. Quinn, V. A. Semenova, C. M. Elie et al., Emerg. Infect. Dis. 8:1103-1110, 2002). The ELISA had a minimum detectable concentration (MDC) of 0.06 microgram/ml, which, when dilution adjusted, yielded a whole-serum MDC of 3.0 micro g of anti-PA IgG per ml. The reliable detection limit (RDL) was 0.09 microgram/ml, while the dynamic range was 0.06 to 1.7 microgram/ml. The diagnostic sensitivity of the assay was 97.6% and the diagnostic specificity was 94.2% for clinically verified cases of anthrax. A competitive inhibition anti-PA IgG ELISA was also developed to enhance the diagnostic specificity to 100%. We report a newly developed fluorescence covalent microbead immunosorbent assay (FCMIA) for B. anthracis PA which was Luminex xMap technology. The FCMIA MDC was 0.006 microgram of anti-PA IgG per ml, the RDL was 0.016 microgram/ml, and the whole-serum equivalent MDC was 1.5 micrograms/ml. The dynamic range was 0.006 to 6.8 microgram/ml. Using this system, we analyzed 20 serum samples for anti-PA IgG and compared our results to those measured by ELISA in a double-masked analysis. The two methods had a high positive correlation ($r2 = 0.852$; $P < 0.001$). The FCMIA appears to have benefits over the ELISA for the measurement of anti-PA IgG, including greater sensitivity and speed, enhanced dynamic range and reagent stability, the use of smaller sample volumes, and the ability to be multiplexed (measurement of more than one analyte simultaneously), as evidenced by the multiplexed measurement in the present report of anti-PA and anti-lethal factor IgG in serum from a confirmed clinical anthrax infection.

Biagini, R. E., et al. (2004). "Development of a sensitivity enhanced multiplexed fluorescence covalent microbead immunosorbent assay (FCMIA) for the measurement of glyphosate, atrazine and metolachlor mercapturate in water and urine." Analytical & Bioanalytical Chemistry **379**(3): 368-374.

Body burdens from exposures to pesticides may be estimated from urinary analyses of pesticide

parent/metabolite concentrations. Pesticide applicators and others are often exposed to numerous unrelated pesticides, either sequentially or simultaneously. Classically, body burdens of pesticides are analyzed using chemical/instrumental analysis (CIM) or enzyme immunoassays (EIAs). Both of these technologies can usually be used to quantitate one analyte (or closely related groups of analytes) per analysis. Alternatively, multiple analytes can be measured simultaneously using a multiplexed fluorescence covalent microbead immunoassay (FCMIA). We developed a multiplexed FCMIA to simultaneously measure glyphosate (Gly), atrazine (Atz), and metolachlor mercapturate (MM) in water and urine. The assay had least detectable doses (LDDs) in water/diluted urine of 0.11/0.09 ng/ml (Gly, water/urine LDD), 0.10/0.07 ng/ml (Atz) and 0.09/0.03 ng/ml (MM). The sensitivity for the measurement of Gly was enhanced by derivatization. All assays gave linear responses from the LDDs for each respective pesticide to 300 ng/ml. There was no cross-reactivity between the three analytes. Using a 96-well microplate and an autosampler, as many as 288 separate analyses can be completed in approximately 120 min with precision, sensitivity, and specificity equivalent to, if not better, than that found when these same analytes are measured by CIM or EIA.

Bian, J., et al. (2019). "Study on safety of melamine tableware in market." Journal of Food Safety and Quality **10**(23): 8157-8163.

Objective: To determine and analyze the sensory, formaldehyde migration and melamine migration of commercially available melamine tableware, and to evaluate the safety of commercially available melamine tableware.

Biber, N. F. A., et al. (2019). "Characterising the deterioration of different plastics in air and seawater." Marine Pollution Bulletin **141**: 595-602.

In situ studies of plastic deterioration can help us understand the longevity of macroplastic as well as the generation of microplastics in the environment. Photo-oxidation contributing to the generation of microplastics in the marine environment was explored using four types of plastic (polyethene, polystyrene, poly(ethylene terephthalate) and Biothene exposed in light and in shade, in both air and sea water. Metrics for deterioration were tensile extensibility and oxidation rate. Measurements were conducted at intervals between 7 and 600days' exposure. Deterioration was faster in air than in sea water and was further accelerated in direct light compared to shade. Extensibility and oxidation were significantly inversely correlated in samples exposed in air. Samples in sea water lost extensibility at a slower rate. Polystyrene, which enters the waste stream rapidly due to its wide application in packaging, deteriorated fastest and is, therefore, likely to form microplastics more rapidly than other materials, especially when exposed to high levels of irradiation, for example when stranded on the shore.

Bierbaum, S. and H. Notbohm (1998). "Tyrosine phosphorylation of 40 kDa proteins in osteoblastic cells after mechanical stimulation of beta1-integrins." European Journal of Cell Biology **77**(1): 60-67.

Using a method for the mechanical stimulation of cells which was adapted from one developed by Wang and Ingber employing magnetic microbeads [Wang, N. D., D. E. Ingber: Control of cytoskeletal mechanics by extracellular matrix, cell shape, and mechanical tension. Biophys. J. 66, 2181-2189 (1994)], mechanical stress could be applied to specific receptors on the cell surface. To achieve this, ferromagnetic microbeads coated with different ligands were magnetized after adhesion to the cells. The beads were then 'twisted' using a second magnetic field oriented perpendicular to the magnetizing one. Contrary to most current methods, it was possible to confer the strain without deforming the cell as a whole, thus being able to observe the individual reactions of transmembrane receptors to mechanical stress. An increase in

tyrosine phosphorylation of proteins migrating at approximately 40 kDa could be observed as a reaction to stress on the beta1-subunits of the integrin family, while stress to other transmembrane molecules like the transferrin or low density lipoprotein receptors with no connection to the cytoskeleton did not give this reaction. Fibroblastic cells showed, contrary to osteoblastic cells, no reaction to stress applied on transmembrane proteins.

Biginagwa, F. J., et al. (2016). "First evidence of microplastics in the African Great Lakes: recovery from Lake Victoria Nile perch and Nile tilapia." Journal of Great Lakes Research **42**(1): 146-149.

Microplastic contamination in the African Great Lakes is currently unreported, and compared to other regions of the world little is known about the occurrence of microplastics in African waters and their fauna. The present study was conducted in the Mwanza region of Tanzania, located on the southern shore of Lake Victoria. The gastrointestinal tracts of locally fished Nile perch (Lates niloticus) and Nile tilapia (Oreochromis niloticus) were examined for plastics. Plastics were confirmed in 20% of fish from each species by Attenuated Total Reflectance Fourier Transform Infrared (ATR-FTIR) spectroscopy. A variety of polymer types were identified with likely sources being urban waste and consumer use. Although further research is required to fully assess the impact of plastic pollution in this region, our study is the first to report the presence of microplastics in Africa's Great Lakes and within the fish species that inhabit them.

Bilgili, M. S., et al. (2019). "Characterisation of wastes collected from beaches, coastlines, marine surface cleaning processes and ships: A case study of Istanbul." Waste Management and Research **37**(6): 621-630.

Marine waste management is crucial for Istanbul because of the significant location for intercontinental transition, international trade, tourism, industry and shipping. This study is the first one realised in Turkey for the detailed characterisation of marine waste. The amount and characteristics of solid wastes originating from beaches, coastlines, sea surface cleaning processes and ships (both cargo and cruise ships) were determined. It was observed that marine wastes includes a significant amount of recyclable materials. Although, it was ascertained that the amount and composition of waste differs according to the collecting sources, the majority of wastes are composed of different types of plastics. The average calorific value of marine waste was determined as 2500 kcal kg⁻¹, which is higher than that of mixed municipal solid waste. There is a lack of studies on the pathways of disposal alternatives of marine waste after collection. As landfilling is the common pathway for disposal after collecting, it is clear that recycle/reuse and energy recovery options are possible for marine waste. Copyright © The Author(s) 2019.

Bimali Koongolla, J., et al. (2018). "Evidence of microplastics pollution in coastal beaches and waters in southern Sri Lanka." Marine Pollution Bulletin **137**: 277-284.

The abundance of microplastics (MPs) in surface water and beach sediment in Southern Sri Lanka covering a distance of 91km of coastline is reported. MPs were classified according to polymer type, geometry and color of the sites tested 60% showed MP contamination in sand and 70% in surface waters off the coast. The size range of MPs from surface waters and beaches were to 1.5-2.5mm and 3-4.5mm, respectively. Majority of these were identified as polyethylene (PE) and polypropylene (PP) with some polystyrene (PS) foam at a few sites. Fragments derived from larger debris appears to be the dominant type of MP at most sites and only 2 sites showed virgin pellets that accounted for 14% of the samples collected.

Binelli, A., et al. (2020). "Hazard evaluation of plastic mixtures from four Italian subalpine great lakes on the basis of laboratory exposures of zebra mussels." Science of the Total Environment **699**: N.PAG-N.PAG.

Studies related to the evaluation of plastics in freshwaters have been increasing in recent years because approximately 80% of plastic items found in the sea are from inland waters. Despite the ecological relevance of these surveys, no information has been available until now about the hazard related to plastic mixtures in freshwaters. To fill this knowledge gap, we carried out a study aimed to assess the environmental risk associated with the "cocktail" of plastics and environmental pollutants adsorbed on their surface in one of the larger European freshwater basins. Plastic debris was collected by a manta trawl along one transect each in four of the Italian subalpine great lakes (Lake Maggiore, Como, Iseo and Garda) and administered to zebra mussels (Dreissena polymorpha), a useful freshwater biological model present in all these lakes. We estimated a plastic density from 4908 MPs/km2 (Lake Iseo) to 272,261 MPs/km2 (Lake Maggiore), while the most common polymers found were polyethylene and polypropylene, with percentages varying between 73% and 100%. A biomarkers suite consisting of 10 different endpoints was performed after 7 days of exposure to investigate the molecular and cellular effects of plastics and related adsorbed pollutants. The main results highlighted a diffuse but different toxicity due to plastics for each lake, and there were significant changes in the antioxidant and detoxifying enzyme activities in Lake Maggiore, Iseo and Garda, an increase in protein carbonylation in L. Como, and a cellular viability decrease of approximately 30% for zebra mussels from L. Iseo and Garda. Despite this variability in the endpoints' responses, the application of the biomarker response index showed a similar environmental hazard due to plastics for all the sampled lakes. Unlabelled Image • Plastics were from 11,000 MPs/km2 (L. Iseo) up to 100,000/km2 (L. Maggiore). • A similar environmental hazard due to plastics was found for all the sampled lakes. • Some enzymatic activities, protein carbonylation and cell viability were changed. • No relation between sampled plastic amount and biomarkers data was found. [ABSTRACT FROM AUTHOR]

Binhussain, M. A. and M. M. El-Tonsy (2013). "Palm leave and plastic waste wood composite for out-door structures." Construction and Building Materials **47**: 1431-1435.

The objective of this paper is to produce an environmentally friendly artificial wood for structural application, by recycling mixed plastic waste and date palm leaves waste. Several pretreated wood plastic composites mixtures, using a 1:1 ratio of palm leaves and plastic waste, were designed and developed - namely, polycarbonate (PC-mix), polystyrene (PS-mix), and polyvinyl chloride (PVC-mix). The batch mixture of each type was extruded at different temperature profiles. The density, water absorption, hardness, modulus of elasticity (tensile and flexure), impact strength, and linear burning rate of the WPC samples produced were determined, and the results were compared with the natural hard, soft wood, and medium density fiberboard (MDF) woods. The developed wood plastic composites exhibited less water absorption, linear burning and hardness, higher density than that of natural and MDF wood, and can be used in outdoor structures.

Biniaz, S. (2019). "The UNGA Resolution on a 'Global Pact for the Environment': A chance to put the horse before the cart." Review of European Comparative & International Environmental Law **28**(1): 33-39.

While the 'Global Pact for the Environment' endorsed by France did not provide a compelling link between its approach and a particular environmental problem, United Nations General Assembly (UNGA) Resolution 72/277 sets out a linear methodological approach by asking a working group to consider whether there are possible 'gaps' in existing environmental law and policy and, if so, to discuss possible options for addressing them. This article discusses the concept of a 'gap', identifies several types of gaps that could be included in the UNGA work and points to possible ways in which such gaps may be filled. It illustrates how States could analyse gaps using four possible cases, including the domestic implementation of international commitments, climate change, substantive environmental rights and ocean plastics. Rather than jumping to pursue an overarching agreement including legally binding principles, the article argues that Resolution 72/277 offers States the opportunity to step back and methodically consider the most important missing pieces in international environmental law and policy, and the best manner and forum to address them. [ABSTRACT FROM AUTHOR]

Biozzi, G., et al. (1998). "Effect of genetic modification of acute inflammatory responsiveness on tumorigenesis in the mouse." Carcinogenesis **19**(2): 337-346.

Two distinct bidirectional selective breedings for quantitative traits were initiated from identical genetically heterogeneous mouse populations. The resulting lines are characterized by maximal or minimal acute inflammatory responsiveness (AIR): AIRmax and AIRmin lines, respectively, and by resistance or susceptibility to chemical skin tumorigenesis: Car-R and Car-S lines, respectively. The AIR response to s.c. injection of polyacrylamide microbeads, measured by cell content in the local exudate, was 10 times higher in AIRmax than in AIRmin mice. The response to selection was asymmetrical: the realized heritability was 0.26 in AIRmax and 0.008 in AIRmin, and resulted from the additive effect of 7-11 quantitative trait loci (QTL). Low responsiveness was globally dominant in F1 and 48% of F2 segregant variance was found to be due to genetic factors. These findings are the first demonstration of innate regulation of AIR by germ line genes. Susceptibility to skin tumorigenesis induced by a two-stage initiation (DMBA)-promotion (TPA) protocol was lower in AIRmax mice than in AIRmin mice, a 6-fold difference in tumor induction rate. Intense AIR was found to be associated with resistance, and low AIR with susceptibility to tumorigenesis, in F2 segregants chosen for extreme AIR phenotypes. At least some of the AIR QTLs therefore contain genes controlling tumorigenesis. Tumor phenotypes differed more in Car-R and Car-S than in AIRmax and AIRmin lines, indicating that QTLs unrelated to AIR, contribute to the host response to tumorigenesis. The extreme phenotypes/genotypes of the four selected lines and the known genetic constitution of their foundation population, offer new possibilities to discriminate the genes/mechanisms controlling two important traits: AIR and response to chemical tumorigenesis. Collaborative projects will be favorably considered. The description of tumor resistance genes in AIRmax and Car-R mice may be helpful for epidemiology and therapy of human cancer.

Bird, A. (2014). "Recycling tubs and yoghurt pots: Challenges and opportunities." Local Authority Waste & Recycling **22**(6): 14-14.

The article focuses on developments in plastics recycling all over Great Britain, as the trends emphasized more on household plastic waste. Topics covered include an Exter University research which revealed the role of food chain issues in affecting the waste management of people, the complexities over plastics as a type of recyclable waste, and the importance of events like the Plastics Recycling Expo in addressing plastics recycling issues.

Birlik, E., et al. (2006). "Preconcentration of copper using double-imprinted polymer via solid phase extraction." Analytica Chimica Acta **565**(2): 145-151.

The aim of this study is to prepare double-imprinted polymers which can be used for the selective removal of Cu(II) ions from synthetic waters. Chitosan-succinate (CS) was choosen as the metal complexing polymer. In the first step, chitosan was modified with succinic anhydrides. Modified chitosan was complexed with copper(II) ions and then reacted with 3-(2-aminoethylamino) propyltrimethoxysilane (AAPTS). In the prepared imprinted sorbent, both Cu(II) and AAPTS were used as templates. Then polymeric beads were crosslinked with tetraethoxysilane (TEOS). After that, the template (i.e., Cu(II) ions) was removed using 0.1 M HNO<inf>3</inf> solution. These Cu(II)-imprinted microbeads were used in the adsorption-desorption process. The effect of initial concentration of metal, the adsorption equilibria and the pH of the medium on adsorption capacity of Cu(II)-imprinting sorbents were studied. The maximum adsorption capacity and the relative selectivity coefficients of imprinted beads for Cu(II)/Zn(II), Cu(II)/Ni(II) and Cu(II)/Co(II) were also calculated. The double-imprinted polymers could be used many times without decreasing their adsorption capacities significantly.

Birnbaum, S., et al. (1988). "Production and release of human proinsulin by recombinant Escherichia coli immobilized in agarose microbeads." Enzyme and Microbial Technology **10**(10): 601-605.

Escherichia coli cells, releasing human proinsulin, were entrapped in 2% agarose microbeads. In order to optimize production of proinsulin in shake flask cultures, a number of parameters were evaluated, including temperature, pH, initial cell loading, bead size, agarose concentration, and bead/volume ratios. Maximum production was about 2 mg l super(-1) day super(-1). Production decreased by over 70% per day. Storage stability, t sub(0.5), was 6 and 10 days at 21 and 4 degree C, respectively, with regard to proinsulin production. Extensive protein and cell release was observed after induction.

Biswas, S. and K. H. Wan (2019). "Review of rodent hypertensive glaucoma models." Acta Ophthalmologica **97**(3): e331-e340.

Glaucoma is a neurodegenerative disease characterized by the progressive loss of retinal ganglion cells (RGCs). Elevated intraocular pressure (IOP) is a primary risk factor for the development and progression of glaucoma. Rodent models of glaucoma have greatly improved our understanding of the pathophysiology of glaucoma and served as a useful tool to investigate neuroprotective agents. An ideal glaucoma animal model should be easy to induce, reproducible, biologically plausible and predictable. Of the available animal models of glaucoma, rodents are commonly studied because they have a relatively short life span and can be genetically altered. A successful hypertensive glaucoma model should induce structural glaucomatous changes: including loss of retinal nerve fibres, retinal ganglion cells and optic-disc cupping along with IOP elevation. The level and duration of IOP elevation should be titratable depending on the targeted glaucomatous damage. This review summarizes the outcomes of induced rodent hypertensive glaucoma models including intracameral injection of microbeads, laser photocoagulation, episcleral vein cauterization, injection of hypertonic saline and hyaluronic acid. We aim to provide a detailed overview of each of the models with a focus on parameters that defines a successful glaucoma model. The induced IOP elevation and duration of elevation varied among the different models and strain of rodent; nonetheless, they all achieved a sustainable raised IOP with corresponding RGC loss. The limitations of each model are discussed. Copyright © 2018 Acta Ophthalmologica Scandinavica Foundation. Published by John Wiley & Sons Ltd

Biswas, S. B., et al. (2013). "Altered expression of A1 antigen in acute myeloid leukemia." Vox Sanguinis **2)**: 111.

Background: Loss of A, B and H antigens from red blood cells is known to occur in patients with haematological malignancies. Such events can result in blood group discrepancies as there would be disagreement between the results of forward and reverse grouping. Group discrepancy cases are usually resolved by checking for technical errors and by serologic evaluation. Occasionally, elaborate testing is necessary. Aim(s): We report a case of altered A1 expression in a case of acute myeloid leukemia, arising from MDS trisomy 8. During routine cross matching, a group discrepancy was noted and the abnormality was confirmed by molecular blood grouping. Method(s): Request for 2 units RBC was received for the correction of anemia in a 27 years old acute myeloid leukemia patient. During the forward and reverse grouping by tube technique (TT) (AABB technical manual 16th edition), a disagreement was noted. Subsequently, extended incubation at 22 and 4degreeC, and grouping by column agglutination technique (CAT) Biovue was performed. Anti A1 and anti H lectins and human O and B sera were also used. Molecular blood grouping after DNA extraction, was done with BAGene DNA SSP kit, BAG health care, GmbH, Germany. Result(s): Tube grouping showed no agglutination with anti A, anti B, and gave 4+ reaction with B reagent cells. Similar results were obtained on prolonged incubation at 22 and 4degreeC and also when 40% cell suspension was used for forward grouping. Reaction with A1 lectin was negative and anti H gave 4+ agglutination. Repeat TT using commercial antisera from another manufacturer, and CAT (micro beads) also yielded similar results. The forward grouping performed using human group O and B sera, showed 1+ and 3+ reaction by tube and CAT respectively. Though cross match with a A1 red cell unit was compatible, we issued two O packed RBC units. To resolve the discrepancy, we used the SSP kit for determination of the ABO blood group. Eight PCR mixes were used. Comparison of strength and size of bands with the given worksheet, showed the OA genotype with A phenotype.(Image is attached) In the literature, loss of ABO antigens is seen frequently in myelodysplasia, prior to the diagnosis of hematologic malignancy, and the original blood type returns on remission of the hematologic malignancy. Conclusion(s): Blood group discrepancies could be an indicator of an underlying hematologic malignancy. Molecular blood grouping may be required to resolvegroup discrepancies Whether the original blood group phenotype ie. 'A' returns after remission, remains to be seen.

Bittencourt, L. L. d. A., et al. (2018). "Blueberry residue encapsulation by ionotropic gelation." Plant Foods for Human Nutrition **73**(4): 278-286.

In the processing of fruits such as blueberry (Vaccinium sp.), that has high levels of phenolic acid, the food industry produces tons of organic waste that causes harm to the environment. Encapsulation is a technique used to take advantage of these wastes. Several methods are used to encapsulate substances, among them ionotropic gelation proves to be a simple, precise,

efficient and economical method for obtaining particles with encapsulated bioactives. In this manner, the aim of this study was to test sodium alginate as wall material to encapsulate blueberry residue by ionotropic gelation. The microbeads were characterized by scanning electron microscopy (SEM), x-ray diffraction (XRD), total phenolic compounds, antioxidant capacity and in vitro dissolution. The results showed that the microbeads had surface invagination; retention of 67.01% of the phenolic compounds after encapsulation and 68.2%, phenolic release 120 min after in vitro dissolution. The results suggest that the tested matrix was suitable for encapsulation. The produced microbeads are promising for applications in food products, once the phenolic compounds present in the blueberry residues were maintained after encapsulation.

Bittencourt, P. R. S. and F. R. Scremin (2019). "Evolved Gas Analysis of PE:PVC Systems Thermodegradation Under Inert and Oxidizing Atmosphere." Journal of Polymers & the Environment **27**(3): 612-617.

Incineration of plastic materials for the energy generation is one of the types of polymer recycling, however the composition of the atmosphere used in this process must be controlled, since the products generated during the incineration and released into the atmosphere can be harmful to environment. Combination of different polymers and the mixing of this with other municipal solid wastes can generate varied products, accentuating the toxicity of the evolved gases. Thus, in this work, mass loss, amount of main stages and the gases evolved during polyethylene (PE) and polyvinyl chloride (PVC) thermolysis, as well as the physical mixture of both polymers, were analyzed by the evolved gas analysis using hyphenated techniques Thermogravimetry and Infrared Spectroscopy. Analyzes were conducted under inert and oxidizing atmosphere and showed that the products formed in the samples thermolysis were chemically different in the two atmospheres. During the thermogravimetric analysis under oxidizing atmosphere, even O2 is present in a significant amount, the products formed are dependent on the temperature of the thermolysis process, being able to generate carbon dioxide and carbonylated, carboxylated compounds, carbon monoxide and others products. Biver, T., et al. (2018). "Selective determination of poly(styrene) and polyolefin microplastics in sandy beach sediments by gel permeation chromatography coupled with fluorescence detection." Marine Pollution Bulletin **136**: 269-275.

Microplastics generated by plastics waste degradation are ubiquitous in marine and freshwater basins, posing serious environmental concerns. Raman and FTIR spectroscopies, along with techniques such as pyrolysis-GC/MS, are typically used for their identification. We present a procedure based on gel permeation chromatography (GPC) coupled with fluorescence detection for semi-quantitative selective determination of the most common microplastics found in marine shoreline sediments: poly(styrene) (PS) and partially degraded polyolefins (LDPEox). By operating the detector at either 260/280 or 370/420nm excitation/emission wavelengths PS can be distinguished from LDPEox upon GPC separation. Semi-quantitative determination of microplastics contents is also possible: dichloromethane extracts of PS and LDPEox yield linear

plots of fluorescence peak area vs concentration (0-5.0mg/mL range) and were used as reference materials for quantification of the microplastics content in sand samples collected in the winter berm and dune sectors of a Tuscany beach in Italy.

Bixler, H. J. and H. Porse (2011). "A decade of change in the seaweed hydrocolloids industry." Journal of Applied Phycology **23**(3): 321-335.

Seaweed hydrocolloid markets continue to grow, but instead of the 3-5% achieved in the 1980s and 1990s, the growth rate has fallen to 1-3% per year. This growth has been largely driven by emerging markets in China, Eastern Europe, Brazil, etc. Sales of agar, alginates and carrageenans in the US and Europe are holding up reasonably well in spite of the recession. However, price increases to offset costs in 2008 and 2009 have begun to have a dampening effect on sales, especially in markets where substitution or extension with less expensive ingredients is possible. These higher prices have been driven by higher energy, chemicals and seaweed costs. The higher seaweed costs reflect seaweed shortages, particularly for carrageenan-bearing seaweeds. The Philippines and Indonesia are the dominant producers of the farmed Kappaphycus and Eucheuma species upon which the carrageenan industry depends and both countries are experiencing factors limiting seaweed production. Similar tightening of seaweed supplies are beginning to show up in brown seaweeds used for extracting alginates, and in the red seaweeds for extracting agar. The structure of the industry is also undergoing change. Producers in China are getting stronger, and while they have not yet developed the marketing skills to compete effectively in the developed world markets, they have captured much of their home market. China does not produce the red and brown seaweeds needed for higher end food hydrocolloid production. Stocking their factories with raw material has led to the supply problems. Sales growth continues to suffer from few new product development successes in recent years; although some health care applications are showing some promise, i.e., carrageenan gel capsules and alginate micro-beads.

Blair, R. M., et al. (2019). "Average daily flow of microplastics through a tertiary wastewater treatment plant over a ten-month period." Water Research **163 (no pagination)**(114909).

Microplastics (MPs, <5 mm in size) are classified as emerging contaminants but treatment processes are not designed to remove these small particles. Wastewater treatment systems have been proposed as pathways for MPs pollution to receiving waters but quantitative and qualitative data on MP occurrence and transport remains limited, hindering risk assessment and regulation. Here, for the first time, the stepwise abundance and loading of MPs (60-2800 mum) in a tertiary wastewater treatment plant in the UK was assessed by sampling from May 2017 to February 2018. Microplastics were found in all sampling campaigns, with an average inflow of 8.1 x 10⁸ (95% CI, 3.8 x 10⁸ to 1.2 x 10⁹) items day⁻¹. Their prevalence decreased from influent to final effluent. Overall abundances decreased on average by 6%, 68%, 92%, and 96% after the pre-treatment, primary, secondary, and tertiary treatment stages respectively, although considerable variability occurred throughout the year. Sufficient particles remained in the treated effluent to generate an average discharge of 2.2 x 10⁷ (95% CI, 1.2 x 10⁷ to 3.2 x 10⁷]) particles day⁻¹ to the recipient river. Secondary MPs were predominant, while primary MP abundances were minimal. Fibres comprised 67% of all items, followed by films (18%) and fragments (15%). Chemical characterisation confirmed the presence of different types of polymers, with polypropylene fibres and fragments most abundant (23%). This research informs understanding of how wastewater effluent may channel MPs to the natural environment and their composition, and helps understand control points for optimising advanced treatment processes. Blair, R. M., et al. (2019). "Microscopy and elemental analysis characterisation of microplastics in sediment of a freshwater urban river in Scotland, UK." Environmental Science & Pollution Research **26**(12): 12491-12504.

Understanding of the sources, fate, and impact of microplastics (MPs, < 5 mm) remains limited, particularly in freshwater environments, while limited comparability across available surveys hinders adequate monitoring and risk assessment of these contaminants. Here, the distribution of microscopic debris in an urban river close to the marine environment in the West of Scotland was investigated to assess concentration and distribution of primary and secondary MPs. Also, the efficiency of light and scanning electron microscopy with energy-dispersive spectroscopy (SEM-EDS) was evaluated for characterisation and quantification of MPs sized 2.8 mm-11 mum. Bank sediment samples were collected twice from the River Kelvin in Glasgow and were size-fractionated and processed for extraction of MPs by density separation. Sample MPs spiking and use of procedural blanks allowed the influence of processing on field data quality to be considered. Total abundances were 161-432 MPs kg⁻¹ dry sediment, with fibres as the dominant type, comprising > 88% of total counts. Nevertheless, fibres in blanks suggest potential contributions from atmospheric contamination. Moreover, fibres concentrated mainly in fractions < 0.09 mm suggesting that their fate may be influenced by drivers of fine sediment dynamics in rivers. While no primary MPs were observed, metallic and glass pellets were present in high abundances in settled material and could be easily misidentified by visual inspection, demonstrating that compositional analysis is needed to avoid analytical errors from MP misidentification and overestimation. SEM-EDS allowed for a quick screening of plastic vs non-plastic pellets and improved identification of smaller fragments, whereas more advanced techniques are needed for proper identification of fibres. This study is the first to report on MPs in freshwater rivers in Scotland and suggests that diffuse sources of pollution may be delivering secondary MPs to the river. Their sources, fate, and risk in these systems will thus warrant further attention.

Blanco, B., et al. (2009). "Treatment with bortezomib of human CD4+ T cells preserves natural regulatory T cells and allows the emergence of a distinct suppressor T-cell population." Haematologica **94**(7): 975-983.

BACKGROUND: In vitro depletion of alloreactive T cells using the proteasome inhibitor bortezomib is a promising approach to prevent graft-versus-host disease after allogeneic stem cell transplantation. We have previously described the ability of bortezomib to selectively eliminate alloreactive T cells in a mixed leukocyte culture, preserving non-activated T cells. Due to the role of regulatory T cells in the control of graft versus host disease, in the current manuscript we have analyzed the effect of bortezomib in regulatory T cells.

DESIGN AND METHODS: Conventional or regulatory CD4(+) T cells were isolated with immunomagnetic microbeads based on the expression of CD4 and CD25. The effect of bortezomib on T-cell viability was analyzed by flow cytometry using 7-amino-actinomycin D staining. To investigate the possibility of obtaining an enriched regulatory T-cell population in vitro with the use of bortezomib, CD4(+) T cells were cultured during four weeks in the presence of anti-CD3 and anti-CD28 antibodies, IL-2 and bortezomib. The phenotype of these long-term cultured cells was studied, analyzing the expression of CD25, CD127 and FOXP3 by flow cytometry, and mRNA levels were determined by RT-PCR. Their suppressive capacity was assessed in co-culture experiments, analyzing proliferation and IFN-gamma and CD40L expression of stimulated responder T cells by flow cytometry.

RESULTS: We observed that naturally occurring CD4(+)CD25(+) regulatory T cells are resistant to the pro-apoptotic effect of bortezomib. Furthermore, we found that long-term culture of CD4(+) T cells in the presence of bortezomib promotes the emergence of a regulatory T-cell population that significantly inhibits proliferation, IFN-gamma production and CD40L expression among stimulated effector T cells.

CONCLUSIONS: These results reinforce the proposal of using bortezomib in the prevention of graft versus host disease and, moreover, in the generation of regulatory T-cell populations, that could be used in the treatment of multiple T-cell mediated diseases.

Blanco, I., et al. (2018). "Agricultural plastic waste mapping using GIS. A case study in Italy." Resources, Conservation & Recycling **137**: 229-242.

Plastic materials used in agriculture mostly derive from synthetic petro-chemical polymers. They require at the end of their lifetime a suitable waste management system for the collection and treatment. A research was carried out in order to define a GIS methodology for mapping the agricultural plastic waste on the land. The use in agriculture of plastics in Barletta-Andria-Trani Province – Apulia Region – was investigated by applying orthophotos analysis and remote sensing survey. Besides purposed Plastic Waste Indexes were created to release land use to waste generation. The data were organized in a specific geo-database. The analysis showed that the agricultural plastic waste yearly produced from covering films was 627 kg ha −1 , from the anti-hail nets was 159 kg ha −1 , from nets for crop protection was 192 kg ha −1 , from shading nets was 131 kg ha −1 , from irrigation pipes was 104 kg ha −1 . Through GIS, the areas with high density of plastic wastes were pointed out and the suitable location of collection centres was defined. The produced maps and the GIS database can be always updatable tools, useful for monitoring and optimizing the collection of agricultural plastic waste from the farms and their transport to the recycling companies. [ABSTRACT FROM AUTHOR]

Bland, J. B. and W. T. Tse (2016). "MYC inhibition and TP53 activation synergistically suppress immune checkpoint ligand PD-L1 expression in AML cells." Blood. Conference: 58th Annual Meeting of the American Society of Hematology, ASH **128**(22).

Expression of immune checkpoint ligands is a mechanism that many tumors use to escape attack by host immune cells. PD-L1, the ligand for checkpoint receptor PD-1 on T cells, is often expressed on tumor cells. Engagement of PD-1 on T cells by PD-L1 on tumor cells attenuates T-cell receptor signaling and suppresses anti-tumor response. PD-1 and PD-L1 blocking antibodies have been implemented clinically as treatment for many cancers, but the pattern of PD-L1 expression on AML is not well characterized. To answer this question, we studied how PD-L1 expression on AML is regulated under in vitro conditions that simulate the leukemia-host microenvironment. We examined surface expression of PD-L1 by flow cytometry on 4 AML lines, THP-1, KG1, KG1a, HL60, and a CML line, K562. Under basal conditions, these lines expressed no or low levels of PDL1. The AML cells were then subjected to conditions that mimic the leukemia-host microenvironment. AML cells were stained with the green fluorescent dye CFSE and co-cultured with Ficoll-separated PMNCs from healthy donors. After a day of co-culture, expression of PD L1 was analyzed on AML cells and PD-1, CD25 and CD69 activation markers on

PMNCs. Only a small increase of PD-L1, up to 2-4 fold, was seen on AML cells under this condition. To simulate the pro-inflammatory milieu in the tumor microenvironment, anti-CD3/CD28 microbeads were then added in culture to activate T cells. We observed a marked up-regulation of PD-L1 on AML cells, up to 5-60 fold, plus prominent expression of PD-1, CD25 and CD69 on T cells. These findings were confirmed by an alternative method of T cell activation in which AML cells were first coated with an anti-CD123 antibody, linked to anti-CD3/CD28 antibodies via a biotinstreptavidin bridge, and then cultured with PMNCs. To test whether pro-inflammatory cytokines were the sole inducers of PD-L1 expression, AML cells were treated with IFN-gamma or TNF-alpha alone. IFN-gamma treatment enhanced PD-L1 expression by 2-10 fold, while TNF-alpha showed a <2-fold increase. These results show that expression of PD-L1 on AML is dynamically regulated through interaction with activated T cells, by multiple mechanisms including cytokine production and cell-cell interaction. MYC has been shown to regulate PD-L1 expression on T-ALL and solid tumors (Science 2016; 352:227). We asked whether MYC inhibition would suppress PD-L1 on AML. AML and PMNCs were co-cultured in the presence of anti-CD3/CD28 beads, with JQ1, a BET bromodomain inhibitor that blocks MYC expression. JQ1 inhibited PD-L1 expression by >90%. Dose-effect titration showed sigmoidal curves with ED50 of 0.03 to 0.1 muM for the 5 AML lines. Treatment with another MYC inhibitor, CPI-203, yielded similar results. These observations indicate that MYC inhibition can suppress PD-L1 expression on AML induced by activated T cells. TP53 has been shown to regulate PD-L1 expression on non-small cell lung cancer (JNCI 2016; 108: djv303). We asked whether TP53 activation in AML would also affect PD-L1 expression. Since the AML lines we used did not express wild-type TP53, we overexpressed TP53 in these cells by transfecting with a TP53-GFP plasmid. Expression of TP53 in the cells decreased PD-L1 levels by >80%. Treatment of the cells with pifithrin, an inhibitor that blocks trans-activating function of TP53, did not rescue PD-L1 expression, suggesting that the effect of TP53 on PDL1 expression is independent of its canonical trans-activating pathway. We asked if MYC and TP53 would synergistically affect PD-L1 expression on AML. We transfected AML cells with the TP53-GFP plasmid and co-cultured the cells with PMNCs and anti-CD3-/CD28 beads, in the presence or absence of JQ1. We found that JQ1 treatment of TP53-transfected cells further decreased PD-L1 expression by another 15%, indicating that MYC and TP53 independently and synergistically affect PD-L1 expression on AML. In summary, PD-L1 expression on AML cells is dynamically up-regulated upon interaction with activated T cells and suppressed by perturbation of the MYC and TP53 pathways. These findings have implications in the use of immune effector cell therapy against AML, since the activated effector cells could up-regulate PD-L1 expression on target cells and attenuate anti-leukemia effects. MYC inhibitors and TP53 activators could potentially be used in combination to suppress PD-L1 up-regulation and abrogate the ability of AML cells to escape host immune elimination.

Blandinieres, A., et al. (2019). "Interleukin-8 release by endothelial colony-forming cells isolated from idiopathic pulmonary fibrosis patients might contribute to their pathogenicity." American Journal of Respiratory and Critical Care Medicine. Conference **199**(9).

RATIONALE: Idiopathic pulmonary fibrosis (IPF) is a devastating lung disease characterized by obliteration of alveolar architecture, resulting in declining lung function and ultimately death. Pathogenic mechanisms involve a concomitant accumulation of scar tissue together with myofibroblasts activation and a strong abnormal vascular remodeling. We previously demonstrated that endothelial progenitor cells (Endothelial colony-forming cells (ECFC) subtype), which are post-natal vasculogenic cells in humans, are down regulated in IPF in contrast to healthy controls. We postulated here that ECFCs might behave as a liquid biopsy in IPF patients and exert modified vasculogenic properties compared to control ECFCs.

METHOD(S): ECFCs have been isolated from IPF patients (IPF-ECFCs) and controls (PBECFCs) blood samples. Endothelial phenotype was assessed by RTQ-PCR and flow cytometry assay. Functional properties of these two populations were compared (adhesion on several matrix and migration by Wound healing and Transwell assays) such as differentiation and vasculogenic properties (Matrigel assay in vitro and in vivo and 3D vasculogenic assay on microbeads-loaded fibrin gel). We also studied senescence state (BrDU incorporation, sgalactosidase staining and p16, p21, p53 expression), secretion of mediators that belong to the "senescence associated-secretory phenotype "(SASP) and apoptotic state (annexin-V staining). Last, we assessed the ability of ECFC conditioned medium to induce the migration of neutrophils in vitro and in vivo and we quantified IPF lungs infiltration by these cells. RESULT(S): IPF-ECFCs and PB-ECFCs expressed markers of the endothelial lineage and did not differ concerning adhesion, migration and differentiation properties in vitro and in vivo. However, senescent and apoptotic states were increased in ECFCs from IPF patients as shown by beta-galactosidase staining, p16 expression and annexin-V staining increase. Furthermore, conditioned medium of IPF-ECFCs had increased level of interleukin-8 (IL-8) that induced migration of neutrophils in vitro and in vivo. In addition, an infiltration by neutrophils was shown in IPF lung biopsies and we found in a prospective clinical study that a high level of neutrophils in peripheral blood of IPF patients was associated to a poor prognosis. CONCLUSION(S): To conclude, our study shows that IPF patients have a senescent ECFC phenotype associated with an increased IL-8 secretion potential that might contribute to lung neutrophils invasion during IPF.

Blank, L. M., et al. (2019). "Biotechnological upcycling of plastic waste and other non-conventional feedstocks in a circular economy." Current Opinion in Biotechnology **62**: 212-219.

The envisaged circular economy requires absolute carbon efficiency and in the long run abstinence from fossil feedstocks, and integration of industrial production with end-of-life waste management. Non-conventional feedstocks arising from industrial production and societal consumption such as CO₂ and plastic waste may soon enable manufacture of multiple products from simple bulk chemicals to pharmaceuticals using biotechnology. The change to these feedstocks could be faster than expected by many, especially if the true cost, including the carbon footprint of products, is considered. The efficiency of biotechnological processes can be improved through metabolic engineering, which can help fulfill the promises of the Paris agreement.

Blarer, P. and P. Burkhardt-Holm (2016). "Microplastics affect assimilation efficiency in the freshwater amphipod Gammarus fossarum." Environmental science and pollution research international **23**(23): 23522-23532.

An important issue in assessing microplastics is whether this newly emerging type of pollution affects freshwater invertebrates. This study was designed to examine the interactions between the amphipod Gammarus fossarum and two types of microplastics. To determine the ingestion and egestion of polyamide (PA) fibres (500 20 mu m), amphipods were exposed to four concentrations (100, 540, 2680, 13,380 PA fibres cm super(-2) base area of glass beakers) and four exposure times (0.5, 2, 8, 32 h) as well as four post-exposure times (1, 2, 4, 16 h). We demonstrate a positive correlation between concentration and ingestion of PA fibres. Fibres were found in the gut after 0.5 h of exposure. Egestion was rapid and the digestive tract was empty 16 h after exposure ended. To investigate whether polystyrene (PS) beads (1.6 mu m) can be taken up in the epithelial cells of the gut and the midgut glands, four concentrations (500, 2500, 12,500, 60,000 PS beads mL super(-1)) were tested. Cryosections exhibited fluorescent PS beads only within the gut lumen. In a 28-day feeding experiment with both, fibres and beads,

we studied the amphipod's feeding rate, assimilation efficiency and wet weight change. The exposure to PA fibres (2680 PA fibres cm super(-2) base area of glass beakers) significantly reduced the assimilation efficiency of the animals. While both tested polymer types are ingested and egested, PA fibres can impair the health and ecological functions of freshwater amphipods under continuous exposure.

Blasco, J., et al. (2015). "Particles in the oceans: Implication for a safe marine environment." Marine Environmental Research **111**: 1-4.

Strategies and technologies for the ecosafety assessment and design of engineered particles entering the marine environment are urgently needed. As the application of nanoparticles in science and technology grows, the need to understand their impact on the marine environment becomes increasingly important. This Editorial introduces a Special Issue on the topic of a sustainable and safety use of nanoparticles for protecting, recovering and supporting the oceans' environment and consequently human health. The issue focus on the impact of micro/nano-plastics and metallic nanoparticles on marine organisms, as well as some methodological aspects associated to the eco/toxicity and analytical approaches for in deep physico-chemical characterization of nanoparticles in marine waters and sediment media. Important and urgent topics are addressed in the field of nano-ecosafety in order to assess more precisely both exposure routes and environmental hazards of nanoparticles in the ocean. Ecotoxicological and toxicological data, obtained using a wide variety of organisms representative of different trophic levels and biological organization, from whole animals to macromolecules, will be useful for a better definition of cleaner and safer nanoparticles. Efforts in developing a broad understanding of target species, expected results, benchmarks and timelines, will be of primary importance.

Blasetti, N., et al. (2014). "Adipose mesenchymal stromal cells (aMSC) differentiate into neural progenitor cells (NPC) after 24 hours of co culture with effecter cells (EC) against central nervous system (CNS) proteins." Cytotherapy **4)**: S63.

Introduction: In 2006 (Cytotherapy 2006, 8:196-201) was reported that BM MSC co cultured with anti-CNS EC differentiate into NPC. To prove that aMSC share the same property and this process may be conducted under GMP rules we performed the following experiment. Method(s): Adipose tissue obtained by lipectomy and dissociated with colla-genase 4 in a GMP facility. aMSC were isolated by attachment and cultured for a week. EC were obtained from peripheral blood mononuclear cells, concentrated, were activated and expanded culturing them in DEMEM + human recombinant Insulin (Humalin), and 1% of Cerebrolysin . After 96 hours cells were harvested, washed and marked with anti CD8, CD56 and CD25. and negative selected with Clinimacs. EC and aMSC were co cultured for 24 hr to 120 hours. To test the aMSC differentiation into NPC cells were immune-fluorescent stained with anti nestin, tubulin 3, neu66, GFAP and Sox2 and MBP. and analyzed using confocal microscopy and FACS analysis. Result(s): After 24 hours most of aMSC showed positive stain to nestin . At 48, 96 and 120 hours free cells and neurosphere structures showed positive stain for the rest of cell markers. In the neurosphere was able to distinguish cells positive for neu66, GFAP and sox2 proving multiple linage differentiation of these structures. No microbial contamination, persistence of lymphocytes or immune magnetic microbeads was detected in the harvested NPC cells. Conclusion(s): aMSC may differentiate into NPC done from an adult individual without use of any cytokine, neurotropin, gene transpher, in a GMP facility.

Blasing, M. and W. Amelung (2018). "Plastics in soil: Analytical methods and possible sources." Science

of the Total Environment **612**: 422-435.

At least 300 Mio t of plastic are produced annually, from which large parts end up in the environment, where it persists over decades, harms biota and enters the food chain. Yet, almost nothing is known about plastic pollution of soil; hence, the aims of this work are to review current knowledge on i) available methods for the quantification and identification of plastic in soil, ii) the quantity and possible input pathways of plastic into soil, (including first preliminary screening of plastic in compost), and iii) its fate in soil.

Blazquez, M., et al. (1991). "[Caustic esophago-gastric and liver lesions caused by ingestion of a plastic resin hardener]." Gastroenterologie Clinique et Biologique **15**(6-7): 554-555.

Blenkharn, J. I. and C. Odd (2008). "Sharps injuries in healthcare waste handlers." Annals of Occupational Hygiene **52**(4): 281-286.

Clinical waste disposal carries with it a risk of serious and possibly life-threatening infection. Combining confidential questionnaires and structured interviews with discrete observation, the attitudes and approach to safe handling of bulk clinical wastes by staff in a specialist waste treatment facility were assessed. With particular attention to glove use and hand hygiene, observations were supplemented by review of group-wide accident and incident records, with emphasis on sharps injuries and related blood and bloodstained body fluid exposures. Deficiencies in glove selection and use, and in hand hygiene, were noted despite extensive and on-going training and supervision of waste handlers. Though ballistic puncture-resistant gloves protect against sharps injury, these were uncomfortable in use and were sometimes rejected by waste handlers who preferred thin-walled nitrile gloves that were more comfortable in use though provide no resistance to penetrating injury. Among the waste handlers working for a single specialist waste disposal company, sharps injuries (n = 40) occurred at a rate of approximately 1 per 29 000 man hours. Injuries were caused by hypodermic needles from improperly closed or overfilled sharps boxes (n = 6) or from sharps incorrectly discarded into thin-walled plastic sacks intended only for soft wastes (n = 34). Most injuries occurred to the fingers or hands. No seroconversions occurred, though two individuals suffered anxiety/stress disorder necessitating prolonged leave of absence with professional counselling and support. Glove use and hand hygiene must feature prominently in the on-going training of waste handlers. Though ballistic gloves afford protection against sharps injury, the initial segregation and safe disposal of clinical wastes by healthcare professionals must provide the primary control measure. Despite robust and unambiguous legislation and good practice guidelines, serious errors by healthcare staff that result in the disposal of hypodermic needles and other sharps to thin-walled plastic waste sacks places waste handlers at risk of bloodborne virus infection. Further improvement in the standards of waste segregation and disposal by healthcare professionals are still required to protect ancillary and support staff and waste handlers working in the disposal sector.

Blettler, M. C. M., et al. (2019). "Massive plastic pollution in a mega-river of a developing country: sediment deposition and ingestion by fish (Prochilodus lineatus)." Environmental Pollution **255**(Part 3).

The aim of this study was to determine the amount, composition and origin of plastic debris in one of the world largest river, the Parana River in Argentina (South America), focusing on the impact of urban rivers, relationships among macro, meso and microplastic, socio-political issues and microplastic ingestion by fish. We recorded a huge concentration of macroplastic debris of domestic origin (up to 5.05 macroplastic items per m²) dominated largely by bags (mainly high- and low-density polyethylene), foodwrapper (polypropylene and polystyrene),

foam plastics (expanded polystyrene) and beverage bottles (polyethylene terephthalate), particularly downstream from the confluence with an urban stream. This suggests inadequate waste collection, processing and final disposal in the region, which is regrettably recurrent in many cities of the Global South and Argentina in particular. We found an average of 4654 microplastic fragments m⁻² in shoreline sediments of the river, ranging from 131 to 12687 microplastics m⁻². In contrast to other studies from industrialized countries from Europe and North America, secondary microplastics (resulting from comminution of larger particles) were more abundant than primary ones (microbeads to cosmetics or pellets to the industry). This could be explained by differences in consumer habits and industrialization level between societies and economies. Microplastic particles (mostly fibres) were recorded in the digestive tract of 100% of the studied Prochilodus lineatus (commercial species). Contrary to recently published statements by other researchers, our results suggest neither macroplastic nor mesoplastics would serve as surrogate for microplastic items in pollution surveys, suggesting the need to consider all three size categories. The massive plastic pollution found in the Parana River is caused by an inadequate waste management. New actions are required to properly manage waste from its inception to its final disposal.

Blettler, M. C. M., et al. (2017). "Plastic pollution in freshwater ecosystems: macro-, meso-, and microplastic debris in a floodplain lake." <u>Environmental Monitoring & Assessment</u> **189**(11): 581.

Plastic pollution is considered an important environmental problem by the United Nations Environment Programme, and it is identified, alongside climate change, as an emerging issue that might affect biological diversity and human health. However, despite research efforts investigating plastics in oceans, relatively little studies have focused on freshwater systems. The aim of this study was to estimate the spatial distribution, types, and characteristics of macro-, meso-, and microplastic fragments in shoreline sediments of a freshwater lake. Food wrappers (mainly polypropylene and polystyrene), bags (high- and low-density polyethylene), bottles (polyethylene terephthalate), and disposable Styrofoam food containers (expanded polystyrene) were the dominant macroplastics recorded in this study. Contrary to other studies, herein macroplastic item surveys would not serve as surrogates for microplastic items. This is disadvantageous since macroplastic surveys are relatively easier to conduct. Otherwise, an average of 25 mesoplastics (mainly expanded polystyrene) and 704 microplastic particles (diverse resins) were recorded per square meter in sandy sediments. Comparisons with other studies from freshwater and marine beaches indicated similar relevance of plastic contamination, demonstrating for the first time that plastic pollution is a serious problem in the Parana floodplain lakes. This study is also valuable from a social/educational point of view, since plastic waste has been ignored in the Parana catchment as a pollutant problem, and therefore, the outcome of the current study is a relevant contribution for decision makers.

Blettler, M. C. M. and K. M. Wantzen (2019). "Threats Underestimated in Freshwater Plastic Pollution: Mini-Review." <u>Water, Air & Soil Pollution</u> **230**(7): N.PAG-N.PAG.

Plastic pollution is one of the most acute environmental topics of our time. While there is a great scientific effort to tackle this problem, it has not always been well-coordinated or properly targeted. In this short review, we call for scientists to get involved in three crucial topics (threats) underestimated—or ignored—in freshwater systems: (i) plastic-species entanglement, (ii) plastic as nesting material, and (iii) macroplastic debris coming from mismanaged household solid waste. Reducing the knowledge gaps between marine and freshwater environments will be crucial to solute the plastic pollution problem effectively and globally. Therefore, we make a plea here to reinforce research activities on these three issues in freshwater environments

worldwide. [ABSTRACT FROM AUTHOR]

Blickley, L. C., et al. (2016). "Trends and drivers of debris accumulation on Maui shorelines: Implications for local mitigation strategies." Marine Pollution Bulletin **105**(1): 292-298.
Marine debris, particularly plastic, is an identified concern for coastal areas and is known to accumulate in large quantities in the North Pacific. Here we present results from the first study to quantify and compare the types and amounts of marine debris on Maui shorelines. Surveys were conducted monthly between May 2013 and December 2014, with additional daily surveys conducted on Maui's north shore during January 2015. Debris accumulation rates, loads, and sources varied between sites, with plastics being the most prevalent type of debris at all sites. Large debris loads on windward shores were attributed to the influence of the North Pacific Subtropical Gyre and northerly trade winds. Daily surveys resulted in a significantly higher rate of debris deposition than monthly surveys. The efficacy of local policy in debris mitigation showed promise, but was dependent upon the level of enforcement and consumer responsibility.

Blight, L. K. and A. E. Burger (1997). "Occurrence of Plastic Particles in Seabirds from the Eastern North Pacific." Marine Pollution Bulletin **34**(5): 323.
Researchers analyzed a total of 11 species of seabirds caught as bycatch in pelagic waters in eastern parts of the North Pacific. Particles of plastic were found in the stomaches of eight of these 11 species. All surface-feeding birds had ingested plastic particles, including two species of storm-petrel, one species of albatross, one species of petrel, and one species of fulmar. In addition, plastic particles were detected in 75% of the shearwaters examined. In certain individual petrels, shearwaters, and storm-petrels, plastic particle densities were judged sufficient to restrict digestion. In other birds, the densities were judged to be negligible. Plastic was also found in two species of puffins. The most likely sources of the plastic particles are identified.

Blockstein, D. E. (1988). "Congress tackles ocean plastic pollution." BioScience **38**(1): 19-19.
Discusses the efforts of the U.S. Congress to address the environmental problem of plastic pollution in the world's oceans. Impact of the solid waste which is discharged by ocean vessels, according to a 1975 study by the National Academy of Sciences; Way that plastic can kill ocean wildlife, after animals become entangled in plastic debris or ingest plastic; Harm which is done to sea turtles, an endangered species, by plastic; Prevalence of plastic fishing nets, which drown seabirds, fur seals, and other marine animals; Denial of permits to the Japanese salmon fishing industry to fish in Alaskan waters; Idea that there is a need to substitute biodegradable materials for plastics.

Blumenroder, J., et al. (2017). "Microplastic contamination of intertidal sediments of Scapa Flow, Orkney: A first assessment." Marine Pollution Bulletin **124**(1): 112-120.
The concentration of microplastic particles and fibres was determined in the intertidal sediments at selected sites in Scapa Flow, Orkney, using a super-saturated NaCl flotation

technique to extract the plastic and FT-IR spectroscopy to determine the polymer types. Mean concentrations were 730 and 2300kg⁻¹ sediment (DW), respectively. Detailed spatial and quantitative analysis revealed that their distribution was a function of proximity to populated areas and associated wastewater effluent, industrial installations, degree of shore exposure and complex tidal flow patterns. Sediment samples from Orkney showed similar levels of microplastic contamination as in two highly populate industrialized mainland UK areas, The Clyde and the Firth of Forth. It was concluded that relative remoteness and a comparative small island population are not predictors of lower microplastic pollution. Furthermore, a larger concerted effort across Scotland and the UK is required to establish a baseline microplastic database for the evaluation of future policy measures.

Boano, E., et al. (2012). "Catheter-related infections and the nurse. New strategies." <u>Early Human Development</u> **2)**: S102-S103.

The preterm infant is a special guest in which there is a physiological immune deficiency related to prematurity making him particularly vulnerable to infections. The existence and importance of infectious and septic disease is remarkable in Neonatology, and it is clear that, even in developed countries, infections are the main obstacle to the viability of premature infants. Premature infants are immunocompromised hosts by definition: in such patients, proper management of all the devices needed to perform cares and assistance is mandatory to reduce the risk of infection and to ultimately improve the overall clinical course and to achieve a good long-term quality of life. In this context one of the key moments is the placement and management of Central Venous Catheter (CVC), since up to 60% of nosocomial infections are, in fact, catheter related. Prolonged intravenous treatments, need for parenteral nutrition, the difficulty of finding peripheral venous access and need of alternative vessel accesses in case of emergency make the placement of a CVC in premature infants a priority, at least for the first weeks of stay in NICU. Whenever catheter-related infections occur, the clinical worsening and the overall health threats for the neonate produce a consequent prolongation of hospitalisation thus translating into higher costs. A skilled, appropriate management of all intravenous accesses, therefore, reduces the times for care, antibiotic therapy and duration of stay. The management and maintenance of the CVC are a nurse's responsibility. It is obvious that it is not possible to entirely avoid the risk of infection and eliminate catheter-related infections, thus the goal is to reduce to a minimum the presence of microorganisms able to develop in an infection in young patients, with the help of technology and care strategies. The key moments of such nursing management of CVCs are: Replacement of Administration Sets, administration of intravenous therapies and the dressing of the insertion site. The high rate of glucose typical of TPN favours the proliferation of pathogens. The lines of infusion may also be contaminated with microparticles from plastic syringes and needles, which are deposited in the catheter or into the bloodstream resulting in lung and intestinal infections. It also exists a correlation between microbial contamination and the frequency with whom infusion lines and taps are manipulated. According to the CDC guidelines, it is essential to minimise the access routes using catheters with a suitable number of lamps. A similar argument applies to the three-way taps that must not be greater than the number of infusions that the patient may have at one time. Therefore, other devices such as luer-lock caps might be helpful, as they allow the nurse to replace several times a day the infusions without opening the entire venous access. Noteworthy, it is recommended to repeatedly disinfect the site of entry of the syringe or the ramp with chlorexidine. The most appropriate frequency of infusion lines replacement is a debated issue. The latest CDC guidelines show that - in general - there is no proven additional benefit in performing replacement more frequently than one every 72 hours. The high concentrations of glucose in

the TPN infusion and the presence of lipids, however, better suggest to replace the set every 24 hours. In case of blood transfusions, the infusion's circuit should be removed within 4 hours. The catheters are also a repository for micro-plastics that can enter the bloodstream via the connections and syringes used for drug delivery. These particles can then enter the bloodstream giving rise to serious infectious and pathological phenomena for the baby such as necrotising enterocolitis (NEC), thrombophlebitis and pulmonary embolism. This can happen even in the case of incompatibility of infusions or when formation of air bubbles in the lines occurs. Several studies have shown that the use of in-line filters placed proximally to the catheter insertion site greatly reduces the risk of contamination a d flow of plastic and precipitated particles in the bloodstream, thus resulting in reduced risk of developing infections. The filters also separate the precipitates resulting from the combinations of infusions that may be not compatible. For the dressing of the insertion site, it is recommended the use of non-alcoholic chlorexidine gluconate, because povidone-iodine may be detrimental to the neonate as it is active on the thyroid of immature infants, and also because the presence of alcoholic disinfectants may produce skin burns. The dressing should be performed at the time of the insertion of the CVC and every time it looks dirty or bloody at inspection. It is advisable to secure the catheter with a transparent film that will be replaced only in case of deterioration or if it looks dirty and polluted at visual inspection. This is because the risk of rupture and dislodging of the catheter in premature infants is greater than the benefit of a more frequent disinfection. The catheter-related infections are one of a major problem of neonatal intensive care units, and in such area the nurses play a key role in the related risk-management. Simple but rigorous steps and bundles to be implemented in the daily practice, along with the use of equipments such as filters, valves and three-way connector clubs can help reducing the risk of infection while concomitantly reducing duration of the hospitalisation, related costs and related poor outcomes. Conflict of Interest: None declared.

Bochenska-Marciniak, M., et al. (2004). "The effect of recombinant Il-8 on eosinophils' migration in vitro and in vivo." Journal of Allergy and Clinical Immunology **113**(2).

Rationale Il-8 is a chemokine which causes chemotaxis of neutrophils, eosinophils and lymphocytes in vitro, however its role as a chemoatractant in allergic inflammation is unclear. The aim of this study was to investigate the in vitro Il-8 induced chemotaxis of eosinophils and the effect of nasal lavage of Il-8 solution on the influx of eosinophils. Methods Twelve patients (5 women and 7 men) suffering from seasonal allergic rhinitis with average age 30,1 ± 2,67 years were included into the study. Eosinophils from peripheral blood were isolated using the CD16 MicroBeads (MACS, Miltenyi Biotec®) and chemotaxis to Il-8, FMLP, RANTES, Il-5 and C5a were determined. Patients were challenged with Il-8 solution and diluent for Il-8 during the pollen season. The nasal lavage fluids were collected before, during Il-8 or placebo challenge and 30 minutes, 2 hours and 3 hours after the challenge. The number of eosinophils in the lavages was determined. Results The optimal concentration of Il-8 for eosinophils chemotaxis was 10-9M, the chemotactic index was 2,03 ± 0,6. The chemotactic index for FMLP (10-7M), RANTES (10-8M), Il-5 (10-7M) and C5a (10-8M) was: 3,24 ± 0,83; 3,51 ± 0,7; 4,02 ± 0,68 and 2,5 ± 0,77, respectively. After the challenge with Il-8 of nasal mucosa we observed a peak of eosinophil influx at 3 hours after challenge reaching the number of 3050 ± 760 cell/ml, but the number of eosinophils after the Il-8 challenge in comparison with diluent was not significantly higher (p>0,05). Conclusion Il-8, which is a chemoatractant for eosinophils in vitro, does not provoke a significant influx of eosinophils into the allergen primed nasal mucosa.

Boehm, A. B., et al. (2017). "Oceans in Peril: Grand Challenges in Applied Water Quality Research for the

21st Century." Environmental Engineering Science **34**(1): 3-15.
Oceans cover most of the planet and 60% of the world's population lives near the coast. Anthropogenic activities along coastlines and in the open ocean have placed the oceans in peril. According to a Pew Oceans Commission Report, among the greatest threats to the ocean are land-based runoff from coastal development, nutrient pollution, overfishing, and invasive species. Here, we describe threats due to microbial, nutrient, chemical, and plastic pollution in addition to declining biodiversity and describe fundamental and applied research needed to mitigate the threats. While the research needs are diverse, we identify several research foci that transcend individual threats: monitoring, fate and transport studies, modeling, innovative natural and engineered treatment systems, and toxicity and health studies. Research within the environmental engineering and science community that addresses these needs will contribute to improving ocean health. © Copyright 2017, Mary Ann Liebert, Inc. 2017.

Boerger, C. M., et al. (2010). "Plastic ingestion by planktivorous fishes in the North Pacific Central Gyre." Marine Pollution Bulletin **60**(12): 2275-2278.
A significant amount of marine debris has accumulated in the North Pacific Central Gyre (NPCG). The effects on larger marine organisms have been documented through cases of entanglement and ingestion; however, little is known about the effects on lower trophic level marine organisms. This study is the first to document ingestion and quantify the amount of plastic found in the gut of common planktivorous fish in the NPCG. From February 11 to 14, 2008, 11 neuston samples were collected by manta trawl in the NPCG. Plastic from each trawl and fish stomach was counted and weighed and categorized by type, size class and color. Approximately 35% of the fish studied had ingested plastic, averaging 2.1 pieces per fish. Additional studies are needed to determine the residence time of ingested plastics and their effects on fish health and the food chain implications. © 2010 Elsevier Ltd.

Boffi, A., et al. (2015). "Amine oxidase-based biosensors for spermine and spermidine determination." Analytical and bioanalytical chemistry **407**(4): 1131-1137.
Issue Title: A different way of looking at vibrational hyperspectral data/Micellar extraction for the analysis of Alzheimer's disease brain proteome/Quantification of polyolefin microplastics in personal-care products/Removal of Triton X-100 by microdialysis The present work describes the development and optimization of electrochemical biosensors for specific determination of the biogenic polyamine spermine (Spm) and spermidine (Spmd) whose assessment represents a novel important analytical tool in food analysis and human diagnostics. These biosensors have been prepared using novel engineered enzymes: polyamine oxidase (PAO) endowed with selectivity towards Spm and Spmd and spermine oxidase (SMO) characterized by strict specificity towards Spm. The current design entails biosensors in which the enzymes were entrapped in poly(vinyl alcohol) bearing styrylpyridinium groups (PVA-SbQ), a photocrosslinkable gel, onto an electrode surface. Screen-printed electrodes (SPEs) were used as electrochemical transducers for enzymatically produced hydrogen peroxide, operating at different potential vs Ag/AgCl according to the material of the working electrode (WE): +700 mV for graphite (GP) or -100 mV for Prussian blue (PB)-modified SPE, respectively. Biosensor performances were evaluated by means of flow injection amperometric (FIA) measurements. The modified electrodes showed good sensitivity, long-term stability and reproducibility. Under optimal conditions, the PAO biosensor showed a linear range 0.003-0.3 mM for Spm and 0.01-0.4 mM for Spmd, while with the SMO biosensor, a linear range of 0.004-0.5 mM for Spm has been obtained. The main kinetic parameters apparent Michaelis constant (K ^sub M^), turnover number (K ^sub cat^) and steady-state current (I ^sub max^) were determined. The

proposed device was then applied to the determination of biogenic amines in blood samples. The results obtained were in good agreement with those obtained with the GC-MS reference method.

Bogen, D. C. (1968). "Rapid determination of strontium-90 in urine." Health Physics **14**(2): 131-133.

Reverse-phase partition chromatography has been adapted for rapid determination of Sr^{9O} in large urine samples. A column is prepared containing the ligand, di(2-ethylhexyl) phosphoric acid which is coated onto the inert support, glass micro beads. The Y⁹⁰ daughter of Sr ⁹⁰ is selectively absorbed by the column and subsequently eluted. The Y⁹⁰ is precipitated as the oxalate, beta counted, and the sample activity level obtained by computer data reduction. The chemical recoveries are better than 80%, precision of analysis is better than 5% and no overall bias is observed. The procedure is rapid, large sample sizes can be used for good sensitivity, and decontamination factors are satisfactory.

Boissel, L., et al. (2008). "Umbilical cord mesenchymal stem cells increase expansion of cord blood natural killer cells." Biology of Blood & Marrow Transplantation **14**(9): 1031-1038.

Natural killer (NK) cell-mediated cytotoxicity can control leukemia relapse while protecting patients from graft-versus-host disease (GVHD) after allogeneic stem cell transplant. Cord blood (CB) is rich in NK cell progenitors with similar properties of proliferation and cytotoxicity as adult blood NK cells. Hence, it is attractive to expand and potentially utilize these cells for adoptive immunotherapy. In this study, CB mononuclear cells were CD3-depleted by immunomagnetic microbead selection to remove T cells. This CD3(dep) CB-MNC fraction was then plated for ex vivo expansion, with or without a feeder layer of irradiated umbilical cord mesenchymal stem cells (UC-MSC), with or without cytokines that have been shown to be critical for NK expansion: IL-2, IL-15, IL-3, and FLT-3L. At an average of 2 weeks of culture, there was significantly higher expansion (64.7 +/- 8.4-fold) of CD56(+)/CD3(-) NK cells in the presence of the UC-MSC feeder layer and cytokines compared to controls (no increase with feeder layer only and 6.4 +/- 1.5-fold increase with cytokines only, P < .05). Contact between CD3(dep) CB-MNC cells and UC-MSC augmented NK expansion. The combination of all 4 cytokines was superior to IL-2 alone or 2 cytokines combinations: mean 64.7 +/- 8.4-fold expansion with 4 cytokines combination versus IL-2 alone, IL-2 + FLT-3L, IL-2 + IL-15 or IL-2 + IL-3 (12.2 +/- 2.0, 14.4 +/- 2.4, 10.4 +/- 4.1, 25.2 +/- 8.1 respectively). We also observed that only fresh CD3(dep) CB-MNC preparations could be expanded reliably, whereas frozen and thawed CD3(dep) CB-MNC cells did not expand consistently (mean fold increase 6.5 +/- 3.2). Cytotoxicity of expanded NK cells was compared with NK cells from fresh and overnight IL-2 activated CD3(dep) CB-MNC. Whereas fresh cells displayed no discernible killing, strong cytotoxicity against K562, Raji, REH, and SUP-B15 cells lines was noted after overnight activation in IL-2. Cytotoxicity of expanded NK cells against Raji, REH, and SUP-B15 was lower, which, however, correlated with a predominant expansion of CD56(+)/CD16(-) cells known to have less cytolytic activity than CD56(+)/CD16(+). To test the transfection efficiency in NK cells, fresh or expanded CD3(dep) CB-MNC cells were electroporated with either DNA or mRNA constructs for GFP. DNA had a low transfection efficiency (<10%), whereas the one for mRNA reached 52%, but at the cost of significant cell death. Our results suggest that CB NK cell progenitors can be expanded to obtain large numbers by using an irradiated feeder of UC-MSC. They maintain an elevated cytotoxic profile, and may be genetically manipulated-all characteristics that make them suitable for cellular therapies.

Bollain Pastor, C. and D. Vicente Agullo (2019). "[Presence of microplastics in water and the potential

impact on public health]." Revista Espanola de Salud Publica **93**: 28.
The use of plastics has increased exponentially over recent years. Difficulties in their recycling and their low degradability result in their accumulation in the environment. Despite their great stability, they are subject to physical and chemical erosion resulting in smaller fragments. Although there is no standard definition of microplastics, the maximum limit of 5 mm has been accepted as a criterion. Plastics, in addition to the consequences on the environment, have a direct effect on living beings, either by ingestion or toxicity. They may also act as a vehicle for invasive species and adsorb other contaminants on their surface such as PCBs, PAHs or DDT. This, increases the toxic effect of their own components such as plasticizers, additives, heavy metals, etc. There is disparity in the published results regarding the presence of microplastics in both water supplies and drinking water and bottled water. There are no standard analytical methods, nor a consensus in the definition and description of microplastics that allow an appropriate comparison of results. In the absence of scientific evidence, it is necessary to study in depth the presence of microplastics in water and the potential effects on health, in order to be able to consider microplastics as a monitoring parameter in drinking water.

Bollmann, U. E., et al. (2019). "Assessment of input of organic micropollutants and microplastics into the Baltic Sea by urban waters." Marine Pollution Bulletin **148**: 149-155.
We assess how different micropollutants and microplastics, connected to wastewater are introduced into the Baltic Sea. The relevance of untreated wastewater, treated wastewater, treated and untreated rain runoff, as well as combined sewer overflow (CSO), is assessed in respect to mass balance, as well as relative inflows of micropollutants and -plastics into the Baltic Sea. To achieve this, modelling based on data on exemplary sewer systems and measured micropollutant concentrations in the single sources were used. Most compounds reach the receiving Baltic Sea via treated wastewater. A few exceptions are compounds that are removed to a very high extent in wastewater treatment plants. For these compounds, the emissions with stormwater (e.g., terbutryn) or untreated wastewater (e.g., triclosan) are dominating. Additionally, compounds that are discharged with the water that is running off urban surfaces are introduced into marine areas via rain runoff. These data are used to forecast a total mass load and concentrations that can be expected in the Baltic Sea. Massloads are expected to be between 0.1 and 5.9 t/a for triclosan and TCPP (tris (2-chloropropyl) phosphate) and 0.2 t/a for microplastic particles. The expected concentrations in open Baltic Sea waters range from 0.01 to 26 ng/L. Copyright © 2019 Elsevier Ltd

Bolto, B. A., et al. (1975). "The use of magnetic polymers in water treatment." J.Polymer Sci.Symp **49 (49)**: 211-219.
Magnetic polymers, originally conceived in ion exchange form as a means of handling microbeads in a thermally regenerable desalination process, have now been prepared in a variety of configurations for use in a number of water purification procedures. Processes have been devised which employ magnetic polymers in filtration, in oil slick removal, and in the adsorption of metal ions. Suitably shaped particles, when magnetized, form a filter bed of high voidage volume. Tests have been run on a variety of turbid waters. The particles give considerably better performance as filter aids than the diatomaceous earth normally used. An extremely important advantage is that the magnetic filter aids can be recovered and reused after washing. Vesicular forms of magnetic hydrophobic polymers float on water and have application in the removal of oil spills from water surfaces. The oil becomes trapped in the voids between the particles; the resulting mass is readily removed from the water by magnetic means, after which the oil is separated from the particles simply by centrifugation. The particles and

residual oil are then recycled. Magnetic ion exchangers, smaller in size than conventional resins, can be employed in continuous contacting systems, such as fluidized and semifluidized beds. When compared with normal continuous ion exchange systems, the same removal of ions can be accomplished using considerably less resin in a plant which is smaller, simpler, and much cheaper to construct. Magnetic polymers, originally conceived in ion-exchange form as a means of handling microbeads in a thermally regenerable desalination process, have now been prepared in a variety of configurations for use in a number of water purification procedures. Processes have been devised which employ magnetic polymers in filtration, in oil slick removal, and in the adsorption of metal ions. Suitably shaped particles, when magnetized, form a filter bed of high voidage volume. Tests have been run on a variety of turbid waters. Vesicular forms of magnetic hydrophobic polymers float on water and have application in the removal of oil spills from water surfaces. The oil becomes trapped in the voids between the particles; the resulting mass is readily removed from the water by magnetic means. Magnetic ion exchangers, smaller in size than conventional resins, can be employed in continuous contacting systems, such as fluidized and semifluidized beds.

Bolto, B. A., et al. (1982). "Desalination by continuous ion exchange based on thermally regenerable magnetic microresins." Water Science and Technology **14 (6-7 /7)**: 523-534.

This paper describes the unique hydrodynamic and kinetic properties of Sirotherm thermally regenerable desalting resins when made in the form of magnetic microbeads, and the development of continuous contacting systems which exploit these properties. A novel multistage contactor has been evaluated on laboratory and pilot-plant scales. A prototype plant is to be installed near Perth, Western Australia, in order to demonstrate the process. It is truly continuous, simple and economic, and does not require preclarification of the raw water. The removal of small quantities of salt at the 500 to 2000 mg/L level is becoming increasingly necessary to counter one of the most widespread forms of water pollution encountered throughout the world. Ion-exchange resins which can be regenerated with hot water have been used previously in a batch mode for the desalting of both natural waters, and municipal and industrial wastewaters. Continuous operation would offer many advantages, especially for productivity, heat economy and ease of control. Unfortunately existing continuous ion-exchange contactors are intermittent in operation and somewhat complex. This paper describes the unique hydrodynamic and kinetic properties of 'Sirotherm' thermally regenerable desalting resins when made in the form of magnetic microbeads, and the development of continuous contacting systems which exploit these properties. A novel multistage contactor has been evaluated on laboratory and pilot-plant scales. A prototype plant, with a throughput of 1 ML/day, is to be installed near Perth, Western Australia, in order to demonstrate the process. It is truly continuous, simple and economic, and does not require preclarification of the raw water.

Bolzoni, M., et al. (2014). "Transcriptional and proteomic profiles of bone marrow CD14+ cells in multiple myeloma (MM) compared to smoldering mm and MGUS: Overexpression of interleukin (IL)-21 receptor and its involvement in mm-induced osteoclastogenesis." Haematologica **2)**: S23.

Introduction. Multiple myeloma (MM) patients are characterized by bone marrow (BM) microenvironment alterations, as compared to patients affected by smoldering MM (SMM) and monoclonal gammopathy of uncertain significance (MGUS). The aim of this study was to analyze the transcriptional and proteomic profiles of the BM CD14+ cells across different types of monoclonal gammopathies, based on their primarily involvement in osteoclastogenesis, vasculogenesis and immune system. Methods. CD14+ monocytes were purified from a total cohort of 59 patients including 30 patients with symptomatic MM, 16 patients with SMM and 13 patients with MGUS. CD14+ cells were isolated from the CD138 negative fraction of patient BM samples by an immunomagnetic method with anti-CD14 mAb conjugated with microbeads (purity >94%). CD14+ gene expression profiles (GEPs) were evaluated by GeneChip HG-U133Plus 2.0 arrays (Affymetrix) in 25 MM, 11 SMM and 8 MGUS. The proteomic analysis was performed on CD14+ cells of 5 MM, 5 SMM and 5 MGUS. Samples were run on Q Exactive Hybrid Quadrupole-Orbitrap Mass Spectrometer (Thermo Scientific) after labeling with tandem mass tags and data analyzed with Proteome Discoverer software. Results. Different types of GEP analysis were conducted. A multiclass analysis identified 18 differentially expressed genes in MGUS, SMM and MM. The comparison of MM with both SMM and MGUS samples identified 61 genes differentially expressed in CD14+ cells (37 up-regulated and 24 down-regulated). Interestingly, we found that CD14+ of MM patients, as compared to SMM and MGUS, over-expressed some cytokine receptors (IL21R and IL-15R), pro-osteoclastogenic chemokines (CXCL10 and CXCL11), interferon-inducible proteins (IFI27 and IFI44) and SLAMF7. By a proteomic approach, different CD14+ monocyte expression profiles were found comparing MM patients with MGUS and SMM ones. Interestingly, MM monocytes over-expressed proteins involved in cell adhesion and inflammation and down-regulated molecules implicated in antimicrobial functions. Further we investigated the potential role of IL-21R up-regulation in CD14+ cells. Firstly, any significant difference was not observed in the BM IL-21 levels between MM, SMM and MGUS in a large cohort of 160 patients. On the other hand, we confirmed that IL- 21R was up-regulated at protein level in CD14+ of MM patients as compared to both SMM and MGUS; the conditioned media of MM cells up-regulated IL21R mRNA in CD14+ cells. The treatment with rhIL-21, at the concentration observed in BM plasma (30pg/ml), stimulated CD14+-derived in vitro osteoclastogenesis increasing number and size of osteoclasts, in MM patients but not in SMM and MGUS. Conclusions. Our results indicate that different expression fingerprints characterize BM CD14+ monocytes of patients with MM as compared to those with SMM and MGUS, including over-expression of IL-21R possibly involved in MM-induced osteoclast activation through an increased sensitivity to IL-21.

Bolzoni, M., et al. (2014). "Bone marrow CD14⁺ cells show different transcriptional profiles in multiple myeloma (MM) as compared to smoldering MM and MGUS: Overexpression of IL-21R and its involvement in osteoclastogenesis." Haematologica **1)**: 94-95.

Background: Bone marrow (BM) microenvironment alterations characterize patients with multiple myeloma (MM), as compared to smoldering MM (SMM) and monoclonal gammopathy of uncertain significance (MGUS). Studies focusing on the presence of potential molecular alterations in the BM microenvironment cells are ongoing. Aim(s): This study was aimed at analyzing the transcriptional profile of the BM CD14⁺ cells across different types of monoclonal gammopathies, based on their primarily involvement in osteoclastogenesis that is typically increased in MM patients. Method(s): CD14⁺ monocytes were purified from a total cohort of 36 patients including 21 patients with symptomatic MM, 8 patients with SMM and 7 patients with MGUS. CD14⁺, cells were isolated from the CD138 negative fraction of BM samples of patients by immunomagnetic method with anti-CD14 monoclonal antibody conjugated with microbeads. The presence of potential hemopoietic and CD138⁺ contaminating cells was excluded by FACS analysis. Only samples with CD14 purity greater than 95% were profiled on GeneChip HGU133Plus 2.0 arrays (Affymetrix). Selected genes were then validated by Real-Time quantitative PCR. Result(s): A multiclass analysis identified 14 differentially expressed genes in MGUS, SMM and symptomatic MM. The comparison of symptomatic MM with both SMM and MGUS samples identified 101 genes differentially expressed in CD14⁺ (58 up-regulated and 43 down-regulated genes in

MM). Interestingly, among the differentially expressed genes we found cytokine receptors (IL21R and IL-15R), chemokines with pro-osteoclastogenic properties (CXCL10 and CXCL11), interferon-inducible proteins (IFI27 and IFI44) and SLAM7 that were up-regulated in CD14⁺ of MM patients as compared to SMM and MGUS. Because recent data indicate that IL-21 is a growth factor for MM cells and may promote osteoclastogenesis in pathophysiological conditions such as rheumatoid arthritis, we further investigate the potential role of IL-21R over-expression in CD14⁺, cells. Firstly, by western blot analysis we confirmed that IL-21 receptor was up-regulated at protein level in CD14⁺, of MM patients as compared to both SMM and MGUS; whereas the BM IL-21 levels detected by ELISA in a proprietary larger cohort of 77 newly diagnosed MM, 42 SMM and 41 MGUS patients did not showed any statistically significant difference across the three groups of patients (IL-21 median levels: 34, 30.6, and 33.71 pg/ml, respectively). On the other hand, the treatment with rhIL-21 at the concentration levels detected into the BM (30 pg/ml) stimulated BM CD14⁺-derived in vitro osteoclastogenesis and increased the number and the size of osteoclasts, in the presence of RANKL (20-30 ng/ml), in BM samples of MM patients; conversely, this was not observed in samples obtained from SMM and MGUS. Finally, we showed that rhIL-21 stimulated the expression of the RANKL receptor RANK in CD14⁺, indicating that IL-21 increased the sensitivity of CD14⁺ cells to the pro-osteoclastogenic effect of RANKL. Summary and Conclusion(s): Overall, our results indicate that a different transcriptional signature may be identified in BM CD14⁺ cells of patients with MM as compared to those with SMM and MGUS, including the overexpression of IL-21R. Consequently the involvement of IL-21/IL-21R axis has been demonstrated in the increased CD14⁺-derived osteoclastogenesis that characterizes MM patients.

Bommer, J., et al. (1984). "Plastic filing from dialysis tubing induces prostanoid release from macrophages." Kidney International **26**(3): 331-337.

Multiorgan abnormalities in dialysis patients (for example, hepatosplenomegaly, granulomatous hepatitis, cytopenia from hypersplenism) have recently been ascribed to the loading of macrophages (M) with silicone particles released from the pump segment of dialysis tubing. In the present study, the effect of chronic intravenous or intraperitoneal loading of rats with silicone, polyvinylchloride (PVC) and polyurethane (PU) particles on arachidonic acid metabolism of peritoneal M and splenic cells was examined in vitro. Intravenous injections of silicone, PVC, or PU particles caused accumulation of the material within the lysosomes of M of spleen, liver, and lung. Spontaneous release of prostaglandin E<inf>2</inf> (PGE<inf>2</inf>) and thromboxane B<inf>2</inf> (TXB<inf>2</inf>) was significantly increased in peritoneal M of rats injected with silicone, PVC, or PU (Control: 4.27 +/- 0.85 ng PGE<inf>2</inf>/ml/24 hr; silicone 51.9 +/- 13.2; PVC 57.5 +/- 10.6; PU 28.8 +/- 2.3). Zymosan or LPS stimulated PGE<inf>2</inf> release from control M, but caused no consistent further elevation of high basal PGE<inf>2</inf> release from M after particle loading. Furthermore, increased spontaneous and stimulated TXB<inf>2</inf> release was also observed in spleen cells of rats given intravenous injection of silicone particles. It is concluded that storage of plastic particles (silicone, PVC, and PU) by macrophages stimulates arachidonic acid metabolism.

Bonanno, G., et al. (2007). "Human cord blood CD133+ cells immunoselected by a clinical-grade apparatus differentiate in vitro into endothelial- and cardiomyocyte-like cells." Transfusion **47**(2): 280-289.

BACKGROUND: Recent findings on human hematopoietic stem cell (HSC) properties suggest a

possible therapeutic role of human umbilical cord blood (UCB) HSC-based cellular therapies in the treatment of myocardial infarction.
STUDY DESIGN AND METHODS: Nine UCB units were subjected to sequential red cell removal, freezing, and postthawing CD133+ HSC immunoselection by a clinical-grade, CE-approved, magnetic apparatus and microbead-coated anti-CD133 monoclonal antibody. Selected UCB CD133+ cells were cultured in vitro in medium supporting either endothelial or cardiomyocytic differentiation in parallel experiments.
RESULTS: Immunoselection allowed recovery of 79 percent of initial CD133+ cells with a CD133+ cell purity of 81 percent, on average. Parallel cultures showed the appearance of endothelial markers (VE-cadherin, CD146, and KDR and bright expression of CD105), morphofunctional features of endothelium in endothelial-supporting cultures, of cardiac muscle proteins (troponin I and myosin ventricular heavy chain alpha/beta; MYHC) and specific gene expression (GATA4, NKX2.5, troponin I, and MYHC) in cardiomyocyte-oriented cultures.
CONCLUSIONS: The appearance of both endothelial- and cardiomyocyte-like cells from parallel cultures of frozen-thawed-immunoselected UCB CD133+ cells by a clinical-grade method and previously reported data on lack of major signs of rejection of these cells in immunocompetent rats subjected to experimental liver damage suggest a possible role of these allogeneic HSCs in cell therapies designed for regenerative treatments of ischemic diseases of human myocardium.

Bonanno, G. and M. Orlando-Bonaca (2018). "Perspectives on using marine species as bioindicators of plastic pollution." Marine Pollution Bulletin **137**: 209-221.
The ever-increasing level of marine pollution due to plastic debris is a globally recognized threat that needs effective actions of control and mitigation. Using marine organisms as bioindicators of plastic pollution can provide crucial information that would better integrate the spatial and temporal presence of plastic debris in the sea. Given their long and frequent migrations, numerous marine species that ingest plastics can provide information on the presence of plastic debris but only on large spatial and temporal scales, thus making it difficult to identify quantitative correlations of ingested plastics within well-defined spatio-temporal patterns. Given the complex dynamics of plastics in the sea, the biomonitoring of marine plastic debris should rely on the combination of several bioindicator species with different characteristics that complement each other. Other critical aspects include the standardization of sampling protocols, analytical detection methods and metrics to evaluate the effects of ingested plastics in marine species.

Bonanno, G. and M. Orlando-Bonaca (2018). "Ten inconvenient questions about plastics in the sea." Environmental Science & Policy **85**: 146-154.
This paper aims to investigate some of the hottest issues that concern the increasing presence of plastics in the sea. In an attempt to identify the main knowledge gaps and to suggest future research, we discuss priority topics on marine plastic pollution through ten thought-provoking questions on the current knowledge of multiple consequences of plastics on the marine ecosystem. Our investigation found that the majority of knowledge gaps include not only intrinsic aspects of plastics (e.g. quantification, typology, fate), but also biological, ecological and legislative implications (e.g. ingestion rate by wildlife, biomagnification across food webs, spread of alien species, consequences for human nutrition, mitigation measures). The current scenario shows that science is still far from assessing the real magnitude of the impact that plastics have on the sea. In particular, the transfer of plastics across marine trophic levels emerged as one of the most critical knowledge gaps. Current regulations seem not sufficient to tackle the massive release of plastics into the sea. Within this complex picture, a positive note is

the ever-increasing public awareness. The release of plastics into the sea is certainly a serious environmental issue that can be effectively addressed only through the combined efforts of the three main stakeholders: ordinary citizens through more eco-friendly behaviours, scientists by filling knowledge gaps, and policymakers by passing conservation laws relying on prevention and scientific evidence. Bond, A. L. (2016). "Diet changes in breeding Herring Gulls (Larus argentatus) in Witless Bay, Newfoundland and Labrador, Canada, over 40 years." Waterbirds **39**(sp1): 152-158.

The diets of gulls (Laridae) can have consequences for reproductive success, chick growth, and survival, yet there have been no quantitative assessments in eastern Newfoundland since the early 1970 s. The diet of Herring Gulls (Larus argentatus) was examined through regurgitated prey items and pellets on Gull Island, Witless Bay, Newfoundland and Labrador, Canada, in 2012, and compared with similar data from 1970-1971. There was a significant shift in Herring Gull diet composition from blue mussels (Mytilus edulis) and capelin (Mallotus villosus) in the 1970 s to garbage and Common Murre (Uria aalge) eggs in 2012. Delays in capelin spawning and the large increase in breeding Common Murres on Gull Island are likely factors influencing Herring Gull diet. Garbage, which includes human food scraps as well as plastic debris, now constitutes the single largest diet item for Herring Gulls, corresponding with a global increase in plastic pollution. The consistently low contribution of fisheries discards suggests that changes in fishing practices and availability of discards are only one possible factor in the Herring Gull decline in Witless Bay.

Bond, A. L., et al. (2014). "Plastic ingestion by fulmars and shearwaters at Sable Island, Nova Scotia, Canada." Marine Pollution Bulletin **87**(1/2): 68-75.

Plastic pollution is widespread in the marine environment, and plastic ingestion by seabirds is now widely reported for dozens of species. Beached Northern Fulmars, Great Shearwaters, Sooty Shearwaters and Cory's Shearwaters are found on Sable Island, Nova Scotia, Canada regularly, and they can be used to assess plastic pollution. All species except Cory's Shearwaters contained plastic debris in their gastrointestinal tracts. Northern Fulmars, Sooty Shearwaters and Great Shearwaters all showed high prevalence of plastic ingestion (>72%), with Northern Fulmars having the highest number and mass of plastics among the species examined. There was no difference in plastic ingestion between sexes or age classes. In all species user plastics made up the majority of the pieces found, with industrial pellets representing only a small proportion in the samples. Sable Island could be an important monitoring site for plastic pollution in Atlantic Canada.

Bond, W. S., et al. (2016). "Virus-mediated EpoR76E Therapy Slows Optic Nerve Axonopathy in Experimental Glaucoma." Molecular Therapy: the Journal of the American Society of Gene Therapy **24**(2): 230-239.

Glaucoma, a common cause of blindness, is currently treated by intraocular pressure (IOP)-lowering interventions. However, this approach is insufficient to completely prevent vision loss. Here, we evaluate an IOP-independent gene therapy strategy using a modified erythropoietin, EPO-R76E, which has reduced erythropoietic function. We used two models of glaucoma, the murine microbead occlusion model and the DBA/2J mouse. Systemic recombinant adeno-associated virus-mediated gene delivery of EpoR76E (rAAV.EpoR76E) was performed concurrent with elevation of IOP. Axon structure and active anterograde transport were preserved in both models. Vision, as determined by the flash visual evoked potential, was preserved in the DBA/2J. These results show that systemic EpoR76E gene therapy protects retinal ganglion cells from glaucomatous degeneration in two different models. This suggests that EPO targets a component of the neurodegenerative pathway that is common to both models. The efficacy of rAAV.EpoR76E delivered at onset of IOP elevation supports clinical relevance of this treatment.

Bone, C. (2017). "Supermarkets criticised over black food trays." Materials Recycling World: 1-1.

Bonello, G., et al. (2018). "First evaluation of microplastic content in benthic filter-feeders of the Gulf of La Spezia (Ligurian Sea)." Journal of Aquatic Food Product Technology **27**(3): 284-291.

The ingestion and retention of microplastics of filter-feeder organisms represent a risk for the final consumers and the environment. Biomonitoring is necessary to deal with the effects of plastic material pollution. The selection of the monitored organisms strongly affects the relevance of the results and the understanding of the environmental conditions. The results discussed in this paper highlight the differences in the estimate of microplastic pollution depending on the species subject of study. Ascidia spp. specimens retained a value five-fold higher (0.62 MP/g) than bivalve species (Crassostrea gigas 0.11 MP/g; Mytilus galloprovincialis 0.05 MP/g; Anomia ephippium 0.12 MP/g).

Bonifacio, A., et al. (2015). "Application of R-mode analysis to Raman maps: a different way of looking at vibrational hyperspectral data." Analytical and bioanalytical chemistry **407**(4): 1089-1095.

Issue Title: A different way of looking at vibrational hyperspectral data/Micellar extraction for the analysis of Alzheimer's disease brain proteome/Quantification of polyolefin microplastics in personal-care products/Removal of Triton X-100 by microdialysis Hierarchical cluster analysis (HCA) is extensively used for the analysis of hyperspectral data. In this work, hyperspectral data sets obtained from Raman maps were analyzed using an alternative mode of cluster analysis, clustering "images" instead of spectra, under the assumption that images showing similar spatial distributions are related to the same chemical species. Such an approach was tested with two Raman maps: one simple "test map" of micro-crystals of four different compounds for a proof of principle and a map of a biological tissue (i.e., cartilage) as an example of chemically complex sample. In both cases, the "image-clustering" approach gave similar results as the traditional HCA, but at lower computational effort. The alternative approach proved to be particularly helpful in cases, as for the cartilage tissue, where concentration gradients of chemical composition are present. Moreover, with this approach, yielded information about correlation between bands in the average spectrum makes band assignment and spectral interpretation easier.

Bonifazi, G., et al. (2009). "INNOVATIVE SENSING TECHNOLOGIES APPLIED TO POST-CONSUMER POLYOLEFINS RECOVERY." Metalurgia International: 5-10.

Polyolefins can be considered as one of the most important polymers for consumer goods being polyethylene (PE) and polypropylene (PP) the most commonly utilized. Even if post-consumer wastes could be considered as a good resource ofpolyolefins, their recovery and recycling is very low. The reason can be mainly attributed to the complexity of these wastes according to different polymers (rubber, foam. etc.) and polluting (not polymers) materials (wood, aluminium, copper, stones, glass. etc.) commonly present in plastic waste streams. In this paper two innovative sensing technologies, and related detection architectures, in order to develop new sorting strategies for pure PP and PE recovery from mixed waste, are presented and discussed. The first one based is on an hyperspectral imaging (HSI) approach and the second one is based on differential melting point (DMP) approach. HSI was investigated to evaluate the possibilities of this technology to determine the quality of waste plastic fred (in terms of presence and characteristics of polyolefin and contaminants). The DMP technology was developed to utilize the different PE and PP particles melting characteristics to perform their quality control as resulting from magnetic density separation (MDS). Results showed as both the approaches can be profitably utilized to develop reliable detection and/or processing architectures and related quality control strategies to implement inside the different sections of a plastic waste recycling plant. [ABSTRACT FROM AUTHOR]

Bonifazi, G., et al. (2017). "Gravity packaging final waste recovery based on gravity separation and chemical imaging control." Waste Management **60**: 50-55.

Plastic polymers are characterized by a high calorific value. Post-consumer plastic waste can be thus considered, in many cases, as a typical secondary solid fuels according to the European Commission directive on End of Waste (EoW). In Europe the practice of incineration is considered one of the solutions for waste disposal waste, for energy recovery and, as a consequence, for the reduction of waste sent to landfill. A full characterization of these products represents the first step to profitably and correctly utilize them. Several techniques have been investigated in this paper in order to separate and characterize post-consumer plastic packaging waste fulfilling the previous goals, that is: gravity separation (i.e. Reflux Classifier), FT-IR spectroscopy, NIR HyperSpectralImaging (HSI) based techniques and calorimetric test. The study demonstrated as the proposed separation technique and the HyperSpectral NIR Imaging approach allow to separate and recognize the different polymers (i.e. PolyVinyl Chloride (PVC), PolyStyrene (PS), PolyEthylene (PE), PoliEtilene Tereftalato (PET), PolyPropylene (PP)) in order to maximize the removal of the PVC fraction from plastic waste and to perform the full quality control of the resulting products, can be profitably utilized to set up analytical/control strategies finalized to obtain a low content of PVC in the final Solid Recovered Fuel (SRF), thus enhancing SRF quality, increasing its value and reducing the "final waste".

Bontinck, W. J. (1979). "Prospects for recycling of plastics in Belgian industry. [Dutch]." Extern Tijdschrift voor Omgevingswetenschappen **8**(5): 273-292.

A general survey of macro-economic data of plastics production and consumption in western Europe as well as the principal areas of use are given. Figures of actual known amounts of plastic waste from industrial and household origin are also discussed. When the recycling of homogeneous plastic industrial waste of a well defined polymer type gives no technical problems, the revalorisation of mixed polymer waste is technically much more complicated. An industrial experiment performed on mixed plastics from the urban waste of the city of Ghent is described. A rough cost price calculation is made. Actually the recycling of selected

homogeneous plastic waste can have an economic justification. A question remains unanswered: what is the public's attitude towards recycled plastic objects of inferior quality?

Booth, A. M., et al. (2016). "Uptake and toxicity of methylmethacrylate-based nanoplastic particles in aquatic organisms." Environmental Toxicology & Chemistry **35**(7): 1641-1649.

The uptake and toxicity of 2 poly(methylmethacrylate)-based plastic nanoparticles (PNPs) with different surface chemistries (medium and hydrophobic) were assessed using aquatic organisms selected for their relevance based on the environmental behavior of the PNPs. Pure poly(methylmethacrylate) (medium; PMMA PNPs) and poly(methylmethacrylate-co-stearylmethacrylate) copolymer (hydrophobic; PMMA-PSMA PNPs) of 86 nm to 125 nm were synthesized using a miniemulsion polymerization method. Fluorescent analogs of each PNP were also synthesized using monomer 7-[4-(trifluoromethyl)coumarin]acrylamide and studied. Daphnia magna, Corophium volutator, and Vibrio fischeri were employed in a series of standard acute ecotoxicity tests, being exposed to the PNPs at 3 different environmentally realistic concentrations (0.01 mg/L, 0.1 mg/L, and 1.0 mg/L) and a high concentration 500 mg/L to 1000 mg/L. In addition, sublethal effects of PNPs in C. volutator were determined using a sediment reburial test, and the uptake and depuration of fluorescent PNPs was studied in D. magna. The PNPs and fluorescent PNPs did not exhibit any observable toxicity at concentrations up to 500 mg/L to 1000 mg/L in any of the tests except for PMMA-PSMA PNPs and fluorescent PNPs following 48-h exposure to D. magna (median lethal concentration values of 879 mg/L and 887 mg/L, respectively). No significant differences were observed between labeled and nonlabeled PNPs, indicating the suitability of using fluorescent labeling. Significant uptake and rapid excretion of the fluorescent PNPs was observed in D. magna. Environ Toxicol Chem 2016;35:1641-1649. © 2015 SETAC [ABSTRACT FROM AUTHOR]

Boots, B., et al. (2019). "Effects of Microplastics in Soil Ecosystems: Above and Below Ground." Environmental Science & Technology **53**(19): 11496.

Environmental contamination by microplastics is now considered an emerging threat to biodiversity and ecosystem functioning. Soil ecosystems, particularly agricultural land, have been recognized as a major sink of microplastics, but the impacts of microplastics on soil ecosystems (e.g., above and below ground) remain largely unknown. In this study, different types of microplastics [biodegradable polylactic acid (PLA)], conventional high-density polyethylene (HDPE), and microplastic clothing fibers were added to soil containing the endogeic Aporrectodea rosea (rosy-tipped earthworm) and planted with Lolium perenne (perennial ryegrass) to assess the biophysical soil response in a mesocosm experiment. When exposed to fibers or PLA microplastics, fewer seeds germinated. There was also a reduction in shoot height with PLA. The biomass of A. rosea exposed to HDPE was significantly reduced compared to control samples. Furthermore, with HDPE present there was a decrease in soil pH. The size distribution of water-stable soil aggregates was altered when microplastics were present, suggesting potential alterations of soil stability. This study provides evidence that microplastics manufactured of HDPE and PLA, and synthetic fibers can affect the development of L. perenne, health of A. rosea and basic, but crucial soil properties, with potential further

impacts on soil ecosystem functioning.

Boppana, R., et al. (2010). "Carboxymethylcellulose - aluminum hydrogel microbeads for prolonged release of simvastatin." Acta Pharmaceutica Sciencia **52**(2): 137-143.

Carboxymethylcellulose based hydrogel microbeads loaded with simvastatin were prepared using ionotropic gelation method. The beads were characterized by differential scanning calorimetric (DSC) analysis, and scanning electron microscopy (SEM). DSC studies confirmed the amorphous dispersion of the drug in the hydrogel matrix. The effect of crosslinking agent and polymer concentration on drug release was studied. Increase in concentration of crosslinking agent and polymers decreased the release rate of simvastatin. The release data were fitted to an empirical equation to determine the transport mechanism. Drug release followed anomalous/non-Fickian transport mechanism.

Borchers, M. T., et al. (2019). "NK cell activation is increased in lymphangioleiomyomatosis." American Journal of Respiratory and Critical Care Medicine. Conference **199**(9).

Rationale: Lymphangioleiomyomatosis (LAM) is a rare lung disease almost exclusively affecting women. Neoplastic smooth muscle-like cells (LAM cells) of unknown origin metastasize to the lung leading to the formation of nodules, progressive cyst formation, and destructive remodeling. Natural Killer (NK) cells are important components of immune function due to their roles in detecting and destroying transformed cells and their involvement in tissue remodeling. To begin to define the potential role of NK cells in LAM pathogenesis, we examined the effector functions of NK cells in the peripheral blood and lung tissue of LAM patients. Method(s): Peripheral blood mononuclear cells (PBMC) were obtained from fresh blood from LAM patients and healthy controls after informed consent (IRB 2013-8157). NK cells were isolated by positive selection using CD56 microbeads (Miltenyi). NK cells were used in multiple assays to define effector functions including; cytotoxicity assays, IFNg elaboration (ELISA) and intracellular signaling (phosphorylation status of ERK and STAT4) in response to cytokine (IL12 and IL18), and growth factor stimulation (VEGF-D). NK cell activation in lung tissue was defined by single cell RNA sequencing derived from explanted lungs from LAM patients undergoing transplantation. Result(s): In all assays examined, NK cells from LAM patients exhibited increased responsiveness compared to healthy control patients. LAM NK cells were ~40% more effective at killing labelled target cells in in vitro cytotoxicity assays. LAM NK cells were hypersensitive to stimulation by multiple cytokines including IL12 and IL18 which was accompanied by increased activation of both the ERK and STAT4 signaling pathways compared to controls. Moreover, we report the novel finding that NK cells respond to VEGF stimulation by producing large quantities of IFNg and this effect is increased in LAM patients with a concomitant increase in ERK/STAT4 activation. Finally, single cell sequencing analyses of NK cells from the lungs of LAM patients show significant upregulation of multiple effector function pathways including those involved in cytotoxicity and degranulation. Conclusion(s): Taken together, these data reveal that NK cells from multiple tissue compartments in LAM patients exist in a state of hyperresponsiveness to multiple stimuli including a newly defined pathway of VEGF receptor signaling. This suggests that functional alterations in NK cells contribute to LAM progression and pathogenesis.

Bordós, G., et al. (2019). "Identification of microplastics in fish ponds and natural freshwater environments of the Carpathian basin, Europe." Chemosphere **216**: 110-116.

In the past few years, there has been a significant development in freshwater microplastic research. Pollution has been detected in lakes and rivers of several continents, but the number of papers is still marginal compared to the ones investigating marine environments. In this

study, we present the first detection of microplastics (MPs) in Central and Eastern European (CEE) surface waters and, globally, the first detection in fish ponds. Samples were taken from different types of fish ponds and natural water bodies along a novel concept down to a particle size of 100 µm, then, after sample preparation, MPs were characterized using an FTIR microscope. 92% of the water samples contained MPs ranging from 3.52 to 32.05 particles/m3. MPs were detected in 69% of the sediment samples ranging from 0.46 to 1.62 particles/kg. Dominant abundance of polypropylene (PP) and polyethylene was shown in water and PP and polystyrene in sediment samples. First results also indicate that fish ponds may act as a deposition area for MPs. Highlights • First detection of microplastics in fish ponds and in Central and Eastern Europe. • New sampling system was developed, collecting particles down to 100 µm. • Concentrations of MPs in pond outlets were always lower compared to the inlets. • Dominance of polyethylene, polypropylene and polystyrene was confirmed by FTIR. • Microplastic concentrations of sediments were much below the international results. [ABSTRACT FROM AUTHOR]

Borges Ramirez, M. M., et al. (2019). "Occurrence and seasonal distribution of microplastics and phthalates in sediments from the urban channel of the Ria and coast of Campeche, Mexico." Science of the Total Environment **672**: 97-105.

Microplastics (MPs) are part of a global problem affecting all countries including those with smaller populations. Coastal sediments are a reservoir of pollutants generated in basins. Phthalate esters (PAEs) are used as additives to make plastics stronger and more flexible. Urban ecosystems are the most susceptible to receive and transport pollutants. In this study, we determined the presence of MPs and PAEs in coastal sediments and in an urban and natural drainage system, known as the "Ria" in San Francisco de Campeche city. Plastics were detected in all samples taken from both regions, with plastics ranging in size from 0.3 to 5mm in diameter. This indicates that they are particles of plastics, paints, and fibers, which may come from boats and nylon nets or synthetic products. The greatest abundance of MPs was detected on the coast with quantities of 1392 items/m² (dry weight), which is double than that seen in the urban channel. As for PAEs, the highest concentrations were determined in two sites: M7A with 18.292mugg⁻¹ dw and PE with 21.702mugg⁻¹ dw, with the Ria channel being the area with the highest concentration of PAEs totaling 49.315mugg⁻¹ dw. The amounts of MPs detected in the sediments of the coast and the Ria vary significantly among the sites (p=0.001) and seasons (p=0.001), with the rainy season being the season where the greatest amount of MPs were detected. Likewise, the concentrations of PAEs varied significantly among seasons (p=0.0002) and sampling sites (p=0.0001), with the west sub-basin being the site where the greatest concentration of PAEs was detected. A strong correlation was found between the PAEs and MPs, which indicates that the conditions of the system favor the release and extended presence of PAEs on the coast.

Borisenko, G. G., et al. (2003). "Macrophage recognition of externalized phosphatidylserine and phagocytosis of apoptotic Jurkat cells--existence of a threshold." Archives of Biochemistry & Biophysics **413**(1): 41-52.

Phosphatidylserine (PS) is predominantly confined to the inner leaflet of plasma membrane in cells, but it is externalized on the cell surface during apoptosis. This externalized PS is required for effective phagocytosis of apoptotic cells by macrophages. Because PS trans-bilayer asymmetry is not absolute in different types of nonapoptotic cells, we hypothesized that the amounts of externalized PS may be critical for macrophage discrimination between apoptotic and nonapoptotic cells. We developed a sensitive electron paramagnetic resonance method to quantify the amounts of externalized PS based on specific binding of paramagnetic annexin V-microbead conjugates with PS on cell surfaces. Using this technique, we found that nonapoptotic Jurkat cells externalize 0.9 pmol of endogenous PS/10(6) Jurkat cells. For cells with different amounts of integrated exogenous PS on their surface, no phagocytic response was observed at PS levels <5 pmol/10(6) Jurkat cells; at higher PS concentrations, phagocytosis increased in a concentration-dependent manner. Apoptosis in Jurkat cells caused externalization of approximately 240 pmol PS/10(6) Jurkat cells; these amounts of externalized PS are manyfold higher than the threshold amounts of PS required for phagocytosis. Thus, macrophages have a sensitivity threshold for PS externalized on the cell surface that provides for reliable recognition and distinction between normal cells with low contents of externalized PS and apoptotic cells with remarkably elevated PS levels.

Borisov, S. M. and O. S. Wolfbeis (2006). "Temperature-sensitive europium(III) probes and their use for simultaneous luminescent sensing of temperature and oxygen." Analytical Chemistry **78**(14): 5094-5101.

Highly photostable and strongly luminescent europium(III) beta-diketonate complexes are presented that can act as new probes for optical sensing of temperature. They can be excited with the light of a 405-nm LED and possess strong brightnesses. The decay times of the probes contained in a poly(vinyl methyl ketone) film and in poly(tert-butyl styrene) microparticles are highly temperature-dependent between 0 and 70 degrees C. The temperature-sensitive microparticles were dispersed, along with oxygen-sensitive microbeads consisting of a palladium porphyrin oxygen indicator in poly(styrene-co-acrylonitrile), in a thin layer of a hydrogel to give a dually sensing material which is excitable by a single light source. The two emissions can be separated by appropriate optical filters. The response to oxygen and temperature is described by 3D plots, and unbiased values can be obtained for temperature and oxygen, respectively, from the two luminescence signals if refined in an iteration step. The sensing scheme is intended for use in temperature-compensated sensing of oxygen, in contactless sensing of oxygen and temperature in (micro)biological and medical applications, in high-resolution oxygen profiling, and for simultaneous imaging of air pressure and temperature in wind tunnels.

Borja, A. and M. Elliott (2019). "So when will we have enough papers on microplastics and ocean litter?" Marine Pollution Bulletin **146**: 312-316.

Bornscheuer, U. T. (2016). "Feeding on plastic. (Special Issue: Forensics.)." Science **351**(6278): 1154-1155.

An estimated 311 million tons of plastics are produced annually worldwide; 90% of these are derived from petrol. A considerable portion of these plastics is used for packaging (such as drinking bottles), but only ~14% is collected for recycling (1). Most plastics degrade extremely slowly, thus constituting a major environmental hazard (2), especially in the oceans, where microplastics are a matter of major concern (3). One potential solution for this problem is the synthesis of degradable plastics from renewable resources (4). This approach provides hope for the future but does not help to get rid of the plastics already in the environment. On page 1196 of this issue, Yoshida et al. (5) address this problem by reporting an organism that can fully degrade a widely used plastic.

Borrelle, S. B., et al. (2017). "Why we need an international agreement on marine plastic pollution." Proceedings of the National Academy of Sciences of the United States of America **114**(38): 9994-9997.

Borrero-Lopez, O., et al. (2019). "Wear of ceramic-based dental materials." Journal of the Mechanical Behavior of Biomedical Materials **92**: 144-151.

An investigation is made of wear mechanisms in a suite of dental materials with a ceramic component and tooth enamel using a laboratory test that simulates clinically observable wear facets. A ball-on-3-specimen wear tester in a tetrahedral configuration with a rotating hard antagonist zirconia sphere is used to produce circular wear scars on polished surfaces of dental materials in artificial saliva. Images of the wear scars enable interpretation of wear mechanisms, and measurements of scar dimensions quantify wear rates. Rates are lowest for zirconia ceramics, highest for lithium disilicate, with feldspathic ceramic and ceramic-polymer composite intermediate. Examination of wear scars reveals surface debris, indicative of a mechanism of material removal at the microstructural level. Microplasticity and microcracking models account for mild and severe wear regions. Wear models are used to evaluate potential longevity for each dental material. It is demonstrated that controlled laboratory testing can identify and quantify wear susceptibility under conditions that reflect the essence of basic occlusal contact. In addition to causing severe material loss, wear damage can lead to premature tooth or prosthetic failure. Copyright © 2019 Elsevier Ltd

Borrero-Lopez, O., et al. (2014). "A model for predicting wear rates in tooth enamel." Journal of the Mechanical Behavior of Biomedical Materials **37**: 226-234.

It is hypothesized that wear of enamel is sensitive to the presence of sharp particulates in oral fluids and masticated foods. To this end, a generic model for predicting wear rates in brittle materials is developed, with specific application to tooth enamel. Wear is assumed to result from an accumulation of elastic-plastic micro-asperity events. Integration over all such events leads to a wear rate relation analogous to Archard's law, but with allowance for variation in asperity angle and compliance. The coefficient K in this relation quantifies the wear severity, with an arbitrary distinction between 'mild' wear (low K) and 'severe' wear (high K). Data from the literature and in-house wear-test experiments on enamel specimens in lubricant media (water, oil) with and without sharp third-body particulates (silica, diamond) are used to validate the model. Measured wear rates can vary over several orders of magnitude, depending on contact asperity conditions, accounting for the occurrence of severe enamel removal in some human patients (bruxing). Expressions for the depth removal rate and number of cycles to wear down occlusal enamel in the low-crowned tooth forms of some mammals are derived, with tooth size and enamel thickness as key variables. The role of 'hard' versus 'soft' food diets in determining evolutionary paths in different hominin species is briefly considered. A feature of the model is that it does not require recourse to specific material removal mechanisms, although processes involving microplastic extrusion and microcrack coalescence are indicated.

Borrero-Lopez, O., et al. (2015). "Mechanics of microwear traces in tooth enamel." Acta Biomaterialia **14**: 146-153.

It is hypothesized that microwear traces in natural tooth enamel can be simulated and quantified using microindentation mechanics. Microcontacts associated with particulates in the oral wear medium are modeled as sharp indenters with fixed semi-apical angle. Distinction is made between markings from static contacts (pits) and translational contacts (scratches).

Relations for the forces required to produce contacts of given dimensions are derived, with particle angularity and compliance specifically taken into account so as to distinguish between different abrasives in food sources. Images of patterns made on human enamel with sharp indenters in axial and sliding loading are correlated with theoretical predictions. Special attention is given to threshold conditions for transition from a microplasticity to a microcracking mode, corresponding to mild and severe wear domains. It is demonstrated that the typical microwear trace is generated at loads on the order of 1N - i.e. much less than the forces exerted in normal biting - attesting to the susceptibility of teeth to wear in everyday mastication, especially in diets with sharp, hard and large inclusive intrinsic or extraneous particulates.

Bos, U., et al. (2008). "Life Cycle Assessment of common used agricultural plastic products in the EU." Acta Horticulturae **801**(Vol 1): 341-350.

Agriculture plastic wastes (APW) generate about 615 000 tonnes of waste per year in Europe. This presents a serious challenge concerning the production of the plastic as well as the disposal or recycling of the materials. To address the specific issues of APW, the European Commission funds a project called LABELAGRIWASTE, labelling agricultural plastic waste to valorise the waste stream. In the consortium, partners from Belgium, Cyprus, Finland, France, Germany, Greece, Italy and Spain are working together on developing a labelling scheme for European APW. To identify the environmental impact of the main agricultural plastic products, a life cycle assessment (LCA) is performed. The LCA is done before the development of a labelling scheme starts to examine the different life cycles of the most commonly used agricultural products in Europe. The study includes the LCA of mulch films, pipes, and greenhouse films, each with two different plastics and different end-of-life options. Also, differences in four countries and the whole European Union were investigated. The LCA includes the production of the plastics and the following different end-of-life scenarios: mechanical recycling, landfill and incineration. As a result the environmental profiles of different materials with various end-of-life options are generated. The environmental categories global warming potential, acidification potential, eutrophication potential, photochemical ozone creation potential and the primary energy consumption are shown. The results varied depending on the end-of-life option, the country and the material studied. This paper presents the results for the life cycle of mulch film including the production and different end-of-life options for the global warming potential.

Bosker, T., et al. (2019). "Microplastics accumulate on pores in seed capsule and delay germination and root growth of the terrestrial vascular plant Lepidium sativum." Chemosphere **226**: 774-781.

The impacts of nano- and microplastics (<100nm and <5mm, respectively) on terrestrial systems is to the present largely unexplored. Plastic particles are likely to accumulate in these systems primarily by the application of sewage sludge. The aim of the current study was to investigate the effects of three sizes of plastic particles (50, 500, and 4800nm) on a terrestrial plant (cress; Lepidium sativum), using a standardized 72h bioassay. Cress seeds were exposed to five different concentrations of plastics, ranging from 10³ to 10⁷ particles mL⁻¹. Germination rate was significantly reduced after 8h of exposure for all three sizes of plastics, with increased adverse effect with increasing plastic sizes. Seeds exposed to 4800nm microplastics showed a germination rate decline from 78% in control to 17% in the highest exposure. No difference in germination rate occurred after 24h of exposure, regardless of the size of the plastic used. Significant differences in root growth were observed after 24h, but not after 48 or 72h of exposure. Impacts on germination are likely due to physical blockage of the pores in the seed capsule by microplastics as shown by confocal microscopy of fluorescent microplastics. In later stages, the microplastics particularly accumulated on the root

hairs. This is the first detailed study on the effect of nano- and microplastics on a vascular, terrestrial plant, and our results indicate short-term and transient adverse effects.

Bosker, T., et al. (2018). "Microplastic pollution on Caribbean beaches in the Lesser Antilles." Marine Pollution Bulletin **133**: 442-447.

Here we investigate microplastics contamination on beaches of four islands of the Lesser Antilles (Anguilla, St. Barthelemy, St. Eustatius and St. Martin/Maarten). These islands are close to the North Atlantic subtropical gyre, which contains high levels of microplastics. On average 261+/-6microplastics/kg of dry sand were found, with a maximum of 620+/-96 microplastics on Grandes Cayes, Saint Martin. The vast majority of these microplastics (>95%) were fibers. Levels of microplastics differed among islands, with significantly lower levels found in St. Eustatius compared to the other Islands. No difference in microplastic levels was found between windward and leeward beaches. Our research provides a detailed study on microplastics on beaches in the Lesser Antilles. These results are important in developing a deeper understanding of the extent of the microplastic challenge within the Caribbean region, a hotspot of biodiversity.

Bosker, T., et al. (2019). "Significant decline of Daphnia magna population biomass due to microplastic exposure." Environmental Pollution **250**: 669-675.

Even though microplastics are intensively studied, the focus of the research is mainly on relatively short term effects at high doses. Therefore there is a need to shift the focus toward more realistic, longer-term endpoints. Studies with a range of chemicals have shown that the response of populations often differs from studies in which a single organism is exposed in an individual container (as often described within standard ecotox screening assays). Here we investigate the impact of primary microplastics (1-5 micro m in size) on a population of Daphnia magna. We first allowed a stable population of D. magna to develop over 29 d, after which the populations were exposed to microplastics for three weeks (concentrations ranging from 10² to 10⁵ particles mL⁻¹ and a control). We found a significant impact of microplastics on the total population of D. magna, with a reduction in the amount of adult daphnids. Importantly, when expressed as total biomass, exposure to 10⁵ microplastics mL⁻¹ resulted in a 21% reduction in total biomass compared to control. These results indicate that exposure to microplastics can result in significant adverse effects on the population of D. magna, including a reduction in the number of individuals as well as total biomass. Given the importance of D. magna in freshwater food webs, both as a grazer as well as a food source, this can potentially impact the functioning of the ecosystem.

Bottari, T., et al. (2019). "Plastics occurrence in the gastrointestinal tract of Zeus faber and Lepidopus caudatus from the Tyrrhenian Sea." Marine Pollution Bulletin **146**: 408-416.

The present study investigates the occurrence of plastic pollution in two commercially important marine teleosts (Zeus faber and Lepidopus caudatus) from the northern coasts of Sicily (Tyrrhenian Sea). Plastics occurrence in the gastrointestinal tract was higher in Lepidopus caudatus (78.1%) than Zeus faber (51.4%). Debris characterization, carried out by micro-Raman spectroscopy, allowed identified the main types of found polymers as: polypropylene (PP), polyamide (PA), nylon and, to a lesser extent, polyethylene (PE). Of the two fish species studied, the silver scabbardfish appeared to be the more vulnerable to plastic ingestion. Our study represents a starting point that may pave the way for future investigation of the fate, accumulation and transfer of plastic debris to upper trophic levels, to verify their potential toxicity and to better understand strategies to mitigate this phenomenon.

Botterell, Z. L. R., et al. (2019). "Bioavailability and effects of microplastics on marine zooplankton: A review." Environmental Pollution **245**: 98-110.

Microplastics are abundant and widespread in the marine environment. They are a contaminant of global environmental and economic concern. Due to their small size a wide range of marine species, including zooplankton can ingest them. Research has shown that microplastics are readily ingested by several zooplankton taxa, with associated negative impacts on biological processes. Zooplankton is a crucial food source for many secondary consumers, consequently this represents a route whereby microplastic could enter the food web and transfer up the trophic levels. In this review we aim to: 1) evaluate the current knowledge base regarding microplastic ingestion by zooplankton in both the laboratory and the field; and 2) summarise the factors which contribute to the bioavailability of microplastics to zooplankton. Current literature shows that microplastic ingestion has been recorded in 39 zooplankton species from 28 taxonomic orders including holo- and meroplanktonic species. The majority of studies occurred under laboratory conditions and negative effects were reported in ten studies (45%) demonstrating effects on feeding behaviour, growth, development, reproduction and lifespan. In contrast, three studies (14%) reported no negative effects from microplastic ingestion. Several physical and biological factors can influence the bioavailability of microplastics to zooplankton, such as size, shape, age and abundance. We identified that microplastics used in experiments are often different to those quantified in the marine environment, particularly in terms of concentration, shape, type and age. We therefore suggest that future research should include microplastics that are more representative of those found in the marine environment at relevant concentrations. Additionally, investigating the effects of microplastic ingestion on a broader range of zooplankton species and life stages, will help to answer key knowledge gaps regarding the effect of microplastic on recruitment, species populations and ultimately broader economic consequences such as impacts on shell- and finfish stocks. Review of the current knowledge regarding microplastic ingestion by zooplankton and summary of factors which contribute to the bioavailability of microplastics to zooplankton. Bottier, M., et al. (2015). "Characterization of upper airway ciliary beat by coupling isolated and collective cilia motion analysis." Cilia **(SUPPLEMENT 1) (no pagination)**(P86).

Bottier, M., et al. (2017). "A new index for characterizing micro-bead motion in a flow induced by ciliary beating: Part I, experimental analysis." PLoS Computational Biology **13**(7): e1005605.

Mucociliary clearance is one of the major lines of defense of the respiratory system. The mucus layer coating the pulmonary airways is moved along and out of the lung by the activity of motile cilia, thus expelling the particles trapped in it. Here we compare ex vivo measurements of a Newtonian flow induced by cilia beating (using micro-beads as tracers) and a mathematical model of this fluid flow, presented in greater detail in a second companion article. Samples of nasal epithelial cells placed in water are recorded by high-speed video-microscopy and ciliary beat pattern is inferred. Automatic tracking of micro-beads, used as markers of the flow generated by cilia motion, enables us also to assess the velocity profile as a function of the distance above the cilia. This profile is shown to be essentially parabolic. The obtained experimental data are used to feed a 2D mathematical and numerical model of the coupling between cilia, fluid, and micro-bead motion. From the model and the experimental measurements, the shear stress exerted by the cilia is deduced. Finally, this shear stress, which can easily be measured in the clinical setting, is proposed as a new index for characterizing the efficiency of ciliary beating.

Bottier, M., et al. (2017). "A new index for characterizing micro-bead motion in a flow induced by ciliary beating: Part II, modeling." PLoS Computational Biology **13**(7): e1005552.

Mucociliary clearance is one of the major lines of defense of the human respiratory system. The mucus layer coating the airways is constantly moved along and out of the lung by the activity of motile cilia, expelling at the same time particles trapped in it. The efficiency of the cilia motion can experimentally be assessed by measuring the velocity of micro-beads traveling through the fluid surrounding the cilia. Here we present a mathematical model of the fluid flow and of the micro-beads motion. The coordinated movement of the ciliated edge is represented as a continuous envelope imposing a periodic moving velocity boundary condition on the surrounding fluid. Vanishing velocity and vanishing shear stress boundary conditions are applied to the fluid at a finite distance above the ciliated edge. The flow field is expanded in powers of the amplitude of the individual cilium movement. It is found that the continuous component of the horizontal velocity at the ciliated edge generates a 2D fluid velocity field with a parabolic profile in the vertical direction, in agreement with the experimental measurements. Conversely, we show than this model can be used to extract microscopic properties of the cilia motion by extrapolating the micro-bead velocity measurement at the ciliated edge. Finally, we derive from these measurements a scalar index providing a direct assessment of the cilia beating efficiency. This index can easily be measured in patients without any modification of the current clinical procedures.

Boudy, V., et al. (2002). "Adsorption of an ionizable drug onto microspheres: experimental and modeling studies." International Journal of Pharmaceutics **239**(1-2): 13-22.

The purpose of this work was to study the in vitro equilibria and the adsorption kinetics of an ionizable drug, indomethacin, onto commercially available cationic polymeric microspheres: DEAE Trisacryl LS and QA Trisacryl LS. Isotherms were fitted to theoretical equations allowing accurate predictions of drug loading at different salt concentrations. Isotherm measurements were quickly obtained by simple column breakthrough experiments. The nature of the ion exchange group of the microspheres was observed to be preponderant for adsorption, as the tertiary amine derivative exhibited 53% more capacity than its quaternary amine counterpart. The maximum equilibrium uptake capacity in a 5 mM Tris-HCl buffer at pH 7.4 is 303 mmol/ml of particle volume, for DEAE microspheres. Transport properties of indomethacin into the tertiary amine microspheres were obtained in agitated contactor. Microbeads loading was completed in a 1-6 min range and was found to be controlled by pore diffusion mechanism. Equilibrium uptake data was fitted to the Langmuir and the mass action law models. Adsorption kinetics were fitted to a pore diffusion model. Good correlation was obtained between the theoretical models and the experimental data. The methodology outlined in this work provided a simple approach of estimating adsorption behavior of drugs onto ion-exchange macroporous microspheres. Although significant indomethacin loading was obtained onto the DEAE microspheres, the rapid rate of diffusion is not compatible with sustained release properties sought for this type of microspheres.

Boueri, M., et al. (2011). "Identification of polymer materials using laser-induced breakdown spectroscopy combined with artificial neural networks." Applied Spectroscopy **65**(3): 307-314.

A combination of laser-induced breakdown spectroscopy (LIBS) and artificial neural networks (ANNs) has been used for the identification of polymer materials, including polypropylene (PP), polyvinyl chloride (PVC), polytetrafluoroethylene (PTFE), polyoxymethylene (POM), polyethylene

(PE), polyamide or nylon (PA), polycarbonate (PC) and poly(methyl methacrylate) (PMMA). After optimization of the experimental setup and the spectrum acquisition protocol, successful identification rates between 81 and 100% were achieved using spectral features gathered from single spectra without averaging (1 second acquisition time) over a wide spectral range (240-820 nm). Furthermore, ten different materials based on PVC were tested using the identification procedure. Correct identifications were obtained as well. Sorting of the materials into sub-categories of PVC materials according to their charges (concentration in trace elements such as Ca) was performed. The demonstrated capacities fit, in practice, the needs of plastic-waste sorting and of producing high-grade recycled plastic materials.

Bour, A., et al. (2018). "Presence of microplastics in benthic and epibenthic organisms: Influence of habitat, feeding mode and trophic level." <u>Environmental Pollution</u> **243**: 1217-1225.

The exponential production and use of plastics has generated increasing environmental release over the past decades, and microplastics (MPs) have been reported across all the oceans. Field studies have documented the occurrence of MPs in several species, but important knowledge gaps still remain. In the present study, we characterized the distribution of MPs in ten sediment-dwelling and epibenthic species representative of different habitat, feeding modes and trophic levels within the inner Oslofjord (Oslo, Norway), an area subjected to moderate anthropogenic pressures. Analysed species included fish, bivalves, echinoderms, crustaceans and polychaetes. MPs were present in all the species with a frequency up to 65% of positive individuals for some species. In most cases, 1 or 2 MPs were found per individual, but some organisms contained up to 7 particles. A total of 8 polymer typologies were identified, with PE and PP being the most common according to our extraction protocol. MP sizes ranged from 41 µm to lines as long as 9 mm. Our results indicate that occurrence of MPs in analysed biota is not influenced by organism habitat or trophic level, while characteristics and typology of polymers might be significantly affected by feeding mode of organisms. Graphical abstract Image 1 Highlights • The presence of microplastics (MPs) was analysed in biota from a Norwegian fjord. • MPs were found in all species sampled. • PE and PP are the polymers most found. • MPs smaller than 200 µm account for more than 58% of the total extracted MPs. • Presence of MPs is influenced by feeding mode, but not habitat or trophic level. This field study investigates the influence of three major parameters, habitat, feeding mode and trophic level, on the presence of microplastics in benthic and epibenthic organisms. [ABSTRACT FROM AUTHOR]

Bour, A., et al. (2018). "Environmentally relevant microplastic exposure affects sediment-dwelling bivalves." <u>Environmental Pollution</u> **236**: 652-660.

Most microplastics are expected to sink and end up in marine sediments. However, very little is known concerning their potential impact on sediment-dwelling organisms. We studied the long-term impact of microplastic exposure on two sediment-dwelling bivalve species. Ennucula tenuis and Abra nitida were exposed to polyethylene microparticles at three concentrations (1; 10 and 25 mg/kg of sediment) for four weeks. Three size classes (4-6; 20-25 and 125-500 micro m) were used to study the influence of size on microplastic ecotoxicity. Microplastic exposure did not affect survival, condition index or burrowing behaviour in either bivalve species.

However, significant changes in energy reserves were observed. No changes were observed in protein, carbohydrate or lipid contents in E. tenuis, with the exception of a decrease in lipid content for one condition. However, total energy decreased in a dose-dependent manner for bivalves exposed to the largest particles. To the contrary, no significant changes in total energy were observed for A. nitida, although a significant decrease of protein content was observed for individuals exposed to the largest particles, at all concentrations. Concentration and particle size significantly influenced microplastic impacts on bivalves, the largest particles and higher concentrations leading to more severe effects. Several hypotheses are presented to explain the observed modulation of energy reserves, including the influence of microplastic size and concentration. Our results suggest that long-term exposure to microplastics at environmentally relevant concentrations can impact marine benthic biota.

Bourdages, M. P. T., et al. (2020). "No plastics detected in seal (Phocidae) stomachs harvested in the eastern Canadian Arctic." Marine Pollution Bulletin **150**: 110772.

Through collaboration with Inuit hunters, we examined the stomach contents of 142 seals (ringed seals [Phoca hispida; n = 135], bearded seals [Erignathus barbatus; n = 6], and one harbour seal [Phoca vitualina; n = 1]) hunted between 2007 and 2019 from communities around Nunavut to assess whether seals in the eastern Canadian Arctic ingest and retain plastics in their stomachs. The seals in this study ranged from juveniles to adults of up to 30 years of age, and 55% of the seals were males. We found no evidence of plastic ingestion in any of the seals suggesting that seals in Nunavut are not accumulating plastics (>425 mum) in their stomachs. These data provide important baseline information for future plastic pollution monitoring programs in the Arctic.

Bour-Dill, C., et al. (2000). "Determination of intracellular organelles implicated in daunorubicin cytoplasmic sequestration in multidrug-resistant MCF-7 cells using fluorescence microscopy image analysis." Cytometry **39**(1): 16-25.

Background: Anthracycline resistance is known to be mediated by P- glycoprotein (P-gp) or multidrug-resistance related protein (MRP) as well as intracellular sequestration of drugs. Method(s): The resistance phenotype of doxorubicin-selected MCF-7(DXR) human breast adenocarcinoma cell line was characterized by cellular and nuclear daunorubicin efflux, P-gp and MRP expression and apoptosis induction. Daunorubicin sequestration was investigated through organelle markers (lysosomes, endoplasmic reticulum and Golgi apparatus) and daunorubicin co-localization by dual-color image analysis fluorescence microscopy using high numerical aperture objective lenses to achieve the smallest field depth and the best lateral resolution. Signal to noise and specificity ratios were optimized for daunorubicin and organelle fluorescent probes labeling. Result(s): An original image analysis procedure was developed to investigate daunorubicin and organelles co- localization. The reliability of the image analysis was controlled through chromatic shift and intensity linearity measurement using calibrated microbeads. The main contribution (65%) of Golgi vesicles in daunorubicin sequestration was demonstrated. Although no rational relationship could be established between daunorubicin sequestration and apoptosis induction, no apoptosis was observed in MCF-7(DXR) cells. Conclusion(s): In addition to P- glycoprotein mediated drug efflux and without MRP overexpression, MCF-7(DXR) daunorubicin resistance phenotype involves drug sequestration within intracellular vesicles identified as Golgi vesicles and resistance to apoptosis induction.

Bouwmeester, H., et al. (2015). "Potential Health Impact of Environmentally Released Micro- and Nanoplastics in the Human Food Production Chain: Experiences from Nanotoxicology." Environmental

Science & Technology **49**(15): 8932-8947.
High concentrations of plastic debris have been observed in the oceans. Much of the recent concern has focused on microplastics in the marine environment. Recent studies of the size distribution of the plastic debris suggested that continued fragmenting of microplastics into nanosized particles may occur. In this review we assess the current literature on the occurrence of environmentally released micro- and nanoplastics in the human food production chain and their potential health impact. The currently used analytical techniques introduce a great bias in the knowledge, since they are only able to detect plastic particles well above the nanorange. We discuss the potential use of the very sensitive analytical techniques that have been developed for the detection and quantification of engineered nanoparticles. We recognize three possible toxic effects of plastic particles: first due to the plastic particles themselves, second to the release of persistent organic pollutant adsorbed to the plastics, and third to the leaching of additives of the plastics. The limited data on microplastics in foods do not predict adverse effect of these pollutants or additives. Potential toxic effects of microplastic particles will be confined to the gut. The potential human toxicity of nanoplastics is poorly studied. Based on our experiences in nanotoxicology we prioritized future research questions.

Bowles, K. S., et al. (2002). "A novel model for equine recurrent airway obstruction." Veterinary Immunology and Immunopathology **87**(3/4): 385-389.
Equine recurrent airway obstruction (RAO; a term combining both chronic obstructive pulmonary disease (COPD) and summer pasture associated obstructive pulmonary disease (SPAOPD)) is one of the most common equine respiratory diseases with up to 50% of horses affected worldwide. The etiopathogenesis of RAO is unknown although pulmonary hypersensitivity to inhaled mold antigens may be involved. Recent work in our laboratory demonstrating elevated levels of IL-4 and IL-13 mRNA in the airways and peripheral blood of horses with RAO is consistent with an atopic component to RAO. Little is known regarding the earliest phases of RAO in horses. Here we describe the development of a novel airway model for equine RAO that utilizes ovalbumin-coated polystyrene beads for airway sensitization and challenge. Aerosol challenge of sensitized ponies with OVA-coated microbeads resulted in decreased airway compliance, increased percentage of lymphocytes and neutrophils in the bronchoalveolar lavage fluid, and evidence of a Th2 cytokine response in the bronchoalveolar cells. These results suggest that this approach may be useful in describing the initial stages of RAO development in the horse.

Boyaci, I. H., et al. (2005). "Amperometric determination of live Escherichia coli using antibody-coated paramagnetic beads." Analytical & Bioanalytical Chemistry **382**(5): 1234-1241.
Detecting and enumerating fecal coliforms, especially Escherichia coli, as indicators of fecal contamination, are essential for the quality control of supplied and recreational waters. We have developed a sensitive, inexpensive, and small-volume amperometric detection method for E. coli beta-galactosidase by bead-based immunoassay. The technique uses biotin-labeled capture antibodies (Ab) immobilized on paramagnetic microbeads that have been functionalized with streptavidin (bead-Ab). The bead-Ab conjugate captures E. coli from solution. The captured E. coli is incubated in Luria Bertani (LB) broth medium with the added inducer isopropyl beta-D: -thiogalactopyranoside (IPTG). The induced beta-galactosidase converts p-aminophenyl beta-D: -galactopyranoside (PAPG) into p-aminophenol (PAP), which is measured by amperometry using a gold rotating disc electrode. A good linear correlation (R2 = 0.989) was obtained between log cfu mL(-1) E. coli and the time necessary to product a specific concentration of PAP. Amperometric detection enabled determination of 2x10(6) cfu mL(-1) E. coli within a 30 min

incubation period, and the total analysis time was less than 1 h. It was also possible to determine as few as 20 cfu mL(-1) E. coli under optimized conditions within 6-7 h. This process may be easily adapted as an automated portable bioanalytical device for the rapid detection of live E. coli.

Boyero, L., et al. (2019). "Microplastics impair amphibian survival, body condition and function." Chemosphere **244**: 125500.

Microplastics (MPs) are contaminants of increasing concern; they are abundant, ubiquitous and persistent over time, representing potential risks for organisms and ecosystems. However, such risks are still virtually unknown for amphibians, despite the particular attention that these organisms often receive because of their global decline. We examined the effects of MPs (fluorescent, 10-mum polystyrene microspheres) at different concentrations (from 0 to 10³ particles mL⁻¹) on tadpoles of the common midwife toad, Alytes obstetricans, using a microcosm experiment. We assessed MP effects on tadpole feeding, growth and body condition, as well as their ingestion and egestion of MPs (estimated through fluorescence). Additionally, we explored whether MPs became attached to periphyton (the main food source for these tadpoles, thus potentially representing a major way of MP ingestion), and the effect of MPs on periphyton growth (which may translate into altered freshwater ecosystem functioning). Our results showed significant effects on all the examined variables, and caused tadpole mortality at the highest concentration; also, fluorescence indicated the presence of MPs in tadpoles, tadpole faeces and periphyton. This suggests that MPs can be an important source of stress for amphibians in addition to other pollutants, climate change, habitat loss or chytrid infections, and that amphibians can be a major transfer path for MPs from freshwater to terrestrial ecosystems.

Boyko, A., et al. (2016). "The role of dopamine in regulating interactions of the immune and nervous system in multiple sclerosis." Multiple Sclerosis **22 (Supplement 3)**: 177-178.

Introduction: Multiple sclerosis (MS) - chronic autoimmune disease of the CNS predominantly mediated by T-cells. Dopamine (DA) can participate in MS pathogenesis modulating immune cells activity and cytokine production. Objective(s): To study the relationship between clinical impairment, DA concentration in the serum, quantitative characteristics of Th17-cells, and to clarify the influence of DA on the function of Th17 cells. Material(s) and Method(s): Data from 43 patients with relapsingremitting MS and 20 healthy controls were included. Fourteen patients were examined during relapses, 29 during clinical remission. The DA concentration in the serum was measured by ELISA. Circulating Th17-cells were determined by flow cytometry (CD4+CD26+CD161+CD196+). The levels of interleukin-17 (IL-17) and interferon-gamma (IFN-gamma) were studied by ELISA in supernatants of peripheral blood mononuclear cells (PBMC) stimulated with microbeads coated with anti-CD3 and anti-CD28 antibodies in the absence and in the presence of DA and antagonists of DA-receptors at a concentration of 10-5 M. Result(s): The level of DA was lower in MS patients during relapse than in patients during remission and in healthy subjects ($p< 0.05$). The percentages of Th17-cells and production of IL-17 and IFN-gamma by PBMC were higher in patients in relapse compared to patients in remission or to the control group ($p< 0.01$). DA reduced IL-17 and IFN-gamma production in all groups ($p< 0.05$). Blockade of D1-like receptors enhanced the inhibitory effect of DA on IL-17 production ($p< 0.05$) while blockade of D2-like receptors abolished the suppressive effect of DA in all groups. Blockade of D1-like receptors without the subsequent addition of DA reduced the production of IL-17 ($p< 0.05$) while blockade of D2-like receptors stimulated production of IL-17 in all groups ($p< 0.05$). Conclusion(s): These data suggest an anti-inflammatory role for DA in MS

which is mediated by D2-receptors.

Boyko, A., et al. (2016). "The Role of Biogenic Amines in the Regulation of Interaction between the Immune and Nervous Systems in Multiple Sclerosis." Neuroimmunomodulation **23**(4): 217-223.
OBJECTIVE: Multiple sclerosis (MS) is a demyelinating, presumably autoimmune disease of the central nervous system. Biogenic amines may participate in MS pathogenesis modulating immune cell activity and cytokine production.
METHODS: Forty-three patients with relapsing-remitting MS were examined. Serotonin (SE), norepinephrine (NE) and epinephrine (EPI) concentrations in sera were measured by ELISA. The functional activity of Th17 and Th1 cells was assessed by the ability of peripheral blood mononuclear cells (PBMCs) to produce interferon-gamma (IFN-gamma) and interleukin-17 (IL-17) and cell proliferation upon stimulation with microbeads coated with anti-CD3 and anti-CD28 antibodies. To evaluate the effect of biogenic amines on Th17 and Th1 cells, PBMCs were cultured in the presence of SE and NE. Statistical analysis was performed using Prism 6 software.
RESULTS: Concentrations of SE and EPI in sera were not different between the groups. Concentrations of NE in sera from MS patients were lower than those in the healthy control group. The production of IL-17 and IFN-gamma in MS patients in relapse was higher than that in patients in remission or in the control group. SE at a concentration of 10-4M suppressed IL-17 production. NE at a concentration of 10-4M suppressed both IL-17 and IFN-gamma production.
CONCLUSIONS: These data suggest an anti-inflammatory role for biogenic amines in MS.

Bożek, M., et al. (2017). The studies on waste biodegradation by <i>Tenebrio molitor</i>. Les Ulis, EDP Sciences. **17**.
As cities are growing in size with a rise in the population, the amount of plastic waste generated is increasing and becoming unmanageable. The treatment and disposal of plastic waste is an urgent need of our present and future. It has been proved recently that mealworms, the larvae of Tenebrio molitor Linnaeus, are able eat styrofoam, a common polystyrene product. Polystyrene is one of the most widely used plastics, the scale of its production being several million tons per year. Tenebrio molitor is one of the largest pests found in stored-grain products. The insect is indigenous to Europe, but is currently cosmopolitan in distribution. The styrofoam is efficiently degraded in the larval gut by microorganisms. We have used the larvae of T. molitor to biodegrade three types of food packaging plastics: polystyrene (PS), polyvinyl chloride (PVC) and polylactide (PLA). PVC is a thermoplastic made of 57% chlorine (derived from industrial grade salt) and 43% carbon (derived predominantly from oil /gas via ethylene). It is the world's third-most widely produced synthetic plastic polymer, which is not biodegradable easily. On the other hand, PLA is an easily biodegradable and bioactive thermoplastic aliphatic polyester derived from corn and tapioca starch or sugarcane. Three groups of larvae were fed selected types of polymers as an only food, while a control population was fed on oatmeal. The mass loss, dry matter content and biochemical composition of mealworms were assessed in the performed laboratory experiments. The protein concentration in homogenates of the larvae was determined by the Bradford method. To determine the level of hydrolized carbohydrates we used anthrone method. The classical sulfo-phospho-vanillin assay (SPVA) was used to quantitate total lipids in mealworms. The results allowed to compare the decomposition efficiency of selected polymer materials by mealworms and to recognize the mechanism of decomposition contributing to the future use of these animals for the treatment and disposal of plastic waste.

Bozhinova, D., et al. (2004). "Evaluation of magnetic polymer micro-beads as carriers of immobilised

biocatalysts for selective and stereoselective transformations." Biotechnology Letters **26**(4): 343-350.
The kinetic, selective and stereoselective properties of enzyme immobilised on magnetic polymer beads with diameters in the range 1 microm was studied with penicillin amidase from E. coli. The enzyme was immobilised on epoxy and glutaraldehyde-activated poly(vinyl alcohol), poly(methylmetacrylate) and poly(vinyl acetate-divinylbenzene) magnetic beads. The amount of covalently bound active protein was dependent on the chemical modification of the matrix and increased at higher ionic strength of the immobilisation buffer. The small size of the magnetic beads, that reduces mass transfer limitations, and the decreased charge density in the electric double layer resulted in lower apparent Km values and higher efficiency for benzylpenicillin hydrolysis, higher stereoselectivity in condensation of R-phenylglycine amide with S- and R-Phe and in hydrolysis of racemic phenylacetyl-Phe and higher selectivity in kinetically controlled synthesis of cephalexin compared to the enzyme immobilised on larger and porous carriers.

Bozza, F. A., et al. (2008). "Multiplex cytokine profile from dengue patients: MIP-1beta and IFN-gamma as predictive factors for severity." BMC Infectious Diseases **8**: 86.
BACKGROUND: Dengue virus pathogenesis is not yet fully understood and the identification of patients at high risk for developing severe disease forms is still a great challenge in dengue patient care. During the present study, we evaluated prospectively the potential of cytokines present in plasma from patients with dengue in stratifying disease severity.
METHODS: Seventeen-cytokine multiplex fluorescent microbead immunoassay was used for the simultaneous detection in 59 dengue patients. GLM models using bimodal or Gaussian family were determined in order to associate cytokines with clinical manifestations and laboratory diagnosis.
RESULTS: IL-1beta, IFN-gamma, IL-4, IL-6, IL-13, IL-7 and GM-CSF were significantly increased in patients with severe clinical manifestations (severe dengue) when compared to mild disease forms (mild dengue). In contrast, increased MIP-1beta levels were observed in patients with mild dengue. MIP-1beta was also associated with CD56+NK cell circulating rates. IL-1beta, IL-8, TNF-alpha and MCP-1 were associated with marked thrombocytopenia. Increased MCP-1 and GM-CSF levels correlated with hypotension. Moreover, MIP-1beta and IFN-gamma were independently associated with both dengue severity and disease outcome.
CONCLUSION: Our data demonstrated that the use of a multiple cytokine assay platform was suitable for identifying distinct cytokine profiles associated with the dengue clinical manifestations and severity. MIP-beta is indicated for the first time as a good prognostic marker in contrast to IFN-gamma that was associated with disease severity.

Brach, L., et al. (2018). "Anticyclonic eddies increase accumulation of microplastic in the North Atlantic subtropical gyre." Marine Pollution Bulletin **126**: 191.
There are fundamental gaps in our understanding of the fates of microplastics in the ocean, which must be overcome if the severity of this pollution is to be fully assessed. The predominant pattern is high accumulation of microplastic in subtropical gyres. Using in situ measurements from the 7th Continent expedition in the North Atlantic subtropical gyre, data from satellite observations and models, we show how microplastic concentrations were up to 9.4 times higher in an anticyclonic eddy explored, compared to the cyclonic eddy. Although our sample size is small, this is the first suggestive evidence that mesoscale eddies might trap, concentrate and potentially transport microplastics. As eddies are known to congregate nutrients and organisms, this phenomenon should be considered with regards to the potential impact of plastic pollution on the ecosystem in the open ocean.

Bradley, M., et al. (2017). "Tracking Microplastics in the Environment via FT-IR Microscopy." Spectroscopy **32**(s8): 17-23.

Microplastics are particulates, roughly 20-1000 µm in size, originating from materials such as clothing, abrasive action on plastics, or engineered microbeads as found in some exfoliating cosmetics. The microplastics enter aquifers where the particles can be consumed by filter feeders. Microplastics are chemically stable, giving them a long lifetime in the environment and making excretion or digestion difficult. Analytically, the size and polymeric nature of microplastics makes Fourier transform infrared (FT-IR) microscopy an ideal tool for detection and identification. Standard analyses typically start with a filtration step, extracting the material from the matrix. The analysis can proceed directly on the dried filter without further sample preparation. This simplicity in both sampling and analysis enables the rapid assessment of microplastic encroachment and can assist in the development of remediation techniques. We show examples from both prepared and field samples using microattenuated total reflection (ATR) FT-IR.

Bradney, L., et al. (2019). "Particulate plastics as a vector for toxic trace-element uptake by aquatic and terrestrial organisms and human health risk." Environment International **131**: 104937.

Particulate plastics in the terrestrial and aquatic environments are small plastic fragments or beads (i.e., 5mm down to the nanometre range). They have been frequently referred to as 'micro-plastics' or 'nano-plastics'. Research has identified particulate plastics as a vector for toxic trace elements in the environment. The adsorption of toxic trace elements by particulate plastics may be facilitated by their high surface area and functionalized surfaces (e.g., through the attachment of natural organic matter). Other factors, such as environmental conditions (e.g., pH and water salinity), surface charge, and trace element oxidation status, also influence the adsorption of trace elements onto particulate plastics. Because of their small size and persistence, particulate plastics and the associated toxic trace elements are readily ingested and accumulated in many terrestrial and aquatic organisms. Thus, these plastics can have severe environmental consequences, such as the development of metal toxicity, within aquatic and terrestrial organisms. Humans could also become exposed to particulate plastics through food chain contamination and airborne ingestion. This review provides an overview of the sources of particulate plastics in the environment. To this end, we describe particulate plastics made of synthetic polymers, their origin, and characteristics with emphasis on how particulate plastics and associated toxic trace elements contaminate terrestrial and aquatic ecosystems. Future research needs and strategies are discussed to help reduce the environmental risks of particulate plastics as a potent vector for the transportation of toxic trace elements.

Braeth, S., et al. (2015). "Novel assay of TSH receptor stimulating autoantibodies using paramagnetic micro beads as solid phase." Clinical Chemistry and Laboratory Medicine **1)**: S231.

BACKGROUND-AIM Graves' disease (GD) is caused by thyroid stimulating immunoglobulins (TSI) directed against the thyrotropin receptor (TSHR). Assays for the diagnosis of GD are practised by detecting TSI indirectly by competition with TSH or monoclonal antibodies. Herewith a Bridge Assay is presented for direct detection of TSI by TSHR chimera. The main object to anchor the capture TSHR on paramagnetic micro beads (PMB) is a challenge but when working enables high through-put on automates. METHODS The capture receptor is constructed as a chimeric human TSHR (CTR) where in the extra cellular domain (ECD) aa residues 261-330 are replaced with residues 261-329 from rat LH/CG receptor and fused with a serum protein. (Patent filed). Fixed to PMB this CTR construct binds one arm of the TSI. The second arm bridges to a detection CTR constructed from aa 21-261 and fused with secretory alkaline phosphatase. All experiments were performed manually with simple lab scale equipment and a 12-tube magnet. RESULTS ROC analysis of 184 samples (134 GD positive, 50 GD negative) showed a sensitivity of 94.8%, a specificity of 98.0% and a cut-off of 1.5 U/L with an AUC of 0.985. Analytical and functional sensitivity were determined at 1.1 U/L, with a working range up to 50 U/L, a mean between-run precision of 15.8% and a within-run precision of 4.0%. Due to manual assay performance, all data were tested for outliers (generalized ESD test with alpha =0.05 and Tukey). Two patients with hypothyroidism and positive TRAb had negative results. Both receptors are secreted in cell culture supernatant realizing comfortable production. The new capture receptor yielded very good stability data (functionality and half life) at 4degreeC (up to 12d / up to 15d) and at 37degreeC (3h / 4.5h) as well as after drying (at least 4 weeks). The lyophilized detection receptor has a proven stability for >2 years. CONCLUSION The assay shows excellent sensitivity and specificity and a cut-off comparable to current high through-put TRAb assays. Further improvement of technical statistics (sensitivity and specificity) are expected by means of establishment of this prototype on fully automated machines. Together with the good stability data, these results suggest interesting possibilities for high through-put systems.

Braeuning, A. (2019). "Uptake of microplastics and related health effects: a critical discussion of Deng et al., Scientific reports 7:46687, 2017." Archives of Toxicology **93**(1): 219-220.

Brander, S. M., et al. (2011). "The Ecotoxicology of Plastic Marine Debris." American Biology Teacher (University of California Press) **73**(8): 474-478.

The accumulation of plastic in the oceans is an ever-growing environmental concern. Plastic debris is a choking and entanglement hazard for wildlife; plastics also leach toxic compounds into organisms and ecosystems. Educating students about the marine debris problem introduces fundamental concepts in toxicology, ecology, and oceanography. Students will learn about the toxicity of plastics, collect and analyze data on plastic debris, and put their new knowledge to work by writing a congressional bill that addresses the problem of marine debris. Brando, B., et al. (2001). "The "vanishing counting bead" phenomenon: effect on absolute CD34+ cell counting in phosphate-buffered saline-diluted leukapheresis samples." Cytometry **43**(2): 154-160.

BACKGROUND: Using a single-platform protocol to count absolute CD34+ hematopoietic precursor cell (HPC) levels with different reference microbeads, we recorded occasionally artifactually high CD34+ HPC counts in some leukapheresis bags, whereas dual-platform calculations were always consistent. Abnormal countings were observed only when phosphate-buffered saline (PBS)-diluted leukapheresis samples were vortexed before analysis. A large series of blood samples analyzed similarly for CD34+ and CD4+ absolute counts did not show any sample or vortexing effect. With the volumetric absolute counting cytometer Partec-PAS, lower counts were also observed when different reference beads were vortexed before the instrument checking procedures. The counting abnormality was caused by a drop in microbead concentration (the "vanishing bead phenomenon"). This phenomenon reduced the total and relative bead event number in experimental and routine samples and in calibration

procedures. This altered the bead denominator used to calculate absolute CD34+ HPC levels and it also reduced the concentration of standard calibration beads.
METHODS: Using the Partec-PAS to measure volumetrically the actual bead concentration, we studied the vanishing bead phenomenon. Different types of counting and reference microbeads were resuspended in media with or without proteins or cells. Replicates were submitted either to gentle manual mixing or to vortexing before counting.
RESULTS: Vortex agitation almost invariably induced the vanishing bead phenomenon when beads were resuspended in saline media or when an insufficient protein concentration was present, such as in diluted leukapheresis samples. Different bead types showed various degrees of sensitivity to vortexing. The bead disappearance was not caused by bubble formation or disruption. The addition of small amounts of protein completely prevented the vanishing bead phenomenon. The causative effect of the electrostatic charging of tube induced by vortexing is hypothesized.
CONCLUSIONS: Sample suspensions containing counting beads for single-platform analysis must be resuspended in media with protein supplements to prevent the vanishing bead phenomenon and to ensure accurate counting.

Brandon, A. M., et al. (2019). "Fate of Hexabromocyclododecane (HBCD), A Common Flame Retardant, In Polystyrene-Degrading Mealworms: Elevated HBCD Levels in Egested Polymer but No Bioaccumulation." Environmental Science & Technology **19**: 19.

As awareness of the ubiquity and magnitude of plastic pollution has increased, so has interest in the long term fate of plastics. To date, however, the fate of potentially toxic plastic additives has received comparatively little attention. In this study, we investigated the fate of the flame retardant hexabromocyclododecane (HBCD) in polystyrene (PS)-degrading mealworms and in mealworm-fed shrimp. Most of the commercial HBCD consumed by the mealworms was egested in frass within 24 h (1-log removal) with nearly a 3-log removal after 48 h. In mealworms fed PS containing high HBCD levels, only 0.27 +/- 0.10%, of the ingested HBCD remained in the mealworm body tissue. This value did not increase over the course of the experiment, indicating little or no bioaccumulation. Additionally, no evidence of higher trophic level bioaccumulation or toxicity was observed when L. vannamei (Pacific whiteleg shrimp) were fed mealworm biomass grown with PS containing HBCD. Differences in shrimp survival were attributable to the fraction of mealworm biomass incorporated into the diet, not HBCD. We conclude that the environmental effects of PS ingestion need further evaluation as the generation of smaller, more contaminated particles is possible, and may contribute to toxicity at nanoscale.

Brandon, J., et al. (2016). "Long-term aging and degradation of microplastic particles: Comparing in situ oceanic and experimental weathering patterns." Marine Pollution Bulletin **110**(1): 299-308.

Polypropylene, low-density polyethylene, and high-density polyethylene pre-production plastic pellets were weathered for three years in three experimental treatments: dry/sunlight, seawater/sunlight, and seawater/darkness. Changes in chemical bond structures (hydroxyl, carbonyl groups and carbon-oxygen) with weathering were measured via Fourier Transform Infrared (FTIR) spectroscopy. These indices from experimentally weathered particles were compared to microplastic particles collected from oceanic surface waters in the California Current, the North Pacific Subtropical Gyre, and the transition region between the two, in order to estimate the exposure time of the oceanic plastics. Although chemical bonds exhibited some nonlinear changes with environmental exposure, they can potentially approximate the weathering time of some plastics, especially high-density polyethylene. The majority of the North Pacific Subtropical Gyre polyethylene particles we measured have inferred exposure times>18months, with some >30months. Inferred particle weathering times are consistent with ocean circulation models suggesting a long residence time in the open ocean.

Brandon, J. A., et al. (2019). "Multidecadal increase in plastic particles in coastal ocean sediments." Science Advances **5**(9): eaax0587.

We analyzed coastal sediments of the Santa Barbara Basin, California, for historical changes in microplastic deposition using a box core that spanned 1834-2009. The sediment was visually sorted for plastic, and a subset was confirmed as plastic polymers via FTIR (Fourier transform infrared) spectroscopy. After correcting for contamination introduced during sample processing, we found an exponential increase in plastic deposition from 1945 to 2009 with a doubling time of 15 years. This increase correlated closely with worldwide plastic production and southern California coastal population increases over the same period. Increased plastic loading in sediments has unknown consequences for deposit-feeding benthic organisms. This increase in plastic deposition in the post-World War II years can be used as a geological proxy for the Great Acceleration of the Anthropocene in the sedimentary record.

Brandt, B. H., et al. (2001). "Predictive laboratory diagnostics in oncology utilizing blood-borne cancer cells--current best practice and unmet needs." Cancer Letters **162 Suppl**: S11-S16.

The aim of laboratory diagnostics in oncology is to improve the clinical outcome of cancer by allowing earlier detection. Molecular knowledge of cancer should increase the number of risk and prognostic factors and will allow development of methods for detection and elimination of even very small tumors. Thus, the race for the specific tumor antigen in peripheral blood and the race for the blood-borne cancer cell happened simultaneously. The direct detection of the cells which have the highest probability to harbor all the properties mandatory to be life-threatening, conceivably metastatic, would be the most promising way to find the target structure of malignancy.

Brandts, I., et al. (2018). "Effects of nanoplastics on Mytilus galloprovincialis after individual and combined exposure with carbamazepine." Science of the Total Environment **643**: 775-784.

Plastic pollution is a worldwide problem, highlighted by the fact that plastic materials degrade into nano-size particles (<100 nm), potentially becoming more bioavailable as well as a source of entry of other contaminants into organisms. The present study aimed to assess the effects of polystyrene nanoplastics (PS), individually or combined with carbamazepine (Cbz), on the Mediterranean mussel, Mytilus galloprovincialis. For this purpose, mussels were exposed for 96 h to a concentration range of PS (from 0.05 up to 50 mg L⁻¹), to Cbz (6.3 micro g L⁻¹) alone and to the mixture of PS+Cbz (0.05 mg L⁻¹+ 6.3 micro g L⁻¹). Molecular and biochemical biomarkers were assessed in the digestive glands, gills and haemolymph. The abundance of mRNA in the digestive glands and gills revealed significant alterations in the expression of genes associated with biotransformation, DNA repair, cell stress-response and innate immunity. Combined exposure of PS+Cbz induced significant downregulation in gene expression (e.g., hsp70) when compared to individual exposure. Total oxidant status increased in digestive glands after exposure to 0.5 mg L⁻¹ PS. Moreover, increased total antioxidant capacity and esterase activity were observed for PS 50 mg L⁻¹, in digestive glands and gills, respectively. The PS induced effects on neurotransmission, measured as inhibition of cholinesterase activity in haemolymph. Genotoxicity was found in haemocytes after exposure to PS, Cbz and their mixture. Moreover, lipid peroxidation was observed for 0.05 mg L⁻¹ PS exposure, showing that nanoplastics can induce oxidative damage. The present study demonstrated that PS, even at low concentrations, led to alterations on the assessed mussels' endpoints.

Bras, E. J. S., et al. (2019). "Microfluidic device for the point of need detection of a pathogen infection biomarker in grapes." Analyst **144**(16): 4871-4879.

Bacterial, fungal and viral infections in plant systems are on the rise, most of which tend to spread quickly amongst crops. These pathogens are also gaining resistance to known treatments, which makes their early detection a priority to avoid extensive loss of crops and the spreading of disease to animal systems. In this work, we propose a microfluidic platform coupled with integrated thin-film silicon photosensors for the detection of pathogen infections in grapes. This detection was achieved by monitoring the concentration of Azelaic Acid (AzA). This small organic acid plays a significant role in the defense mechanism in plant systems. In this platform, the enzyme tyrosinase was immobilized on microbeads inside a microfluidic system. By colorimetric monitoring of the inhibitory effect of AzA on the enzyme tyrosinase in real time, it was possible, in under 10 minutes, to detect different concentrations of AzA in both buffer and spiked solutions of grape juice, in both cases with limits of detection in the 5-10 nM range. In addition, with this microfluidic device, it was possible to clearly distinguish infected from healthy grape samples at three different grape maturation points. Healthy grape samples showed AzA concentrations in the range of 10-20 nM (post-dilution) while infected samples have an estimated increase of AzA of 10-30x, results which were confirmed using HPLC. In both juice and grape samples an integrated sample preparation stage that decreases the phenol content of the solutions was required to achieve fit-for-purpose sensitivities to AzA.

Brate, I. L. N., et al. (2018). "Weathering impacts the uptake of polyethylene microparticles from toothpaste in Mediterranean mussels (M. galloprovincialis)." Science of the Total Environment **626**: 1310-1318.

Mediterranean mussels (Mytilus galloprovincialis) were exposed over 21 days to polyethylene (PE) particles (0.01 mg ml⁻¹; 50-570 micro m) isolated from toothpaste. PE was deployed in the Outer Oslofjord (Norway) for 21 days, before exposing the mussels to both virgin (PE-V) and weathered PE (PE-W) particles. The mussels ingested both types of particles, but significantly more weathered particles were ingested than virgin (p=.0317), based on PE dosed by weight (mg ml⁻¹) but not when considering particle number (PE-V: 1.18+or-0.16 particles ml⁻¹; PE-W 1.86+or-0.66 particles ml^{-1;}). PE particle ingestion resulted in structural changes to the gills and digestive gland, as well as necrosis in other tissues such as the mantle. No differences were found regarding the degree of tissue alteration between PE-virgin and PE-weathered exposures. This current study illustrates the importance of using weathered particles in microplastic exposure studies to reflect the behaviour of plastic particles after entering the marine environment. The observed tissue alterations demonstrate the potential adverse effects to mussels exposed to microplastic particles.

Brate, I. L. N., et al. (2016). "Plastic ingestion by Atlantic cod (Gadus morhua) from the Norwegian coast." Marine Pollution Bulletin **112**(1/2): 105-110.

This study documents the occurrence of microplastic (<5 mm), mesoplastics (5-20 mm) and macroplastic (>20 mm) in Atlantic cod (Gadus morhua), a common and economically important species of marine fish in Norway. Fish stomachs (n=302) were examined from six different locations along the coast of Norway. Three percent of the individual stomachs contained items identified by Fourier transform infrared spectroscopy (FTIR) as synthetic polymers. Bergen City Harbour was a hotspot with 27% of the cod examined found to contain plastic. Polyester was

the most frequently detected polymer. All bar one of the stomachs that contained plastic were full of organic stomach content, suggesting a plastic gut clearance rate similar to the ingested food. It is proposed that stomach fullness is an important metric in order to avoid underestimations when assessing the levels of microplastic ingested by fish.

Brate, I. L. N., et al. (2018). "Mytilus spp. as sentinels for monitoring microplastic pollution in Norwegian coastal waters: a qualitative and quantitative study." Environmental Pollution **243**(Part A): 383-393.

Microplastic (MP) contamination is ubiquitous in the environment and many species worldwide have been shown to contain MP. The ecological impact of MP pollution is still unknown, thus there is an urgent need for more knowledge. One key task is to identify species suitable as sentinels for monitoring in key eco-compartments, such as coastal waters. In Norway, mussels (Mytilus spp.) have been monitored for hazardous contaminants through OSPAR since 1981. Norway has the longest coastline in Europe and adding MP to the Norwegian Mussel Watch is therefore important in a European and global context. The present study reports MP data in mussels (332 specimens) collected from multiple sites (n=15) spanning the whole Norwegian coastline. MPs were detected at all locations, except at one site on the west coast. Among the most surprising findings, mussels from the Barents Sea coastline in the Finnmark region, contained significantly more MPs than mussels from most of the southern part of the country, despite the latter sites being located much closer to major urban areas. Only mussels from a site located very close to Oslo, the capital, contained levels similar to those observed in the remote site in Finnmark. In total an average of 1.5 (+or-2.3) particles ind⁻¹ and 0.97 (+or-2.61) particles w.w. g⁻¹ was found. The most common MPs were <1 mm in size, and fibres accounted for 83% of particles identified, although there was inter-site variability. Thirteen different polymeric groups were identified; cellulosic being the most common and black rubbery particles being the second. This study suggests Mytilus spp. are suitable for semi-quantitative and qualitatively monitoring of MPs in coastal waters. However, some uncertainties remain including mussel size as a confounding factor that may influence ingestion, the role of depuration and other fate related processes, and this call for further research.

Braune, B. M. (1987). "Seasonal aspects of the diet of Bonaparte's gulls (Larus philadelphia) in the Quoddy region, New Brunswick, Canada." Auk **104**(2): 167-172.

During July-December 1978-1984, Bonaparte's Gulls (Larus philadelphia) on annual migration through the Quoddy region off New Brunswick, Canada, fed on fish, euphausiids, insects, and other marine invertebrates (mainly polychaetes and amphipods) in varying proportions as the summer and autumn progressed. The seasonal variation in the diet was related directly to food availability, which, in turn, was dictated by natural cycles of prey in the region. The frequency with which plastic particles were found in the stomachs also had a statistically significant seasonal trend. Fish provided the largest energy contribution (75-91%) to the diet at all times in the region. There was no significant difference between diets of juvenile and adult birds.

Bray, L., et al. (2019). "Determining suitable fish to monitor plastic ingestion trends in the Mediterranean Sea." Environmental Pollution **247**: 1071-1077.

The presence of marine litter is a complex, yet persistent, threat to the health and biodiversity of the marine environment, and plastic is the most abundant, and ubiquitous type of marine litter. To monitor the level of plastic waste in an area, and the prospect of it entering the food chain, bioindicator species are used extensively throughout Northern European Seas, however due to their distribution ranges many are not applicable to the Mediterranean Sea. Guidance

published for the Marine Strategy Framework Directive suggests that the contents of fish stomachs may be analyzed to determine trends of marine plastic ingestion. In order to equate transnational trends in marine plastic ingestion, the use of standardized fish species that widely occur throughout the basin is favoured, however for the Mediterranean Sea, specific species are not listed. Here we propose a methodology to assess how effective Mediterranean fish species, that are known to have ingested marine plastic, are as bioindicators. A new Bioindicator Index (BI) was established by incorporating several parameters considered important for bioindicators. These parameters included species distribution throughout the Mediterranean basin, several life history traits, the commercial value of each species, and the occurrence of marine litter in their gut contents. By collecting existing data for Mediterranean fish, ranked scores were assigned to each trait and an average value (BI value) was calculated for each species. Based on their habitat preferences, Engraulis encrasicolus (pelagic), Boops boops (benthopelagic), three species of Myctophidae (Hygophum benoiti, Myctophum punctatum and Electrona risso) (mesopelagic), Mullus barbatus barbartus (demersal) and Chelidonichthys lucerna (benthic), were identified as currently, the most suitable fish for monitoring the ingestion of marine plastics throughout the Mediterranean basin. The use of standardized indicator species will ensure coherence in the reporting of marine litter ingestion trends throughout the Mediterranean Sea.

Brazhnik, K., et al. (2015). "Quantum dot-based lab-on-a-bead system for multiplexed detection of free and total prostate-specific antigens in clinical human serum samples." Nanomedicine **11**(5): 1065-1075.

UNLABELLED: An immunodiagnostic lab-on-a-bead suspension microarray based on microbeads encoded with quantum dots (QDs) has been developed and preclinically validated for multiplexed quantitative detection of prostate cancer markers in human serum samples. The sensitivity and specificity of the microarray are similar to those of "gold-standard" single-analyte ELISA. Moreover, the array has an improved immunoassay capacity, ensures quantitative detection of multiple cancer biomarkers and may be operational in a considerably wider dynamic range of concentrations. The array is characterized by reduced time and cost of analysis and is compatible with classical flow cytometers. Proof-of-concept preclinical tests ensured simultaneous quantitative determination of free and total prostate-specific antigens in human serum, with clear discrimination between the control and clinical samples. The proposed approach is flexible and paves the way to development of a wide variety of immunodiagnostic assays for multiplexed early diagnosis of various diseases.

FROM THE CLINICAL EDITOR: Early diagnosis of cancer can result in better prognosis for patients. Thus, the use of specific tumor markers is widely employed in clinical practice. Traditional screening methods only employ single markers. The authors here developed a microarray system based on microbeads encoded with quantum dots (QDs), which can be used for multiplexed quantitative detection. The validated results on patient samples should lead to the development of a wider variety of assays for other diseases.

Breitburg, D., et al. (2018). "Declining oxygen in the global ocean and coastal waters." Science **359**(6371).

Beneath the waves, oxygen disappearsAs plastic waste pollutes the oceans and fish stocks decline, unseen below the surface another problem grows: deoxygenation. Breitburg et al. review the evidence for the downward trajectory of oxygen levels in increasing areas of the open ocean and coastal waters. Rising nutrient loads coupled with climate change—each resulting from human activities—are changing ocean biogeochemistry and increasing oxygen consumption. This results in destabilization of sediments and fundamental shifts in the availability of key nutrients. In the short term, some compensatory effects may result in

improvements in local fisheries, such as in cases where stocks are squeezed between the surface and elevated oxygen minimum zones. In the longer term, these conditions are unsustainable and may result in ecosystem collapses, which ultimately will cause societal and economic harm.Science, this issue p. eaam7240BACKGROUNDOxygen concentrations in both the open ocean and coastal waters have been declining since at least the middle of the 20th century. This oxygen loss, or deoxygenation, is one of the most important changes occurring in an ocean increasingly modified by human activities that have raised temperatures, CO2 levels, and nutrient inputs and have altered the abundances and distributions of marine species. Oxygen is fundamental to biological and biogeochemical processes in the ocean. Its decline can cause major changes in ocean productivity, biodiversity, and biogeochemical cycles. Analyses of direct measurements at sites around the world indicate that oxygen-minimum zones in the open ocean have expanded by several million square kilometers and that hundreds of coastal sites now have oxygen concentrations low enough to limit the distribution and abundance of animal populations and alter the cycling of important nutrients.ADVANCESIn the open ocean, global warming, which is primarily caused by increased greenhouse gas emissions, is considered the primary cause of ongoing deoxygenation. Numerical models project further oxygen declines during the 21st century, even with ambitious emission reductions. Rising global temperatures decrease oxygen solubility in water, increase the rate of oxygen consumption via respiration, and are predicted to reduce the introduction of oxygen from the atmosphere and surface waters into the ocean interior by increasing stratification and weakening ocean overturning circulation.In estuaries and other coastal systems strongly influenced by their watershed, oxygen declines have been caused by increased loadings of nutrients (nitrogen and phosphorus) and organic matter, primarily from agriculture; sewage; and the combustion of fossil fuels. In many regions, further increases in nitrogen discharges to coastal waters are projected as human populations and agricultural production rise. Climate change exacerbates oxygen decline in coastal systems through similar mechanisms as those in the open ocean, as well as by increasing nutrient delivery from watersheds that will experience increased precipitation.Expansion of low-oxygen zones can increase production of N2O, a potent greenhouse gas; reduce eukaryote biodiversity; alter the structure of food webs; and negatively affect food security and livelihoods. Both acidification and increasing temperature are mechanistically linked with the process of deoxygenation and combine with low-oxygen conditions to affect biogeochemical, physiological, and ecological processes. However, an important paradox to consider in predicting large-scale effects of future deoxygenation is that high levels of productivity in nutrient-enriched coastal systems and upwelling areas associated with oxygen-minimum zones also support some of the world’s most prolific fisheries.OUTLOOKMajor advances have been made toward understanding patterns, drivers, and consequences of ocean deoxygenation, but there is a need to improve predictions at large spatial and temporal scales important to ecosystem services provided by the ocean. Improved numerical models of ocean graphic processes that control oxygen depletion and the large-scale influence of altered biogeochemical cycles are needed to better predict the magnitude and spatial patterns of deoxygenation in the open ocean, as well as feedbacks to climate. Developing and verifying the next generation of these models will require increased in situ observations and improved mechanistic understanding on a variety of scales. Models useful for managing nutrient loads can simulate oxygen loss in coastal waters with some skill, but their ability to project future oxygen loss is often hampered by insufficient data and climate model projections on drivers at appropriate temporal and spatial scales. Predicting deoxygenation-induced changes in ecosystem services and human welfare requires scaling effects that are measured on individual organisms to populations, food webs, and fisheries stocks; considering combined effects of deoxygenation

and other ocean stressors; and placing an increased research emphasis on developing nations. Reducing the impacts of other stressors may provide some protection to species negatively affected by low-oxygen conditions. Ultimately, though, limiting deoxygenation and its negative effects will necessitate a substantial global decrease in greenhouse gas emissions, as well as reductions in nutrient discharges to coastal waters.Oxygen is fundamental to life. Not only is it essential for the survival of individual animals, but it regulates global cycles of major nutrients and carbon. The oxygen content of the open ocean and coastal waters has been declining for at least the past half-century, largely because of human activities that have increased global temperatures and nutrients discharged to coastal waters. These changes have accelerated consumption of oxygen by microbial respiration, reduced solubility of oxygen in water, and reduced the rate of oxygen resupply from the atmosphere to the ocean interior, with a wide range of biological and ecological consequences. Further research is needed to understand and predict long-term, global- and regional-scale oxygen changes and their effects on marine and estuarine fisheries and ecosystems.

Breithaupt, A., et al. (2016). "Profiles of growth factors and neurotrophins in normal and neuroinflammatory cerebrospinal fluid." Neurology. Conference: 68th American Academy of Neurology Annual Meeting, AAN **86**(16 SUPPL. 1).

Objective: To determine the profiles of growth factors (GFs) and neurotrophins (NTs) in the cerebrospinal fluid (CSF) of subjects with neuroinflammatory disorders, neurodegenerative disorders and normal controls. Background(s): CSF provides reliable insight into the central nervous system environment and metabolism. GFs and NTs are critical elements for growth, development, synaptogenesis and modulation of neurological function. Method(s): The prevalence and profiles of 41 GFs and NTs were evaluated in CSF of normal controls (n=4) and subjects with meningitis (n=4) to determine the effect of inflammatory responses using slide-coated protein arrays. The panel of growth factors included the insulin-like growth factor binding protein (IGFBP) family, hematopoeitin family, platelet-derived growth factor (PDGF) family, transforming growth factor (TGF) family, neurotrophins, and others. We then established a quantitative assessment of the most common GFs and NTs in 29 subjects with neurodegenerative and neuroinflammatory disorders as well as controls by using microbead multiplexed array assays. Result(s): IGFBPs were the most prevalent GFs in the CSF of normal subjects and patients affected by neuroinflammatory disorders. Among IGFBPs, IGFBP-2, -3, -4, -6 and -7 were the most prevalent proteins in the CSF and, with exception of IGFBP-7, appeared to be further increased in inflammatory conditions. Conclusion(s): Among GFs and NTs, IGFBPs are the most prevalent growth factors present in the CSF. Measures of GFs may provide clues to biological pathways associated with neurodevelopment and pathological conditions such as inflammation and neurodegeneration.

Brekkan, A., et al. (1975). "Glass fragments and other particles contaminating contrast media." Acta Radiologica - Series Diagnosis **16**(6): 600-608.

Microscopy of filtrates made from contrast media of routinely opened glass ampoules substantiates previous assumptions that small fragments of glass may enter into the ampoule and the medium with considerable frequency. Such glass fragments may cause embolic lesions on intraarterial injections of the medium; the lesions, however, are histologically non specific consisting of proliferation of intima and small granulomas associated with dilated nephrons in a ray like arrangement. A significant amount of plastic particles may be added to injectable fluids on usage of disposable syringes.

Brems, A., et al. (2012). "RECYCLING AND RECOVERY OF POST-CONSUMER PLASTIC SOLID WASTE IN A EUROPEAN CONTEXT." Thermal Science **16**(3): 669-685.

The disposal of waste plastics has become a major worldwide environmental problem. The USA, Europe and Japan generate annually about 50 million tons of post-consumer plastic waste, previously landfilled, generally considered as a non-sustainable and environmentally questionable option. Landfill sites and their capacity are, moreover, decreasing rapidly, and legislation is stringent. Several European directives and US legislation concern plastic wastes and the required management. They are briefly discussed in this paper. New processes have emerged, i. e., advanced mechanical recycling of plastic waste as virgin or second grade plastic feedstock, and thermal treatments to recycle the waste as virgin monomer, as synthetic fuel gas, or as heat source (incineration with energy recovery). These processes avoid land filling, where the non-biodegradable plastics remain a lasting environmental burden. The paper reviews these alternative options through mostly thermal processing (pyrolysis, gasification, and waste-to-energy). Additional research is, however, still needed to confirm the potential on pilot and commercial scale.

Brems, A., et al. (2013). "Gasification of plastic waste as waste-to-energy or waste-to-syngas recovery route." Natural Science **5**(6): 695-704.

The disposal of plastic solid waste (PSW) has become a major worldwide environmental problem. New sustainable processes have emerged, i.e. either advanced mechanical recycling of PSW as virgin or second grade plastic feedstock, or thermal treatments to recycle the waste as virgin monomer, as synthetic fuel gas, or as heat source (incineration with energy recovery). These processes avoid land filling, where the non-biodegradable plastics remain a lasting environmental burden. Within the thermal treatments, gasification and pyrolysis gain increased interest. Gasification has been widely studied and applied for biomass and coal, with results reported and published in literature. The application to the treatment of PSW is less documented. Gasification is commonly operated at high temperatures (> 600 to 800) in an air-lean environment (or oxygen-deficient in some applications): the air factor is generally between 20% and 40% of the amount of air needed for the combustion of the PSW. Gasification produces mostly a gas phase and a solid residue (char and ashes). The use of air introduces N2 in the product gases, thus considerably reducing the calorific value of the syngas, because of the dilution. The paper will review the existing literature data on PSW gasification, both as the result of laboratory and pilot-scale research. Processes developed in the past will be illustrated. Recently, the use of a sequential gasification and combustion system (at very high temperatures) has been applied to various plastic-containing wastes, with atmospheric emissions shown to be invariably below the legal limits. Operating results and conditions will be reviewed in the paper, and completed with recent own lab-scale experimental results. These results demonstrate that gasification of PSW can be considered as a first order reaction, with values of the activation energy in the order of 187 to 289 kJ/mol as a function of the PSW nature.

Brennan, E., et al. (2018). "Connecting flux, deposition and resuspension in coastal debris surveys." Science of the Total Environment **644**: 1019-1026.

For decades, community groups and scientists have sampled coastal waste along shorelines to understand the distribution of debris. However, when debris is washed ashore or locally deposited, it may be washed away before it is removed or recorded. Using statistical models to understand the movement of debris in coastal processes may identify potential sinks of anthropogenic debris. We modelled arrival and departure of debris using data from repeated removal and marking experiments. Both the arrival and departure of debris were affected by the substrate of the shoreline and by seasonal changes (e.g. autumn and winter). Different substrates accumulated different types of debris. The backshore, coastal shape and wind exposure had all affected the departure but not the arrival of debris. Our findings suggest that areas with high accumulation have lower departure, rather than higher arrival of debris. The implication is that counting debris in dirty locations, as when cleanup activities are used for monitoring, will provide a misleading measure of the actual debris in adjoining waters. We found that onshore winds and lower profile backshore vegetation increase the departure of debris. Debris may be moving inland and accumulating in the backshore vegetation, suggesting the backshore vegetation could be a substantial sink of missing marine debris. Overall, inferring the state of plastic pollution in the ocean using one "snapshot" on shore may underestimate the output of debris from land-based sources, whilst overestimating ocean loads near sites that retain or accumulate high levels of debris.

Brennecke, D., et al. (2016). "Microplastics as vector for heavy metal contamination from the marine environment." Estuarine, Coastal and Shelf Science **178**: 189-195.

The permanent presence of microplastics in the marine environment is considered a global threat to several marine animals. Heavy metals and microplastics are typically included in two different classes of pollutants but the interaction between these two stressors is poorly understood. During 14 days of experimental manipulation, we examined the adsorption of two heavy metals, copper (Cu) and zinc (Zn), leached from an antifouling paint to virgin polystyrene (PS) beads and aged polyvinyl chloride (PVC) fragments in seawater. We demonstrated that heavy metals were released from the antifouling paint to the water and both microplastic types adsorbed the two heavy metals. This adsorption kinetics was described using partition coefficients and mathematical models. Partition coefficients between pellets and water ranged between 650 and 850 for Cu on PS and PVC, respectively. The adsorption of Cu was significantly greater in PVC fragments than in PS, probably due to higher surface area and polarity of PVC. Concentrations of Cu and Zn increased significantly on PVC and PS over the course of the experiment with the exception of Zn on PS. As a result, we show a significant interaction between these types of microplastics and heavy metals, which can have implications for marine life and the environment. These results strongly support recent findings where plastics can play a key role as vectors for heavy metal ions in the marine system. Finally, our findings highlight the importance of monitoring marine litter and heavy metals, mainly associated with antifouling paints, particularly in the framework of the Marine Strategy Framework Directive (MSFD).

Brennecke, D., et al. (2015). "Ingested microplastics (>100 mu m) are translocated to organs of the tropical fiddler crab Uca rapax." Marine Pollution Bulletin **96**(1-2): 491-495.

Microplastics, which are accumulating in marine sediments, are assumed to pose a risk for deposit feeding invertebrates. We tested whether the fiddler crab Uca rapax ingests and retains microplastics in its body. Furthermore, we investigated whether retention rates depend on (a) the quality of the marine environment in which the plastics were pre-weathered and on (b) their abundance. For this, polystyrene pellets were submersed at a polluted and a pristine site near Niteroi, Brazil, for 2weeks. Then specimens of U. rapax were, in laboratory experiments, exposed to fragments (180-250 mu m) derived from these pellets for 2months. After this period, microplastics were observed in the gills, stomach and hepatopancreas of the animals. However, fragment retention was not influenced by the two factors that we manipulated. The presence of microplastics in different organs of the crab supports the assumption that these particles have the potential to harm marine invertebrates.

Brennecke, D., et al. (2015). "Ingested microplastics (>100 micro m) are translocated to organs of the tropical fiddler crab Uca rapax." Marine Pollution Bulletin **96**(1/2): 491-495.
Microplastics, which are accumulating in marine sediments, are assumed to pose a risk for deposit feeding invertebrates. We tested whether the fiddler crab Uca rapax ingests and retains microplastics in its body. Furthermore, we investigated whether retention rates depend on (a) the quality of the marine environment in which the plastics were pre-weathered and on (b) their abundance. The presence of microplastics in different organs of the crab supports the assumption that these particles have the potential to harm marine invertebrates.

Brenner, S., et al. (2000). "In vitro cloning of complex mixtures of DNA on microbeads: physical separation of differentially expressed cDNAs." Proceedings of the National Academy of Sciences of the United States of America **97**(4): 1665-1670.
We describe a method for cloning nucleic acid molecules onto the surfaces of 5-micrometer microbeads rather than in biological hosts. A unique tag sequence is attached to each molecule, and the tagged library is amplified. Unique tagging of the molecules is achieved by sampling a small fraction (1%) of a very large repertoire of tag sequences. The resulting library is hybridized to microbeads that each carry approximately 10(6) strands complementary to one of the tags. About 10(5) copies of each molecule are collected on each microbead. Because such clones are segregated on microbeads, they can be operated on simultaneously and then assayed separately. To demonstrate the utility of this approach, we show how to label and extract microbeads bearing clones differentially expressed between two libraries by using a fluorescence-activated cell sorter (FACS). Because no prior information about the cloned molecules is required, this process is obviously useful where sequence databases are incomplete or nonexistent. More importantly, the process also permits the isolation of clones that are expressed only in given tissues or that are differentially expressed between normal and diseased states. Such clones then may be spotted on much more cost-effective, tissue- or disease-directed, low-density planar microarrays.

Bretas Alvim, C., et al. (2020). "Wastewater treatment plant as microplastics release source - Quantification and identification techniques." Journal of Environmental Management **255 (no pagination)**(109739).
The high presence of microplastics (MPs) in different sizes, materials and concentrations in the aquatic environment is a global concern due to their potential physically and chemically harm to aquatic organisms including mammals. Furthermore, the bioaccumulation of these compounds is leading to their ingestion by humans through the consumption of sea food and even through the terrestrial food chain. Even though conventional wastewater treatment plants are capable of eliminating more than 90% of the influent MPs, these systems are still the main source of MPs introduction in the environment due to the high volumes of effluents generated and returned to the environment. The amount of MPs dumped by WWTP is influenced by the configuration of the WWTP, population served and influent flow. Thus, the average of MP/L disposed vary widely depending on the region. In addition to MPs disposed in water bodies, more than 80% of these emerging contaminants, which enter the WWTP, are retained in

biosolids that can be applied as fertilizers, representing a potential source of soil contamination. Due to the continuous disposal of MPs in the environment by effluent treatment systems and their polluting potential, separation and identification techniques have been assessed by several researchers, but unfortunately, there are no standard protocols for them. Aiming to provide insight about the relevance of studying the WWTP as source of MPs, this review summarizes the currently methodologies used to classify and identify them. Briassoulis, D., et al. (2008). "Correlation of key agricultural plastic waste parameters with the quality of the resulting waste stream." Acta Horticulturae **801**(Vol 1): 333-340.
The mechanical and chemical degradation of the agricultural plastic waste as well as its soil/moisture contamination, may affect its quality with regards to its exploitation for recycling or for energy recovery. These critical parameters were investigated in an effort to assess and control the quality of the agricultural plastic waste streams in the framework of the European research project Labelagriwaste. Samples of agricultural plastics from greenhouses, low-medium tunnels, mulching films, bale wrapping films, etc. (from various cultivations, across Greece and Europe) were collected before and after use as well as after storage in the field, and were tested in the laboratory for mechanical properties, degradation and moisture-soil contamination. The results obtained indicate that the degree of mechanical degradation of the agricultural plastic waste is highly dependent on a combination of application and material characteristics. Among the dominant factors affecting the quality of the agricultural plastic waste included are the thickness of the film versus the period of exposure, the material composition and additives, the use of agrochemicals and the exposure of the material to contamination by soil during use and handling after the removal. The duration and conditions (location, exposure to the open field conditions) of the storage affect greatly the soil contamination and moisture level. The mechanical degradation tests will be combined with on-going chemical and thermal analysis tests to establish the technical requirements the agricultural plastic waste should fulfil for disposal (mechanical recycling, energy recovery, composting etc).

Briassoulis, D., et al. (2015). "Degradation in soil behavior of artificially aged polyethylene films with pro-oxidants." Journal of Applied Polymer Science **132**(30).
Bio-based, biodegradable in soil, as well as degradable polyethylene mulching films with pro-oxidants, have been introduced in the market in an effort to deal with the serious problem of managing plastic waste streams generated from conventional mulching films. In a previous experimental investigation, a series of naturally degraded under water melon cultivation conditions linear low density polyethylene (LLDPE) mulching films with pro-oxidants, buried in the field for 8.5 years, were recovered intact even though undergoing a continuous slow abiotic degradation in soil. The aim of the present article was to simulate the behavior of the LLDPE mulching films with pro-oxidants under a much longer time-scale (e.g. some decades). Toward this purpose, samples of LLDPE with pro-oxidants film were artificially degraded to simulate severe degradation/fragmentation of these films while been buried in the soil for many years, following the end of the cultivation season. Further degradation of these severely degraded samples was investigated by burying them in the soil over a period of seven years. During this burial period, all degradation parameters and their evolution with time were measured. The artificially degraded LLDPE film samples with pro-oxidants, in contrast to the naturally degraded film that remained intact for 8.5 years, were gradually transformed into tiny micro-fragments in the soil. These fragments, through a continuing abiotic degradation process under natural soil conditions are eventually transformed into invisible micro-fragments. The fate of these micro-fragments and their long-term impact to the environment and human health is

unpredictable. 2015 Wiley Periodicals, Inc. J. Appl. Polym. Sci. 2015, 132, 42289. 2015 Wiley Periodicals, Inc.

Briassoulis, D., et al. (2013). "Review, mapping and analysis of the agricultural plastic waste generation and consolidation in Europe." Waste Management & Research **31**(12): 1262-1278.
A review of agricultural plastic waste generation and consolidation in Europe is presented. A detailed geographical mapping of the agricultural plastic use and waste generation in Europe was conducted focusing on areas of high concentration of agricultural plastics. Quantitative data and analysis of the agricultural plastic waste generation by category, geographical distribution and compositional range, and physical characteristics of the agricultural plastic waste per use and the temporal distribution of the waste generation are presented. Data were collected and cross-checked from a variety of sources, including European, national and regional services and organizations, local agronomists, retailers and farmers, importers and converters. Missing data were estimated indirectly based on the recorded cultivated areas and the characteristics of the agricultural plastics commonly used in the particular regions. The temporal distribution, the composition and physical characteristics of the agricultural plastic waste streams were mapped by category and by application. This study represents the first systematic effort to map and analyse agricultural plastic waste generation and consolidation in Europe.

Briassoulis, D. and C. Dejean (2010). "Critical Review of Norms and Standards for Biodegradable Agricultural Plastics Part I. Biodegradation in Soil." Journal of Polymers & the Environment **18**(3): 384-400.
critical review of norms and standards and corresponding tests to determine the biodegradability in soil for biodegradable plastics, possibly applicable also to biodegradable agricultural plastics, is presented. There are only a few norms available at the international level about biodegradable plastics in soil. The criteria, parameters and testing methodologies for the characterization, labelling and validation of the agricultural plastic waste streams with respect to possible biodegradation in soil according to existing international standards are analysed while the relevant controversies are identified. To derive the best suited for agricultural plastics specs and testing methods, the possible developments or adaptation of available specs, is investigated. Considering the existing types of biodegradable plastic products in agriculture and their effective life management at the agricultural field, only a few norms appear to provide suitable tests that could be adapted, following appropriate research work, for testing biodegradability in soil under real field conditions. It is shown that some major revisions are needed, with the support of systematic research work, before a new universal norm and standard testing methods become available for testing agricultural plastics for biodegradation under real, and highly variable, soil conditions. Based on the analysis of the different norms and their content it appears necessary to incorporate provisions for transferability of results to different soils and climates, validation of tests through a positive reference and also, set prerequisites for soil media. Long term biodegradation in soil prediction is another open issue. [ABSTRACT FROM AUTHOR]

Briassoulis, D., et al. (2008). "Biodegradable irrigation systems for protected cultivation." Acta Horticulturae **801**(Vol 1): 373-380.

New environmental regulations, societal concerns, and a growing environmental awareness throughout the world have triggered the search for new products and processes that are compatible with the environment. This paper presents the results of a research project carried out by the Agricultural University of Athens (Greece) with the cooperation of Eurodrip S.A. investigating the possibilities and limitations in developing biodegradable irrigation pipes for agriculture. Biodegradable drip irrigation systems are especially needed in protected cultivation systems using biodegradable mulching and low tunnel films. The aim is that all biodegradable materials, films and irrigation system are roto-tilled into the soil following the end of the cultivation period to eliminate the agricultural plastic waste management problem. The first ever experimental biodegradable irrigation tapes and pipes with drippers were produced using 'Mater Bi'. The processing conditions were investigated thoroughly and optimized under the constraint of the available conventional equipment. The mechanical and irrigation performance and degradation behaviour of the pipes produced were evaluated under laboratory and real field conditions. The results obtained are promising concerning the feasibility to develop in the future optimised commercial products.

Briassoulis, D., et al. (2013). "Technical specifications for mechanical recycling of agricultural plastic waste." Waste Management **33**(6): 1516-1530.

Technical specifications appropriate for the recycling of agricultural plastic wastes (APWs), widely accepted by the recycling industry were developed. The specifications establish quality standards to be met by the agricultural plastics producers, users and the agricultural plastic waste management chain. They constitute the base for the best economical and environmental valorisation of the APW. The analysis of the APW streams conducted across Europe in the framework of the European project "LabelAgriWaste" revealed the inherent characteristics of the APW streams and the inherent constraints (technical or economical) of the APW. The APW stream properties related to its recycling potential and measured during pilot trials are presented and a subsequent universally accepted simplified and expanded list of APW recycling technical specifications is proposed and justified. The list includes two sets of specifications, applied to two different quality categories of recyclable APW: one for pellet production process ("Quality I") and another one for plastic profile production process ("Quality II"). Parameters that are taken into consideration in the specifications include the APW physical characteristics, contamination, composition and degradation. The proposed specifications are focused on polyethylene based APW that represents the vast majority of the APW stream. However, the specifications can be adjusted to cover also APW of different materials (e.g. PP or PVC) that are found in very small quantities in protected cultivations in Europe. The adoption of the proposed specifications could transform this waste stream into a labelled commodity traded freely in the market and will constitute the base for the best economical and environmental valorisation of the APW.

Briassoulis, D., et al. (2012). "Experimental investigation of the quality characteristics of agricultural plastic wastes regarding their recycling and energy recovery potential." Waste Management **32**(6): 1075-1090.

A holistic environmentally sound waste management scheme that transforms agricultural plastic waste (APW) streams into labelled guaranteed quality commodities freely traded in open market has been developed by the European research project LabelAgriWaste. The APW quality is defined by the APW material requirements, translated to technical specifications, for recycling or energy recovery. The present work investigates the characteristics of the APW quality and the key factors affecting it from the introduction of the virgin product to the market to the APW stream reaching the disposer. Samples of APW from different countries were traced from their application to the field through their storage phase and transportation to the final destination. The test results showed that the majority of APW retained their mechanical properties after their use preserving a "very good quality" for recycling in terms of degradation. The degree of soil contamination concerning the APW recycling and energy recovery potential fluctuates depending on the agricultural plastic category and application. The chlorine and heavy metal content of the tested APW materials was much lower than the maximum acceptable limits for their potential use in cement industries.

Briassoulis, D., et al. (2019). "End-of-waste life: Inventory of alternative end-of-use recirculation routes of bio-based plastics in the European Union context." Critical Reviews in Environmental Science and Technology **49**(20): 1835-1892.

The bio-based products market is currently limited resulting in relatively small quantities of waste streams, viewed as contaminants of conventional waste streams. The steady growth of bio-based products however, drives the need to investigate their End-of-Use (EoU)/End-of-Life (EoL) alternatives. A critical review of the inventory of targeted valorization options for bio-based plastic waste is presented with limitations and opportunities. Impacts on the conventional waste management routes and the environment are considered. The provisions of the circular economy package, the targets and objectives set by the relevant EU environmental legislation, are used as key drivers for developing the inventory of the alternative EoU/EoL routes. Optimal alternative EoU/EoL routes are defined for the bio-based products in such a way that they are turned into valuable resources for the circular economy. This is a prerequisite to promote recirculation of bio-based by-products and waste streams along the whole chain of their production and use. The expected impacts include reduction of public health and environmental pollution problems, preservation of natural resources, reduction of GHG emissions, avoidance of landscape deterioration and land and marine littering. Bridson, J. H., et al. (2020). "Microplastic contamination in Auckland (New Zealand) beach sediments." Marine Pollution Bulletin **151 (no pagination)**(110867).

We report the first large-scale investigation of microplastic contamination in beach sediments across Auckland, New Zealand's most populous region. Sediment samples were taken from the high tide and intertidal zones at 39 sites across estuary, harbour and ocean environments of the East and West Coasts. Microplastic contamination was present at the majority of beaches studied with a mean abundance of 459 particles.m⁻ ² ranging from 0 to 2615 particles.m⁻ ². High variability was observed between the sites, indicating the importance of small-scale factors on microplastic contamination. Samples from high and intertidal zones showed no significant difference in microplastic contamination (p = 0.225). The West Coast beaches exhibited higher microplastic contamination compared with East Coast beaches (p = 0.004). Microplastics were predominately fibres (88%), with lower proportions of fragments (8%) and films (4%). The majority of the microplastics analysed were regenerated cellulose (34%), polyethylene terephthalate (22%) and polyethylene (15%). Copyright © 2020 Elsevier Ltd

Brignac, K. C., et al. (2019). "Marine Debris Polymers on Main Hawaiian Island Beaches, Sea Surface, and Seafloor." Environmental Science & Technology **53**(21): 12218-12226.

Polymeric differences of plastic debris were assessed across four compartments of the Main Hawaiian Islands (sea surface, windward beaches, leeward beaches, and seafloor) to better describe sources and fate. Plastic debris pieces (n = 4671) were collected from 11 beaches, three sea surface tows, and three seafloor dives. Fourier transform infrared spectroscopy identified the polymers of 3551 pieces. Significant differences ($p < 0.05$) in concentration, types, polymer composition, and weathering were found among four compartments. Windward beaches had 1-2 orders of magnitude more plastic pollution (g/m²) than leeward beaches, despite smaller human populations on windward sides. Sea surface and windward beaches were dominated by severely weathered, less dense floating polymers (polyethylene and polypropylene comprised 92.7 and 93.5% on average, respectively, of the total debris mass), while leeward beaches and the seafloor debris consisted of less weathered and more dense sinking polymers (e.g., 41.0 and 44.7% of total mass consisted of the sum of polystyrene, nylon, cellulose acetate, polyethylene terephthalate, and additive-masked debris). These results are some of the first to provide evidence of polymeric stratification in the marine environment and emphasize that the majority of marine debris in Hawaii is floating in from distant sources rather than from Hawaii's residents or tourists.

Brizgys, M. V., et al. (1988). "Characterization of monoclonal antidigoxin antibodies immobilized to a solid support." Biotechnology and Applied Biochemistry **10**(4): 373-384.

A high-affinity monoclonal antidigoxin antibody, produced by somatic cell fusion, was amplified by the formation of ascites. purification from ascites was accomplished by affinity chromatography by passing the ascites over a digitoxin-amine-agarose column. Affinity-purified antidigoxin antibody was coupled to a pellicular microbead at concentrations of 10, 25, 50, and 100 mg/g bead. The immobilized antibody was characterized for binding affinity, for specificity to other cardiac glycosides, and for binding capacity. The data demonstrate that antidrug antibodies immobilized on solid supports remain functional and may have the capability of removing drug from biological fluids passed over the support.

Brockhoff, G., et al. (1994). "Flow cytometric detection and quantitation of the epidermal growth factor receptor in comparison to Scatchard analysis in human bladder carcinoma cell lines." Cytometry **17**(1): 75-83.

The epidermal growth factor receptor (EGFR) is considered a tumor-related marker with potential diagnostic and prognostic value. In order to assess the sensitivity of flow cytometry to detect EGFR and to quantify receptors objectively, two human bladder carcinoma cell lines with different urothelial differentiation, RT4 and J82, were grown in vitro, and their membrane EGFR content was measured by flow cytometry. Exponential monolayers showed decrease of EGFR content after 20 min pulses with 10 ng/ml EGF in medium, as detected with the antibody EGFR1 in a double staining technique with propidium iodide for DNA evaluation. Further decrease of green fluorescence intensity was seen in cells constantly exposed to EGF. Absolute receptor numbers were determined by Scatchard analysis with radioactive EGF and resulted in relatively low receptor numbers for both cell lines (approximately 3-4 x 10(4) EGFR/cell), as well as one affinity class. These findings could be matched by absolute receptor quantification by flow cytometry, adding beads with defined antigenic sites (Quantum Simply Cellular, Microbead Corporation) to the cell suspension for staining. Our data suggest that flow cytometric EGFR detection and quantitation may be supplied to in vivo tumor samples and that measurements by multiparameter analysis may define subpopulations valuable for tumor diagnosis and judgment on tumor progression.

Brodhagen, M., et al. (2017). "Policy considerations for limiting unintended residual plastic in agricultural soils." Environmental Science and Policy **69**: 81-84.

Growing crops under high-intensity agriculture entails the use of numerous plastic products, especially polyethylene plastic films used as crop mulches. As a result, some of the world's most productive agricultural soils are now being affected by plastic pollution, seriously threatening soil health and food security. Plastic film mulches designed to biodegrade in soil provide an appealing alternative to polyethylene films. What may be surprising, however, is that biodegradable plastic films do not necessarily represent a long-term solution to the problem of contaminating soil with plastic residues. Transformative science and policies are needed to mitigate uncertainty of biodegradable plastic residue accumulation in agricultural soils. Copyright © 2016 Elsevier Ltd

Broggini, T., et al. (2016). "Passive Entrapment of Tumor Cells Determines Metastatic Dissemination to Spinal Bone and Other Osseous Tissues." PLoS ONE [Electronic Resource] **11**(9): e0162540.

During the metastatic process tumor cells circulate in the blood stream and are carried to various organs. In order to spread to different organs tumor cell-endothelial cell interactions are crucial for extravasation mechanisms. It remains unclear if tumor cell dissemination to the spinal bone occurs by passive entrapment of circulating tumor cells or by active cellular mechanisms mediated by cell surface molecules or secreted factors. We investigated the seeding of three different tumor cell lines (melanoma, lung and prostate carcinoma) to the microvasculature of different organs. Their dissemination was compared to biologically passive microbeads. The spine and other organs were resected three hours after intraarterial injection of tumor cells or microbeads. Ex vivo homogenization and fluorescence analysis allowed quantification of tumor cells or microbeads in different organs. Interestingly, tumor cell distribution to the spinal bone was comparable to dissemination of microbeads independent of the tumor cell type (melanoma: 5.646% +/- 7.614%, lung: 6.007% +/- 1.785%, prostate: 3.469% +/- 0.602%, 7 mum beads: 9.884% +/- 7.379%, 16 mum beads: 7.23% +/- 1.488%). Tumor cell seeding differed significantly between tumor cells and microbeads in all soft tissue organs. Moreover, there were significant differences between the different tumor cell lines in their dissemination behaviour to soft tissue organs only. These findings demonstrate that metastatic dissemination of tumor cells to spinal bone and other osseous organs is mediated by passive entrapment of tumor cells similar to passive plugging of microvasculature observed after intraarterial microbeads injection.

Bronge, M., et al. (2019). "Sensitive detection of antigen-specific T-cells using bead-bound antigen for in vitro re-stimulation." MethodsX **6**: 1635-1641.

Reliable and sensitive detection of antigen specific cells is essential in several fields of research, whether it concerns monitoring responses to infectious agents or exploring the auto-antigen repertoire in autoimmune diseases. Identification of these cells is however difficult, especially when the cells often are rare and methods not sensitive, specific or practical enough. We propose a novel method of processing antigens before stimulation of cells which consists of covalently binding protein antigen to superparamagnetic micro-beads and using denaturing washes to remove contaminants. Peripheral blood mononuclear cells (PBMCs) from healthy donors were stimulated using both cytomegalovirus and tetanus-diphtheria antigen-beads as well as non-antigenic protein-beads as negative control in an IFNgamma FluoroSpot assay in order to detect Th1 and CD8⁺ responses. The responses toward the antigen beads were both antigen specific and sensitive, with a detection threshold of 1 IFNgamma producing T-cell per 18,000 PBMCs. *Covalently binding antigen to paramagnetic beads allows for harsh denaturing washes without loss of antigen.*Microbeads are phagocytosed by antigen presenting cells, resulting in efficient uptake, processing and presentation of the antigens.*The method allows the usage of relatively impure starting antigen material and whole PBMC samples without high background levels in follow up cellular assays.

Brookson, C. B., et al. (2019). "Microplastics in the diet of nestling double-crested cormorants (Phalacrocorax auritus), an obligate piscivore in a freshwater ecosystem." Canadian Journal of Fisheries and Aquatic Sciences **76**(11): 2156-2163.

Anthropogenic debris, namely plastic, is a concern across aquatic ecosystems worldwide, with freshwater systems being understudied relative to marine systems. In this study, we quantified and characterized debris in the diet of double-crested cormorant chicks (Phalacrocorax auritus) from three sites in two of the Laurentian Great Lakes to (i) determine whether or not the diet of double-crested cormorants in the Laurentian Great Lakes includes anthropogenic debris, (ii) characterize the size, shape, and type of debris incorporated, and (iii) examine relationships between the amount of debris ingested and their proximity to industrial–urban centres. Overall, >86% of cormorants in our study had anthropogenic debris (mostly fibers) in their digestive tracts with no correlation between site and the amount of debris ingested. The ingested debris includes microplastics, natural fibres from textiles, and other anthropogenic materials (e.g., glass). To the best of our knowledge, this is one of the first studies to examine anthropogenic debris in a diving bird in the Laurentian Great Lakes and one of few studies investigating this in freshwater birds.La présence de débris d’origine humaine, notamment de plastique, dans les écosystèmes aquatiques du monde entier est préoccupante, les systèmes d’eau douce étant sous-étudiés à cet égard par rapport aux systèmes marins. Nous avons quantifié et caractérisé les débris dans le régime alimentaire de bébés cormorans à aigrettes (Phalacrocorax auritus) de trois sites dans deux des Grands Lacs laurentiens afin de (i) déterminer si le régime alimentaire des cormorans à aigrettes dans les Grands Lacs laurentiens comprend des débris d’origine humaine et (ii) caractériser la taille, la forme et le type des débris incorporés et (iii) examiner les relations entre la quantité de débris ingérés et la proximité de centres industriels ou urbains. Globalement, il y avait des débris d’origine humaine (principalement des fibres) dans le tube digestif de >86 % des cormorans étudiés et il n’y avait pas de corrélation entre le site et la quantité de débris ingérés. Les débris ingérés comprenaient des microplastiques, de fibres naturelles provenant de textiles et d’autres matières d’origine humaine (p. ex. du verre). À notre connaissance, il s’agit d’une des premières études à examiner les débris d’origine humaine dans un oiseau plongeur dans les Grands Lacs laurentiens et une des rares études à examiner ce phénomène chez des oiseaux d’eau douce. Brossault, D. F. F. and A. F. Routh (2020). "Salt-driven assembly of magnetic silica microbeads with tunable porosity." Journal of Colloid & Interface Science **562**: 381-390.

HYPOTHESIS: Porous magnetic silica beads are promising materials for biological and environmental applications due to their enhanced adsorption and ease of recovery. This work aims to develop a new, inexpensive and environmentally friendly approach based on agglomeration of nanoparticles in aqueous droplets. The use of an emulsion as a geometrical constraint is expected to result in the formation of spherical beads with tunable composition depending on the aqueous phase content.

EXPERIMENTS: Magnetic silica beads are produced at room temperature by colloidal destabilization induced by addition of CaCl₂ to a water-in-oil emulsion containing SiO₂ and Fe₃O₄ nanoparticles. The impact of the salt concentration, emulsification method, concentration of hydrophobic surfactant as well as silica content is presented in this paper.

FINDINGS: This method enables the production of spherical beads with diameters between 1 and 9 micro m. The incorporation of magnetic nanoparticles inside the bead's structure is confirmed using Energy Dispersive X-ray spectrometry (EDX) and Scanning Transmission Electron Microscopy (STEM) and results in the production of magnetic responsive beads with a preparation yield up to 84%. By incorporating the surfactant Span 80 in the oil phase it is possible to tune the roughness and porosity of the beads.

Brown, S. (2019). "Connections." BioCycle **60**(8): 47-47.
The article suggests ways by incorporating which one can contribute to the sustainable environment. Topics include carrying reusable bag to the grocery store for shopping, reducing your meat consumption by choosing vegan or being vegetarian, and making the community aware of home and community composting..

Brown, T. and H. Takada (2017). "Indicators of Marine Pollution in the North Pacific Ocean." Archives of Environmental Contamination & Toxicology **73**(2): 171-175.
The complex nature of ocean pollution underscores the utility in identifying and characterizing a limited number of 'indicators' that enables scientists and managers to track trends over space and time. This paper introduces a special issue on indicators of marine pollution in the North Pacific Ocean and builds on a scientific session that was held at the North Pacific Marine Science Organization. The special issue highlights studies using a variety of indicators to provide insight into the identification of legacy and emerging contaminants, the ranking of priority pollutants from various sources, and the effects of contaminants on ecosystem health in the North Pacific Ocean. Examples include the use of mussels to illustrate spatial and temporal trends of a number of contaminants following the 2011 tsunami in Japan, the use of molecular marker (linear alkylbenzenes, hopanes, and polycyclic aromatic hydrocarbons) profiles to identify pollution sources, and the use of plastic resin pellets to illustrate spatial trends of petroleum pollution around the world. Stable isotopes were used to strengthen the utility of the Glaucous-winged gull (Larus glaucescens) as an indicator of marine pollution. Examples also demonstrate the development and application of biomarker approaches, including gene transcripts, oxidative stress, estradiol, hatchability, and respiration and swimming behavior abnormalities, as a function of exposure to polychlorinated biphenyls, sulfur-diesel, Pinghu crude oil, galaxolide and antifouling biocides. We provide a brief review of indicators of marine pollution, identify research gaps, and summarize key findings from the articles published within the issue. This special issue represents the first compilation of research pertaining to marine pollution indicators in the North Pacific Ocean and provides guidance to inform mitigation and monitoring efforts of contaminants in the region. The complex nature of ocean pollution underscores the utility in identifying and characterizing a limited number of "indicators" that enables scientists and managers to track trends over space

and time. This paper introduces a special issue on indicators of marine pollution in the North Pacific Ocean and builds on a scientific session that was held at the North Pacific Marine Science Organization. The special issue highlights studies using a variety of indicators to provide insight into the identification of legacy and emerging contaminants, the ranking of priority pollutants from various sources, and the effects of contaminants on ecosystem health in the North Pacific Ocean. Examples include the use of mussels to illustrate spatial and temporal trends of a number of contaminants following the 2011 tsunami in Japan, the use of molecular marker (linear alkylbenzenes, hopanes, and polycyclic aromatic hydrocarbons) profiles to identify pollution sources, and the use of plastic resin pellets to illustrate spatial trends of petroleum pollution around the world. Stable isotopes were used to strengthen the utility of the Glaucous-winged gull (Larus glaucescens) as an indicator of marine pollution. Examples also demonstrate the development and application of biomarker approaches, including gene transcripts, oxidative stress, estradiol, hatchability, and respiration and swimming behavior abnormalities, as a function of exposure to polychlorinated biphenyls, sulfur-diesel, Pinghu crude oil, galaxolide and antifouling biocides. We provide a brief review of indicators of marine pollution, identify research gaps, and summarize key findings from the articles published within the issue. This special issue represents the first compilation of research pertaining to marine pollution indicators in the North Pacific Ocean and provides guidance to inform mitigation and monitoring efforts of contaminants in the region.

Brown, T. P., et al. (2013). "Histamine reduces GPIbalpha-mediated adhesion of platelets to TNF-alpha-activated vascular endothelium." Thrombosis Research **131**(2): 150-157.

Histamine and tumor necrosis factor-alpha (TNF-alpha) are critical mediators of acute and chronic inflammation that are generated by mast cells and macrophages in atherosclerotic lesions or systemically during allergic attacks. Both of them induce activation of vascular endothelium and thus may play a role in thrombosis. Here we studied the interplay between histamine and TNF-alpha in glycoprotein (GP) Ibalpha-mediated platelet adhesion to cultured human vascular endothelial cells under static and shear flow conditions. The stimulation of endothelial cells with histamine or TNF-alpha increased the number of adherent or slow rolling GP Ibalpha-coated microbeads or washed human platelets. However, the application of histamine to endothelium pre-activated by TNF-alpha inhibited GP Ibalpha-mediated platelet adhesion. These effects were found to be associated with changes in the concentration of ultra large von Willebrand factor (ULVWF) strings anchored to endothelium. The results of this study indicate that histamine released during mast cell degranulation may cause or inhibit thrombosis, depending on whether it acts on resting endothelial cells or on cells pre-activated by other inflammatory stimuli.

Browne, M. A., et al. (2011). "Accumulation of microplastic on shorelines woldwide: sources and sinks." Environmental Science & Technology **45**(21): 9175-9179.

Plastic debris <1 mm (defined here as microplastic) is accumulating in marine habitats. Ingestion of microplastic provides a potential pathway for the transfer of pollutants, monomers, and plastic-additives to organisms with uncertain consequences for their health. Here, we show that microplastic contaminates the shorelines at 18 sites worldwide representing six continents from the poles to the equator, with more material in densely populated areas, but no clear relationship between the abundance of miocroplastics and the mean size-distribution of natural particulates. An important source of microplastic appears to be through sewage contaminated by fibers from washing clothes. Forensic evaluation of microplastic from sediments showed that the proportions of polyester and acrylic fibers used in clothing resembled those found in

habitats that receive sewage-discharges and sewage-effluent itself. Experiments sampling wastewater from domestic washing machines demonstrated that a single garment can produce >1900 fibers per wash. This suggests that a large proportion of microplastic fibers found in the marine environment may be derived from sewage as a consequence of washing of clothes. As the human population grows and people use more synthetic textiles, contamination of habitats and animals by microplastic is likely to increase.

Browne, M. A., et al. (2008). "Ingested microscopic plastic translocates to the circulatory system of the mussel, Mytilus edulis (L.)." Environmental Science & Technology **42**(13): 5026-5031.

Plastics debris is accumulating in the environment and is fragmenting into smaller pieces; as it does, the potential for ingestion by animals increases. The consequences of macroplastic debris for wildlife are well documented, however the impacts of microplastic (<1 mm) are poorly understood. The mussel, Mytilus edulis, was used to investigate ingestion, translocation, and accumulation of this debris. Initial experiments showed that upon ingestion, microplastic accumulated in the gut. Mussels were subsequently exposed to treatments containing seawater and microplastic (3.0 or 9.6 micro m). After transfer to clean conditions, microplastic was tracked in the hemolymph. Particles translocated from the gut to the circulatory system within 3 days and persisted for over 48 days. Abundance of microplastic was greatest after 12 days and declined thereafter. Smaller particles were more abundant than larger particles and our data indicate as plastic fragments into smaller particles, the potential for accumulation in the tissues of an organism increases. The short-term pulse exposure used here did not result in significant biological effects. However, plastics are exceedingly durable and so further work using a wider range of organisms, polymers, and periods of exposure will be required to establish the biological consequences of this debris.

Browne, M. A., et al. (2007). "MICROPLASTIC--AN EMERGING CONTAMINANT OF POTENTIAL CONCERN?" Integrated Environmental Assessment & Management **3**(4): 559-561.

The article examines the potential environmental impacts of microscopic plastic debris. Microplastic comes from fragmentation of larger plastic items and the use of small particles of plastic as abrasive scrubbers in cleaning products. These plastics fragment in the environment as a result of photolytic, mechanical and biological degradation. Plastics also fragment within the marine environment through the combined effects of wave action and abrasion from sediment particles. There is a greater potential for microplastics to be ingested by a wide range of animals.

Browne, M. A., et al. (2010). "Spatial patterns of plastic debris along Estuarine shorelines." Environmental Science & Technology **44**(9): 3404-3409.

The human population generates vast quantities of waste material. Macro (>1 mm) and microscopic (<1 mm) fragments of plastic debris represent a substantial contamination problem. Here, we test hypotheses about the influence of wind and depositional regime on spatial patterns of micro- and macro-plastic debris within the Tamar Estuary, UK. Debris was identified to the type of polymer using Fourier-transform infrared spectroscopy (FT-IR) and categorized according to density. In terms of abundance, microplastic accounted for 65% of debris recorded and mainly comprised polyvinylchloride, polyester, and polyamide. Generally, there were greater quantities of plastic at downwind sites. For macroplastic, there were clear patterns of distribution for less dense items, while for microplastic debris, clear patterns were for denser material. Small particles of sediment and plastic are both likely to settle slowly from the water-column and are likely to be transported by the flow of water and be deposited in areas where the movements of water are slower. There was, however, no relationship between the abundance of microplastic and the proportion of clay in sediments from the strandline. These results illustrate how FT-IR spectroscopy can be used to identify the different types of plastic and in this case was used to indicate spatial patterns, demonstrating habitats that are downwind acting as potential sinks for the accumulation of debris.

Browne, M. A., et al. (2013). "Microplastic moves pollutants and additives to worms, reducing functions linked to health and biodiversity." Current Biology **23**(23): 2388-2392.

Inadequate products, waste management, and policy are struggling to prevent plastic waste from infiltrating ecosystems. Disintegration into smaller pieces means that the abundance of micrometer-sized plastic (microplastic) in habitats has increased and outnumbers larger debris. When ingested by animals, plastic provides a feasible pathway to transfer attached pollutants and additive chemicals into their tissues. Despite positive correlations between concentrations of ingested plastic and pollutants in tissues of animals, few, if any, controlled experiments have examined whether ingested plastic transfers pollutants and additives to animals. We exposed lugworms (Arenicola marina) to sand with 5% microplastic that was presorbed with pollutants (nonylphenol and phenanthrene) and additive chemicals (Triclosan and PBDE-47). Microplastic transferred pollutants and additive chemicals into gut tissues of lugworms, causing some biological effects, although clean sand transferred larger concentrations of pollutants into their tissues. Uptake of nonylphenol from PVC or sand reduced the ability of coelomocytes to remove pathogenic bacteria by >60%. Uptake of Triclosan from PVC diminished the ability of worms to engineer sediments and caused mortality, each by >55%, while PVC alone made worms >30% more susceptible to oxidative stress. As global microplastic contamination accelerates, our findings indicate that large concentrations of microplastic and additives can harm ecophysiological functions performed by organisms.

Browne, M. A., et al. (2015). "Linking effects of anthropogenic debris to ecological impacts." Proceedings of the Royal Society of London, Series B: Biological Sciences **282**(1807): 20142929.

Accelerated contamination of habitats with debris has caused increased effort to determine ecological impacts. Strikingly, most work on organisms focuses on sublethal responses to plastic debris. This is controversial because (i) researchers have ignored medical insights about the mechanisms that link effects of debris across lower levels of biological organization to disease and mortality, and (ii) debris is considered non-hazardous by policy-makers, possibly because individuals can be injured or removed from populations and assemblages without ecological impacts. We reviewed the mechanisms that link effects of debris across lower levels of biological organization to assemblages and populations. Using plastic, we show microplastics reduce the 'health', feeding, growth and survival of ecosystem engineers. Larger debris alters assemblages because fishing-gear and tyres kill animals and damage habitat-forming plants, and because floating bottles facilitate recruitment and survival of novel taxa. Where ecological linkages are not known, we show how to establish hypothetical links by synthesizing studies to assess the likelihood of impacts. We also consider how population models examine ecological linkages and guide management of ecological impacts. We show that by focusing on linkages to ecological impacts rather than the presence of debris and its sublethal impacts, we could reduce threats posed by debris.

Bruce, S., et al. (2014). "Anti-aging proof of concept study: results and summary." Journal of Drugs in Dermatology: JDD **13**(9): 1074-1081.

BACKGROUND AND OBJECTIVES: The etiology of aging human skin includes intrinsic physiologic

changes greatly accelerated by photoaging, predominantly through exposure to UV light. Consumer interest and demand for anti-aging skin care products is extremely high especially in light of aging populations. Prenatal (fetal) tissue has been shown to possess healing characteristics and regenerative effects. A proprietary tissue engineering technology has been developed to produce a soluble human extracellular matrix material with growth factors and proteins. Neonatal cells are cultured on microbeads under conditions of low oxygen tension. This human cell-conditioned media (hCCM) contains a variety of growth factors and cytokines similar to those found in fetal cells and has been incorporated into a topical preparation for use in facial wound healing (after laser resurfacing procedures) and improving the appearance of aging skin. The objective of this study was to observe the effects of an MRCxTM-containing topical skincare regimen on subjects with demonstrated aging skin damage (photodamage) when used consistently over a 3 month time period.

METHODS: Female subjects age 35-65 with Fitzpatrick Skin Type I-IV and mild to moderate amounts of photodamage, fine lines, and wrinkles used Regenica Replenishing Creme and Regenica Renew SPF 15 for 3 months. At each visit, photos were taken of subjects while investigators completed skin grading assessments and subjects completed self-assessments. Investigator assessments included evaluation of tactile roughness, visual texture, wrinkles, blotchiness, skin tone evenness, radiance, and translucence on a 5-point scale. Subjects' self-assessments included assessment of fine lines and wrinkles, firmness, evenness of skin tone, brightness, resilience, clarity, and radiance. Changes from baseline were evaluated for each parameter and P values for changes from baseline to each study visit for investigator's assessments and to end-of-study for self-assessments were calculated.

RESULTS: Eighteen of 21 enrolled female subjects completed the study. Three subjects chose to drop from the study. Statistically significant improvements in investigator assessments of tactile roughness, visual texture, wrinkles, blotchiness, skin tone evenness, radiance and translucency compared to baseline were observed at weeks 4, 8, and 12 after initiating treatments. Progressive improvement was seen through the last study visit (visit 5, week 12). Similar statistically significant improvements in subjects' self-assessments were seen comparing the first post-baseline visit (visit 2, week 2) to subsequent visits. 93.5 % subjects agreed (somewhat or strongly) with all of the positive subject assessment statements at week 12. Importantly, 100 % of subjects indicated at the end of the study that they would recommend the product to a friend and would want to purchase the product. No treatment-related adverse events were recorded during the study.

CONCLUSIONS: Regenica was safe and clinically effective in reducing anti-aging effects in this group of female subjects aged 35-65 years as measured by both investigator assessments and subjects' self-assessments.

Bruce-Vanderpuije, P., et al. (2019). "The state of POPs in Ghana- A review on persistent organic pollutants: Environmental and human exposure." Environmental Pollution **245**: 331-342.

Ghana is one of the top pesticide users and highest persistent organic pollutant (POP) emitters in sub-saharan Africa. Despite recent increases in published data, there is limited information on how POP concentrations have changed, post ratification of the Stockholm Convention. As a result, this review aims to address these knowledge gaps by collating available data that reported POPs in Ghanaian environmental matrices, identify spatial and temporal trends, and establish potential health risks. It is worth noting that Ghana has not developed its own regulatory standards for POPs, but adapts United States Environmental Protection Agency (USEPA) standards. Results obtained showed concentrations in excess of USEPA regulatory standards for per- and poly-fluoroalkyl sulphonates (PFASs) and dichlorodiphenyldichloroethane

(DDD) in water, polychlorinated and polybrominated dibenzo-p-dioxins and furans (PCDD/Fs and PBDD/Fs) in e-waste soils, and polybrominated diphenyl ethers in aquatic organisms and dairy products. The published studies do not cover major regions nationwide. The inconsistency in methods and analytes measured, along with data scarcity in some regions, makes it challenging to identify temporal trends. However, the data did indicate decreasing concentrations of some legacy POPs in soil/sediment and aquatic organisms, with increasing concentrations of some POPs in water, fish, fruits and vegetables. Studies that performed health risks assessments were limited although the data indicated risks to e-waste workers, some farmers and vulnerable sub-populations. This review identified potential human health risks from POPs in the Ghanaian environment and the need for more consistent and widespread monitoring program. This paper provides a critical review of studies of POPs in Ghana which can be used as a reference for all of Africa, as well as other developing countries, for compliance with the requirements for POPs monitoring in the e-waste, food and environmental sectors to inform the mitigation of health risks. Bruck, F., et al. (2009). "I.P. Co-transplantation of mesenchymal stem cells (MSC) failed to prevent acute GVHD in a humanized MICE model." Experimental Hematology **1)**: S87-S88.

Background. Graft-versus-host disease (GVHD) is a life-threatening complication of allogeneic hematopoietic cell transplantation caused by donor T-cells reacting against host tissues. Previous studies have shown that mesenchymal stem cells (MSC) could exert a potent immunosuppressive effect in vitro and in vivo. Aim. The aim of the current study was first to establish a humanized model of GVHD in NOD/SCID/gammaC null mice, secondly to assess MSC ability to prevent GVHD. Methods. 30x106 human peripheral blood mononuclear cells (PBMC) were injected intraperitonealy (i.p.) into NOD/SCID/gammaC null mice. MSC ability to suppress in vitro CD3T-cell proliferation induced by PHA or anti-alphaCD3/CD28 microbeads was assessed by the ³[H]-thymidine test and by FACS cell cycle analysis. In vivo, 3x106 MSC were injected in i.p. into NOD/SCID/gammaC null mice not only at time of PBMC injection but also subsequently at weekly intervals for four administrations. Results. 30x106 PBMCT into NOD/SCID/gammaC null mice recipients (n=15) induced a weight decrease >20% (n=15), these mice presented severe hunching, ruffled fur, tachypnea, anaemia, and decrease of locomotion. CD3Tcells percentages in the mice were 68,83+/-13,83% in the spleen (n=11), 28,11+/-19,79% in the BM (n=11), and 56,93+/-15,84% in the blood (n=11). Repeat injection of 3x106 MSC with PBMC in i.p. into NOD/SCID/gammaC null mice (n=10) failed to prevent GVHD. Mice present clinical and pathologic signs of GVHD with a weight loss >20% in all of these mice. CD3T-cells percentages in these mice were 58,42+/-14,84% in the spleen (n=6), 35,33+/-14,15% in the BM (n=6), and 57,71+/-13,25% in the blood (n=6). We have also analysed the percentage of human CD3+CD4+Foxp3+ in these mice. We have observed an increase of human CD3+CD4+Foxp3+ in blood of mice injected with MSC (3,88+/-1,37%) (n=5) compared with controls mice (1,85+/-1,25%) (n=7). Conclusion. Although MSC exhibited potent immunosuppressive properties in vitro, MSC in i.p. injection failed to prevent GVHD in that model.

Bruck, S. and A. T. Ford (2018). "Chronic ingestion of polystyrene microparticles in low doses has no effect on food consumption and growth to the intertidal amphipod Echinogammarus marinus?" Environmental Pollution **233**: 1125-1130.

The ingestion of microplastics (plastic particles <5 mm) has been observed in a range of marine organisms, and adverse effects have been reported in several species after high concentration exposure. However, the long-term effects of low-dose ingestion remains unclear. The aim of this study was thus to assess the chronic effects of low concentrations of polystyrene microparticles

to the intertidal amphipod Echinogammarus marinus, using food consumption, growth, and moulting as endpoints. Amphipods were fed a gelatinous algal feed spiked with microbeads (8 micro m) in concentrations of ~0.9, 9 and 99 microplastics/g for 35 days. E. marinus was also analysed for retention of microplastics, and egestion rate was calculated in a separate high-dose feeding experiment. No significant effects were found in the food consumption or growth assays. There was no accumulation of microplastics in the gut, with only one microbead recorded internally in three (8%) of the exposed amphipods. The low number is likely linked to gastrointestinal functions, allowing for easy egestion of indigestible items. This assumption was supported by the observation that after high-dose exposure, 60% of E. marinus egested all microbeads within 24 h. This study suggests that ingesting low concentrations of 8 micro m microplastics do not impair the feeding or growth of amphipods along the exposure period. We hope that negative results such as these may further assist in assessing the impact posed by microplastics to marine organisms.

Bruckner-Lea, C. J., et al. (2002). "Renewable microcolumns for automated DNA purification and flow-through amplification: From sediment samples through polymerase chain reaction." Analytica Chimica Acta **469**(1): 129-140.

There is an increasing need for field-portable systems for the detection and characterization of microorganisms in the environment. Nucleic acids analysis is frequently the method of choice for discriminating between bacteria in complex systems, but standard protocols are difficult to automate and current microfluidic devices are not configured specifically for environmental sample analysis. In this report, we describe the development of an integrated DNA purification and polymerase chain reaction (PCR) amplification system and demonstrate its use for the automated purification and amplification of Geobacter chapellei DNA (genomic DNA or plasmid targets) from sediments. The system includes renewable separation columns for the automated capture and release of microparticle purification matrices, and can be easily reprogrammed for new separation chemistries and sample types. The DNA extraction efficiency for the automated system ranged from 3 to 25%, depending on the length and concentration of the DNA target. The system was more efficient than batch capture methods for the recovery of dilute genomic DNA even though the reagent volumes were smaller than required for the batch procedure. The automated DNA concentration and purification module was coupled to a flow-through, Peltier-controlled DNA amplification chamber, and used to successfully purify and amplify genomic and plasmid DNA from sediment extracts. Cleaning protocols were also developed to allow reuse of the integrated sample preparation system, including the flow-through PCR tube. © 2002 Elsevier Science B.V.

Brunner, K., et al. (2015). "Passive buoyant tracers in the ocean surface boundary layer: 2. Observations and simulations of microplastic marine debris." Journal of Geophysical Research: Oceans **120**(11): 7559-7573.

This paper is the second of a two-part series that investigates passive buoyant tracers in the ocean surface boundary layer (OSBL). The first part examines the influence of equilibrium wind-waves on vertical tracer distributions, based on large eddy simulations (LESs) of the wave-averaged Navier-Stokes equation. Motivated by observations of buoyant microplastic marine debris (MPMD), this study applies the LES model and the parametric one-dimensional column model from part one to examine the vertical distributions of MPMD. MPMD is widely distributed in vast regions of the subtropical gyres and has emerged as a major open ocean pollutant whose distribution is subject to upper ocean turbulence. The models capture shear-driven turbulence, Langmuir turbulence (LT), and enhanced turbulent kinetic energy input due to breaking waves (BWs). Model results are only consistent with observations of MPMD profiles and the relationship between surface concentrations and wind speed if LT effects are included. Neither BW nor shear-driven turbulence is capable of deeply submerging MPMD, suggesting that the observed vertical MPMD distributions are a characteristic signature of wave-driven LT. Thus, this study demonstrates that LT substantially increases turbulent transport in the OSBL, resulting in deep submergence of buoyant tracers. The parametric model is applied to 11 years of observations in the North Atlantic and North Pacific subtropical gyres to show that surface measurements substantially underestimate MPMD concentrations by a factor of 3-13. Key Points: * Langmuir turbulence deeply submerges microplastic marine debris * Microplastic marine debris content is underestimated by surface measurements * Sea state and rise velocity are key parameters for marine debris distributions

Brus, J., et al. (2017). "Structure and Dynamics of Alginate Gels Cross-Linked by Polyvalent Ions Probed via Solid State NMR Spectroscopy." Biomacromolecules **18**(8): 2478-2488.

Alginate gels are an outstanding biomaterial widely applicable in tissue engineering, medicine, and pharmacy for cell transplantation, wound healing and efficient bioactive agent delivery, respectively. This contribution provides new and comprehensive insight into the atomic-resolution structure and dynamics of polyvalent ion-cross-linked alginate gels in microbead formulations. By applying various advanced solid-state NMR (ssNMR) spectroscopy techniques, we verified the homogeneous distribution of the cross-linking ions in the alginate gels and the high degree of ion exchange. We also established that the two-component character of the alginate gels arises from the concentration fluctuations of residual water molecules that are preferentially localized along polymer chains containing abundant mannuronic acid (M) residues. These hydrated M-rich blocks tend to self-aggregate into subnanometer domains. The resulting coexistence of two types of alginate chains differing in segmental dynamics was revealed by ¹H-¹³C dipolar profile analysis, which indicated that the average fluctuation angles of the stiff and mobile alginate segments were about 5-9degree or 30degree, respectively. Next, the ¹³C CP/MAS NMR spectra indicated that the alginate polymer microstructure was strongly dependent on the type of cross-linking ion. The polymer chain regularity was determined to systematically decrease as the cross-linking ion radius decreased. Consistent with the ¹H-¹H correlation spectra, regular structures were found for the gels cross-linked by relatively large alkaline earth cations (Ba²⁺, Sr²⁺, or Ca²⁺), whereas the alginate chains cross-linked by bivalent transition metal ions (Zn²⁺) and trivalent metal cations (Al³⁺) exhibited significant irregularities. Notably, however, the observed disordering of the alginate chains was exclusively attributed to the M residues, whereas the structurally well-defined gels all contained guluronic acid (G) residues. Therefore, a key role of the units in M-rich blocks as mediators promoting the self-assembly of alginate chains was experimentally confirmed. Finally, combining 2D ²⁷Al 3Q/MAS NMR spectroscopy with density functional theory (DFT) calculations provided previously unreported insight into the structure of the Al³⁺ cross-linking centers. Notably, even with a low residual amount of water, these cross-linking units adopt exclusively 6-fold octahedral coordination and exhibit significant motion, which considerably reduces quadrupolar coupling constants. Thus, the experimental strategy presented in this study provides a new perspective on cross-linked alginate structure and dynamics for which high-quality diffraction data at the atomic resolution level are inherently unavailable.

Bruyere, D., et al. (2016). "Cryogenic ball milling: A key for elemental analysis of plastic-rich automotive shedder residue." Powder Technology **294**: 454-462.

End-of-life vehicles have become an environmental and sustainability issue in most developed countries, and require sophisticated organic- and inorganic-elemental analyses to evaluate the efficiency of post-shredder technologies applied to automotive shredder residue. The difficulties of milling such heterogeneous material, especially when plastic-rich, have to be overcome to allow such chemical analyses. To tackle this aspect, plastic-rich fluff sampled from the process line of an industrial waste management centre was subjected to pilot-float separation (d = 1.34) and cryogenic ball milling at BRGM. The cryogenic milling, tested in terms of plastic-rich fluff density, grinding time and feed size, was found to reach an acceptable final particle size (81-98% of particles at <. 250 mum) to allow total digestion and accurate and repeatable elemental analyses after a grinding time of between 27 min and 2 x 27 min (iterative two-step process). The results are contrasted, the milling being more efficient with the heavier fractions of plastic-rich fluff and a finer feed size. The varied grindability of the different fractions could result from a combination of one or more of the following effects: (i) a dilution of the plastics by more cryo-grindable rubber, (ii) the action of remnant minerals and non-ferrous metals as milling agents, (iii) the inherent cryo-grindability of various types of plastics, and (iv) the potential action of mineral and metallic fillers as weakening agents. The elemental analyses of our case study allowed us to determine a mass balance and show, in particular, that the pilot-float separation (i) recovers most of the organochlorine plastics, and (ii) concentrates Cu, Pb, Ba and B in the heavier fraction with respective ratios of 100:1, 8:1, 6:1 and 5:1. The high elemental recovery (95.8% up to 99.7%) and good repeatability of the C and Cl analyses on small test portions (100 mg to 3 g) represent a technical progress that could benefit other types of heterogeneous plastic-rich matrix samples such as waste electrical and electronic equipment (WEEE). Copyright © 2016 Elsevier B.V.

Bryant, J. A., et al. (2016). "Diversity and Activity of Communities Inhabiting Plastic Debris in the North Pacific Gyre." Msystems **1**(3): May-Jun.

Marine plastic debris has become a significant concern in ocean ecosystems worldwide. Little is known, however, about its influence on microbial community structure and function. In 2008, we surveyed microbial communities and metabolic activities in seawater and on plastic on an oceanographic expedition through the "great Pacific garbage patch." The concentration of plastic particles in surface seawater within different size classes (2 to 5 mm and >5 mm) ranged from 0.35 to 3.7 particles m⁻³ across sampling stations. These densities and the particle size distribution were consistent with previous values reported in the North Pacific Ocean. Net community oxygen production (NCP = gross primary production - community respiration) on plastic debris was positive and so net autotrophic, whereas NCP in bulk seawater was close to zero. Scanning electron microscopy and metagenomic sequencing of plastic-attached communities revealed the dominance of a few metazoan taxa and a diverse assemblage of photoautotrophic and heterotrophic protists and bacteria. Bryozoa, Cyanobacteria, Alphaproteobacteria, and Bacteroidetes dominated all plastic particles, regardless of particle size. Bacteria inhabiting plastic were taxonomically distinct from the surrounding picoplankton and appeared well adapted to a surface-associated lifestyle. Genes with significantly higher abundances among plastic-attached bacteria included che genes, secretion system genes, and nifH genes, suggesting enrichment for chemotaxis, frequent cell-to-cell interactions, and nitrogen fixation. In aggregate, our findings suggest that plastic debris forms a habitat for complex microbial assemblages that have lifestyles, metabolic pathways, and biogeochemical activities that are distinct from those of free-living planktonic microbial communities. IMPORTANCE Marine plastic debris is a growing concern that

has captured the general public's attention. While the negative impacts of plastic debris on oceanic macrobiota, including mammals and birds, are well documented, little is known about its influence on smaller marine residents, including microbes that have key roles in ocean biogeochemistry. Our work provides a new perspective on microbial communities inhabiting microplastics that includes its effect on microbial biogeochemical activities and a description of the cross-domain communities inhabiting plastic particles. This study is among the first molecular ecology, plastic debris biota surveys in the North Pacific Subtropical Gyre. It has identified fundamental differences in the functional potential and taxonomic composition of plastic-associated microbes versus planktonic microbes found in the surrounding open-ocean habitat. Bryk, J. A., et al. (2010). "Nature of myeloid cells expressing arginase 1 in peripheral blood after trauma." <u>Journal of Trauma-Injury Infection & Critical Care</u> **68**(4): 843-852.

BACKGROUND: Myeloid cells that express arginase 1 are upregulated by different stimuli, including trauma, and are capable of depleting arginine from the surrounding environment. Through arginine depletion, myeloid cells are capable of regulating T-cell function. We have previously reported increased arginase 1 expression in the peripheral blood mononuclear cells (PBMCs) after injury. The nature of the cells expressing arginase in humans after trauma is unknown and is the focus of this article.

METHODS: PBMCs were isolated using a Ficoll-Hypaque gradient. Arginase activity was measured by conversion of arginine to ornithine, and arginase 1 protein expression was measured by Western blot. The percent CD16 granulocytes and phenotypical analysis of the cells present in PBMCs were determined by flow cytometry. Magnetic microbeads were used for isolation and exclusion of specific cell subpopulations.

RESULTS: Trauma patients exhibited a dramatic increase in arginase activity ($p < 0.05$) and an increased percentage of CD16 granulocytes in the PBMC layer ($p < 0.05$) compared with control volunteers. Increased arginase activity in the PBMC layer was due to the contamination of this layer by granulocytes, as their exclusion decreased arginase activity back to baseline ($p < 0.05$). Granulocytes isolated from the PBMC layer expressed increased CD11b ($p < 0.05$) and CD66b ($p < 0.05$), markers of granulocyte activation. Furthermore, these granulocytes were significantly more swollen and degranulated compared with noncontaminating granulocytes.

CONCLUSION: In humans, increased arginase 1 expression after trauma observed in the PBMC layer seems to be exclusively the result of an increased number of activated granulocytes.

Bucci, K., et al. (2019). "What is known and unknown about the effects of plastic pollution: A meta-analysis and systematic review." <u>Ecological Applications</u>: e02044.

As a consequence of the global ubiquity of plastic pollution, scientists, decision-makers, and the public often ask whether macroplastics (>5 mm) and microplastics (<5 mm) have a realized ecological threat. In 2016, we conducted a systematic review of the literature and made a call for further research testing hypotheses about ecological effects. In the subsequent years, the amount of relevant research has risen tremendously. Here, we reassess the literature to determine the current weight of evidence about the effects of plastic pollution across all levels of biological organization. Our data spans marine, freshwater, and terrestrial environments. We extracted data from 139 lab and field studies testing 577 independent effects across a variety of taxa and with various types, sizes, and shapes of plastic. Overall, 59% of the tested effects were detected. Of these, 58% were due to microplastics and 42% were due to macroplastics. Of the effects that were not detected, 94% were from microplastics and 6% were from macroplastics. We found evidence that whether or not an effect is detected, as well as the severity and

direction of the effect, is driven by dose, particle shape, polymer type, and particle size. Based on our analyses, there is no doubt that macroplastics are causing ecological effects, however, the effects of microplastics are much more complex. We also assessed the environmental relevancy of experimental studies by comparing the doses used in each exposure to the concentrations and sizes of microplastics found in the environment. We determined that only 17% of the concentrations used in experimental studies have been found in nature, and that 80% of particle sizes used in experiments fall below the size range of the majority of environmental sampling. Based on our systematic review and meta-analysis, we make a call for future work that recognizes the complexity of microplastics and designs tests to better understand how different types, sizes, shapes, doses, and exposure durations affect wildlife. We also call for more ecologically and environmentally relevant studies, particularly in freshwater and terrestrial environments.

Bucio, L., et al. (2016). "Phenotype characterization of exosomes derived from bone marrow dendritic cells treated with different stimuli." Tissue Engineering - Part A **22 (Supplement 1)**: S149.

Introduction: Exosomes produced by dendritic cells, DCs, are vesicles able to present antigen to T cells. According to the levels of molecules expressed on the exosomes membrane, such as CD80, CD86, CD274, CD273, MHC I and MHC II, the immune response developed by exosomes may be stimulatory or tolerogenic. Since DCs-derived exosomes could be used as a novel cell-free cancer vaccine, it is important to know the expression of the molecules mentioned above. So, the aim of this investigation was determinate the immunological phenotype of exosomes derived of DCs treated with different stimuli. Material(s) and Method(s): we produced bone marrow dendritic cells (BMDCs) treated with different stimuli: BMDCs immature differentiated for 4 or 7 days with GM-CSF; and DCs treated with two different concentration of IFN-gamma (500 and 10, 000Uml); TNFalpha (1mgml) or LPS (1mgml). Then, the DCs-derived exosomes were isolated with CD11c-alpha microbeads and the levels of molecules CD80, CD86, CD274, CD273, MHC I and MHC II on the exosomes were evaluated by flow cytometry. Results and Discussion: As result, the immature 4 and 7 days- DCs, the DCs treated with 500 Uml and the exosomes derived of all these cells exhibited a tolerogenic phenotype. While the DCs treated with IFN-gamma in 10, 000Uml, 1mgml of TNF-alpha, 1mgml of LPS and the exosomes released by all these cells, showed an activator phenotype. So, the exosomes, depending the stimuli used, may be used in immunotherapy for developing a stimulatory or a tolerogenic immune response.

Buckley, J., et al. (2006). "Embryonic exposure to the fungicide vinclozolin causes virilization of females and alteration of progesterone receptor expression in vivo: An experimental study in mice." Environmental Health: A Global Access Science Source **5 (no pagination)**(4).

Background: Vinclozolin is a fungicide that has been reported to have anti-androgenic effects in rats. We have found that in utero exposure to natural or synthetic progesterones can induce hypospadias in mice, and that the synthetic progesterone medroxyprogesterone acetate (MPA) feminizes male and virilizes female genital tubercles. In the current work, we selected a relatively low dose of vinclozolin to examine its in utero effects on the development of the genital tubercle, both at the morphological and molecular levels. Method(s): We gave pregnant dams vinclozolin by oral gavage from gestational days 13 through 17. We assessed the fetal genital tubercles from exposed fetuses at E19 to determine location of the urethral opening. After determination of gonadal sex, either genital tubercles were harvested for mRNA quantitation, or urethras were injected with a plastic resin for casting. We analyzed quantified mRNA levels between treated and untreated animals for mRNA levels of estrogen receptors alpha and beta, progesterone receptor, and androgen receptor using nonparametric tests or ANOVA. To determine effects on urethral length (males have long urethras compared to females), we measured the lengths of the casts and performed ANOVA analysis on these data. Result(s): Our morphological results indicated that vinclozolin has morphological effects similar to those of MPA, feminizing males (hypospadias) and masculinizing females (longer urethras). Because these results reflected our MPA results, we investigated the effects of in utero vinclozolin exposure on the mRNA expression levels of androgen, estrogen alpha and beta, and progesterone receptors. At the molecular level, vinclozolin down-regulated estrogen receptor alpha mRNA in females and up-regulated progesterone receptor mRNA. Vinclozolin-exposed males exhibited up-regulated estrogen receptor alpha and progesterone receptor mRNA, effects we have also seen with exposure to the synthetic estrogen, ethinyl estradiol. Conclusion(s): The results suggest that vinclozolin virilizes females and directly or indirectly affects progesterone receptor expression. It also affects estrogen receptor expression in a sex-based manner. We found no in vivo effect of vinclozolin on androgen receptor expression. We propose that vinclozolin, which has been designated an anti-androgen, may also exert its effects by involving additional steroid-signaling pathways. © 2006 Buckley et al; licensee BioMed Central Ltd.

Bucol, L. A., et al. (2020). "Microplastics in marine sediments and rabbitfish (Siganus fuscescens) from selected coastal areas of Negros Oriental, Philippines." Marine Pollution Bulletin **150**: 110685.

The Philippines is currently ranked as the third top producer of plastic wastes, yet little research has been conducted on marine plastic pollution in this fishery-dependent, developing country. This study is the first in the nation to quantify and characterize microplastics ingested by a commercially important fish, the rabbitfish (Siganus fuscescens), in the coastal areas of Negros Oriental, central Philippines. Across all sites, the diversity of microplastic polymer types was highest in the guts of S. fuscescens from Dumaguete, a densely populated city. Microplastic particles extracted from subtidal sediment samples from Silliman Beach in Dumaguete were dominated by semi-synthetic microfibers (rayon), probably from clothing and textiles. However, these microplastic types were absent in the guts of fish, likely due to the different location and character of their feeding habitats. This study confirms for the first time the presence and diversity of microplastics in an edible finfish in the Philippines.

Bueno-Delgado, M. V., et al. (2019). "Optimal Path Planning for Selective Waste Collection in Smart Cities." Sensors **19**(9): 27.

Waste collection is one of the targets of smart cities. It is a daily task in urban areas and it entails the planning of waste truck routes, taking into account environmental, economic and social factors. In this work, an optimal path planning algorithm has been developed together with a practical software platform for smart and sustainable cities that enables computing the optimal waste collection routes, minimizing the impact, both environmental (CO₂ emissions and acoustic damage) and socioeconomic (number of trucks to be used and fuel consumption). The algorithm is executed in Net2Plan, an open-source planning tool, typically used for modeling and planning communication networks. Net2Plan facilitates the introduction of the city layout input information to the algorithm, automatically importing it from geographical information system (GIS) databases using the so-called Net2Plan-GIS library, which can also include positions of smart bins. The algorithm, Net2Plan tool and its extension are open-source, available in a public repository. A practical case in the city of Cartagena (Spain) is presented, where the optimal path planning for plastic waste collection is addressed. This work contributes to the urban mobility plans of smart cities and could be extended to other smart cities scenarios with requests of optimal path planning.

Bui, N. K., et al. (2018). "Recycling woven plastic sack waste and PET bottle waste as fiber in recycled aggregate concrete: An experimental study." Waste Management **78**: 79-93.

The objective of this study was to investigate the potential engineering of Recycled PET Bottles Waste (RPET) and Recycled Woven Plastic Sack Waste (RWS) fiber reinforced Recycled Aggregate Concrete (RAC). Currently, the amount of Construction and Demolition Waste (CDW) and plastic waste are rapidly increasing and becoming a burden for many nations. The present research is an effort to reduce the amount of solid waste as a good solution for waste management and preserve the environment. The effects of RWS and RPET fibers on RAC were evaluated based on mechanical properties and durability of concrete. The experimental results indicated that RPET and RWS fibers have high alkali resistance in alkaline environments and showed no detectable degradation in RAC at 90 days. The combination of Silica Fume (SF) and RPET fiber increased 3.6-9% compressive strength, 16.9-21.5% elastic modulus, 11.8-20.3% splitting tensile strength, 7-15% shear strength of RAC in comparison with RAC samples without fiber, while these values in RWS fiber reinforced RAC were lower. RWS and RPET fiber enhanced the post-cracking behavior of RAC. The contribution of RPET in the improvement of the RAC properties was better than that of RWS fiber although the RWS fiber has higher tensile strength than that of RPET fiber. Furthermore, SF and the proposed mixing technique increased the performance of RAC with 100% coarse RCA and compensated the loss of the compressive strength due to RPET and RWS fiber. Bukkarapu, K. R., et al. (2018). "Management, conversion, and utilization of waste plastic as a source of sustainable energy to run automotive: a review." Energy Sources Part A: Recovery, Utilization & Environmental Effects **40**(14): 1681-1692.

Increased usage of plastic and absence of an efficient system to address its non-degradability has become a serious issue threatening the human life. On the other hand, increased fossil fuel consumption which led to their depletion necessitates the search for an alternative that could replace the conventional fuels and alongside abate the emissions. Both the nondegradability of plastic and need for an alternative fuel can be addressed by converting the waste plastic to useful energy. The present article reviews about pyrolysis, a chemical treatment to convert waste plastic to energy. It also focuses on its functional feasibility as a fuel in a compression ignition engine. Reportedly, waste plastic oil when used in a diesel engine yields lesser thermal efficiency, higher brake specific fuel consumption, increased emissions of carbon monoxides, and oxides of nitrogen and unburnt hydrocarbons. Irrespective of its disadvantages, it is worthwhile to note that it is waste plastic which is converted to useful energy. However, not much work on the technical feasibility and functional efficacy of waste plastic oil as a fuel in a diesel engine is reported, and hence, research in this application seems to gain its focus in near future. Buldur, P. M. and F. N. Kok (2011). "Encapsulation of food flavors via coacervation method." Current Opinion in Biotechnology **1)**: S96.

Flavors are used in many areas, such as food, cosmetic, pharmaceutical and detergent industries to increase taste and/or odor. These highly valuable compounds lose their effect beginning from the production step due to their volatile and oxidation labile nature. The decreases in properties continue during the transfer and storage of the product. Encapsulation of flavors into different materials (e.g. gelatin, gum arabic, whey proteins, and pectin) is a well known method to solve this problem. In this study, the potential of coacervation method in the efficient encapsulation of food flavors were studied. The model flavors, d-limonene and 2-phenylethanol, were encapsulated into different ratio of gum arabic/gelatin mixtures. Prepared microcapsules were crosslinked by a natural, non-toxic agent, namely genipin. The microbeads were then collected and dried by lyophilization. Preparation conditions and different crosslinking agent concentrations were studied for their effect on coacervation properties and flavor retention during drying and storage. Microbeads were visualized in fluorescence microscopy using nile red as lipid staining dye. It was seen that increasing the gelatin and gum arabic concentration in the medium to more than 40% and 50%, respectively, caused aggregation of the newly formed microbeads. Optimum ratio was found to be 2:3 for gum arabic/gelatin.

Bulmus, V., et al. (1997). "Modified PMMA monosize microbeads for glucose oxidase immobilization." Chemical Engineering Journal **65**(1): 71-76.

Glucose oxidase (GOD) was immobilized onto modified polymethylmethacrylate (PMMA) microspheres by covalent bonding. Monosize PMMA microbeads with 1.5 mu m diameter were produced by dispersion polymerization of methylmethacrylate by using polyvinyl alcohol as a stabilizer. Hydroxyl groups on the microbeads were first converted to aldehyde groups by periodate oxidation. Three amino compounds, namely ammonium hydroxide, ethylene diamine and hexamethylene diamine were incorporated through the aldehyde groups. Then, GOD molecules were immobilized through the spacer-arms by using glutaraldehyde. The highest amount of immobilization and activity were obtained in which hexamethylene diamine was used as the spacer-arm with 14 atom length, and were 2.1 mg g super(-1) polymer and 129 IU g super(-1) polymer, respectively. The optimal conditions for GOD immobilization were obtained as follows: pH, 6.0; temperature, 30 degree C; immobilization time, 60 min; and GOD initial concentration, 0.10 mg ml super(-1). The optimal conditions for the GOD-immobilized PMMA microbeads were at pH 6.0 and at a temperature of 30 degree C. The K sub(m) and V sub(max) values of the GOD-immobilized PMMA microbeads were, 13.79 mM and 26.31 mM min super(-1) calculated by non-linear regression, respectively.

Bunce, C., et al. (1992). "Murine model of cutaneous infection with gram-positive cocci." Infection and Immunity **60**(7): 2636-2640.

Staphylococcus aureus has remained an important cause of nosocomial wound infections, but standardized or reproducible systems for analyzing cutaneous infections caused by S. aureus do not exist. A variety of foreign materials, variable inocula, and skin traumas have been used to promote infection. To minimize these variables and ensure reproducibility, we chose a model using subcutaneous injections of a fixed quantity of dextran microbeads (Cytodex) as the foreign material added to standardized broth suspensions of S. aureus. Suspensions (0.2 ml) injected into an outbred strain of immunocompetent hairless mice generated reproducible, measurable lesions. With S. aureus Smith Diffuse, fluctuant, erythematous lesions with a peak diameter of 15 mm were observed; these lesions yielded purulent material containing gram-positive cocci and neutrophils and yielded growth of S. aureus on culture. Lesion size was proportional to the bacterial inoculum size. Histologic examination of excised lesions revealed typical abscesses. A second strain of S. aureus (SLC3) produced dermonecrosis instead of abscesses at an inoculum size of 10 super(7) CFU. Control injections with a sterile Cytodex suspension regularly produced nondraining, nonerythematous nodules with maximum diameters of less than or equal to 5 mm. Streptococcus pyogenes produced late-onset necrotic lesions and abscesses. Using a foreign substance, this model generates easily observed and reproducible cutaneous infection with S. aureus and streptococci that can potentially discriminate between inter- and intrastrain differences. Such a model could be used to test the pathogenicity of isogeneic strains of these bacterial species and to evaluate the efficacy of antimicrobial agents.

Burange, A. S., et al. (2015). "Heterogeneously catalyzed strategies for the deconstruction of high density polyethylene: plastic waste valorisation to fuels." Green Chemistry **17**(1): 146-156.
The plastic industry generates enormous quantities of plastics at projected rates (both production and consumption) which can significantly threaten our environment in terms of plastic waste generation. High density polyethylene (HDPE) is one of the main fractions of municipal solid waste which has a remarkable potential to be valorised into fuels (e.g. bio-oils). Catalytic degradation is an innovative alternative process to transform plastic waste into such value added products. This mini review was aimed to discuss the most relevant and recent catalysts developed for the catalytic degradation of HDPE including metal oxides, sulphated metal oxides, zeolites, nanostructured zeolites, molecular sieves, fluid catalytic cracking (FCC) catalysts, metal carbonates and mesoporous materials for the production of chemicals and fuels (e.g. diesel and gasolines). Activities and selectivities as well as important effects of additives, particle size, catalyst to polymer ratios and also recent approaches for waste management will be discussed.

Burbank, F. (2010). "Placental formation, childbirth, and fibroid treatment: An integration and review of the circulation of the placenta and the uterus during a woman's life-cycle.(1)." Placenta **31 (9)**: A106.
During pregnancy, mother's blood prepares for an enormous hemostatic event that is 9 months away: the delivery of the placenta - the fetal organ that is the vascular link between mother and child. At childbirth, 1/10th of mother's cardiac output flows through the placenta. When the placenta is sheared from the uterus, 200 large, uteroplacental arteries are ripped apart and bleed profusely into the uterine cavity. For hours following delivery, uterine contractions slow blood flow within the uterus, which then allows the high concentration of clotting factors in mother's blood to solidify throughout the uterus and stop blood loss. Hours later, the tide reverses and most of these blood clots dissolve and blood flow returns to the uterus. For many hours following delivery, the uterus is ischemic and hypoxic. Unlike brain and heart, which can only survive minutes of decreased blood flow, the uterus can withstand dramatically diminished blood flow for hours. In fact, not only can the uterus tolerate low blood flow, it is evolutionally programmed to experience very low blood flow every few years. Uterine ischemia and hypoxia are a natural part of every woman's genetic past and are necessary for uterine health. In 1995 a group of French physicians discovered that it was possible to emulate the vascular physiology of childbirth by stopping blood flow to the uterus with small, plastic particles. Initially, they injected these particles to diminish blood loss duringmyomectomy. However, they soon learned that the injection of these particles was therapeutic in-and-of-itself for women with symptomatic fibroids. Unbeknownst to this French group, earlier, in 1964, an American physician surgically occluded the uterine arteries to treat women without fibroids who had excessive monthly menstrual blood loss. Subsequent physicians have occluded the uterine arteries in various ways to treat a third common disorder, adenomyosis. Finally, these clinical successes suggest that future episodes of endometriosis may be preventable in some women treated with uterine artery closure.

Burdett, B. C. (1996). "DYESTUFFS, TILE MYTHS EXPLODED, THE PROBLEMS AIRED." Recycling Textile & Plastic Waste: 165-171.

The article focuses on the impact of dyestuffs consumption particularly of the textile industries in Great Britain on the environment. The use of coloring agents to merchandise such as apparel, furnishings or household led to the consumption of an excess of about 700,000 tons of dyes annually. The application to textile materials is not at all beneficial to the environment but increasing changes are occurring through the excellent work of dye manufacturers, research organizations and the coming of dye application technology. Disposal of the textile products through recycling, reuse or safe burning without air pollution should be addressed. Unless there will be changes in human behavior, the demand will continue.

Burkhardt-Holm, P. and A. N'Guyen (2019). "Ingestion of microplastics by fish and other prey organisms of cetaceans, exemplified for two large baleen whale species." Marine Pollution Bulletin **144**: 224-234.

Knowledge on microplastic (MP) ingestion by cetaceans is difficult to obtain. We infer the potential for MP uptake by cetaceans from the occurrence of MP in prey species. First, we reviewed information on whale prey species, focussing on common minke (Balaenoptera acutorostrata) and sei whale (B. borealis), for which the most comprehensive quantitative datasets exist. Second, evidence of MP ingestion by their prey species was reviewed. We found common minke whales forage opportunistically on fish from various families: Ammodytidae, Clupeidae, Gadidae, Engraulidae and Osmeridae. Sei whales mostly feed on copepods, Engraulidae, Clupeidae and Scombridae. High levels of MP contamination are reported for Scombridae in the Atlantic and Engraulidae in the Northwest Pacific Ocean. Copepods exhibit low levels of MP ingestion in the Northeast Pacific Ocean. Species-specific prey preferences and feeding strategies imply different cetaceans have varied potential for MP uptake, even if they feed in similar geographic areas.

Burns, E. E. and A. B. A. Boxall (2018). "Microplastics in the aquatic environment: Evidence for or against adverse impacts and major knowledge gaps." Environmental Toxicology & Chemistry **37**(11): 2776-2796.

There is increasing scientific and public concern over the presence of microplastics in the natural environment. We present the results of a systematic review of the literature to assess the weight of evidence for microplastics causing environmental harm. We conclude that microplastics do occur in surface water and sediments. Fragments and fibers predominate, with beads making up only a small proportion of the detected microplastic types. Concentrations detected are orders of magnitude lower than those reported to affect endpoints such as biochemistry, feeding, reproduction, growth, tissue inflammation and mortality in organisms. The evidence for microplastics acting as a vector for hydrophobic organic compounds to accumulate in organisms is also weak. The available data therefore suggest that these materials are not causing harm to the environment. There is, however, a mismatch between the particle types, size ranges, and concentrations of microplastics used in laboratory tests and those measured in the environment. Select environmental compartments have also received limited attention. There is an urgent need for studies that address this mismatch by performing high quality and more holistic monitoring studies alongside more environmentally realistic effects studies. Only then will we be able to fully characterize risks of microplastics to the environment to support the introduction of regulatory controls that can make a real positive difference to environmental quality. Bursac, P., et al. (2007). "Cytoskeleton dynamics: Fluctuations within the network." Biochemical and Biophysical Research Communications **355**(2): 324-330.

Out-of-equilibrium systems, such as the dynamics of a living cytoskeleton (CSK), are inherently noisy with fluctuations arising from the stochastic nature of the underlying biochemical and molecular events. Recently, such fluctuations within the cell were characterized by observing spontaneous nano-scale motions of an RGD-coated microbead bound to the cell surface [Bursac et al., Nat. Mater. 4 (2005) 557-561]. While these reported anomalous bead motions represent a molecular level reorganization (remodeling) of microstructures in contact with the bead, a precise nature of these cytoskeletal constituents and forces that drive their remodeling dynamics are largely unclear. Here, we focused upon spontaneous motions of an RGD-coated bead and, in particular, assessed to what extent these motions are attributable to (i) bulk cell movement (cell crawling), (ii) dynamics of focal adhesions, (iii) dynamics of lipid membrane, and/or (iv) dynamics of the underlying actin CSK driven by myosin motors. © 2007 Elsevier Inc. Burton, G. A., Jr. (2017). "Stressor Exposures Determine Risk: So, Why Do Fellow Scientists Continue To Focus on Superficial Microplastics Risk?" Environmental Science & Technology **51**(23): 13515-13516.

Burylo, A. M., et al. (2017). "Enrichment of Circulating Endothelial Cells by CD34 Microbeads Followed by Enumeration Using Flow Cytometry." Thrombosis and Haemostasis **117**(12): 2356-2368.

Background Circulating endothelial cells (CECs) are a potential biomarker of angiogenesis. CECs increase in numbers after vessel injury. Higher CEC numbers are reported in cancer patients. Most methods for CEC detection and enumeration rely on flow cytometry (FCM); however, there is no agreement on CEC phenotype and the detection method to be used. This leads to uncertainty about the clinical applicability and variation between studies on CEC numbers reported. Objective To develop a selective and accurate method for CEC enumeration in peripheral blood by enrichment, followed by FCM in healthy volunteers (HV) and cancer patients. Methods Samples were enriched using CD34 microbeads, stained with nuclear dye and anti-CD14, CD15, CD45, CD34 and CD146 antibodies. Putative CECs were examined for Weibel-Palade bodies (WPBs) using anti-von Willebrand factor (vWF) antibody and fluorescence microscopy. Linear range of detection (R ²), recovery and precision (coefficient of

variation percentage [CV%]) were defined in three experiments by spiking a known number (range 12-12,800 CECs/4 mL) of surrogate endothelial cells in peripheral blood. Sample storage was determined at -80degreeC for up to 2 months. Results Sorted CECs showed vWF in the WPBs. The relationship between spiked and detected surrogate cells was R ² = 1.0, recovery of 94.0 to 101.4% and CV% of 1.0 to 18.4%. Recovery +/- standard deviation (within-run days 1, 2 and 3) were, respectively, 102.5% +/- 8.2, 97.8% +/- 4.6, 99.1% +/- 7.7, and after 2 months 94.3% +/- 15.3. The median CECs/mL in patients was 24.1 versus 14.4 in HVs. Conclusion This method for selective, sensitive and reliable CEC analysis by FCM allows for investigation of CECs as a biomarker in clinical research. Copyright © 2017 Schattauer.

Busetti, F., et al. (2016). "To anticoagulate or not to anticoagulate?" Italian Journal of Medicine **10 (Supplement 2)**: 16-17.

Atrial fibrillation (AF) affects at least 9% of octogenarian patients. The choice of anti-coagulation depends on CHADS-VASC, HAS-BLED, patient's comorbidities. Nevertheless, rare conditions may contraindicate the treatment and have to be taken into account before starting anticoagulation. A 88 year-old woman was admitted for acute dyspnoea; a new onset AF was detected. The patient had recently been discharged from the Neurology ward for recurrent and stereotyped transient ischemic attacks (TIAs) presenting with dysartria. The clinical presentation was suggestive for heart failure (HF) probably due to new onset AF. Thus, after treatment of HF, we started anticoagulation (CHADSVASC 7, HAS-BLED 2), but brain MRI revealed sulcal hemosiderin deposits and microbeads (CHADS-VASC2 5, HASBLED 3). These findings were highly suggestive for cerebral amyloid angiopathy (CAA), an absolute contraindication to anticoagulation due to the increased risk of major hemorrhages. Thus, even though chronic AF, balancing the risks, we decided to stop anticoagulation. Prevalence of CAA is about 12% in over 85 year-old subjects and represents an important cause of primary lobar intracerebral hemorrhage; this risk is increased mostly by anticoagulants. Monomorphic recurrent TIAs are the main clinical presentation of CAA. Diagnosis requires 2 or more lobar microhemorrhages or/and sulcal haemosiderin deposition at cerebral MRI. CAA is a common, underestimated pathology in the elderly. It should be investigated in patients with monomorphic recurrent TIAs before starting a chronic anticoagulant treatment.

Busnach, G., et al. (1989). "Polymorphonuclear cell phagocytosis and surface receptor modulation after extracorporeal circulation." ASAIO Transactions **35**(3): 361-364.

Polymorphonuclear cells (PMN) from patients treated with hemodialysis (HD) or plasma exchange (PE) were analyzed by flow cytometry to determine modulation in phagocytic capacity and Fc-gamma and C3bi receptor expression following extracorporeal circulation (EC). Fluorescent microbeads (phi 2.02 m) were used in the evaluation of phagocytosis, and phycoerythrin conjugated Leu11c and Leu15 monoclonals identified Fc-gamma and C3bi receptors respectively. The percentage of positive cells and mean receptor density on PMN surfaces were calculated for each antibody before and after the procedures. Fc-gamma receptor expression was reduced overall in HD and PE cases, but unaffected after EC even with specific paraprotein removal. C3bi receptor was normally expressed on PMNs before and after EC, but receptor density on the cell surface increased, and phagocytosis was qualitatively and quantitatively depressed after EC. The resulting effect of EC on PMNs was therefore a temporary increase in C3bi receptor density after the procedure, which was independent of HD or PE technique, of the primary disease, and of the quality of the PE reinfusion solutions, suggesting a procedure-related effect, and a down-regulation of PMN phagocytic activity. Both effects may be related to membrane biocompatibility.

Busquets, R., et al. (2016). "Carbon-cryogel hierarchical composites as effective and scalable filters for removal of trace organic pollutants from water." Journal of Environmental Management **182**: 141-148.

Effective technologies are required to remove organic micropollutants from large fluid volumes to overcome present and future challenges in water and effluent treatment. A novel hierarchical composite filter material for rapid and effective removal of polar organic contaminants from water was developed. The composite is fabricated from phenolic resin-derived carbon microbeads with controllable porous structure and specific surface area embedded in a monolithic, flow permeable, poly(vinyl alcohol) cryogel. The bead-embedded monolithic composite filter retains the bulk of the high adsorptive capacity of the carbon microbeads while improving pore diffusion rates of organic pollutants. Water spiked with organic contaminants, both at environmentally relevant concentrations and at high levels of contamination, was used to determine the purification limits of the filter. Flow through tests using water spiked with the pesticides atrazine (32 mg/L) and malathion (16 mg/L) indicated maximum adsorptive capacities of 641 and 591 mg pollutant/g carbon, respectively. Over 400 bed volumes of water contaminated with 32 mg atrazine/L, and over 27,400 bed volumes of water contaminated with 2 mug atrazine/L, were treated before pesticide guideline values of 0.1 mug/L were exceeded. High adsorptive capacity was maintained when using water with high total organic carbon (TOC) levels and high salinity. The toxicity of water filtrates was tested in vitro with human epithelial cells with no evidence of cytotoxicity after initial washing.

Buss, D. (2019). "Taming the Tsunami of Plastic Waste." Food Technology **73**(7): 20.

In the annals of photographs that changed history, the 2015 photo of an olive ridley sea turtle may not be the Hindenburg dirigible blowing up in 1939, Neil Armstrong on the moon in 1969, or the man holding off a tank column in Tiananmen Square in 1989. But the image of a turtle captured off the coast of Costa Rica with a plastic straw up its nose accelerated a global movement against plastic disposables and packaging--and now is rippling through the consumer packaged goods and foodservice industries. Indeed, plastic waste has become Public Enemy No. 1 in the food and beverage business these days. As a result, traditional packaged goods giants, huge restaurant chains, and startups in both businesses--and their packaging suppliers--are scrambling to create new single-use plastic packages that are recyclable or biodegradable--or, preferably, are reusable or eliminate plastic altogether. As part of this ethos, in fact, many companies are performing thorough reexaminations of their approach to all their packaging.

Bussolaro, D., et al. (2019). "Co-exposure to polystyrene plastic beads and polycyclic aromatic hydrocarbon contaminants in fish gill (RTgill-W1) and intestinal (RTgutGC) epithelial cells derived from rainbow trout (Oncorhynchus mykiss)." Environmental Pollution **248**: 706-714.

Microscopic plastic (MP) particles are a ubiquitous contaminant in aquatic environments, which may bind hydrophobic chemicals, such as polycyclic aromatic hydrocarbons (PAHs), altering their environmental fate and interactions with biota. Using rainbow trout gill (RTgill-W1) and intestinal (RTgutGC) epithelial cells we investigated the effects of polystyrene microbeads (PS-MBs; 220 nm) on the cyto- and genotoxicity of the environmental pollutants benzo[a]pyrene (BaP) and 3-nitrobenzanthrone (3-NBA) over 48 h (0, 0.1, 1 and 10 micro M). The Alamar Blue bioassay, used to assess cytotoxicity, showed that both pollutants significantly decreased cell viability by 10-20% at 10 micro M in both cell lines after 48 h whereas PS-MBs (5 or 50 micro g mL⁻¹) were non-toxic. Cytotoxicity in cells treated with PS-MBs together with BaP or 3-NBA were similar to those observed after exposure to BaP or 3-NBA alone. Using the formamidopyrimidine-DNA glycosylase (FPG)-modified comet assay 3-NBA, but not BaP, induced

DNA damage in RTgutGC cells at 10 micro M (~10% tail DNA in the absence and ~15% tail DNA in the presence of FPG versus ~1% in controls), whereas PS-MBs alone showed no detrimental effects. Interestingly, comet formation was substantially increased (~4-fold) when RTgutGC cells were exposed to PS-MBs (50 micro g mL⁻¹) and 10 micro M 3-NBA compared to cells treated with 3-NBA alone. Further, using ³²P-postlabelling we observed strong DNA adduct formation in 3-NBA-exposed RTgutGC cells (~900 adducts/10⁸ nucleotides). 3-NBA-derived DNA adduct formation was significantly decreased (~20%) when RTgutGC cells were exposed to MB and 3-NBA compared to cells treated with 3-NBA alone. Our results show that PS-MBs impact on the genotoxicity of 3-NBA, causing a significant increase in DNA damage as measured by the comet assay in the intestinal cell line, providing proof of principle that MPs may alter the genotoxic potential of PAHs in fish cells.

Butcher, J. T., et al. (2006). "Equibiaxial strain stimulates fibroblastic phenotype shift in smooth muscle cells in an engineered tissue model of the aortic wall." Biomaterials **27**(30): 5252-5258.

Many cells in the body reside in a complex three-dimensional (3D) environment stimulated by mechanical force. In vitro bioreactor systems have greatly improved our understanding of the mechanisms behind cell mechanotransduction. Current systems to impose strain in vitro are limited either by the lack of uniform strain profile or inability to strain 3D engineered tissues. In this study, we present a system capable of generating cyclic equibiaxial strain to an engineered vascular wall model. Type I collagen hydrogels populated with rat aortic smooth muscle cells (RASMCs) were created either as a compacting disk or constrained hemisphere. Both models were adhered to silicone membranes precoated with collagen I, fibronectin, or Cell-Tak and assayed for adhesion characteristics. The best performing model was then exposed to 48 h of 10% strain at 1 Hz to simulate wall strain profiles found in vascular aneurysms, with static cultures serving as controls. The finite strain profile at the level of the membrane and the free surface of the construct was quantified using microbeads. The results indicate that the hemisphere model adhered with Cell-Tak had the most stable adhesion, followed by fibronectin and collagen I. Disk models did not adhere well under any coating condition. Uniform strain propagation was possible up to a maximum area strain of 20% with this system. RASMC responded to 10% equibiaxial strain by becoming less elongated, and immunohistochemistry suggested that stretched RASMC shifted to a more synthetic phenotype in comparison to static controls. These results suggest that equibiaxial strain may induce smooth muscle cell differentiation. We conclude that this system is effective in stimulating cells with cyclic equibiaxial strain in 3D cultures, and can be applied to a variety of biomaterial and tissue engineering applications.

Buxton, R. T., et al. (2013). "Incidence of plastic fragments among burrow-nesting seabird colonies on offshore islands in northern New Zealand." Marine Pollution Bulletin **74**(1): 420-424.

Marine plastic pollution is ubiquitous throughout the world's oceans, and has been found in high concentrations in oceanic gyres of both the northern and southern hemispheres. The number of studies demonstrating plastic debris at seabird colonies and plastic ingestion by adult seabirds has increased over the past few decades. Despite the recent discovery of a large aggregation of plastic debris in the South Pacific subtropical gyre, the incidence of plastics at seabird colonies in New Zealand is unknown. Between 2011 and 2012 we surveyed six offshore islands on the northeast coast of New Zealand's North Island for burrow-nesting seabird colonies and the presence of plastic fragments. We found non-research related plastic fragments (0.031 pieces/m²) on one island only, Ohinau, within dense flesh-footed shearwater (Puffinus carneipes) colonies. On Ohinau, we found a linear relationship between burrow

density and plastic density, with 3.5 times more breeding burrows in areas with plastic fragments found. From these data we conclude that plastic ingestion is a potentially a serious issue for flesh-footed shearwaters in New Zealand. Although these results do not rule out plastic ingestion by other species, they suggest the need for further research on the relationship between New Zealand's pelagic seabirds and marine plastic pollution.

Buyuktuncel, E., et al. (2008). "Adsorption and on-line preconcentration of Cu(II), Cd(II) and Pb(II) ions from aqueous solution using Procion Red MX-3B immobilized poly(EGDMA-HEMA) microbeads." Fresenius Environmental Bulletin **17**(4): 467-477.

The adsorption and preconcentration studies of Cu(II), Pb(II) and Cd(II) were investigated on Procion Red MX-3B attached poly(ethylene glycol dimethacrylate-hydroxy-ethyl methacrylate) [poly(EGDMA-HEMA)] microbeads. The effects of various experimental parameters were investigated using a batch and column technique. The adsorption data followed Langmuir, Freundlich and Dubinin-Radushkevich (D-R) isotherms, but the Langmuir model is better to represent the adsorption process. Procion Red MX-3B-poly(EGDMA-HEMA) microbeads were used as packing material for the minicolumn in an on-line preconcentration system for Cu(II), Pb(II) and Cd(II) determination. Metal ions were sorbed in the minicolumn, from which it could be eluted directly to the nebulizer-burner system of the flame atomic absorption spectrometer (FAAS). Elution of all metal ions from minicolumn can be made with 0.2 mol L⁻¹ HNO₃. For a preconcentration time of 2 min, the preconcentration factors were 51, 55 and 48, and the detection limits 1.25, 0.5 and 10 micro g L⁻¹, for Cu(II), Cd(II) and Pb(II), respectively. When using 10 min preconcentration time for Pb(II), the preconcentration factor and detection limit were found to be 273 and 1.1 micro g L⁻¹, respectively. The influence of diverse ions on the microbeads performance was also investigated. The accuracy of the method was tested by analyzing certified reference water (SPS-SW2 - Surface Water and LGC 6010 - Hard Drinking Water) and spiked tap water samples. These results proved that the procedure can be applied satisfactorily for lead, copper and cadmium determination in water samples.

Cabernard, L., et al. (2018). "Comparison of Raman and Fourier Transform Infrared Spectroscopy for the Quantification of Microplastics in the Aquatic Environment." Environmental Science & Technology **52**(22): 13279-13288.

Microplastics (MPs, <5 mm) have been reported as emerging environmental contaminants, but reliable data are still lacking. We compared the two most promising techniques for MP analysis, namely, Raman and Fourier transform infrared (FTIR) spectroscopy, by analyzing MPs extracted from North Sea surface waters. Microplastics >500 mum were visually sorted and manually analyzed by mu-Raman and attenuated total reflection (ATR)-FTIR spectroscopy. Microplastics <=500 mum were concentrated on gold-coated filters and analyzed by automated single-particle exploration coupled to mu-Raman (ASPEx-mu-Raman) and FTIR imaging (reflection mode). The number of identified MPs >500 mum was slightly higher for mu-Raman (+23%) than ATR-FTIR analysis. Concerning MPs <=500 mum, ASPEx-mu-Raman quantified two-times higher MP numbers but required a four-times higher analysis time compared to FTIR imaging. Because ASPEx-mu-Raman revealed far higher MP concentrations (38-2621 particles m⁻³) compared to the results of previous water studies (0-559 particles m⁻³), the environmental concentration of MPs <=500 mum may have been underestimated until now. This may be attributed to the exceptional increase in concentration with decreasing MP size found in this work. Our results demonstrate the need for further research to enable time-efficient routine application of ASPEx-mu-Raman for reliable MP counting down to 1 mum.

Caberoy, N. B., et al. (2010). "Identification of tubby and tubby-like protein 1 as eat-me signals by phage display." Experimental Cell Research **316**(2): 245-257.

Phagocytosis is an important process for the removal of apoptotic cells or cellular debris. Eat-me signals control the initiation of phagocytosis and hold the key for in-depth understanding of its molecular mechanisms. However, because of difficulties to identify unknown eat-me signals, only a limited number of them have been identified and characterized. Using a newly developed functional cloning strategy of open reading frame (ORF) phage display, we identified nine putative eat-me signals, including tubby-like protein 1 (Tulp1). This further led to the elucidation of tubby as the second eat-me signal in the same protein family. Both proteins stimulated phagocytosis of retinal pigment epithelium (RPE) cells and macrophages. Tubby-conjugated fluorescent microbeads facilitated RPE phagocytosis. Tubby and Tulp1, but not other family members, enhanced the uptake of membrane vesicles by RPE cells in synergy. Retinal membrane vesicles of Tubby mice and Tulp1(-/-) mice showed reduced activities for RPE phagocytosis, which were compensated by purified tubby and Tulp1, respectively. These data reveal a novel activity of tubby and Tulp1, and demonstrate that unbiased identification of eat-me signals by the broadly applicable strategy of ORF phage display can provide detailed insights into phagocyte biology.

Cabezudo, E., et al. (1999). "Quantitative analysis of CD79b, CD5 and CD19 in mature B-cell lymphoproliferative disorders." Haematologica **84**(5): 413-418.

BACKGROUND AND OBJECTIVE: Distinction between B-cell chronic leukemias can be difficult due to overlap in cell morphology and immunologic features. We investigated, by quantitative flow cytometry, the expression of CD79b, CD5 and CD19 in cells from a variety of B-cell disorders to see whether this analysis adds further information useful to the diagnosis and characterization of these diseases.

DESIGN AND METHODS: Peripheral blood cells from 6 normal individuals were used as reference controls. The diseases of the 63 patients investigated comprised: 29 chronic lymphocytic leukemia (CLL), six of them with atypical morphology, 6 B-cell prolymphocytic leukemia (PLL), 12 splenic lymphoma with villous lymphocytes (SLVL) and 16 mantle-cell (Mc) lymphoma in leukemic phase. The study was carried out by triple immunostaining with directly conjugated monoclonal antibodies (MoAb) against CD79b, CD5 and CD19 and quantitative estimation of the antigens per cell assessed with standard microbeads (Quantum Simply Cellular).

RESULTS: Compared to normal B-cells, the number of CD19 molecules was significantly lower in cells from all of the B-cell disorders except PLL. The intensity of CD5 in leukemic B-cells was significantly higher in CLL cells, including atypical cases, and Mc lymphoma than in normal B-cells, whilst PLL and SLVL had values similar to those of normal B-lymphocytes. CD79b was expressed at lower levels in all types of leukemic cells compared to normal B-lymphocytes but differences were statistically significant in CLL, Mc lymphoma and SLVL. The number of CD79b molecules per cell was significantly lower in typical CLL than in the remaining B-cell diseases whilst the comparison of CD5 and CD19 intensity between CLL and non-CLL samples failed to show any statistically significant difference.

INTERPRETATION AND CONCLUSIONS: Distinct antigen density patterns for the various conditions emerged from this analysis: Typical CLL was characterized by moderate CD5 and weak or negative CD79b expression. Mc lymphoma showed an homogeneous pattern, characterized by similar expression of CD5 than CLL but significantly stronger expression of CD79b whilst PLL and SLVL had weak CD5 and moderate CD79b expression. Atypical CLL had an intermediate pattern of CD79b antigen expression ranging from weak to moderate with bright CD5. Unlike CD5 and

CD79b, CD19 did not discriminate the various B-cell disorders but only between normal and leukemic cells.

Cabezudo, E., et al. (1997). "Analysis of residual disease in chronic lymphocytic leukemia by flow cytometry." Leukemia **11**(11): 1909-1914.

We have investigated the value of both conventional and quantitative flow cytometry to detect minimal residual disease in 21 CLL patients in remission including bone marrow histology: eight in complete remission (CR), 11 in nodular partial remission (nPR) and two in PR. The techniques used were double immunostaining with CD5 and CD19 and quantitative estimation of the number of both antigens with standard microbeads. Reference values were established on normal peripheral blood and bone marrow controls. Patients were considered in 'immunological' remission when the percentage of CD5+ CD19+/total CD19+ cells was <25% in PB and <15% in BM. In six of the eight patients in CR, CLL cells were still detectable by flow cytometry. Only two patients, that underwent allogeneic bone marrow transplant, achieved immunological remission. CLL samples showed significantly higher CD5 and lower CD19 antigen density than normal controls (P < 0.001). Persistence of residual disease was a predictor of time to progression. None of the two patients in immunological remission relapsed within a period of 13 and 33 months, whilst two of the six patients in CR with positive flow cytometry relapsed 3 and 6 months after achieving CR. This study demonstrates that flow cytometry contributes to increase the sensitivity of the clinicohematological criteria to detect residual malignant cells in CLL patients and may be useful to monitor disease status following treatment.

Cable, R. N., et al. (2017). "Distribution and Modeled Transport of Plastic Pollution in the Great Lakes, the World's Largest Freshwater Resource." Frontiers in Environmental Science.

Most plastic pollution originates on land. As such, freshwater bodies serve as conduits for the transport of plastic litter to the ocean. Understanding the concentrations and fluxes of plastic litter in freshwater ecosystems is critical to our understanding of the global plastic litter budget and underpins the success of future management strategies. We conducted a replicated field survey of surface plastic concentrations in four lakes in the North American Great Lakes system, the largest contiguous freshwater system on the planet. We then modeled plastic transport to resolve spatial and temporal variability of plastic distribution in one of the Great Lakes, Lake Erie. Triplicate surface samples were collected at 38 stations in mid-summer of 2014. Plastic particles >106 µm in size were quantified. Concentrations were highest near populated urban areas and their water infrastructure. In the highest concentration trawl, nearly 2 million fragments km-2 were found in the Detroit River—dwarfing previous reports of Great Lakes plastic abundances by over 4-fold. Yet, the accuracy of single trawl counts was challenged: within-station plastic abundances varied 0- to 3-fold between replicate trawls. In the smallest size class (106-1000 µm), false positive rates of 12-24% were determined analytically for plastic versus non-plastic, while false negative rates averaged ~18%. Though predicted to form in summer by the existing Lake Erie circulation model, our transport model did not predict a permanent surface “Lake Erie Garbage Patch” in its central basin—a trend supported by field survey data. Rather, general eastward transport with recirculation in the major basins was predicted. Further, modeled plastic residence times were drastically influenced by plastic buoyancy. Neutrally buoyant plastics—those with the same density as the ambient water—were flushed several times slower than plastics floating at the water’s surface and exceeded the hydraulic residence time of the lake. It is likely that the ecosystem impacts of plastic litter persist in the Great Lakes longer than assumed based on lake flushing rates. This study furthers our understanding of plastic pollution in the Great Lakes, a model freshwater system to study the

movement of plastic from anthropogenic sources to environmental sinks.

Cabrera, C., et al. (2015). "Fully automated digital immunoassay for p24 on the Simoa HD-1 Analyzer with the sensitivity of nucleic acid amplification fo acute HIV infection." Clinical Chemistry **1)**: S143-S144.

Background: Nucleic acid amplificationtechniques such as PCR have become the mainstay for ultimate sensitivity for detecting low levels of virus, including human immunodeficiencyvirus (HIV). As a sophisticated technology with relative expensive reagents and instrumentation, adoption of nucleic acid testing (NAT) can be inhibited in settings in which access to extreme sensitivity could be clinically advantageous for early detection of HIV infection. We report a simple low cost digital immunoassay for the p24 capsid protein of HIV based single molecule array (Simoa) technology. The assay exhibited over three logs greater sensitivity than conventional immunoassays, and comparable sensitivity to NAT for early detection of HIV infection. Method(s): Reagents were developed for a paramagnetic bead-based ELISA for use in the Simoa HD-1 Analyzer. Anti-p24 capture beads were prepared by covalent coupling of antibody to carboxy paramagnetic microbeads, detector antibody was biotinylated by standard methods, and an enzyme conjugate was prepared by covalent coupling of streptavidin and [[Unsupported Character - Symbol Font]]-galactosidase. The HD-1 Analyzer firstperforms a 2-step sandwich immunoassay using 144 muL of serum or plasma sample, then transfers washed and labeled capture beads to a Simoa disc where the beads are singulated in 50-femtoliter microwells, sealed in the presence of substrate, and interrogated for presence of enzyme label. A single labeled p24 molecule provides sufficientfluorescentsignal in 30 seconds to be counted by the HD-1 optical system. At low p24 concentration, the percentage of bead-containing wells in the array with a positive signal is proportional to the amount of p24 present in the sample. At higher p24 concentration, the total fluorescencesignal is proportional to the amount of p24 in the sample. The concentration of p24 is then interpolated from a standard curve (range 0-30 pg/mL). Time to firstresult is 69 minutes. The assay was evaluated for sensitivity, specificit, precision, recovery, linearity, and correlation to a NAT method across 24 early HIV infection serum samples (prior to seroconversion). Result(s): Limit of detection (2.5 SD) was 0.0025 pg/mL across 10 runs. This corresponds to ~60 RNA copies/mL equivalents by NAT. Limit of quantification(20% dose CV of diluted serum samples) was 0.0076 pg/mL across 11 runs and 58 determinations. Specificitywas 95.1% across 139 normal serum and plasma samples. Recovery of p24 spiked into normal serum averaged 84.1%. Linearity per CLSI EP6-A guideline averaged 102.2%. Precision per EP5-A guideline included three serum-based panels and two p24 controls assayed in replicates of three at two separate times per day for fivedays using a single calibration curve. ANOVA gave CV's <10% for all levels. Method comparison to NAT yielded 100% concordance with a R of 0.961. Samples ranged from 40 to 10 million RNA copies/mL as reported by NAT, most of which were non-reactive by 4th generation HIV combo immunoassay. Conclusion(s): The results show the digital Simoa p24 assay exhibited comparable sensitivity to NAT, as well as good general analytical properties. The assay represents a potential alternative to NAT for early detection of HIV infection.

Cadic, C., et al. (1992). "In vitro culture of hybridoma cells in agarose beads producing antibody secretion for two weeks." Biotechnology and Bioengineering **39**(1): 108-112.

A new process for embedding cells in agarose is described. Beads were obtained by extruding an ultralow gelling temperature agarose solution in a capillary containing a hydrophobic medium flowthrough. The toxicity of the procedure has been evaluated by monitoring the energy status of agarose-embedded C(6) glioma cells with (31)P nuclear magnetic resonance (NMR). Suspension and microbead cultures of hybridoma cell line were compared. In suspension culture

the number of cells and the antibody concentrations increased for 5 days before the stationary phase began, when the cultures were stopped. In agarose bead cultures, the gel provided an enormous support surface area (50 m(2)/ mL of gel). It was possible to seed 20-fold more cells. The gel pressure modified the proliferative process and antibody pattern secretion. In particular, the antibodies could be harvested for two weeks.

Cadic-Amadeuf, C., et al. (1993). "Modified antibody secretions by embedding hybridoma cell lines in agarose gels." Colloids and Surfaces B: Biointerfaces **1**(2): 91-96.

A new process for embedding cells in agarose is described. Beads were obtained by extruding an ultra-low gelling temperature agarose solution in a capillary containing a hydrophobic medium flowthrough. The toxicity of the procedure has been evaluated by monitoring the energy status of agarose embedded C sub(6) glioma cells with super(31)P NMR. Suspension and microbead cultures of hybridoma cell line were compared. In suspension culture the number of cells and the antibody concentrations increased for 5 days before the stationary phase began, when the cultures were stopped. In agarose bead cultures, the gel provided an enormous support surface area (50 m super(2) ml super(-1) of gel). It was possible to seed 20-fold more cells per unit volume. The gel pressure modified the proliferative process and antibody pattern secretion. In particular, the antibodies could be harvested for 2 weeks.

Caffier, D. and J. M. Expert (2001). "Soil-based plant pathogenic bacteria, a complex study. Their detection is difficult and uncertain." Phytoma **542**: 13-16.

The diagnosis of plant pathogenic bacteria living in soil is extremely difficult, owing to the fact that these bacteria are found in random quantities within an environment which is rich in a wide variety of other microorganisms. Traditional microbiological analysis (identification of bacteria colonies cultivated in Petri boxes) is possible in a few cases on semi-selective media (e.g. SMSA medium used in the detection of Ralstonia solanacearum). Another technique which is used is that of trapping plants (i.e. young sensitive plants planted out in a soil sample which is to be tested). This technique provides reliable results but is slow and not particularly sensitive. It should also be noted that trials are ongoing to extract bacteria from soil samples (in order to be subsequently able to use traditional bacteriological techniques such as immunofluoroscence, ELISA, PCR, etc.) For the moment however, nothing is yet ready to be put into practice. Elsewhere, magnetic capturing (using polymer microbeads) would seem to be promising, as would microarrays.

Cai, L., et al. (2019). "Influence of titanium dioxide nanoparticles on the transport and deposition of microplastics in quartz sand." Environmental Pollution **253**: 351-357.

The influence of titanium dioxide nanoparticles (nTiO₂) on the transport and deposition of polystyrene microplastics (MPs) in saturated quartz sand was investigated in NaCl solutions with ionic strengths from 0.1 to 10mMat two pH conditions (pH 5 and 7). Three different-sized polystyrene (PS) MPs (diameter of 0.2, 1, and 2mum) were concerned in present study. We found that for all three different-sized MPs in NaCl solutions (0.1, 1 and 10mM) at both pH 5 and 7, lower breakthrough curves and higher retained profiles of MPs with nTiO₂ copresent in suspensions relative to those without nTiO₂ were obtained, demonstrating that the copresence of nTiO₂ in MPs suspensions decreased MPs transport and increased their deposition in quartz sand under all examined conditions. The mechanisms contributing to the increased MPs deposition with nTiO₂ in suspensions at two pH conditions were different. The formation of MPs-nTiO₂ heteroaggregates and additional deposition sites provided by previously deposited nTiO₂ were found to drive to the increased MPs deposition with nTiO₂ in suspensions at pH 5, while the formation of MPs-nTiO₂ aggregates, additional deposition sites and increased surface roughness induced by the pre-deposited nTiO₂ on quartz sand surfaces were responsible for the enhanced MPs deposition at pH 7. The results give insights to predict the fate and transport of different-sized MPs in porous media in the copresence of engineered nanoparticles.

Cai, L., et al. (2018). "Effects of inorganic ions and natural organic matter on the aggregation of nanoplastics." Chemosphere **197**: 142-151.

The aggregation of nanoplastics (NPs) is a key issue in understanding the dynamic nature of NPs in the environment. The aggregation of NPs under various environmental conditions has not yet been studied. We investigated the influences of inorganic ions and natural organic matter (NOM) on polystyrene (PS) NPs aggregation in solutions.

Cai, L., et al. (2017). "Characteristic of microplastics in the atmospheric fallout from Dongguan city, China: preliminary research and first evidence." Environmental science and pollution research international **24**(32): 24928-24935.

Microplastic pollution has exhibited a global distribution, including seas, lakes, rivers, and terrestrial environment in recent years. However, little attention was paid on the atmospheric environment, though the fact that plastic debris can escape as wind-blown debris was previously reported. Thus, characteristics of microplastics in the atmospheric fallout from Dongguan city were preliminarily studied. Microplastics of three different polymers, i.e., PE, PP, and PS, were identified. Diverse shapes of microplastics including fiber, foam, fragment, and film were found, and fiber was the dominant shape of the microplastics. SEM images illustrated that adhering particles, grooves, pits, fractures, and flakes were the common patterns of degradation. The concentrations of non-fibrous microplastics and fibers ranged from 175 to 313 particles/m2/day in the atmospheric fallout. Thus, dust emission and deposition between atmosphere, land surface, and aquatic environment were associated with the transportation of microplastics.

Cai, L., et al. (2018). "Observation of the degradation of three types of plastic pellets exposed to UV irradiation in three different environments." Science of the Total Environment **628-629**: 740-747.

Plastic debris represents one of the most prevalent and persistent pollution problems in the marine environment. In particular, microplastics that are mainly degraded from larger plastic debris have become a growing environmental concern. However, studies on the degradation of plastics in the aquatic environment that hydrobios reside in have been limited, while several studies regarding the degradation of plastics have been conducted under outdoor or accelerated weathering conditions. Thus, observation of the degradation of three types of virgin plastic pellets exposed to UV irradiation in three different environments (i.e., simulated seawater, ultrapure water, and a waterless (air) condition) was carried out. Data on the changes in physical and chemical properties were collected. The FTIR spectra showed that hydroxyl groups and carbonyl groups developed in three types of weathered plastic pellets under the air and ultrapure water environmental conditions after 3months of UV irradiation, while only carbonyl groups were found in plastic pellets in the simulated seawater environment. In contrast, the Raman spectra showed no significant changes in the weathered plastic pellets, but there were different intensities of characteristic peaks after exposure to UV irradiation. In addition, SEM images illustrated that granular oxidation, cracks and flakes were common patterns during degradation, and the plastic pellets in the three different environments experienced different levels of chemical weathering. We suggest that further studies on the degradation processes of plastic debris are needed to predict the fate of plastic debris in the environment.

Cai, N., et al. (2019). "A new method for the preparation of iron and nitrogen co-doped carbon nanotubes from waste plastics pyrolysis for oxygen reduction reaction." ChemSusChem **28**: 28.

A novel method to prepare iron and nitrogen co-doped carbon nanotubes (Fe-N-CNT) is proposed, based on catalytic pyrolysis of waste plastics. At first carbon nanotubes are produced from pyrolysis of plastic waste over $Fe-Al_2O_3$; then Fe-CNT and melamine are heated together in inert atmosphere. Different co-pyroysis temperatures are tested to optimize the electrocatalyst production. Working at a high doping temperature improved the degree of graphite formation and promoted the conversion of nitrogen to a more stable form. Compared with commercial platinum on carbon, the electrocatalyst obtained from pyrolysis at 850 degreeC, showed remarkable properties, with onset potential of 0.943 V vs RHE and half-wave potential of 0.811 V vs RHE and even better stability and anti-poisoning. In addition, zinc-air batteries tests were also carried out and the optimized catalyst exhibited high maximum power density.

Calderon, E. A., et al. (2019). "Microplastics in the Digestive Tracts of Four Fish Species from the Cienaga Grande de Santa Marta Estuary in Colombia." Water, Air, and Soil Pollution **230 (11) (no pagination)**(257).

This study investigated the presence of microplastics (MPs) in the gastrointestinal tracts of four fish species from the estuarine Cienaga Grande de Santa Marta (CGSM) in northern Colombia. Of the 140 fish purchased at a local market, 17 (12.1%) were found to contain MPs as confirmed by FT-IR analysis. Among the four different species, Mugil incilis (mullet) showed the highest MP prevalence with just over a fifth of the individuals containing MPs in their gastrointestinal tracts (10 out of 46 (frequency of MP occurrence in %) FO% = 21.7%). This was followed by Caranx hippos (crevalle jack, 2 out of 19 (FO% = 10.5%)), Caquetaia kraussii (yellow mojarra, 3 out of 35 (FO% = 8.6%)), and Eugerres plumieri (striped mojarra, 2 out of 40 (FO% = 5.0%)). From the 17 fish, only 19 MPs were found of which 17 (89.5% were fibers) and 2 (10.5%) were fragments. While polyester and polyethylene were the most common fibers, nylon, acrylic, polyethylene, and modacrylic were also identified suggesting a wide variety of origins and sources. These finding provide the first evidence of MP ingestion by resident fish species in Colombian estuarine waters. Since the region has been variously recognized as being of regional and international importance (i.e., RAMSAR site in 1998 and UNESCO Biosphere Reserve in 2000), we advocate the ongoing investigation of MP pollution in both the environment and biota. Caldwell, J., et al. (2019). "Assessing meso- and microplastic pollution in the Ligurian and Tyrrhenian Seas." Marine Pollution Bulletin **149 (no pagination)**(110572).

As the production of plastic products continues to increase, determining the fate of plastic waste in the environment is of high importance. Densely populated areas, such as Mediterranean coastlines, represent locations of high pollution risk for surrounding environments. Thus, this study aims to assess the abundance, size, and composition of floating meso- and microplastics collected during four weeks in 2018 in the Ligurian and Tyrrhenian Seas. The results show average meso- and microplastic particle concentrations of 28,376 +/- 28,917 particles km⁻ ², and an average mass of 268.61 +/- 421.18 g km⁻ ². The particle shape ratio was 65% fragments, 19% films, 10% lines, 4% foams, and 2% pellets. Microplastic particles comprised 65% of the sample. Analysis with attenuated total reflection Fourier transform infrared spectroscopy showed predominant polymer types included polyethylene, polypropylene, polystyrene, and polyamide. These data are an important starting point for long-term monitoring of plastic pollution levels within this region. Copyright © 2019 Elsevier Ltd

Calero, C., et al. (2014). "Differential expression of C-reactive protein and serum amyloid A in different cell types in the lung tissue of chronic obstructive pulmonary disease patients." BMC Pulmonary Medicine **14**: 95.

BACKGROUND: Chronic systemic inflammatory syndrome has been implicated in the pathobiology of extrapulmonary manifestations of chronic obstructive pulmonary disease (COPD). We aimed to investigate which cell types within lung tissue are responsible for expressing major acute-phase reactants in COPD patients and disease-free ("resistant") smokers.

METHODS: An observational case-control study was performed to investigate three different cell types in surgical lung samples of COPD patients and resistant smokers via expression of the C-reactive protein (CRP) and serum amyloid A (SAA1, SAA2 and SAA4) genes. Epithelial cells, macrophages and fibroblasts from the lung parenchyma were separated by magnetic microbeads (CD326, CD14 and anti-fibroblast), and gene expression was evaluated by RT-PCR.

RESULTS: The sample consisted of 74 subjects, including 40 COPD patients and 34 smokers without disease. All three cell types were capable of synthesizing these biomarkers to some extent. In fibroblasts, gene expression analysis of the studied biomarkers demonstrated increased SAA2 and decreased SAA1 in patients with COPD. In epithelial cells, there was a marked increase in CRP, which was not observed in fibroblasts or macrophages. In macrophages, however, gene expression of these markers was decreased in COPD patients compared to controls.

CONCLUSIONS: These results provide novel information regarding the gene expression of CRP and SAA in different cell types in the lung parenchyma. This study revealed differences in the expression of these markers according to cell type and disease status and contributes to the identification of cell types that are responsible for the secretion of these molecules.

Calero, C., et al. (2012). "Differences in cellular expression of Creactive protein and serum amyloid A in lung tissue in patients with chronic obstructive pulmonary disease." European Respiratory Journal. Conference: European Respiratory Society Annual Congress **40**(SUPPL. 56).

Introduction and Objectives: The lung bronchial and parenchyma tissues are a potential source of acute phase reactants in Chronic Obstructive Pulmonary Disease (COPD) patients as compared with resistant smokers. The aim of this study was to determinate the expression of C-Reactive Protein (CRP) and Serum Amyloid A (SAA) in epithelial cells, macrophages and lung fibroblasts between COPD and resistant smokers. This expression was also studied according to the different grades of COPD. Method.This report is based on a cross sectional analysis of a case-control study. These patients included were consecutively recruited, in elective lung surgery.Epithelial cells, macrophages and fibroblasts were obtained by magnetic separation microbeadsand CRP and SAA1, 2 and 4 expression was analysed by real time PCR. Results. The sample was formed by 19 COPD and 27 resistant smokers. Although all cell types were able to synthesize the biomarkers, fibroblasts of COPD patients had a significantly higher expression (5 folds, p=0,015) of SAA1 than resistant smokers. Our results also showed significant differences in the expression of SAA between macrophages from COPD in different stage of the disease, being higher in patients in GOLD II (25 folds higher for SAA1, p=0,021; 9 folds for SAA2, p=0,05 and 30 for SAA4, p=0,014). Conclusions.There are differences in the synthesis of SAA-1 in fibroblasts of COPD and controls. The pattern of expression in macrophages is different for SAA according to stage of disease.These findings could be useful to elucidate the contribution of each cellular compartment in the inflammatory component of the disease.

Camacho, M., et al. (2019). "Organic pollutants in marine plastic debris from Canary Islands beaches." Science of the Total Environment **662**: 22-31.

Given their capacity to adsorb chemical pollutants, microplastics represent a growing environmental concern in the oceans. The levels of 81 chemical compounds in two types of beached microplastic (pellets and fragments) were monitored across the Canary Islands (Spain). The highest concentrations were found for polycyclic aromatic hydrocarbons (PAH) (52.1-17,023.6ng/g and 35.1-8725.8ng/g for pooled pellets and fragments, respectively). The polychlorinated biphenyl (PCB) concentrations were 0.9-2285.8 and 1.6-772.5ng/g for pooled pellets and fragments, respectively, whereas organochlorine pesticides (OCP) ranged from 0.4-13,488.7 and 0.4-3778.8ng/g, respectively. The sum of polychlorinated biphenyls and diphenyl-dichloro-ethane (DDT) metabolites was significantly higher in beaches on Gran Canaria, which is the most populated and industrialized island. The sum of ultraviolet filters (UV-filters) was higher in those beaches more frequented by tourists (Famara and Las Canteras), than in occasionally or very rarely visited beaches (Cuervitos and Lambra), with values ranging from 0 to 37,740.3ng/g and 3.7-2169.3ng/g for pellets and fragments, respectively. Furthermore, the sum of brominated diphenyl ethers (BDE) (0-180.58ng/g for pooled pellets and 0.06-3923.9ng/g for pooled fragments) and organophosphorus flame retardants (OPFR) (20.0-378.0ng/g for pooled pellets, and 22.6-7013.9ng/g for pooled fragments) was significantly higher in an urban beach (Las Canteras) than in the rest of the studied beaches. Finally, the concentrations of the pesticide chlorpyrifos were much higher on Gran Canaria beaches than in the rest. In this research we provide further evidence of the important role of plastic debris in the adsorption of a wide range of marine pollutants. The regional pattern of chemical contamination of plastics reveals that the sorption of many compounds probably occurs in coastal waters. Further investigation is necessary to understand the relationship between plastic types and adsorption of different pollutants, especially for emerging pollutants.

Camins, E., et al. (2020). "Paddle surfing for science on microplastic pollution." Science of the Total Environment **709 (no pagination)**(136178).

Microplastics have pervaded all oceans on Earth and their impact on marine ecosystems is a matter of debate. However, there is a lack of information from a few meters from the coastline even though monitoring the nearshore is absolutely needed to fully understand the paths and magnitude of microplastic pollution, including its implications for coastal management and water quality. Traditional scientific data acquisition using conventional platforms such as research vessels or small boats is expensive and hampered by numerous limitations in the nearshore zone, ranging from too shallow (and risky) depths to the presence of swimmers. Here, we provide the scientific community with an affordable and easy to use manta trawl called paddle trawl to be attached to a paddle surf board to acquire scientific samples in the nearshore within the frame of a citizen science monitoring project with the Spanish delegation of the non-governmental organization Surfrider Foundation Europe. Our results show, as a proof of concept, that a lightweight and low-cost paddle trawl towed behind paddle surfers allows obtaining samples for microplastic characterization and quantification while raising awareness of pollution by the allochtonous particles. An average of 11.7 x 10⁴ items km⁻ ² was found in the nearshore, similar to those found offshore in the Mediterranean Sea. However, a comparison with offshore data obtained with a standard manta trawl shows differences in plastic size distributions. Whereas microplastics dominated in offshore waters mesoplastics and macroplastics prevailed in the nearshore. A larger variety of polymers, including high-density ones and higher average lengths nearshore shows that this area is likely to produce and export microplastics towards offshore waters. Campbell, P. E., et al. (2000). "Coal and plastic waste in a PF boiler." Energy Policy **28**(4): 223.

Plastics wastes from a municipal solid waste (MSW) plant have a high-energy content and are suitable for co-processing with coal. The addition of 5% plastic waste to a coal-fired PF power station reduces its efficiency slightly from 44.0 to 43.7% due to the high moisture content of the plastics. The overall economics however can be favourable. For the cost of electricity to be the same as the coal only case, the plastic waste could have a value of up to 23 €/dry tonne to the power station, assuming that it had been prepared for use. Therefore the maximum amount that the power station can afford to spend on preparing the plastic waste for use is 23 €/dry tonne plus the avoided landfill cost, less the transport cost. The location of the power station plays a key role, since this does not only have an effect on the transport costs of the waste but also on the landfill charges. The sensitivity of the economics of co-processing plastic waste with coal for a variety of power station operational parameters is presented. [ABSTRACT FROM AUTHOR]

Campillo, J. A., et al. (2015). "Mica variability in patients with cutaneous malignant melanoma." Tissue Antigens **85 (5)**: 392.

A limited number of studies have been performed so far on the polymorphism in the transmembrane region (exon 5) of the major histocompatibility complex class I chain-related gene A (MICA) in patients with melanoma. However, the influence of MICA polymorphism in extracellular domains (exons 2, 3 and 4) has not been investigated on melanoma disease. This study aims to characterize the influence of extracellular MICA polymorphism, and its previously described linkage disequilibrium with HLA-B locus, on patients with cutaneous melanoma from southeastern Spain. MICA and HLA-B genotyping was performed in 233 melanoma patients and 200 ethnically matched controls by microbeads array luminex technology. Patients were classified according to the presence of methionine or valine at codon 129 of MICA gene. We found a high frequency ofMICA*009 in melanoma patients compared with controls (P=0.002, Pc=0.03). Additionally, our results also showed an association between MICA*009 and HLA-B*51 alleles both in patients and controls. This association was stronger in patients than in the control group (P=0.015). However, a multivariate logistic regression model showed that neither MICA*009, nor the combination MICA*009/HLA-B*51 were associated with melanoma susceptibility. No relationship was observed between MICA-129 dimorphism and melanoma susceptibility. The study of MICA polymorphism in the extracellular domains shows a lack of association between MICA gene and cutaneous malignant melanoma in our population.

Campisano, S., et al. (2013). "Anti-melanoma vaccinal capacity of CD11c-positive and -negative cell populations present in GM-CSF cultures derived from murine bone marrow precursors." Vaccine **31**(2): 354-361.

We have initially shown that DC/ApoNec vaccine can induce protection against the poorly immunogenic B16F1 melanoma in mice. The population of DC obtained for vaccination after 7 days culture with murine GM-CSF is heterogeneous and presents about 60% of CD11c+DC. Therefore, our purpose was to identify the phenotype of the cells obtained after differentiation and its immunogenicity once injected. DC were separated with anti-CD11c microbeads and the two populations identified in terms of CD11c positivity (DC+ and DC-) were also studied. Approximately 26.6% of the cells in DC+ fraction co-expressed CD11c+ and F4/80 markers and 75.4% were double positive for CD11c and CD11b markers. DC+ fraction also expressed Ly6G. DC- fraction was richer in CD11c-/F4/80+ macrophages (44.7%), some of which co-expressed Ly6G (41.8%), and F4/80-/Ly6-G+ neutrophils (34.6%). Both DC+ and DC- fractions displayed similar capacity to phagocyte and endocyte antigens and even expressed levels of MHC Class II and CD80, CD83 and CD86 costimulatory molecules similar to those in the DC fraction. However, only DC/ApoNec vaccine was capable to induce protection in mice (p<0.01). After 24 h co-culture, no detectable level of IL-12 was recorded in DC/ApoNec vaccine, either in supernatant or intracellularly. Therefore, the protection obtained with DC/ApoNec vaccine seemed to be independent of the vaccine's ability to secrete this inflammatory cytokine at the time of injection. In conclusion, we demonstrated that all cell types derived from the culture of mouse bone marrow with GM-CSF are necessary to induce antitumor protection in vivo.

Can, H. K. and A. Gner (2012). "Experimental approaches to adsorption-desorption dynamism of human serum albumin (HSA) onto crosslinked N,N-diethylaminoethyl (DEAE) dextran microbeads." Journal of Macromolecular Science, Part A: Pure and Applied Chemistry **49**(11): 986-996.

Crosslinked N,N-Diethylaminoethyl (DEAE) groups containing dextran microbeads have been used in human serum albumin (HSA) adsorption-desorption studies. For the HSA adsorption onto positively charged hydrophilic DEAE dextran microbeads, the adsorption kinetic was slightly decreased by the changing concentration of the protein solution. Adsorption kinetics and equilibrium isotherms for the adsorption of HSA on crosslinked DEAE dextran have been determined experimentally. Modeling of the adsorption processes on DEAE dextran microbeads were realized by applying different adsorption isotherms. Among the several isotherm equations, Langmuir and Freundlich adsorption isotherms were investigated depending on the two temperatures. These were only slightly dependent on the initial concentration of HSA but were considerably affected by the pH of the medium. The HSA adsorption capacity factor and the adsorption equilibrium constant were obtained and mathematical modeling of adsorption, adsorption rate constants and maximum adsorption were determined. Besides the adsorption mechanism, optimum ionic strength and optimum pH also were investigated. Desorption studies and desorption ratio of the system were determined for optimum medium conditions. It was been proved both experimentally and theoretically that human HSA is adsorbed by electrostatic attraction, ion-exchange, hydrophobic interaction and/or hydrogen bonding. Copyright © Taylor and Francis Group, LLC.

Can, H. K. and A. Guener (2006). "Investigation of adsorption-desorption dynamism of bovine serum albumin on crosslinked N,N[prime]-diethylaminoethyl dextran microbeads: Solution phase." Journal of Applied Polymer Science **99**(5): 2288-2299.

New hydrogel microspheres based on crosslinked dextran containing N,N[prime]-diethylaminoethyl (DEAE) groups with different chemical structures have been used in adsorption-desorption studies. Bovine serum albumin (BSA) is frequently used in biophysical and biochemical studies. BSA has a well- known primary structure that has been associated with binding of many different categories of small molecules. Both adsorption kinetics and equilibrium isotherms for the adsorption of BSA on crosslinked DEAE dextran have been determined experimentally. These were only slightly dependent on the initial concentration of BSA but were considerably affected by the pH of the medium. The results fitted the Freundlich-Langmuir isotherm model for pH 6.9. The adsorption capacity factor and the adsorption equilibrium constant were obtained and mathematical modeling of adsorption, adsorption rate constants, and maximum adsorption were determined. Swelling kinetics of crosslinked DEAE dextran and optimum ionic strength, pH, and mass of hydrogel were also investigated. Desorption studies were finally determined under optimum medium conditions. J Appl Polym Sci, 2006

Can, H. K. and A. Güner (2006). "A thermodynamic study of the binding of human serum albumin onto N,N′-diethylaminoethyl dextran microbeads." Journal of Applied Polymer Science **101**(6): 3942-3947.

Adsorption of proteins on solid surfaces is widely studied because of its importance in various biotechnological, medical, and technical applications, e.g., biosensors, cardiovascular implants, and chromatography. Adsorption thermodynamics has been studied on the microbeads of N,N′-diethylaminoethyl (DEAE) Dextran anion exchanger for the human serum albumin (HSA) at 25, 30, 35, 40, and 45°C. As a result, some thermodynamic parameters like Freundlich constants, thermodynamic equilibrium constant (K D), standard free energy changes (ΔGassoc), standard entropy changes (ΔSassoc), and standard enthalpy change (ΔHassoc) have been evaluated. Using the linear Van't Hoff plot, ΔHassoc value of the system for the interaction of bovine serum albumin (BSA)-adsorbed crosslinked DEAE dextran microbeads was determined as 20,650 kJ/mol. © 2006 Wiley Periodicals, Inc.

Candido, V., et al. (2006). "Mulching studies in greenhouse by using eco-compatible plastic films on fresh tomato crop." Acta Horticulturae **710**: 415-420.

A high employment of plastics in agriculture causes the production of enormous quantities of waste, whose inappropriate management might have negative effects on the whole agro-ecosystem. To reduce the amount of plastic waste and to facilitate its disposal, one of the most interesting approaches, from an environmental point of view, lies in the use of innovative materials for crop mulching such as co-extrused ultrathin films which are able to reduce the plastic quantity to be managed; and biodegradable laminates, which after the first use, will spontaneously start to degrade. This paper reports the results of a research carried out from March to July of 2002 in southern Italy on mulching of tomato (Lycopersicon esculentum cv. Tomito F₁) using 2 co-extrused ultrathin plastic, 2 biodegradable plastics and a traditional film (LDPE). Coextrused films have spectroradio-metrics and mechanical characteristics able to ensure an anti-weed barrier, thus allowing a good thermal level in the soil. They also gave better yield results than black LDPE. Besides, biodegradable films exhibited an agronomic behaviour equal to LDPE and their degradation times were compatible with the protected tomato crop cycle.

Canesi, L., et al. (2015). "Evidence for immunomodulation and apoptotic processes induced by cationic polystyrene nanoparticles in the hemocytes of the marine bivalve Mytilus." Marine Environmental Research **111**: 34-40.

Polymeric nanoparticles can reach the marine environment from different sources as weathering of plastic debris and nanowaste. Nevertheless, few data are available on their fate and impact on marine biota. Polystyrene nanoparticles (PS NPs) can be considered as a model for studying the effects of nanoplastics in marine organisms: recent data on amino-modified PS NPs (PS-NH₂) toxicity in sea urchin embryos underlined that marine invertebrates can be biological targets of nanoplastics. Cationic PS NPs have been shown to be toxic to mammalian cells, where they can induce apoptotic processes; however, no information is available on their effects and mechanisms of action in the cells of marine organisms. In this work, the effects of 50 nm PS-NH₂ were investigated in the hemocytes of the marine bivalve Mytilus galloprovincialis. Hemocytes were exposed to different concentrations (1, 5, 50 micro g/ml) of PS-NH₂ suspension in ASW. Clear signs of cytoxicity were evident only at the highest concentrations (50 micro g/ml). On the other hand, a dose dependent decrease in phagocytic activity and increase in lysozyme activity were observed. PS-NH₂ NPs also stimulated increase in extracellular ROS (reactive oxygen species) and NO (nitric oxide) production, with maximal effects at lower concentrations. Moreover, at the highest concentration tested, PS-NH₂ NPs induced apoptotic process, as evaluated by Flow cytometry (Annexin V binding and mitochondrial parameters). The results demonstrate that in marine invertebrates the immune function can represent a significant target for PS-NPs. Moreover, in Mytilus hemocytes, PS-NH₂ NPs can act through mechanisms similar to those observed in mammalian cells. Further research is necessary on specific mechanisms of toxicity and cellular uptake of nanoplastics in order to assess their impact on marine biota.

Canesi, L., et al. (2016). "Interactions of cationic polystyrene nanoparticles with marine bivalve hemocytes in a physiological environment: Role of soluble hemolymph proteins." Environmental Research **150**: 73-81.

The bivalve Mytilus galloprovincialis has proven as a suitable model invertebrate for evaluating the potential impact of nanoparticles (NPs) in the marine environment. In particular, in mussels, the immune system represents a sensitive target for different types of NPs. In environmental

conditions, both NP intrinsic properties and those of the receiving medium will affect particle behavior and consequent bioavailability/uptake/toxicity. However, the evaluation of the biological effects of NPs requires additional understanding of how, once within the organism, NPs interact at the molecular level with cells in a physiological environment. In mammalian systems, different NPs associate with serum soluble components, organized into a “protein corona”, which affects particle interactions with target cells. However, no information is available so far on the interactions of NPs with biological fluids of aquatic organisms. In this work, the influence of hemolymph serum (HS) on the in vitro effects of amino modified polystyrene NPs (PS-NH 2) on Mytilus hemocytes was investigated. Hemocytes were incubated with PS-NH 2 suspensions in HS (1, 5 and 50 µg/mL) and the results were compared with those obtained in ASW medium. Cell functional parameters (lysosomal membrane stability, oxyradical production, phagocytosis) were evaluated, and morphological changes were investigated by TEM. The activation state of the signalling components involved in Mytilus immune response (p38 MAPK and PKC) was determined. The results show that in the presence of HS, PS-NH 2 increased cellular damage and ROS production with respect to ASW medium. The effects were apparently mediated by disregulation of p38 MAPK signalling. The formation of a PS-NH 2 -protein corona in HS was investigated by centrifugation, and 1D- gel electrophoresis and nano-HPLC-ESI-MS/MS. The results identified the Putative C1q domain containing protein (MgC1q6) as the only component of the PS-NH 2 hard protein corona in Mytilus hemolymph. These data represent the first evidence for the formation of a NP bio-corona in aquatic organisms and underline the importance of the recognizable biological identity of NPs in physiological exposure medium when testing their potential impact environmental model organisms. Although the results obtained in vitro do not entirely reflect a realistic exposure scenario and the more complex formation of a bio-corona that is likely to occur in vivo , these data will contribute to a better understanding of the effects of NPs in marine invertebrates. [ABSTRACT FROM AUTHOR]

Canniff, P. M. and T. C. Hoang (2018). "Microplastic ingestion by Daphnia magna and its enhancement on algal growth." Science of the Total Environment **633**: 500-507.

The rapid increase in plastic use over the last few decades has resulted in plastic pollution in freshwater and marine ecosystems. However, more attention has been paid to plastic pollution in marine ecosystems than to freshwater ecosystems. This research determined microplastic ingestion by Daphnia magna and the potential effect of microplastics on the organism's survival and reproduction. The study also examined the potential of microplastics to enhance algal growth in support of understanding effects of microplastic ingestion on the organism. When exposed to 25, 50, and 100 mg/L fluorescent green polyethylene microbeads at size of 63-75 micro m, D. magna ingested significant amount of plastic microbeads. The number of ingested beads increased with increasing particle concentration and exposure time. However, no significant effect on survival and reproduction was observed although the gut of D. magna was filled with plastic microbeads. In the algal experiment, Raphidocelis subcapitata grew more in the exposure media with the present of plastic microbeads than without plastic microbeads. This result suggests that plastic microbeads could serve as substrates for R. subcapitata to grow.

Raphidocelis subcapitata then could be transferred to the organism's gut and provided energy for survival and reproduction. Results of the present study add to the literature of microplastic ingestion by aquatic organisms. Caution should be taken when interpreting hazards of microplastics based on ingestion, such as the measurement unit and the presence of algae in the environment.

Cannon, S. M. E., et al. (2016). "Plastic ingestion by fish in the Southern Hemisphere: a baseline study and review of methods." Marine Pollution Bulletin **107**(1): 286-291.

Plastic ingestion is well documented among marine birds and sea turtles but fewer studies have investigated ingestion in fish, particularly in the Southern Hemisphere. We investigated the frequency of plastic ingestion in 21 species of fish and one species of cephalopod. The overall occurrence of plastic ingestion was 0.3%. Two micro-plastic items were recovered from the gastrointestinal tract of a single Antarctic toothfish (Dissostichus mawsoni). Ingestion rates were similar to other studies of fish conducted in both the Northern and Southern Hemispheres, however comparisons across species and locations are challenging due to the lack of consistency in the identification and classification of plastic debris. In response, we propose a standardised sampling protocol based on the available literature to provide a stronger basis for comparisons among existing and future studies of plastic ingestion in fish.

Canopoli, L., et al. (2020). "Degradation of excavated polyethylene and polypropylene waste from landfill." Science of the Total Environment **698 (no pagination)**(134125).

In 2016, it was estimated that 7.4 million tonnes of plastic waste have been disposed in landfill in Europe. This waste represents an important opportunity for resource recovery through enhanced landfill mining consistent with recent Circular Economy initiatives. However, a recent review found a lack of data describing the degradation of excavated plastic waste and the potential impact on recycling products such as pyrolysis oil. In this study, the physicochemical characteristics of the main plastic types found in landfills and their implications for recovery and recycling were investigated using a combination of scanning electron microscopy energy dispersive spectroscopy (SEM-EDS), attenuated total reflectance Fourier transform infrared spectroscopy (FTIR) and differential scanning calorimetry (DSC). Loss of gloss was visually detected for the buried plastic waste samples (polyethylene (PE) and polypropylene (PP)) compared to fresh plastic samples. The SEM-EDS analysis further showed that oxygen was the main element related to the plastic surface alteration. The carbonyl index (CI) of plastic samples buried for >10 years was between 1.5 and 2 times higher than <10 years and fresh materials. Similarly, the degree crystallinity of the old samples (>10 years) was 2 times higher than the fresh and < 10 years samples. Based on these findings, tertiary recycling, such as pyrolysis, seems to be a convenient route for upcycling of recovered plastics from municipal solid waste landfills. Copyright © 2019

Canopoli, L., et al. (2018). "Physico-chemical properties of excavated plastic from landfill mining and current recycling routes." Waste Management **76**: 55-67.

In Europe over 5.25 billion tonnes of waste has been landfilled between 1995 and 2015. Among this large amount of waste, plastic represents typically 5-25wt% which is significant and has the potential to be recycled and reintroduced into the circular economy. To date there is still however little information available of the opportunities and challenges in recovering plastics from landfill sites. In this review, the impacts of landfill chemistry on the degradation and/or contamination of excavated plastic waste are analysed. The feasibility of using excavated plastic waste as feedstock for upcycling to valuable chemicals or liquid fuels through thermochemical

conversion is also critically discussed. The limited degradation that is experienced by many plastics in landfills (>20years) which guarantee that large amount is still available is largely due to thermooxidative degradation and the anaerobic conditions. However, excavated plastic waste cannot be conventionally recycled due to high level of ash, impurities and heavy metals. Recent studies demonstrated that pyrolysis offers a cost effective alternative option to conventional recycling. The produced pyrolysis oil is expected to have similar characteristics to petroleum diesel oil. The production of valuable product from excavated plastic waste will also increase the feasibility of enhanced landfill mining projects. However, further studies are needed to investigate the uncertainties about the contamination level and degradation of excavated plastic waste and address their viability for being processed through pyrolysis.

Cao, L., et al. (2007). "Purification and characterization of alginate lyase from streptomyces species strain A5 isolated from banana rhizosphere." Journal of Agricultural & Food Chemistry **55**(13): 5113-5117.

To characterize the alginate lyase produced by rhizosphere Streptomyces, Streptomyces sp. A5 was isolated from banana rhizosphere, and its extracellular lyase was purified to an electrophoretically homogeneous state. The lyase has a molecular mass of 32 kDa by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). The optimum temperature and pH were 37 degrees C and pH 7.5, respectively. Ninety-two percent of the activity was lost after incubation at 70 degrees C and pH 7.5 for 20 min. The enzyme was inhibited by 0.05 M SDS and 2 mM Hg2+, Cu2+, and Fe3+, but EDTA enhanced the enzyme activity. The Km value of the lyase was 0.13 mg mL-1 with the substrate sodium alginate. The lyase had substrate specificity for polyguluronate units in the alginate molecules. The alginate oligomers prepared by the lyase show growth-promoting activity on the roots of banana plantlets. These results indicated that the encapsulation method using alginate microbeads to inoculate beneficial streptomycete strains might be beneficial to the root growth of banana plantlets.

Cao, L. Y., et al. (2009). "Hand/face/neck localized pattern: sticky problems--resins." Dermatologic Clinics **27**(3): 227-249, v.

Plastic resin systems have an increasingly diverse array of applications but also induce health hazards, the most common of which are allergic and irritant contact dermatitis. Contact urticaria, pigmentary changes, and photoallergic contact dermatitis may occasionally occur. Other health effects, especially respiratory and neurologic signs and symptoms, have also been reported. These resin systems include epoxies, the most frequent synthetic resin systems to cause contact dermatitis, (meth)acrylics, polyurethanes, phenol-formaldehydes, polyesters, amino resins (melamine-formaldehydes, urea-formaldehydes), polyvinyls, polystyrenes, polyolefins, polyamides and polycarbonates. Contact dermatitis usually occurs as a result of exposure to the monomers and additives in the occupational setting, although reports from consumers, using the raw materials or end products periodically surface. Resin- and additive-induced direct contact dermatitis usually presents on the hands, fingers, and forearms, while facial, eyelid, and neck involvement may occur through indirect contact, eg, via the hands, or from airborne exposure. Patch testing with commercially available materials, and in some cases the patient's own resins, is important for diagnosis. Industrial hygiene prevention techniques are essential to reduce contact dermatitis when handling these resin systems. [References: 184]

Cao, M., et al. (2011). "Different radiosensitivity of CD4(+)CD25(+) regulatory T cells and effector T cells to low dose gamma irradiation in vitro." International Journal of Radiation Biology **87**(1): 71-80.

PURPOSE: To determine the radiosensitivity difference of human Cluster of Differentiation (CD)4(+)CD25(+) regulatory T cells (Treg) and effector T cells to low dose gamma ray and elucidate the underlying mechanisms in vitro.

MATERIALS AND METHODS: Blood samples were collected from five health subjects and five patients with advanced hepatocellular carcinoma (HCC). Treg and CD4(+)CD25- T cells were selected using magnetic microbeads. The proliferative profiles, cytokine secretion, and differential expressions of apoptosis-related proteins in Treg and CD4(+)CD25- T cells were compared using [3H]-thymidine incorporation, Luminex assay and flow cytometry when treated with various low doses of gamma-ray.

RESULTS: A dose-dependent reduction of proliferation in response to irradiation which paralleled the induction of apoptosis existed in Treg and CD4(+)CD25- T cells. Treg were more radiosensitive to low-dose irradiation (0.94 Gray [Gy]) than effector T cells. The interferon-gamma (IFNgamma) was significantly upregulated and interleukin 10 (IL-10) was significantly downregulated in irradiated Treg. An enhanced immune response to low dose gamma ray existed in the peripheral blood in patients with advanced HCC. Higher levels of active caspase-3, CD95, B cell lymphoma 2 (Bcl-2)-associated X protein (Bax) expression were observed in Treg compared to CD4(+)CD25- T cells. In addition, gamma irradiation activated CD4(+)CD25- T cells to express CD25.

CONCLUSIONS: These studies revealed that Treg were more radiosensitive than CD4(+)CD25- T cells to low dose irradiation. Higher expressions of apoptosis-related proteins such as caspase-3, CD95 and Bax were observed in Treg when compared to CD4(+)CD25- T cells. Our results suggest that treatment with low doses of gamma irradiation may be a viable strategy to enhance immune response in patients with advanced HCC.

Capillo, G., et al. (2020). "Quali-quantitative analysis of plastics and synthetic microfibers found in demersal species from Southern Tyrrhenian Sea (Central Mediterranean)." Marine Pollution Bulletin **150**: 110596.

This study highlights plastics occurrence in five demersal fish species from the Southern Tyrrhenian Sea: the Red mullet Mullus barbatus barbatus, the Piper gurnard Trigla lyra, the Blackmouth catshark Galeus melastomus, the Lesser spotted dogfish Scyliorhinus canicula and the Brown ray Raja miraletus. Overall, 125 fish were examined: 21 Red mullets, 16 Piper gurnards, 75 Blackmouth catsharks, 72 Dogfish and 1 Brown ray. The percentage of fish with ingested plastics was 14.4% with 0.24 items per specimen. The majority of the debris were fibers and the application of infrared and Raman spectroscopy allowed the identification and discrimination of plastic and non-plastic fibers. The plastic debris isolated were mainly microplastics (94.1%), while macroplastics occurrence was very low (5.9%). The plastics were identified as polypropylene, Teflon, nylon, kraton G (triblock copolymer) and polyethylene. Also cellulose was detected. S. canicula was the species with the highest number of plastic pollutants.

Capolupo, M., et al. (2018). "Uptake and transcriptional effects of polystyrene microplastics in larval stages of the Mediterranean mussel Mytilus galloprovincialis." Environmental Pollution **241**: 1038-1047.

The widespread occurrence of microplastics (MP) in the marine environment is cause of increasing concerns about the safety of the exposed ecosystems. Although the effects associated to the MP uptake have been studied in most marine taxa, the knowledge about their sub-lethal impacts on early life stages of marine species is still limited. Here, we investigated the uptake/retention of 3- micro m polystyrene MP by early stages of the Mediterranean mussel Mytilus galloprovincialis, and the related effects on gut clearance, feeding efficiency, morphological and transcriptional parameters involved in embryo-larval development. Uptake measurements were performed on larvae at 48 h, 3, 6 and 9 days post fertilization (pf) after

exposure to a range of 50-10,000 particles mL⁻¹. At all tested pf periods, treatments resulted in a significant and linear increase of MP uptake with increasing concentrations, though levels measured at 48 h pf were significantly lower compared to 3-9 d pf. Ingested MP were retained up to 192 h in larvae's gut, suggesting a physical impact on digestive functions. No change was noted between the consumption of microalgae Nannochloropsis oculata by larvae when administered alone or in the presence of an identical concentration (2000 items mL⁻¹) of MP. The exposure to 50-10,000 MP mL⁻¹ did not alter the morphological development of mussel embryos; however, transcriptional alterations were observed at 50 and 500 MP mL⁻¹, including the up-regulation of genes involved in shell biogenesis (extrapallial protein; carbonic anhydrase; chitin synthase) and immunomodulation (myticin C; mytilin B), and the inhibition of those coding for lysosomal enzymes (hexosaminidase; beta -glucorinidase; catepsin-L). In conclusion, though not highlighting morphological or feeding abnormalities, data from this study revealed the onset of physical and transcriptional impairments induced by MP in mussel larvae, indicating sub-lethal impacts which could increase their vulnerability toward further environmental stressors.

Capozzi, F., et al. (2018). "Evidence on the effectiveness of mosses for biomonitoring of microplastics in fresh water environment." Chemosphere **205**: 1-7.

Mosses are well known as biomonitors of fresh water for metal pollutants, but no studies were reported so far about their ability to intercept plastic particles, although this kind of pollution has become an urgent issue worldwide. In the present work, the interaction between the moss Sphagnum palustre L. cultured in vitro and polystyrene nanoparticles (NPs) was studied for the first time in a laboratory experiment, in the view of using moss transplants for detecting microplastics in fresh water environments. The ability of S. palustre to intercept and retain polystyrene, and the effects of vitality and post-exposure washing on NP retention by moss were tested. Fluorescence microscope observations showed that polystyrene NPs were retained by moss leaves in form of small (the most abundant fraction) and large aggregates. Particle count analysis highlighted that the number of particles increased while increasing the exposure time. Moreover, moss devitalization favored NP accumulation, likely because of cell membrane damages occurred in dead moss material. Post-exposure washing induced a loss of larger aggregates, suggesting that exposure time is a key point to be carefully evaluated in field conditions. These results encourage the use of S. palustre transplants for monitoring microplastics contamination of fresh water environments.

Captur, G., et al. (2016). "A T1 and ECV phantom for global T1 mapping quality assurance: The T1 mapping and ECV standardisation in CMR (T1MES) program." Journal of Cardiovascular Magnetic Resonance. Conference: 19th Annual SCMR Scientific Sessions. Los Angeles, CA United States. Conference Publication: **18**(SUPPL. 1).

Background: Myocardial T1 and extracellular volume (ECV) estimates have applications in a range of myocardial diseases. Factors responsible for systematic inaccuracies in T1 mapping are beginning to be known1-4 but little is known about its delivery at 'health-care system' scale and there is no global quality assurance (QA) system. Agarose phantoms are common in MRI and nickel ions preferred for lower temperature sensitivity5. This program aims to. 1 Create a partnership to design 1.5/3T phantoms for any manufacturer/ sequence reflecting myocardial/blood T1 pre/post-contrast. 2 Test and mass produce phantoms to regulatory standards. 3 Distribute globally. 4 Analyse serial scans to understand T1 mapping at scale. 5 Publish recipes. 6 Explore delivery of a 'T1/ECV Standard' via local calibration. We report results

of steps 1-3. Method(s): A design collaboration was created (clinicians/physicists/ regulatory bodies/SME). After identifying critical design factors (Fig 1A) and discarding models with excessive B<inf>0</inf>/B<inf>1</inf> distortion, the layout in Fig 1B was adopted. 9 tubes with differently doped agarose were embedded in a gel matrix and high-density polyethylene (HDPE) macrobeads added for B<inf>1</inf> homogeneity. Tube diameter >20 mm was needed for regions of interest to exclude Gibbs artifacts. B<inf>0</inf>/B<inf>1</inf> homogeneity was mapped to evaluate distortion. We hypothesised that dilution of dielectric permittivity by HDPE beads would reduce B<inf>1</inf> inhomogeneity. This design was compared to ones using sodium chloride (NaCl) for increased conductivity, sucrose for reduced permittivity or poly methyl-methacrylate (PMMA) microbeads. Tubes with T1 = 250-1900 ms and T2 = 45-250 ms were reproducibly manufactured and separate ranges adopted for 1.5/3T (Fig 1C). 10 Prototypes were fabricated (5 each for 1.5/3T) for gold standard measurements: T1 by inversion-recovery spin echo(IRSE, 8 inversion times, 25>3200 ms); T2 by SE(8 echo times, 10>640 ms). Prototypes were then distributed to 9 experienced/regulatory centres for further testing. Result(s): T1 maps were free from off-resonance artifacts (Fig 1D). The bottle geometry, coaxial with z and imaged transversely, showed < +/- 0.3 ppm B<inf>0</inf> uniformity (Fig 2A). HDPE beads flattened the B<inf>1</inf> field at 3T (Fig 2B) especially compared to NaCl, sucrose and PMMA beads. T1 increased with temperature (0.19-1.54% change/degreeC) while T2 decreased(-0.93-1.45% change/degreeC). Comparison of gold standard values (Fig 2C,D) between prototypes confirmed reproducible manufacturing(coefficients of variation T1 0.97/1.35%, T2 1.25/2.73% for 1.5T/3T). Recipes were submitted for regulatory approval and manufacture will be complete by Sep'15. Conclusion(s): We created a collaboration to develop CE/FDA-approved phantoms for QA of T1 and ECV protocols. 70 revised phantoms with a multi-vendor user manual are now being distributed to centres worldwide for a 1-year academic exploration of T1 mapping sequences, platform performance and stability. (Figure Presented).

Capuani, S., et al. (2013). "Spatio-temporal anomalous diffusion imaging: Results in controlled phantoms and in excised human meningiomas." Magnetic Resonance Imaging **31**(3): 359-365.

Recently, we measured two anomalous diffusion (AD) parameters: the spatial and the temporal AD indices, called gamma and alpha, respectively, by using spectroscopic pulse gradient field methods. We showed that gamma quantifies pseudo-superdiffusion processes, while alpha quantifies subdiffusion processes. Here, we propose gamma and alpha maps obtained in a controlled heterogeneous phantom, comprised of packed micro-beads in water and in excised human meningiomas. In few words, alpha maps represent the multi-scale spatial distribution of the disorder degree in the system, while gamma maps are influenced by local internal gradients, thus highlighting the interface between compartments characterized by different magnetic susceptibility. gamma maps were already obtained by means of AD stretched exponential imaging and alpha-type maps have been recently achieved for fixed rat brain with the aim of highlighting the fractal dimension of specific brain regions. However, to our knowledge, the maps representative of the spatial distribution of alpha and gamma obtained on the same controlled sample and in the same excised tissue have never been compared. Moreover, we show here, for the first time, that alpha maps are representative of the spatial distribution of the disorder degree of the system.In a first phase, gamma and alpha maps of controlled phantom characterized by an ordered and a disordered rearrangement of packed micro-beads of different sizes in water and by different magnetic susceptibility (deltachi) between beads and water were obtained. In a second phase, we investigated excised human meningiomas of different consistency.Results reported here, obtained at 9.4. T, show that alpha and gamma maps are characterized by a different image contrast. Indeed, unlike gamma maps, alpha maps are insensible to (deltachi) and they are sensible to the disorder degree of the microstructural rearrangement. These observations strongly suggest that AD indices alpha and gamma reflect some additional microstructural information which cannot be obtained using conventional diffusion methods based on Gaussian diffusion. Moreover, alpha and gamma maps obtained in excised meningiomas seem to provide more microstructural details above those obtained with conventional DTI analysis, which could be used to improve the classification of meningiomas based on their consistency. © 2013 Elsevier Inc.

Carbajal, S. (2019). "The Fight to Protect Our National Marine Sanctuaries." Sea Technology **60**(1): 14-15.

Ocean waters have helped us curb climate change impacts by absorbing harmful heat-trapping gases like carbon dioxide emissions and generating half the oxygen we breathe. However, if we do not act quickly to protect our ocean's ecosystem, we are risking the health of our entire planet. From climate change to increased plastic pollution to renewed threats of new offshore oil and gas drilling, our oceans face unprecedented challenges. Many of our oceans are experiencing rising sea levels, changes in water temperature, acidification, loss of marine mammal life and fishery declines due to increasing global temperatures. California's marine sanctuaries were the product of years of public engagement with local communities and enjoy wide support throughout California. In supporting our marine sanctuaries, we recognize that healthy sustainable ecosystems and economic growth are not mutually exclusive.

Carbery, M., et al. (2018). "Trophic transfer of microplastics and mixed contaminants in the marine food web and implications for human health." Environment International **115**: 400-409.

Plastic litter has become one of the most serious threats to the marine environment. Over 690 marine species have been impacted by plastic debris with small plastic particles being observed in the digestive tract of organisms from different trophic levels. The physical and chemical properties of microplastics facilitate the sorption of contaminants to the particle surface, serving as a vector of contaminants to organisms following ingestion. Bioaccumulation factors for higher trophic organisms and impacts on wider marine food webs remain unknown. The main objectives of this review were to discuss the factors influencing microplastic ingestion; describe the biological impacts of associated chemical contaminants; highlight evidence for the trophic transfer of microplastics and contaminants within marine food webs and outline the future research priorities to address potential human health concerns. Controlled laboratory studies looking at the effects of microplastics and contaminants on model organisms employ nominal concentrations and consequently have little relevance to the real environment. Few studies have attempted to track the fate of microplastics and mixed contaminants through a complex marine food web using environmentally relevant concentrations to identify the real level of risk. To our knowledge, there has been no attempt to understand the transfer of microplastics and associated contaminants from seafood to humans and the implications for human health. Research is needed to determine bioaccumulation factors for popular seafood items in order to identify the potential impacts on human health.

Cardozo, D. M., et al. (2011). "Immunoglobulin-like receptors (KIR) assessment on bone marrow donor and host." Bone Marrow Transplantation **1)**: S359.

The natural killer (NK) cells are one kind of lymphocytes and have a special function on immunological response. There are two principal paths: missingself and missingligand, both are used to induce alloreactivity in NK cells. Aim(s): to evaluate the alloreactivity response of NK cells based on presence or not of KIR (immunoglobulin-like receptors) and HLA genes in bone marrow donor and host. Method(s): From March 2009 to February 2010 in the Hemocentro of

University of Campinas 20 pts (patients) were assessed based on NK alloreactivity. A sample of 150 mul total blood was taken by donors' and hosts' genomic DNA, using EDTA tubes and extract by EZ-DNA Kit. The PCRSSO technique was used for genotyping HLA-A, B, C, DR, DQ, 14 KIR genes and 2 pseudogenes, besides that an agarose gel was performed to confirm the reaction. The product was hybridized with microbeads specifically designed to genes and alleles of KIR and HLA, the flow citometry technique was used to detect the beads binding on PCR product. Result(s): 20 pairs were analyzed of identical HLA, 17 AML (Acute Myeloid Leukemia) pts, 2 CML (Chronic Myeloid Leukemia) and one ALL (acute lymphoid leukemia). None of pairs had significant NK alloreactivity. However, 4 showed an haplotype KIR host type B and donor type A, HLA-C group 1 with the presence of ligands KIR2DL2/3, two had severe chronic Graft versus Host disease (GVHD) and 2 did not; 10 pts had haplotype host and donor B, HLA-C group 1 and 2 and the presence of ligands KIR2DL2/3 and KIR2DL1, 7 had severe chronic GVHD, 2 acute GVHD and 1 died for relapse; 2 pts showed haplotype host and donor B, HLA-C group 2 in the presence ligands of KIR2DL1 and one pt died for relapse; 2 pts presented haplotype donor and host B, HLA-C group 1 with ligands KIR2DL2 and had chronic GVHD; 2 pts had haplotype host B and donor A, HLA-C group 2 with ligands KIR2DL1 and the occurrence of severe chronic GVHD. Conclusion(s): More tests will be conducted to establish a correlation between KIR/HLA of donors and hosts of allogeneic bone marrow and with haploidentical donors and hosts to elucidate which influence KIR can have on the response after bone marrow transplantation.

Carey, M. J. (2011). "Intergenerational transfer of plastic debris by Short-tailed Shearwaters (Ardenna tenuirostris)." Emu Austral Ornithology **111**(3): 229-234.

Pollution of the world's oceans affects a wide variety of marine organisms and raises major conservation concerns. Ingestion of plastic debris has increased since the 1970s, particularly among the Procellariiformes, resulting in a range of lethal and sub-lethal side effects. Plastic loads (grams of plastic per bird) of adult Short-tailed Shearwaters (Ardenna tenuirostris) are well known from research in the northern hemisphere, but the amount of plastic ingested by their offspring has yet to be quantified. In this study, the stomach contents of fledgling Short-tailed Shearwaters on Phillip Island, Victoria, were analysed for plastic particles. All birds sampled contained plastic, averaging 7.6 particles per bird. The mean mass of plastic per bird was 113 mg. The most common type of plastic was user plastic, followed by industrial pellets. The birds contained a small proportion of other refuse, such as polystyrene and plastic bag. Plastics were primarily light in colour, though red and grey-black materials were also recorded. Despite a weak trend, no clear influence of ingested plastic on body condition could be demonstrated, although there was some evidence of physical damage to the gizzard. Accumulation of plastic objects in the digestive tract over time may indirectly affect the life cycle of species and their reproductive success, with long-term harm caused to populations. Data suggests that an assessment of the effect of this type of pollution on seabird welfare is urgently required.

Carlini, G. and K. Kleine (2018). "Advancing the international regulation of plastic pollution beyond the United Nations Environment Assembly resolution on marine litter and microplastics." Review of European Comparative & International Environmental Law **27**(3): 234-244.

Plastic pollution has received growing recognition as an issue of global concern, including the question of how to regulate it at the international level. Despite the existence of many instruments relevant to marine plastic litter, there is no international agreement that focuses primarily on combating plastic pollution. While the annual global rate of plastic production is growing, no international instrument is addressing plastic across its full life cycle, from production to consumption to disposal. This article describes the role of the United Nations

Environment Assembly (UNEA) and the evolution of its resolutions on marine plastic pollution. UNEA's latest resolution on marine litter and microplastics is paving the way for the global community to improve the current international framework and address the 'plastic crisis'. This opens questions on the approach and scope of a new framework. The article suggests that framing the problem as one of 'marine litter' limits the scope of possible solutions to waste management. Reframing the subject from a marine litter problem to a broader plastic pollution issue presents an opportunity to develop a comprehensive approach and, therefore, a more effective global framework that encompasses not only plastic litter, but also the reduction of plastic production and consumption. Carnes, R. M. (1989). "Robotics and plastic media, the ultimate way to remove coatings from aerospace vehicles." Technical Paper - Society of Manufacturing Engineers. MS: var paging MS89-131.

Previously, chemicals were the only method to strip coatings from aircraft. They have posed environmental, health, facility and aircraft (hydrogen embrittlement and accelerated corrosion) problems. Plastic media stripping was developed by the U.S.A. Air Force and has now eliminated the chemical negatives. This process of ejecting small angular inert plastic particles against painted surfaces to micro-fracture and remove coatings is very operator sensitive and dependent. Thus, damage to thin skins (.040 and below) from media induced energy saturation is possible. Robotics with vision control of the plastic media parameters eliminates potential damage and is more cost-effective than laborers.

Carney, M. J. and J. H. Fearncombe (1998). "Opportunities and Challenges for Reusable Plastic Containers." Resource Recycling **17**(10): 17.

Although reusable plastic shipping containers (RPSCs) have been considered by many shippers, most are hesitant to replace their current shipping practices, given the absence of information on costs and performance. A marketing study commissioned by the American Plastics Council examined market opportunities and hurdles within four sectors. These sectors: automotives, fresh poultry, fresh produce, and plastic resin, were selected because they are considered conducive to using RPSCs. Almost 100 million RPSCs would be required to meet the needs of these four markets, with a 25% annual replacement rate. This would consume 240 million pounds of resin. The use of RPSCs would divert 1.35 million tons of waste annually. The relative acceptance of RPSCs in each of these markets is reviewed.

Carol, D., et al. (2012). "Synergistic effect of calcium stearate and photo treatment on the rate of biodegradation of low density polyethylene spent saline vials." Indian Journal of Experimental Biology **50**(7): 497-501.

The biodegradation of spent saline bottles, a low density polyethylene product (LDPE) by two selected Arthrobacter sp. under in vitro conditions is reported. Chemical and UV pretreatment play a vital role in enhancing the rate of biodegradation. Treated LDPE film exhibits a higher weight loss and density when compared to untreated films. Arthrobacter oxydans and Arthrobacter globiformis grew better in medium containing pretreated film than in medium containing untreated film. The decrease in density and weight loss of LDPE was also more for

pretreated film when compared to untreated film indicating the affect of abiotic treatment on mechanical properties of LDPE. The decrease in the absorbance corresponding to carbonyl groups and double bonds that were generated during pretreatment suggest that some of the double bonds were cut by Arthrobacter species. Since Arthrobacter sp. are capable of degrading urea, splitting of urea group were also seen in FTIR spectrum indicating the evidence of biodegradation after microbial incubation. The results indicated that biodegradation rate could be enhanced by exposing LDPE to calcium stearate (a pro-oxidant) which acts as an initiator for the oxidation of the polymers leading to a decrease of molecular weight and formation of hydrophilic group. Therefore, the initial step for biodegradation of many inert polymers depends on a photo-oxidation of those polymers. The application in sufficient details with improved procedures utilizing recombinant microorganism with polymer degradation capacity can lead to a better plastic waste management in biomedical field. The present plastic disposal trend of waste accumulation can be minimized with this promising eco-friendly technique.

Caron, A. G. M., et al. (2018). "Ingestion of microplastic debris by green sea turtles (Chelonia mydas) in the Great Barrier Reef: Validation of a sequential extraction protocol." Marine Pollution Bulletin **127**: 743.

Ocean contamination by plastics is a global issue. Although ingestion of plastic debris by sea turtles has been widely documented, contamination by microplastics (< 5 mm) is poorly known and likely to be under-reported. We developed a microplastic extraction protocol for examining green turtle (Chelonia mydos) chyme, which is multifarious in nature, by modifying and combining pre-established methods used to separate microplastics from organic matter and sediments. This protocol consists of visual inspection, nitric acid digestion, emulsification of residual fat, density separation, and chemical identification by Fourier transform infrared spectroscopy. This protocol enables the extraction of polyethylene, high-density polyethylene, (aminoethyl) polystyrene, polypropylene, and polyvinyl chloride microplastics > 100 \im. Two macroplastics and seven microplastics (two plastic paint chips and five synthetic fabric particles) were isolated from subsamples of two green turtles. Our results highlight the need for more research towards understanding the impact of microplastics on these threatened marine reptiles.

Caron, A. G. M., et al. (2018). "Validation of an optimised protocol for quantification of microplastics in heterogenous samples: A case study using green turtle chyme." MethodsX **5**: 812-823.

Quantifying the extent of microplastic (<5mm) contamination in the marine environment is an emerging field of study. Reliable extraction of microplastics from the gastro-intestinal content of marine organisms is crucial to evaluate microplastic contamination in marine fauna. Extraction protocols and variations thereof have been reported, however, these have mostly focussed on relatively homogenous samples (i.e. water, sediment, etc.). Here, we present a microplastic extraction protocol for examining green turtle (Chelonia mydas) chyme (i.e. ingested material and digestive tract fluid), which is a heterogeneous composite of various organic dietary items (e.g. seagrass, jellyfish) and incidentally-ingested inorganic materials (sediment). Established extraction methods were modified and combined. This protocol consists of acid digestion of organic matter, emulsification of residual fat, density separation from sediment, and chemical identification by Fourier transform-infrared spectroscopy. This protocol enables the extraction of the most common microplastic contaminants>100mum: polyethylene, high-density polyethylene, (aminoethyl) polystyrene, polypropylene, and polyvinyl chloride, with 100% efficiency. This validated protocol will enable researchers worldwide to quantify microplastic contamination in turtles in a reliable and comparable way. *Optimization of microplastic

extraction from multifarious tissues by applying established methods in a sequential manner.*Effective for heterogenous samples comprising organic and inorganic material.

Carpenter, E. J. and K. L. Smith, Jr. (1972). "Plastics on the Sargasso sea surface." Science **175**(4027): 1240-1241.

Plastic particles, in concentrations averaging 3500 pieces and 290 grams per square kilometer, are widespread in the western Sargasso Sea. Pieces are brittle, apparently due to the weathering of the plasticizers, and many are in a pellet shape about 0.25 to 0.5 centimeters in diameter. The particles are surfaces for the attachment of diatoms and hydroids. Increasing production of plastics, combined with present waste-disposal practices, will undoubtedly lead to increases in the concentration of these particles. Plastics could be a source of some of the polychlorinated biphenyls recently observed in oceanic organisms.

Carpentier, B., et al. (2008). (OP 234) Production of Bone Substitutes Within Bioreactor-Based Systems: Modeling and Culture of Preosteoblastic Cells, Mary Ann Liebert, Inc. Publishers, 140 Huguenot St 3rd Fl New Rochelle NY 10801 USA. **14:** 770.

Aim: Our project aims at developing a bioreactor-based device dedicated to the production of bone substitutes ex vivo, by combining bone marrow stem cells and biomaterials. The goal of this study is to better characterize the flow and the mechanical stimuli to which the cells are exposed within such systems by means of computational fluid dynamics software, and to identify the appropriate configuration for culturing bone cells on micro-particles. Methods: Modeling software (Gambit, TGrid and Fluent) was used to determine fluid velocity, static pressure and shear stresses, parameters that may greatly impact cell proliferation and differentiation. In parallel, preosteoblastic cells (MC3T3-E1) were seeded and cultured dynamically on glass microbeads. Three bio-reactor configurations were investigated: vertically and horizontally positioned packed beds, fluidized beds as well as monolayers of beads within plane-parallel chambers. Cell survival and proliferation rates were determined by cell counting. Cell distribution and morphology were evaluated using ESEM and methylene blue staining. The experimental data were subsequently correlated to the numerical simulations. Results: The fluidic environment could be investigated. A patent effect of bioreactor configuration was observed on both survival and proliferation of preosteoblastic cells. Horizontally positioned packed beds and monolayers of beads lead to the best results in terms of cell survival and proliferation. Conclusion: Computational fluid dynamics is a valuable tool to better comprehend the effect of dynamic culture on cells and to determine the optimal experimental conditions required to produce bone substitutes. Monolayers seem to represent an appropriate configuration for culturing bone cells on micro-particles.

Carpino, G., et al. (2014). "Evidence for multipotent endodermal stem/progenitor cell populations in human gallbladder." Journal of Hepatology **60**(6): 1194-1202.

BACKGROUND & AIMS: Multipotent stem/progenitor cells are found in peribiliary glands throughout human biliary trees and are able to generate mature cells of hepato-biliary and pancreatic endocrine lineages. The presence of endodermal stem/progenitors in human gallbladder was explored.

METHODS: Gallbladders were obtained from organ donors and laparoscopic surgery for symptomatic cholelithiasis. Tissues or isolated cells were characterized by immunohistochemistry and flow cytometry. EpCAM+ (Epithelial Cell Adhesion Molecule) cells were immunoselected by magnetic microbeads, plated onto plastic in self-replication conditions and subsequently transferred to distinct serum-free, hormonally defined media tailored for differentiation to specific adult fates.

In vivo studies were conducted in an experimental model of liver cirrhosis.
RESULTS: The gallbladder does not have peribiliary glands, but it has stem/progenitors organized instead in mucosal crypts. Most of these can be isolated by immune-selection for EpCAM. Approximately 10% of EpCAM+ cells in situ and of immunoselected EpCAM+ cells co-expressed multiple pluripotency genes and various stem cell markers; other EpCAM+ cells qualified as progenitors. Single EpCAM+ cells demonstrated clonogenic expansion ex vivo with maintenance of stemness in self-replication conditions. Freshly isolated or cultured EpCAM+ cells could be differentiated to multiple, distinct adult fates: cords of albumin-secreting hepatocytes, branching ducts of secretin receptor+ cholangiocytes, or glucose-responsive, insulin/glucagon-secreting neoislets. EpCAM+ cells transplanted in vivo in immune-compromised hosts gave rise to human albumin-producing hepatocytes and to human Cytokeratin7+ cholangiocytes occurring in higher numbers when transplanted in cirrhotic mice.
CONCLUSIONS: Human gallbladders contain easily isolatable cells with phenotypic and biological properties of multipotent, endodermal stem cells.

Carr, S. A., et al. (2016). "Transport and fate of microplastic particles in wastewater treatment plants." Water Research **91**: 174-182.
Municipal wastewater treatment plants (WWTPs) are frequently suspected as significant point sources or conduits of microplastics to the environment. To directly investigate these suspicions, effluent discharges from seven tertiary plants and one secondary plant in Southern California were studied. The study also looked at influent loads, particle size/type, conveyance, and removal at these wastewater treatment facilities. Over 0.189 million liters of effluent at each of the seven tertiary plants were filtered using an assembled stack of sieves with mesh sizes between 400 and 45 mum. Additionally, the surface of 28.4 million liters of final effluent at three tertiary plants was skimmed using a 125 mum filtering assembly. The results suggest that tertiary effluent is not a significant source of microplastics and that these plastic pollutants are effectively removed during the skimming and settling treatment processes. However, at a downstream secondary plant, an average of one micro-particle in every 1.14 thousand liters of final effluent was counted. The majority of microplastics identified in this study had a profile (color, shape, and size) similar to the blue polyethylene particles present in toothpaste formulations. Existing treatment processes were determined to be very effective for removal of microplastic contaminants entering typical municipal WWTPs.

Carrasco, A., et al. (2019). "The influence of microplastics pollution on the feeding behavior of a prominent sandy beach amphipod, Orchestoidea tuberculata (Nicolet, 1849)." Marine Pollution Bulletin **145**: 23-27.
Pollution by microplastics has become a global threat affecting coastal habitats such as sandy beaches and their resident macrofauna. The goal of this study was to assess the influence of microplastics on the feeding behavior and growth rate of a widespread sandy beach amphipod, Orchestoidea tuberculata. These organisms were exposed to artificial food prepared with Poly(styrene-co-divinylbenzene) microspheres (8 micro m particle size) at 3 different concentrations (0%, 5% and 10%). The amphipods consumed significantly more food when the concentration of microplastics was 0% and significantly less when the concentration was 10%, both in trials in which they had a choice (preference experiments) and those in which they did not have a food choice. In contrast to this, the amphipod's absorption efficiency and estimated growth rates were not significantly affected by the concentration of microplastics. Combined, these results indicate that high microplastics concentrations (e.g. 10%) cause a reduction in the amphipod's consumption rates and, indirectly, may affect the role of this species as a main

consumer of stranded seaweeds in sandy beaches ecosystems.

Carreras-Colom, E., et al. (2018). "Spatial occurrence and effects of microplastic ingestion on the deep-water shrimp Aristeus antennatus." Marine Pollution Bulletin **133**: 44-52.

Microplastic (MP) ingestion has been reported in a wide variety of organisms, however, its spatial occurrence and effects on wild populations remain quite unknown. The present study targets an economically and ecologically key species in the Mediterranean Sea, the shrimp Aristeus antennatus. 39.2% of the individuals sampled had MP in their stomachs, albeit in areas close to Barcelona city the percentage reached values of 100%. Overall, MP ingestion was confirmed in a wide spatial and depth (630-1870 m) range, pointing out the great dispersion of this pollutant. The benthophagous diet and close relationship with the sea bottom of A. antennatus might enhance MP exposure and ultimately lead to accidental ingestion. Detailed analysis of shrimps' diet revealed that individuals with MP had a higher presence of endobenthic prey. Microplastic fibers are probably retained for long periods due to stomach's morphology, but no negative effects on shrimp's biological condition were observed.

Carrère-Kremer, S., et al. (2016). "High IFN-γ Release and Impaired Capacity of Multi-Cytokine Secretion in IGRA Supernatants Are Associated with Active Tuberculosis." PLoS ONE **11**(9).

Interferon gamma (IFN-γ) release assays (IGRAs) detect Mycobacterium tuberculosis (Mtb) infection regardless of the active (ATB) or latent (LTBI) forms of tuberculosis (TB). In this study, Mtb-specific T cell response against region of deletion 1 (RD1) antigens were explored by a microbead multiplex assay performed in T-SPOT TB assay (T-SPOT) supernatants from 35 patients with ATB and 115 patients with LTBI. T-SPOT is positive when over 7 IFN-γ secreting cells (SC)/250 000 peripheral blood mononuclear cells (PBMC) are enumerated. However, over 100 IFN-γ SC /250 000 PBMC were more frequently observed in the ATB group compared to the LTBI group. By contrast, lower cytokine concentrations and lower cytokine productions relative to IFN-γ secretion were observed for IL 4, IL-12, TNF-α, GM-CSF, Eotaxin and IFN-α when compared to LTBI. Thus, high IFN-γ release and low cytokine secretions in relation with IFN-γ production appeared as signatures of ATB, corroborating that multicytokine Mtb-specific response against RD1 antigens reflects host capacity to contain TB reactivation. In this way, testing cytokine profile in IGRA supernatants would be helpful to improve ATB screening strategy including immunologic tests.

Carrieri, C., et al. (2012). "Red blood cells stimulate fibrinolysis." Blood Transfusion **4)**: s140.

Background It has recently been shown that red blood cells (RBC) confer lytic resistance to clots derived from purified fibrinogen, which is in contrast with some older studies. Here, we investigated the effect of RBC on fibrinolysis under more physiological conditions. Materials and Methods Washed RBC (10-40% v/v) were added to plasminogen-containing fibrinogen (3 mg/mL) or autologous plasma. Following t-PA addition (20-150 ng per mL of extracellular volume) clotting was induced by $CaCl_2$- thrombin or $CaCl_2$-tissue factor (TF). Fibrinolysis was evaluated by thromboelastography (lysis time) or by the release of FITC-labeled FDPs (% lysis). Results When clots were prepared from purified fibrinogen, RBC inhibited fibrinolysis in a concentration-dependent manner (33% lysis time prolongation at 40% RBC). The effect disappeared in the presence of the GPIIb/IIIa inhibitor abciximab but not when the TAFIa inhibitor PTCI was added. On the contrary, when clots were prepared from plasma, RBC accelerated fibrinolysis (21% lysis time reduction at 40% RBC). The effect of RBC on clot lysis was: 1) concentration-dependent; 2) maintained in the presence of platelets (3x105/uL); 3) insensitive to abciximab; 4) abolished by PTCI, suggesting a TAFI-mediated mechanism.

Replacement of RBC with 40% (v/v) polystyrene microbeads (6 um diameter) did not appreciably influence clot lysis, ruling out an effect due to volume occupancy. Qualitatively similar results were obtained with FITC-fibrinogen clot lysis model. Thrombin generation (two-stage clotting assay) and accumulation of TAFIa (ELISA) in defibrinated plasma activated with TF-Ca++ were 63% and 27% higher in the presence of 40% RBC. However, by functional assay (using fibrin as substrate) the amount of TAFIa activity detected in RBC-containing plasma was 30% lower than in cell-free plasma, suggesting that RBC inhibit TAFIa activity (towards fibrin). Conclusions These data unveil a new function of RBC and underscore the potential role of these cells in fibrinolysis modulation.

Carroll, A. D., et al. (2002). "Label dilution method: a novel tool for bioligand interaction studies using bead injection in the lab-on-valve format." Analyst **127**(9): 1228-1232.

This work introduces a novel method, label dilution, which is analogous to the well-established isotope dilution method. The principle is tested on a model system of commercially available antibodies and protein-coated Sepharose beads and implemented using micro-bead injection in the lab-on-valve format. This micro-scale method uses a labeled form of the target molecule as an internal standard. Label dilution employs ratiometric measurements using the absorbance signals from the label and the target molecules for quantitative determination of an analyte. The label dilution method is shown to discriminate between selective and non-selective binding and provides a means for monitoring bioligand interactions in real time. With a detection limit of 470 ng of IgG, this method provides a sensitive, automated technique for the determination of low-level analytes in complex samples. This technique has been developed with the aim of using it to facilitate diabetes research in which the interactions between autoantibodies and the molecules they target are a central focus.

Carson, H. S. (2013). "The incidence of plastic ingestion by fishes: from the prey's perspective." Marine Pollution Bulletin **74**(1): 170-174.

One of the primary threats to ocean ecosystems from plastic pollution is ingestion by marine organisms. Well-documented in seabirds, turtles, and marine mammals, ingestion by fish and sharks has received less attention until recently. We suggest that fishes of a variety of sizes attack drifting plastic with high frequency, as evidenced by the apparent bite marks commonly left behind. We examined 5518 plastic items from random plots on Kamilo Point, Hawai'i Island, and found 15.8% to have obvious signs of attack. Extrapolated to the entire amount of debris removed from the 15 km area, over 1.3 tons of plastic is attacked each year. Items with a bottle shape, or those blue or yellow in color, were attacked with a higher frequency. The triangular edges or punctures left by teeth ranged from 1 to 20 mm in width suggesting a variety of species attack plastic items. More research is needed to document the specific fishes and rates of plastic ingestion.

Carson, H. S., et al. (2011). "Small plastic debris changes water movement and heat transfer through beach sediments." Marine Pollution Bulletin **62**(8): 1708-1713.

We investigated the physical properties of beaches contaminated with plastic fragments. We compared sediment cores from Hawai'i Island's Kamilo Beach, notable for plastic accumulation, to cores from a nearby beach. Compared to the nearby beach, Kamilo sediments contained more plastics (up to 30.2% by weight), were coarser-grained, and were more permeable (t-test, $p < 0.0001$). 85% of the fragments were polyethylene, and 95% were concentrated in the top 15 cm of the cores. We constructed artificial cores of standardized grain size and varying plastic-to-sediment ratios. Adding plastic significantly increased the permeability (ANOVA, p=

0.002), which was partially attributed to the fragments increasing the mean grain size. Sediments with plastic warmed more slowly (16% maximum decrease in thermal diffusivity), and reached lower maximum temperatures (21% maximum increase in heat capacity). These changes have a variety of potential effects on beach organisms, including those with temperature-dependent sex-determination such as sea turtle eggs. © 2011 Elsevier Ltd.

Carson, H. S., et al. (2013). "The plastic-associated microorganisms of the North Pacific Gyre." Marine Pollution Bulletin **75**(1-2): 126-132.

Microorganisms likely mediate processes affecting the fate and impacts of marine plastic pollution, including degradation, chemical adsorption, and colonization or ingestion by macroorganisms. We investigated the relationship between plastic-associated microorganism communities and factors such as location, temperature, salinity, plankton abundance, plastic concentration, item size, surface roughness, and polymer type. Small plastic items from the surface of the North Pacific Gyre in 2011 were examined using scanning electron microscopy. Bacillus bacteria (mean 1664 +/- 247 individuals mm(-2)) and pennate diatoms (1097 +/- 154 mm(-2)) were most abundant, with coccoid bacteria, centric diatoms, dinoflagellates, coccolithophores, and radiolarians present. Bacterial abundance was patchy, but increased on foamed polystyrene. Diatom abundance increased on items with rough surfaces and at sites with high plastic concentrations. Morphotype richness increased slightly on larger fragments, and a biogeographic transition occurred between pennate diatom groups. Better characterizing this community will aid in understanding how it interacts with plastic pollution.

Carter, J. A. (2006). "The reuse of breathing systems in anesthesia." Respiratory Care Clinics of North America **12**(2): 275-286.

The cheap manufacture of plastics compared with the relatively expensive labor-intensive cost of decontaminating medical equipment encourages the use of disposable single-use equipment. Although the manufacture and disposal of single-use equipment superficially would seem to have more environmental impact than reusable equipment, the processes of cleaning and decontaminating reusable items may impose an even greater cost on the environment. In a recent study at two United States hospitals, anesthetic tubing accounted for less than 10% of medical waste, about half the amount of the plastic waste generated by the cafeterias at the same two hospitals [34]. There may be a higher cost to the organization by using single-use breathing systems. One United States institution has estimated that changing from single-use to re-usable breathing systems, with a new filter for each patient, resulted in savings in initial cost and waste disposal of more than Dollars 100,000 per year [20]. In the light of current knowledge concerning infective agents, reusing breathing systems for up to 1 week with a new appropriate filter for each new patient seems to be safe practice, provided the manufacturer of the breathing system recommends such use, and the breathing system is carefully checked before each new patient. [References: 34]

Carter, J. M., et al. (2016). "Rapid, multiplexed characterization of Shiga toxin-producing Escherichia coli (STEC) isolates using suspension array technology." Frontiers in Microbiology **7**(May).

Molecular methods have emerged as the most reliable techniques to detect and characterize pathogenic Escherichia coli. These molecular techniques include conventional single analyte and multiplex PCR, PCR followed by microarray detection, pulsed-field gel electrophoresis (PFGE), and whole genome sequencing. The choice of methods used depends upon the specific needs of the particular study. One versatile method involves detecting serogroup-specific markers by hybridization or binding to encoded microbeads in a suspension array. This molecular serotyping method has been developed and adopted for investigating E. coli outbreaks. The major advantages of this technique are the ability to simultaneously serotype E. coli and detect the presence of virulence and pathogenicity markers. Here, we describe the development of a family of multiplex molecular serotyping methods for Shiga toxin-producing E. coli, compare their performance to traditional serotyping methods, and discuss the cost-benefit balance of these methods in the context of various food safety objectives.

Cartes, J. E., et al. (2016). "Contributions of allochthonous inputs of food to the diets of benthopelagic fish over the northwest Mediterranean slope (to 2300m)." Deep Sea Research (Part I, Oceanographic Research Papers) **109**: 123-136.

The contributions of allochthonous inputs of food (food falls, plastics and other anthropogenic remains) in the diets of large fish (6 teleosteans, 3 sharks) were analyzed for depths between 500 and 2300m in the deep Balearic basin (western Mediterranean). The analyses were based on gut contents. The identification was based on a multi-analytic approach, comprising morphological features (including morphometric analysis) and molecular genetics (DNA barcoding method). Remains of a number of anthropogenic, inorganic materials (microplastic fibres, plastic bags and cartons) appeared regularly in the guts of deep-sea fish (e.g., in Trachyrhynchus scabrus and Mora moro), though always at low occurrence (9.1% of fish at most) and negligible weights (< 2%W of diet). In our sampling, covering an area of ca. 12km2, large food falls contribute only a little to fish diets by weight, W, e.g., in shark diets they represented 4.5%W for Centroscymnus coelolepis and 11%W for Galeus melastomus. However, the importance of food falls (e.g., cetacean blubber and carcharhinid shark remains) was substantial locally (up to 70.8%W of C. coelolepis diet) particularly near canyons. The arrival of livestock remains (beef flesh, goat ribs and vertebrae) was shown by molecular analyses to contributed to deep-sea shark diets (ca. 5.5%W) comparably to natural food falls. These remains, which originate from human activity, may locally alter the food webs of oligotrophic environments like that of the deep Mediterranean. Food falls of both natural and anthropogenic origin were mainly found in fish collected close to canyon axes. The only cetacean fall documented in the deep Balearic Basin was also near a canyon, the carcass of a small (ca. 1.2m) striped dolphin, Stenella coeruleoalba, collected in a haul at 1750m off Barcelona.

Cartraud, A. E., et al. (2019). "Plastic ingestion in seabirds of the western Indian Ocean." Marine Pollution Bulletin **140**: 308-314.

We investigated seabird plastic ingestion in the western Indian Ocean by analyzing the stomach contents of 222 individuals belonging to nine seabird species (including two endangered species endemics to Reunion Island). The most affected species were tropical shearwaters (79%) and Barau's petrels (59%). The average number of plastic particles per contaminated bird was higher in Barau's petrels (6.10 +/- 1.29) than in tropical shearwaters (3.84 +/- 0.59). All other studied species also showed plastic presence in their stomach contents. The mass of plastic particles was significantly higher both in juvenile's Barau's petrels and tropical shearwaters than in adults. These results demonstrate the foraging areas of seabirds of the western Indian Ocean have a high level of plastic pollution. In Reunion Island, hundreds of tropical shearwaters and Barau's petrels are attracted by urban lights and die each year. We suggest taking advantage of this situation by using these species as long-term indicators of plastic marine pollution in the region. Copyright © 2019 Elsevier Ltd

Cartwright, M., et al. (2016). "A Broad-Spectrum Infection Diagnostic that Detects Pathogen-Associated Molecular Patterns (PAMPs) in Whole Blood." EBioMedicine **9**: 217-227.

BACKGROUND: Blood cultures, and molecular diagnostic tests that directly detect pathogen DNA in blood, fail to detect bloodstream infections in most infected patients. Thus, there is a need for a rapid test that can diagnose the presence of infection to triage patients, guide therapy, and decrease the incidence of sepsis.

METHODS: An Enzyme-Linked Lectin-Sorbent Assay (ELLecSA) that uses magnetic microbeads coated with an engineered version of the human opsonin, Mannose Binding Lectin, containing the Fc immunoglobulin domain linked to its carbohydrate recognition domain (FcMBL) was developed to quantify pathogen-associated molecular patterns (PAMPs) in whole blood. This assay was tested in rats and pigs to explore whether it can detect infections and monitor disease progression, and in prospectively enrolled, emergency room patients with suspected sepsis. These results were also compared with data obtained from non-infected patients with or without traumatic injuries.

RESULTS: The FcMBL ELLecSA was able to detect PAMPS present on, or released by, 85% of clinical isolates representing 47 of 55 different pathogen species, including the most common causes of sepsis. The PAMP assay rapidly (<1h) detected the presence of active infection in animals, even when blood cultures were negative and bacteriocidal antibiotics were administered. In patients with suspected sepsis, the FcMBL ELLecSA detected infection in 55 of 67 patients with high sensitivity (>81%), specificity (>89%), and diagnostic accuracy of 0.87. It also distinguished infection from trauma-related inflammation in the same patient cohorts with a higher specificity than the clinical sepsis biomarker, C-reactive Protein.

CONCLUSION: The FcMBL ELLecSA-based PAMP assay offers a rapid, simple, sensitive and specific method for diagnosing infections, even when blood cultures are negative and antibiotic therapy has been initiated. It may help to triage patients with suspected systemic infections, and serve as a companion diagnostic to guide administration of emerging dialysis-like sepsis therapies.

Caruso, G. (2019). "Microplastics as vectors of contaminants." Marine Pollution Bulletin **146**: 921-924.

Pollution by microplastics and antibiotics is an emerging environmental, human and animal health threat. In spite of several studies documenting the widespread occurrence of plastic debris in aquatic ecosystems, research focusing on occurrence and concentration of biological and chemical contaminants attached on microplastic surface as well as on possible interactions of these contaminants with microplastics is still at its beginning. The present note addresses the role of microplastics as vectors of contaminants in water bodies, stressing the need for future investigations on this hot topic.

Caruso, G., et al. (2018). "Effects of microplastics on trophic parameters, abundance and metabolic activities of seawater and fish gut bacteria in mesocosm conditions." Environmental Science and Pollution Research **25**(30): 30067-30083.

Plastic pollution is an emerging threat with severe implications on animals' and environmental health. Nevertheless, interactions of plastic particles with both microbial structure and metabolism are a new research challenge that needs to be elucidated yet. To improve knowledge on the effects played by microplastics on free-living and fish gut-associated microbial community in aquatic environments, a 90-day study was performed in three replicated mesocosms (control-CTRL, native polyvinyl chloride-MPV and weathered polyvinyl chloride-MPI), where sea bass specimens were hosted. In CTRL mesocosm, fish was fed with no-plastic-added food, whilst in MPV and MPI food was supplemented with native or exposed to polluted waters polyvinylchloride pellets, respectively. Particulate organic carbon (POC) and nitrogen, total and culturable bacteria, extracellular enzymatic activities, and microbial community substrate utilization profiles were analyzed. POC values were lower in MPI than MPV and CRTL mesocosms. Microplastics did not affect severely bacterial metabolism, although enzymatic activities decreased and microbes utilized a lower number of carbon substrates in MPI than MPV and CTRL. No shifts in the bacterial community composition of fish gut microflora were observed by denaturing gradient gel electrophoresis fingerprinting analysis.

Carvalheiro, V. (2009). "Particles and gel foam." CardioVascular and Interventional Radiology **2)**: 163.

Embolotherapy is an evolving field of interventional radiology in which occlusive agents play a major role. The choice of the optimal occlusive agent is of utmost importance for planning an embolization procedure. Particles are the most commons agents used for small vessel permanent distal occlusions. Traditional amorphous polyvinyl alcohol (PVA) is an inert injectable plastic particle of 45 to 1180 mum, which incites an inflammatory reaction, rendering it highly thrombogenic. Supplied as a dry coarse powder, PVA particles must be suspended in contrast medium or saline before injection through the delivery catheter. Clumping is a common problem when using the amorphous form of PVA. Particle size poorly matched to a chosen catheter can lead to catheter occlusion. PVA particles are difficult to calibrate and their behavior can be unpredictable during embolization, which leads to difficulties when performing targeted embolization^{1,2}. Calibrated microspheres have drastically changed the conditions of embolization since the radiologist may adapt the size of microspheres to the size of the vessels to be occluded, so that an accurate targeting can be obtained. Extruded PVA (Contour SE Microspheres, Boston Scientific) is regular in shape and it is slightly compressible when injected through a catheter³. Embosphere Microspheres are particles made of trisacryl gelatin, perfectly round and slightly compressible, delivered suspended in an aqueous solution. This product is colorless and radiolucent and must be mixed with a contrast medium before injection⁴. BeadBlock (Biocompatibles UK) microspheres are another small embolic particle made from PVA hydrogel. They are hydrophilic and compressible, decreasing the risk of clumping. Unlike amorphous PVA or spherical PVA, BeadBlock is suspended in sterile water in prepackaged syringes⁵. Gelatin sponge particles are agents used for small or large vessel temporary occlusions. Gelfoam is a water-insoluble hemostatic agent prepared from purified skin gelatin. The potential to induce the clotting cascade results from the close contact of the platelets when entrapped in the porous gelatin sponge. The overall use of gelfoam is related to its temporary effect and then attempted mainly either to stop a bleeding or to devascularize a lesion before surgical removal⁶. Gelfoam has been used in a variety of clinical indications, such as trauma, gastrointestinal bleeding, postpartum hemorrhage⁷, and also preoperative tumor embolization, including uterine artery embolization for fibroids⁸ and portal vein embolization to induce hepatic hypertrophy of one lobe before surgical resection of the other lobe⁹.

Casale, C., et al. (2014). "Realization a complex skin equivalent tissue." Journal of Investigative Dermatology **2)**: S50.

The aim of this work is the realization of a three-dimensional human skin equivalent tissue (3DHSE) completely made up by endogenous extra cellular matrix (ECM). The realization of 3D-HSE has been pursued by means of a bottom-up tissue engineering strategy that firstly comprises the fabrication of functional micro-metric tissue precursors (mTPs) through dynamic seeding of fibroblasts on biodegradable porous microbeads with a controlled and tunable degradation rate. Then mTPs have been assembled in a 3D dermis tissue and the epidermal cells are lastly seeded on the top of dermal equivalent. In the development of epithelial stratum is important to maintein the culture submerged to allow complete epidermal cells coverage, melanocytes organization along epidermal basal membrane and early keratinocytes

stratification, and later raising the developing culture to the air-liquid interface thus promoting epidermal differentiation. Epidermal differentiation markers have been investigated by means of the immunofluorescence analysis while collagen was assesses by multiphoton microscopy analysis. The functional endogenous dermis has a crucial role in the morphogenesis of a pluristratified epidermis. Transmission electron microscopy well show the fine structure of the dermal-epidermal junction confirming that epidermal layer is well anchored to the dermis. Moreover dermis-epidermis cross-talking is guaranteed as proved by the presence of basal membrane and this structure has a characteristic rete ridge morphology with typical epidermis appendages going deep through the underlying dermis resembling bulge-like structure. In view of its complexity, this skin model can be specifically used for tackling various problems in the chemical/ pharmaceutical and cosmetics industry. Since an endogenous ECM is present it is possible to study not only the cellular response but also the ECM response in terms of change in assembly as well as composition to a drug.

Cascone, S., et al. (2020). "Energy and environmental assessment of plastic granule production from recycled greenhouse covering films in a circular economy perspective." Journal of Environmental Management **254**: 109796.

Plastic films can be considered as a high-value auxiliary material in agriculture with multiple important uses to fulfil, including covering films in greenhouse cultivation system. Such an application enables several benefits and, therefore, it is going through an important upsurge, especially in regions where protected crop cultivation is highly widespread. However, the increased demand for these covering films arouses concerns for their post-use treatment with regard to both the consumption of Non-Renewable Primary Energy (NRPE) resources and the emission of Greenhouse Gases (GHGs). Therefore, environmental analysis is needed to find and follow cleaner paths for the management and treatment of this kind of Agricultural Plastic Waste (APW), especially in the light of the gap currently existing in the specialised literature. In this context, this paper reports upon findings from a combined Life Cycle Assessment (LCA) of single environmental issues (i.e., energy and water consumption, and GHG emissions) applied to a Sicilian firm, representative of APW collection and recycling to obtain Low-Density Polyethylene (LDPE) granules. The results showed that electricity consumption for the whole recycling process is the most NRPE resource demanding and the most GHG emitting input item. Moreover, the washing phase of disused covering films is the highest water demanding within the recycling process. Potential improvements could be achieved by shifting from fossil energy source to renewable one. The installation of a wind power plant would lead to around 56% and 85% reduction in NRPE resource exploitation and GHG emission, respectively. Finally, despite the huge consumption of water and NRPE resources and the resulting GHG emissions, the production of recycled-LDPE granules is far more sustainable than the virgin counterpart.

Caserta, S., et al. (2008). "Synthetic CD4⁺ T cell-targeted antigen-presenting cells elicit protective antitumor responses." Cancer Research **68**(8): 3010-3018.

CD4⁺ helper T cells are critical for protective immune responses and yet suboptimally primed in response to tumors. Cell-based vaccination strategies are under evaluation in clinical trials but limited by the need to derive antigenpresenting cells (APC) from patients or compatible healthy donors. To overcome these limitations, we developed CD4⁺ T cell-targeted synthetic microbead-based artificial APC (aAPC) and used them to activate CD4⁺ T lymphocytes specific for a tumor-associated model antigen (Ag) directly from the naive repertoire. In vitro, aAPC specifically primed Ag-specific CD4⁺ T cells that were activated to express high levels of CD44, produced mainly interleukin 2, and could differentiate into Th1-ike or Th2-like cells in combination with polarizing cytokines. I.v. administration of aAPC led to Ag-specific CD4⁺ T-cell activation and proliferation in secondary lymphoid organs, conferred partial protection against subcutaneous tumors, and prevented the establishment of lung metastasis. Taken together, our data support the use of cell-free, synthetic aAPC as a specific and versatile alternative to expand peptide-specific CD4⁺ T cells in adoptive and active immunotherapy. ©2008 American Association for Cancer Research.

Castaneda, R. A., et al. (2014). "Microplastic pollution in St. Lawrence river sediments." Canadian Journal of Fisheries and Aquatic Sciences **71**(12): 1767-1771.

Although widely detected in marine ecosystems, microplastic pollution has only recently been documented in freshwater environments, almost exclusively in surface waters. Here, we report microplastics (polyethylene microbeads, 0.40-2.16 mm diameter) in the sediments of the St. Lawrence River. We sampled 10 freshwater sites along a 320 km section from Lake St. Francis to Quebec City by passing sediment collected from a benthic grab through a 500 micro m sieve. Microbeads were discovered throughout this section, and their abundances varied by four orders of magnitude across sites. Median and mean (+or-1 SE) densities across sites were 52 microbeads.m⁻² and 13832 (+or-13677) microbeads.m⁻², respectively. The highest site density was 1.4x10⁵ microbeads.m⁻² (or 10³ microbeads.L⁻¹), which is similar in magnitude to microplastic concentrations found in the world's most contaminated marine sediments. Mean diameter of microbeads was smaller at sites receiving municipal or industrial effluent (0.70+or-0.01 mm) than at non-effluent sites (0.98+or-0.01 mm), perhaps suggesting differential origins. Given the prevalence and locally high densities of microplastics in St. Lawrence River sediments, their ingestion by benthivorous fishes and macroinvertebrates warrants investigation.

Castella, L. F., et al. (2010). "A new lock-step mechanism of matrix remodelling based on subcellular contractile events." Journal of Cell Science **123**(10): 1751-1760.

Myofibroblasts promote tissue contractures during fibrotic diseases. To understand how spontaneous changes in the intracellular calcium concentration, [Ca²⁺]<inf>i</inf>, contribute to myofibroblast contraction, we analysed both [Ca²⁺]<inf>i</inf> and subcellular contractions. Contractile events were assessed by tracking stress-fibre-linked microbeads and measured by atomic force microscopy. Myofibroblasts exhibit periodic (~100 seconds) [Ca²⁺]<inf>i</inf> oscillations that control small (~400 nm) and weak (~100 pN) contractions. Whereas depletion of [Ca²⁺] <inf>i</inf> reduces these microcontractions, cell isometric tension is unaffected, as shown by growing cells on deformable substrates. Inhibition of Rho- and ROCK-mediated Ca²⁺-independent contraction has no effect on microcontractions, but abolishes cell tension. On the basis of this two-level regulation of myofibroblast contraction, we propose a single-cell lock-step model. Rho- and ROCK-dependent isometric tension generates slack in extracellular matrix fibrils, which are then accessible for the low-amplitude and high-frequency contractions mediated by [Ca²⁺]<inf>i</inf>. The joint action of both contraction modes can result in macroscopic tissue contractures of ~1 cm per month.

Castelvetro, V., et al. (2020). "Quantification of poly(ethylene terephthalate) micro- and nanoparticle contaminants in marine sediments and other environmental matrices." Journal of Hazardous Materials **385**: 121517.

Microplastics are ubiquitous pollutants in marine and freshwater bodies. Poly(ethylene terephthalate) microfibers (PMFs) are among the main primary microplastics (as-produced polymer microparticles). Released in large amounts in laundry wastewaters, PMFs end up in freshwater and marine sediments due to their high density. PMFs are potentially hazardous pollutants for ecosystems and human health, being a deceiving food source for animal organisms at the base of the food chain (e.g. sediment and water filtrators, including edible shellfish and small crustaceans). This study describes a simple, sensitive and versatile procedure for quantifying the total mass of PET micro- and nano-particles in sediments. The procedure involves aqueous alkaline PET depolymerization with phase transfer catalysis, oxidation and fractionations to remove interfering species and pre-concentrate the terephthalic acid (TPA) monomer, and TPA quantification by reversed-phase HPLC. Recovery of TPA from a model sediment spiked with 800ppm PET micropowder was 98.2 %, with limits of detection/quantification LOD=17.2mug/kg and LOQ=57.0mug/kg. Analyses of sandy sediments from a marine beach in Tuscany, Italy, showed contamination in the 370-460mug/kg range, suggesting that a not negligible fraction of PET microfibers released in surface waters ends up in shore sediments.

Castillo, A. B., et al. (2016). "Prevalence of microplastics in the marine waters of Qatar." Marine Pollution Bulletin **111**(1-2): 260-267.

Microplastics are firmly recognized as a ubiquitous and growing threat to marine biota and their associated marine habitats worldwide. The evidence of the prevalence of microplastics was documented for the first time in the marine waters of Qatar's Exclusive Economic Zone (EEZ). An optimized and validated protocol was developed for the extraction of microplastics from plankton-rich seawater samples without loss of microplastic debris present and characterized using Attenuated Total Reflectance-Fourier Transform Infrared spectroscopy. In total 30 microplastic polymers have been identified with an average concentration of 0.71particlesm(-3) (range 0-3particlesm(-3)). Polypropylene, low density polyethylene, polyethylene, polystyrene, polyamide, polymethyl methacrylate, cellophane, and acrylonitrile butadiene styrene polymers were characterized with majority of the microplastics either granular shape, sizes ranging from 125mum to 1.82mm or fibrous with sizes from 150mum to 15.98mm. The microplastics are evident in areas where nearby anthropogenic activities, including oil-rig installations and shipping operations are present.

Castro, B., et al. (2018). "Portable and power-free serodiagnosis of Chagas disease using magnetic levitating microbeads." Analyst **143**(18): 4379-4386.

This work describes the detection of anti-T. cruzi antibodies in whole blood solutions using magnetic levitating microbeads (MLmuBs). This simple diagnostic method can be easily performed by minimally trained personnel using an inexpensive and portable magnetic stage that requires no electricity. A multiphase test tube containing the MLmuBs facilitates the sequential incubation, filtering, and reading of the immunoassays. The diagnostic method starts by adding a blood sample to the top phase of the test tube where the anti-T. cruzi antibodies present in the blood attach to the T. cruzi antigens on the surface of the MLmuBs. Shaking the test tube after incubation mixes the top layer with a paramagnetic medium loaded with SiO₂ microcrystals. The attachment of SiO₂ microcrystals to those MLmuBs bound to T. cruzi antibodies decreases their levitation height once the tube is placed between two antialigned permanent magnets. Measuring the levitation height of MLmuBs enables the accurate detection and quantification of anti-T. cruzi antibodies in the blood across the clinically relevant range, with a detection limit of 5 mug mL⁻¹. The small size of the test tubes facilitates the simultaneous analysis of over 50 different samples. MLmuBs act as

partial collimators for non-polarized light, facilitating their visual identification by the naked eye or by projecting incident light on a thin paper screen. A machine-vision algorithm was created to automatically interpret the results of the MLmuB tests from a digital image, resulting in a rapid, accurate, and user-friendly assay for Chagas disease that can be used in resource-limited settings.

Castro, C. M., et al. (2016). "Illuminating the shadows of cervical disease using a mobile digital diffraction platform." Molecular Imaging and Biology **1)**: S1184-S1185.

Background: The global burden of cervical cancer and the disproportionate access to prompt pathology services and emerging cell profiling technologies increase the need for low-cost, portable, and rapid pointof- care (POC) approaches. Emerging genomic data for cervical cancers support the need for personalized profiling strategies more accessible to clinical providers and investigators. While conventional microscopy (e.g. fluorescence, confocal) retains diagnostic importance, their costs and complexity challenge reliable and feasible implementation within resource-challenged areas. Method(s): We developed a digital diffraction diagnostic (D3) platform equipped with a portable smartphone module and: 1) optimized its protein and DNA readouts under preclinical conditions; and 2) conducted feasibility and pilot testing using human cervical biopsies from colposcopy. Result(s): Molecular analyses were achieved by labeling cells with polystyrene microbeads linked to antibodies targeting cervical cancer-related proteins. Diffraction patterns generated by the microbeads were detected with the smartphone camera using brightfield settings; digital processing reconstructed the images of bead-bound cells to retrieve molecular information (Fig. 1A). Optimizing the bead linking process and speeding up cell counting algorithms, led us to count thousands of beads and cells without washing steps (i.e. near real time). We enrolled 25 women with abnormal pap smears who were referred to the MGH Cancer Center for colposcopy and analyzed an extra biopsy specimen using our platform. Samples from higher risk patients showed increased numbers of microbeads per cell versus low risk and benign samples (Fig. 1B). The mean bead counts (nad) per targeted cell were significantly different among the clinical risk classifications ($p < 0.05$), indicating that nbead could serve as a single diagnostic measure (Fig. 1C). The D3 assay generated readouts within 45 min and showed excellent agreement with gold-standard pathology (96%). We enhanced our platform's capabilities to enable DNA detection by developing a bead-dimer assay (Fig. 1D). A pair of oligonucleotides, whose sequences were complementary to that of HPV target DNA, were conjugated to silica and polystyrene microbeads, respectively. The target DNA was captured on polystyrene (PS) beads and sequentially labeled with silica (SI) beads. The hybridization yielded PS-SI bead dimers with unique diffraction signatures. The number of PS-SI hybrids correlated with the amount of target DNA. The observed detection sensitivity was in the attomole range for HPV DNA 16 and 18 (Fig. 1D), which account for >70% of cervical cancers worldwide. Conclusion(s): Our approach could have favorable global health applications where medical access is limited or when pathology bottlenecks challenge prompt cancer diagnostic readouts. Once validated prospectively, we anticipate that the D3 platform should enhance the breadth and depth of cervical cancer testing in a manner that is both sustainable and feasible for resource-limited settings. (Figure Presented).

Castro, D., et al. (2018). "High-Throughput Incubation and Quantification of Agglutination Assays in a Microfluidic System." Genes **9**(6): 04.

In this paper, we present a two-phase microfluidic system capable of incubating and quantifying microbead-based agglutination assays. The microfluidic system is based on a simple fabrication solution, which requires only laboratory tubing filled with carrier oil, driven by negative pressure

using a syringe pump. We provide a user-friendly interface, in which a pipette is used to insert single droplets of a 1.25-micro L volume into a system that is continuously running and therefore works entirely on demand without the need for stopping, resetting or washing the system. These assays are incubated by highly efficient passive mixing with a sample-to-answer time of 2.5 min, a 5-10-fold improvement over traditional agglutination assays. We study system parameters such as channel length, incubation time and flow speed to select optimal assay conditions, using the streptavidin-biotin interaction as a model analyte quantified using optical image processing. We then investigate the effect of changing the concentration of both analyte and microbead concentrations, with a minimum detection limit of 100 ng/mL. The system can be both low- and high-throughput, depending on the rate at which assays are inserted. In our experiments, we were able to easily produce throughputs of 360 assays per hour by simple manual pipetting, which could be increased even further by automation and parallelization. Agglutination assays are a versatile tool, capable of detecting an ever-growing catalog of infectious diseases, proteins and metabolites. A system such as this one is a step towards being able to produce high-throughput microfluidic diagnostic solutions with widespread adoption. The development of analytical techniques in the microfluidic format, such as the one presented in this work, is an important step in being able to continuously monitor the performance and microfluidic outputs of organ-on-chip devices.

Castro, R. O., et al. (2016). "Evaluation of microplastics in Jurujuba Cove, Niteroi, RJ, Brazil, an area of mussels farming." Marine Pollution Bulletin. **22**.

Once non-biodegradable, microplastics remain on the environment absorbing toxic hydrophobic compounds making them a risk to biodiversity when ingested or filtered by organisms and entering in the food chain. To evaluate the potential of the contamination by microplastics in mussels cultivated in Jurujuba Cove, Niteroi, RJ, waters of three stations were collected during a rain and dry seasons using a plankton net and later filtered. Microplastics were quantified and characterized morphologically and chemically. The results showed a high concentration of microplastics in both seasons with diversity of colors, types and sizes. Synthetic polymers were present in all samples. The presence of microplastics was probably due to a high and constant load of effluent that this area receives and to the mussel farming activity that use many plastic materials. Areas with high concentrations of microplastics could not be used for mussel cultivation due to the risk of contamination to consumers. Copyright © 2016 Elsevier Ltd.

Castro, R. O., et al. (2016). "Evaluation of microplastics in Jurujuba Cove, Niterói, RJ, Brazil, an area of mussels farming." Marine Pollution Bulletin **110**(1): 555-558.

Cataldi, P., et al. (2018). "Sustainable electronics based on crop plant extracts and graphene: a "bioadvantaged" approach." Advanced Sustainable Systems **2**(11): 1800069.

In today's fast-paced and well-connected world, consumer electronics are evolving rapidly. As a result, the amount of discarded electronic devices is becoming a major health and environmental concern. The rapid expansion of flexible electronics has the potential to transform consumer electronic devices from rigid phones and tablets to robust wearable devices. This means increased use of plastics in consumer electronics and the potential to generate more persistent plastic waste for the environment. Hence, today, the need for flexible biodegradable electronics is at the forefront of minimizing the mounting pile of global electronic waste. A "bioadvantaged" approach to develop a biodegradable, flexible, and application-adaptable electronic components based on crop components and graphene is reported. More specifically, by combining zein, a corn-derived protein, and aleuritic acid, a major monomer of tomato cuticles and sheellac, along with graphene, biocomposite conductors having low electrical resistance (~10 Omega sq⁻¹) with exceptional mechanical and fatigue resilience are fabricated. Further, a number of high-performance electronic applications, such as THz electromagnetic shielding, flexible GHz antenna construction, and flexible solar cell electrode, are demonstrated. Excellent performance results are measured from each application comparable to conventional nondegrading counterparts, thus paving the way for the concept of "plant-e-tronics" towards sustainability.

Catani, L., et al. (2010). "CD133⁺ pluripotent stem cells for the treatment of chronic liver failure." Blood. Conference: 52nd Annual Meeting of the American Society of Hematology, ASH **116**(21).

Background.: The potential role of bone marrow (BM)-derived stem cells (SCs) in patients with end-stage liver disease has been addressed by our group in four studies. Main objectives were: 1) to assess stem/progenitor cell mobilization in 24 patients receiving orthotopic liver transplantation (OLT); 2) to evaluate whether G-CSF can be safely administered to patients with liver cirrhosis in order to expand and mobilize BM-derived SCs; 3) to investigate the effects of transplantation of human G-CSF-mobilized CD34+ and CD133+ SCs in mice with chronic liver injury and fibrosis; 4) to evaluate the feasibility and the safety of the purification and intrahepatic reinfusion of increasing numbers of autologous BM-derived G-CSF-mobilized CD133+ SCs in patients with end-stage liver disease. Methods.: 1) Flow cytometry analysis, clonogenic assays and RT-PCR have been performed after OLT; 2) 18 patients with advanced liver disease were consecutively treated with increasing doses of G-CSF starting from 2 mug/kg/daily; 3) C57BL/6N mice received CCl4 by inhalation for thirteen weeks and were treated with Cyclosporin-A. Transplantation was performed by injection (tail vein) of 106 CD34+ or CD133+ SCs of three cirrhotic patients. After four weeks from transplantation all mice were sacrificed; 4) G-CSF at 7.5mug/Kg/b.i.d. is administered subcutaneosly (sc) from day 1 until the completion of peripheral blood stem cells (PBSC) collection. Collection of PBSC will begin on day + 4 only if the concentration of CD133+ cells is 38/mL. PB mononuclear cells obtained from mobilized standard-volume leukapheresis will be incubated with Macs colloidal superparamagnetic CD133 microbeads. CliniMacs device is used for the positive selection of CD133+ SCs under GMP conditions. At least 4 weeks after SC mobilization, collection and cryopreservation, highly purified autologous G-CSF-mobilized CD133+ cells are re-infused through the hepatic artery by transfemoral or transbranchial arteriography. CD133+ cells are administered to patients starting from 5x10⁴/Kg patient's body weight and increased every 3 patients. The maximum infused cell dose will be 1x10⁶/kg. G-CSF at 5mug/Kg/day is administered sc for 3 days after the reinfusion of SCs for their expansion and to induce a selective proliferative advantage of reinfused cells in vivo. Results and Discussion.: 1) We demonstrated that both early subsets of the hematopoietic SC compartment

(CD34⁺/CD90⁺ cells) and more mature committed progenitors (CFU-C) were mobilized into PB after OLT. We also demonstrated the release from the BM of liver-committed HSCs co-expressing epithelial markers after OLT; 2) We show that the administration of G-CSF to patients with liver cirrhosis is safe and feasible and allows the mobilization and collection of BM-derived SCs at the dose of 15 mg/kg/day. 3) We demonstrated that mice transplanted with either CD133+ or CD34+ human cells appear to have less fibrotic septa than mice without SC transplantation, suggesting the potential therapeutic role of human SCs on the recovery of liver fibrosis. 4) Up to date, three patients with end stage liver disease have been successfully mobilized with G-CSF and highly purified autologous CD133+ SCs have been re-infused. The number of collected CD133+ SCs is 0,7, 0,2 and 0.35x10⁶/Kg, respectively. The number of the re-infused highly purified CD133⁺ SCs is 4.7, 5.0 and 5.4x10⁴/Kg, respectively. No adverse events have been recorded during mobilization or intrahepatic SCs re-infusion. Updated results on current patients and future patients will be presented at the Meeting.

Catarino, A. I., et al. (2019). "Use of fluorescent-labelled nanoplastics (NPs) to demonstrate NP absorption is inconclusive without adequate controls." Science of the Total Environment **670**: 915-920.

Whether nanoplastics (NPs) are able to be absorbed across epithelial membranes and accumulate within internal tissues of organisms is an important determinant of their potential toxicity. Evidence of absorption and accumulation requires detection of NPs within internal tissues, and investigations with fluorescently labelled NPs have attempted to provide this information. We hypothesize that studies that do not control for the fluorescent dye leachate and/or cellular autofluorescence are inconclusive and can be misinterpreted. Our goal was to analyse previous investigations critically and conduct further research to determine if fluorescent-labelled polystyrene NPs (nanoPS) can provide conclusive evidence of absorption and internal accumulation of NPs. We exposed zebrafish embryos and larvae to NPs (500 and 1000nm) labelled with a green or an orange fluorescent dye, to solutions resulting from nanoPS dialysis, and to Nile-Red (a fluorescent dye used as a positive control). Previous studies have claimed that NPs cross epithelia without accounting for dye leachates and/or cellular autofluorescence. Our results demonstrate that commercial fluorescent-labelled nanoPS can leach their fluorophores, and the fluorophore alone can accumulate within internal tissues of zebrafish larvae. We further observed green autofluorescence in fish larvae not exposed to any particles. Previous claims of NP absorption based on observations of fluorescence in zebrafish tissues should thus be considered inconclusive. Although the addition of purification steps and inclusion of controls for leaching of dyes are methodological improvements, the use of fluorescent nanoPS should not be considered to provide absolute conclusive evidence of particle absorption.

Catarino, A. I., et al. (2018). "Low levels of microplastics (MP) in wild mussels indicate that MP ingestion by humans is minimal compared to exposure via household fibres fallout during a meal." Environmental Pollution **237**: 675-684.

Microplastics (MPs) are the most numerous debris reported in marine environments and assessment of the amounts of MPs that accumulate in wild organisms is necessary for risk assessment. Our objective was to assess MP contamination in mussels collected around the coast of Scotland (UK) to identify characteristics of MPs and to evaluate risk of human exposure to MPs via ingestion of mussels. We deployed caged mussels (Mytilus edulis) in an urbanised estuary (Edinburgh, UK) to assess seasonal changes in plastic pollution, and collected mussels (Mytilus spp and subtidal Modiolus modiolus) from eight sampling stations around Scotland to enumerate MP types at different locations. We determined the potential exposure of humans to household dust fibres during a meal to compare with amounts of MPs present in edible mussels. The mean number of MPs in M. modiolus was 0.086+/-0.031 (SE, n=6)/g ww (3.5+/-1.29 (SE) per mussel). In Mytilus spp, the mean number of MPs/g ww was 3.0+/-0.9 (SE, n=36) (3.2+/-0.52 (SE) per mussel), but weight dependent. The visual accuracy of plastic fibres identification was estimated to be between 48 and 50%, using Nile Red staining and FT-IR methodologies, respectively, halving the observed amounts of MPs in wild mussels. We observed an allometric relationship between the number of MPs and the mussels wet weight. Our predictions of MPs ingestion by humans via consumption of mussels is 123MP particles/y/capita in the UK and can go up to 4620 particles/y/capita in countries with a higher shellfish consumption. By comparison, the risk of plastic ingestion via mussel consumption is minimal when compared to fibre exposure during a meal via dust fallout in a household (13,731-68,415 particles/Y/capita).

Cattle, S. R., et al. (2020). "The character and distribution of physical contaminants found in soil previously treated with mixed waste organic outputs and garden waste compost." Waste Management **101**: 94-105.

The re-use of waste materials by application to land is an increasingly common practice around the world, but where municipal solid waste materials are applied, it is almost inevitable that physical contaminants such as glass and plastic will be added to the soil. In many jurisdictions, there are prescribed limits for the amounts of physical contaminants that may be present in these materials, but there is little information on whether these limits safeguard soil functional condition. Here, physical contamination of soil is described after varying rates of a mixed waste organic output (MWOO) and garden waste compost (GWC) were incorporated into field plots. At application rates of 100 and 200t/ha, both treatments resulted in a coarsening of the topsoil particle size distribution, but only in the MWOO-treated soils were physical contaminants largely responsible for this. The physical contaminant particles present were found only to the depth of cultivation, and included glass, rigid and film plastics, and synthetic fibres. These contaminants were most commonly observed in the gravel and coarse sand-sized fractions, and in those soils treated with the highest rates of MWOO application. Physical contaminant particles acted as both enveloping and nucleating agents for mineral grains and organic matter, and blocked some pores. Although soil physical condition is usually improved by the incorporation of organic matter, the extent of pore blockage evident here suggests that soil physical functions such as water percolation may be affected as the organic matter is broken down and the soil undergoes natural re-consolidation.

Cau, A., et al. (2019). "Microplastics in the crustaceans Nephrops norvegicus and Aristeus antennatus: Flagship species for deep-sea environments?" Environmental Pollution **255**(Pt 1): 113107.

Ingestion of microplastics (MPs) has been documented in several marine organisms, but their occurrence in deep-sea species remains almost unknown. In this study, MPs were investigated in two economically and ecologically key crustaceans of the Mediterranean Sea, the Norwegian lobster Nephrops norvegicus and the shrimp Aristeus antennatus. Both the species were collected from 14 sites around Sardinia Island, at depths comprised between 270 and 660m. A total of 89 and 63 stomachs were analysed for N. norvegicus and A. antennatus respectively, and more than 2000MPs-like particles were extracted and sorted for identification and characterization by muFT-IR. In N. norvegicus, 83% of the specimens contained MPs, with an average abundance of 5.5+/-0.8MPs individual⁻¹, while A. antennatus showed a lower frequency of ingestion (67%) and a lower mean number of MPs (1.66+/-0.1MPs individual⁻¹). Composition and size of particles differed significantly between the two species. The non-selective feeding strategy of N. norvegicus could explain the 3-5 folds higher numbers of MPs in its stomach, which were mostly composed of films and fragments derived by polyethylene and polypropylene single-use plastic items. Contrarily, most MPs in the stomachs of A. antennatus were polyester filaments. The MPs abundance observed in N. norvegicus is among the highest detected in Mediterranean species considering both fish and invertebrates species, and provides novel insights on MPs bioavailability in deep-sea habitats. The overall results suggest that both N. norvegicus and A. antennatus, easily available in common fishery markets, could be valuable bioindicators and flagship species for plastic contamination in the deep-sea.

Cauwenberghe, L. v., et al. (2015). "Microplastics are taken up by mussels (Mytilus edulis) and lugworms (Arenicola marina) living in natural habitats." Environmental Pollution **199**: 10-17.

We studied the uptake of microplastics under field conditions. At six locations along the French-Belgian-Dutch coastline we collected two species of marine invertebrates representing different feeding strategies: the blue mussel Mytilus edulis (filter feeder) and the lugworm Arenicola marina (deposit feeder). Additional laboratory experiments were performed to assess possible (adverse) effects of ingestion and translocation of microplastics on the energy metabolism (cellular energy allocation) of these species. Microplastics were present in all organisms collected in the field: on average 0.2+or-0.3 microplastics g⁻¹ (M. edulis) and 1.2+or-2.8 particles g⁻¹ (A. marina). In a proof of principle laboratory experiment, mussels and lugworms exposed to high concentrations of polystyrene microspheres (110 particles mL⁻¹ seawater and 110 particles g⁻¹ sediment, respectively) showed no significant adverse effect on the organisms' overall energy budget. The results are discussed in the context of possible risks as a result of the possible transfer of adsorbed contaminants.

Cauwenberghe, L. v. and C. R. Janssen (2014). "Microplastics in bivalves cultured for human consumption." Environmental Pollution **193**: 65-70.

Microplastics are present throughout the marine environment and ingestion of these plastic particles (<1 mm) has been demonstrated in a laboratory setting for a wide array of marine organisms. Here, we investigate the presence of microplastics in two species of commercially grown bivalves: Mytilus edulis and Crassostrea gigas. Microplastics were recovered from the soft tissues of both species. At time of human consumption, M. edulis contains on average 0.36+or-0.07 particles g⁻¹ (wet weight), while a plastic load of 0.47+or-0.16 particles g⁻¹ ww was detected in C. gigas. As a result, the annual dietary exposure for European shellfish consumers can amount to 11,000 microplastics per year. The presence of marine microplastics in seafood could pose a threat to food safety, however, due to the complexity of estimating microplastic toxicity, estimations of the potential risks for human health posed by microplastics in food stuffs is not (yet) possible.

Cavalieri, F. and F. Padella (2002). "Development of composite materials by mechanochemical treatment of post-consumer plastic waste." Waste Management **22**(8): 913-916.

Improvement of mechanical properties of recycled mixed plastic waste is one of the fundamental goals in any recycling process. However, polymer immiscibility makes the development of any effective reprocessing method difficult. In this work, a polymer milling process with liquid CO2 was applied to polymeric mixed waste, obtaining a powder material which was successfully utilized as a matrix for a new composite material. Developed materials have interesting mechanical properties and material performance can easily be improved.

Investigations on selected mixtures of PP and PE clearly showed evidence of chemical compatibilization.

Cavallari, C., et al. (2018). "MiR-296-5p and PDGF-BB in CD31EV cargo: Novel biomarkers of vascular smooth muscle cell dysfunction in diabetes." Journal of Extracellular Vesicles **7 (Supplement 1)**: 230.

Background: Endothelial cell-derived extracellular vesicles (CD31EVs) are a new entity for therapeutic/diagnostic purposes. The roles of CD31EVs as biomarkers and mediators of smooth muscle cell (VSMC) dysfunction in type 2 diabetes (T2D) are investigated herein. Method(s): Human atherosclerotic plaque specimens from 11 T2D and six non-diabetic individuals undergoing carotid endoarteriectomy surgery were analysed. siRNA technology was performed on vascular smooth muscle cells (VSMCs). The CD31 microbead kit was used to isolate CD31EVs from the sera of T2D (D-CD31EVs) and non-diabetic individuals (ND-CD31EVs). In selected experiments, VSMCs were cultured in HG and then treated with ND-CD31EVs, D-CD31EVs or stimulated with PDGF-BB. CD31EVs were processed for transmission electron microscopy (TEM), biological effects. miR analysis was also performed. PDGF-BB concentration in D-CD31EVs was measured using an ELISA kit. Result(s): We discovered that VSMCs, from human atherosclerotic arteries of T2D individuals, express low bak/bax and high bcl-2 levels. These effects were recapitulated in VSMCs subjected to HG and boosted by diabetic-sera-derived-EVs (D-CD31EVs). Moreover, unlike non-diabetic serum-derived EVs, D-CD31EVs increased HG-cultured VSMC resistance to apoptosis. We also found an increased expression of miR-296-5p in both T2D-derived atherosclerotic specimens and HG-cultured VSMCs treated with D-CD31EVs. D-CD31EVs were found almost depleted of miR-296-5p, while enriched in membrane-bound-plateletderived-growth-factor-BB (mbPDGF-BB). Thus, we postulated that mbPDGF-BB transfer by D-CD31EVs could account for VSMC-miR-296-5p content. By depleting CD31EVs of PDGF-BB or blocking the PDGF-BB receptor-beta, we demonstrated that PDGF-BB contributes to DCD31EV-mediated miR-296-5p expression and downstream events. In fact, while PDGF-BB-treatment recapitulated the D-CD31EV-mediated anti-apoptotic programme and VSMC resistance to apoptosis, PDGFBB-depleted CD31EVs failed. Finally, D-CD31EVs also increased VSMC migration and recruitment to neovessels, by means of mbPDGF-BB. Summary/Conclusion: This study identifies the mbPDGF-BB in DCD31EVs as a relevant mediator of diabetes-associated VSMC dysfunction, and recognizes CD31EV-miR-296-5p-mbPDGF-BB content as novel diabetes-associated biomarkers.

Cavers, C., et al. (2017). "Cotton buds—corporate change leads the way in the UK and Europe." Oryx **51**(4): 581-581.

The article offers conservation-related updates on the plastic pollution from cotton buds stems and ingested by marine animals.

Caykara, T., et al. (2007). "Competitive adsorption of uranyl ions in the presence of Pb(II) and Cd(II) ions by poly(glycidyl methacrylate) microbeads carrying amidoxime groups and polarographic determination." Journal of Applied Polymer Science **104**(6): 4168-4172.

The adsorption capacity of UO in the presence of Pb(II) and Cd(II) ions was investigated with amidoximated poly(glycidyl methacrylate) (PGMA) microbeads with an average size of 135 m packed in a glass column (0.5-cm i.d. and 20-cm length, flow rate = 3 mL/min) under competitive conditions. A differential pulse polarography technique was used for the determination of trace quantities of uptaken elements by the measurement of the reduction peak currents at -200/-950, -400, and -600 mV (vs a saturated calomel electrode) for UO, Pb(II), and Cd(II) ions, respectively. When only UO was found in the eluate, its adsorption was 85.3% from a 50 M initial solution. However, when there was UO with binary systems of Pb(II) or Cd(II), it was 78.2 and 76.3%, respectively. On the other hand, in a ternary mixture of UO with Pb(II) and Cd(II), the adsorption was found to be 75.2% with the same initial concentration. According to the results, the competitive adsorption studies showed that these amidoximated PGMA microbeads had good adsorption selectivity for UO with the coexistence of Pb(II) and Cd(II) ions. The ionic strength of the solution also influenced the UO adsorption capacity of the amidoximated PGMA microbeads.

Ceccarini, A., et al. (2018). "The Hidden Microplastics: New Insights and Figures from the Thorough Separation and Characterization of Microplastics and of Their Degradation Byproducts in Coastal Sediments." Environmental Science & Technology **52**(10): 5634-5643.

The environmental pollution by plastic debris directly dispersed in or eventually reaching marine habitats is raising increasing concern not only for the vulnerability of marine species to ingestion and entanglement by macroscopic debris, but also for the potential hazards from smaller fragments down to a few micrometer size, often referred to as "microplastics". A novel procedure for the selective quantitative and qualitative determination of organic solvent soluble microplastics and microplastics degradation products (<2 mm) in shoreline sediments was adopted to evaluate their concentration and distribution over the different sectors of a Tuscany (Italy) beach. Solvent extraction followed by gravimetric determination and chemical characterization by FT-IR, Pyrolysis-GC-MS, GPC and ¹H NMR analyses showed the presence of up to 30 mg microplastics in 1 kg sand, a figure corresponding to about 5.5 g of generally undetected and largely underestimated microplastics in the upper 10 cm layer of a square meter of sandy beach ! The extracted microplastic material was essentially polystyrene and polyolefin byproducts from oxidative degradation and erosion of larger fragments, with accumulation mainly above the storm berm. Chain scission and oxidation processes cause significant variations in the physical and chemical features of microplastics, promoting their adsorption onto sand particles and thus their persistence in the sediments.

Cedergren, J., et al. (2007). "Intracellular oxidative activation in synovial fluid neutrophils from patients with rheumatoid arthritis but not from other arthritis patients." Journal of Rheumatology **34**(11): 2162-2170.

Objective. To compare total and intracellular oxidative activation of blood and synovial fluid (SF) neutrophils from patients with rheumatoid arthritis (RA) and other arthritides with blood donor neutrophils. Methods. Peripheral blood and SF samples were obtained from 26 gonarthritis patients (13 RA, 13 non-RA) attending the rheumatology unit for therapeutic joint aspiration. Isolated neutrophils were stimulated by a formylated tripeptide (fMLF) or by microbeads coated with collagen-I. Formation of superoxide-anion-derived reactive oxygen species (ROS) was studied by luminol-enhanced chemiluminescence. Paired samples of blood and SF neutrophils from patients with active arthritis were compared with blood neutrophils from patients in remission and from 47 healthy blood donors. Results. SF neutrophils from patients with RA, but not from non-RA patients, showed high baseline intracellular ROS production. Blood neutrophils from arthritis patients in remission existed in a primed state as revealed by more rapid oxidative response after collagen-bead challenge and a more pronounced response after fMLF stimulation compared to healthy blood donors. Blood neutrophils from RA patients with ongoing gonarthritis, however, did not differ from healthy blood donors concerning oxidative activation, whereas blood neutrophils from non-RA patients with gonarthritis showed a significantly lower peak ROS production. Conclusion. A novel finding with pathogenetic implications in our study is that SF neutrophils from patients with RA, but not other arthritides, are activated and produce

ROS intracellularly. This implies that synovial neutrophils in RA are engaged in the processing of endocytosed material.

Cerna, K., et al. (2016). "Methods of sampling airborne fungi in working environments of waste treatment facilities." International Journal of Occupational Medicine & Environmental Health **29**(3): 493-502.

OBJECTIVES: The objective of the present study was to evaluate and compare the efficiency of a filter based sampling method and a high volume sampling method for sampling airborne culturable fungi present in waste sorting facilities.

MATERIAL AND METHODS: Membrane filters method was compared with surface air system method. The selected sampling methods were modified and tested in 2 plastic waste sorting facilities.

RESULTS: The total number of colony-forming units (CFU)/m3 of airborne fungi was dependent on the type of sampling device, on the time of sampling, which was carried out every hour from the beginning of the work shift, and on the type of cultivation medium ($p < 0.001$). Detected concentrations of airborne fungi ranged 2x102-1.7x106 CFU/m3 when using the membrane filters (MF) method, and 3x102-6.4x104 CFU/m3 when using the surface air system (SAS) method.

CONCLUSIONS: Both methods showed comparable sensitivity to the fluctuations of the concentrations of airborne fungi during the work shifts. The SAS method is adequate for a fast indicative determination of concentration of airborne fungi. The MF method is suitable for thorough assessment of working environment contamination by airborne fungi. Therefore we recommend the MF method for the implementation of a uniform standard methodology of airborne fungi sampling in working environments of waste treatment facilities.

Cerna, K., et al. (2017). "Exposure to airborne fungi during sorting of recyclable plastics in waste treatment facilities." Medycyna Pracy **68**(1): 1-9.

BACKGROUND: In working environment of waste treatment facilities, employees are exposed to high concentrations of airborne microorganisms. Fungi constitute an essential part of them. This study aims at evaluating the diurnal variation in concentrations and species composition of the fungal contamination in 2 plastic waste sorting facilities in different seasons.

MATERIAL AND METHODS: Air samples from the 2 sorting facilities were collected through the membrane filters method on 4 different types of cultivation media. Isolated fungi were classified to genera or species by using a light microscopy.

RESULTS: Overall, the highest concentrations of airborne fungi were recorded in summer (9.1x10³-9.0x10⁵ colony-forming units (CFU)/m₃), while the lowest ones in winter (2.7x10³-2.9x10⁵ CFU/m³). The concentration increased from the beginning of the work shift and reached a plateau after 6-7 h of the sorting. The most frequently isolated airborne fungi were those of the genera Penicillium and Aspergillus. The turnover of fungal species between seasons was relatively high as well as changes in the number of detected species, but potentially toxigenic and allergenic fungi were detected in both facilities during all seasons.

CONCLUSIONS: Generally, high concentrations of airborne fungi were detected in the working environment of plastic waste sorting facilities, which raises the question of health risk taken by the employees. Based on our results, the use of protective equipment by employees is recommended and preventive measures should be introduced into the working environment of waste sorting facilities to reduce health risk for employees. Med Pr 2017;68(1):1-9.

Cervero, J. M., et al. (2011). "Development of a technology to produce monodispersed microparticles

based on the formation of drops from viscous non-Newtonian liquids sprayed through a fan jet nozzle." Chemical Engineering Journal **174**(2-3): 699-708.

A new technique has been developed to produce microparticles as small as 30 mu m from a non-Newtonian viscous fluid such as sodium alginate. A fan jet nozzle was employed to produce a laminar jet, which was unstabilized by a rapid air gas stream co-axial to the flow. Behavior studies were conducted to show the performance of the system under the variation of parameters like air and liquid flow (imposed by pressure), and also viscosity, and their influence of the generated particles. Also, the downstream jet flow was parameterized as a function of controlled external variables: air and liquid pressure and viscosity. Agreement was found between the model and experimental data. Microbeads were obtained at different conditions to obtain a mathematical relationship between size parameters (Sauter Mean Diameter) and forces acting in the system, represented as dimensionless numbers: liquid/air mass ratio and Weber (We) and Ohneshorge (Oh) numbers. Based in wave propagation mechanisms, three semi-empirical models have been proposed based in these dimensionless numbers. Further experimental data agrees accurately with the models, and allow the prediction of the microbeads size obtained by this technique.

Cesur, S. (2018). "The Effects of Additives on the Biodegradation of Polycaprolactone Composites." Journal of Polymers & the Environment **26**(4): 1425-1444.

Because environmental pollution caused by plastic waste is a major problem investigations concerning biodegradable packaging are important and required. In this study, the biodegradation of PCL composite films with organic (glycerol monooleate and oleic acid) and inorganic additives (organo nano clay) was investigated to understand which additive and the amount of additive was more effective for biodegradation. The relationship between the degree of crystallinity and the effect of additives on the biodegradability of polycaprolactone (PCL) was examined. PCL composite films were prepared using organo nano clay (0.1-0.4-1-3 wt%) and oleic acid (1-3-5 wt%) or GMO (1-3-5 wt%). The 35 films prepared with PCL (P), clay (C), oleic acid (O), or glycerol monooleate (G) are coded as P_C#wt%_O (or G)#wt%. The composite films, P_C0.4_O5 contains 0.4 wt% clay and 5 wt% oleic acid and the P_C3_G1 contains 3 wt% clay and 1 wt% glycerol monooleate. The biodegradation of PCL films in simulated soil was studied for 36 months. The films were periodically removed from the simulated soil and film thicknesses, weight losses, visual changes, crystal structures, and a functional group analyses were performed. PCL composite films are separated into three groups, depending on degradation time, (1) films that degraded before 8 months (fast degradation), (2) films that degraded around 24 months (similar to neat PCL), and (3) films that take longer to degrade (slow degradation). The films in the first group are PCL films with 1 and 3 wt% clay additive and they begin to biodegrade at the 5th month. However, a composite film of PCL with only 0.4 wt% clay and 5 wt% GMO addition has the shortest degradation time and degraded in 5 months. The films in the last group are; P_G3, P_G5, P_C0.1, P_C0.1_O1, and P_C0.1_O5 and they took around 30 months for biodegradation. It was observed that increasing the organo nanoclay additive increases the biodegradability by disrupting the crystal structure and causing a defective crystal formation. The addition of GMO with organo nano clay also accelerates biodegradation. The addition of organo nano clay in an amount as small as 0.1 wt% acts as the nucleating agent, increases the degree of crystallinity of the PCL composites, and slows the biodegradation period by increasing the time. Chae, D. H., et al. (2015). "Abundance and Distribution Characteristics of Microplastics in Surface Seawaters of the Incheon/Kyeonggi Coastal Region." Archives of Environmental Contamination & Toxicology **69**(3): 269-278.

Microplastics in marine environments are of emerging concern due to their widespread distribution, their ingestion by various marine organisms, and their roles as a source and transfer vector of toxic chemicals. However, our understanding of their abundance and distribution characteristics in surface seawater (SSW) remains limited. We investigated microplastics in the surface microlayer (SML) and the SSW at 12 stations near-shore and offshore of the Korean west coast, Incheon/Kyeonggi region. Variation between stations, sampling media, and sampling methods were compared based on abundances, size distribution, and composition profiles of microsized synthetic polymer particles. The abundance of microplastics was greater in the SML (152,688 +/- 92,384 particles/m(3)) than in SSW and showed a significant difference based on the sampling method for SSWs collected using a hand net (1602 +/- 1274 particles/m(3)) and a zooplankton trawl net (0.19 +/- 0.14 particles/m(3)). Ship paint particles (mostly alkyd resin polymer) accounted for the majority of microplastics detected in both SML and SSWs, and increased levels were observed around the voyage routes of large vessels. This indicates that polymers with marine-based origins become an important contributor to microplastics in coastal SSWs of this coastal region.

Chae, Y. and Y. J. An (2017). "Effects of micro- and nanoplastics on aquatic ecosystems: Current research trends and perspectives." Marine Pollution Bulletin **124**(2): 624-632.

Contamination by bulk plastics and plastic debris is currently the one of the most serious environmental problems in aquatic ecosystems. In particular, small-scale plastic debris such as microplastics and nanoplastics has become leading contributors to the pollution of marine and freshwater ecosystems. Studies are investigating the impacts of micro-and nanoplastics on aquatic organisms and ecosystems worldwide. This review covers 83 studies that investigated the distribution of microplastics and the ecotoxicity of micro- and nanoplastics in marine and freshwater ecosystems. The studies indicated that micro-sized plastics and plastic debris were distributed at various concentrations in aquatic ecosystems around the world. They had various effects on the growth, development, behavior, reproduction, and mortality of aquatic animals. We discuss these studies in detail and suggest directions for future research. Copyright © 2017 Elsevier Ltd

Chae, Y. and Y. J. An (2018). "Current research trends on plastic pollution and ecological impacts on the soil ecosystem: A review." Environmental Pollution **240**: 387-395.

Plastic pollution in the environment is currently receiving worldwide attention. Improper dumping of disused or abandoned plastic wastes leads to contamination of the environment. In particular, the disposal of municipal wastewater effluent, sewage sludge landfill, and plastic mulch from agricultural activities is a serious issue and of major concern regarding soil pollution. Compared to plastic pollution in the marine and freshwater ecosystems, that in the soil ecosystem has been relatively neglected. In this study, we discussed plastic pollution in the soil environment and investigated research on the effects of plastic wastes, especially microplastics, on the soil ecosystem. We found that earthworms have been predominantly used as the test species in investigating the effects of soil plastic pollution on organisms. Therefore, further research investigating the effects of plastic on other species models (invertebrates, plants, microorganisms, and insects) are required to understand the effects of plastic pollution on the overall soil ecosystem. In addition, we suggest other perspectives for future studies on plastic pollution and soil ecotoxicity of plastics wastes, providing a direction for such research.

Chae, Y. and Y. J. An (2020). "Effects of food presence on microplastic ingestion and egestion in Mytilus galloprovincialis." Chemosphere **240**: 124855.

Plastic wastes are widespread pollutants in marine environments and several studies have focused on their impacts on different ecosystems. Microplastics (MPs, < 5mm) have been the focus of a particularly extensive investigation because of their ubiquity, large surface area, interactions with organisms, and the challenges they present in terms of disposal and management. However, studies regarding their fates and life cycle in ecosystems are still limited. This study examined the effects of presence of food (the green microalga Dunaliella salina) on egestion rate of polyethylene MPs in the mussel Mytilus galloprovincialis. Ingestion and egestion rates were calculated after 6, 12, 18, and 24h of depuration. The results suggest that MPs exposed to algal food persisted in the mussels. A single exposure of MPs without food induced relatively rapid excretion by the mussels compared to MPs exposure with food. This could be attributed to the ability of mussels to distinguish between nutritive foods and unusable suspended particles. Thus, environmental factors, such as food abundance, can affect the cycle or fate of MPs in marine environments.

Chae, Y., et al. (2020). "Photosynthesis enhancement in four marine microalgal species exposed to expanded polystyrene leachate." Ecotoxicology & Environmental Safety **189**: N.PAG-N.PAG.

Due to its widespread use, large amounts of expanded polystyrene (EPS) have been released into the marine environment, where it is broken down into small pieces with large surface areas. As such, chemical additives may be released into the environment, which can affect marine organisms; however, studies of the effects of such additives are lacking. We assessed the effects of leachate from EPS on the photosynthetic activities of four microalgal species (Dunaliella salina , Scenedesmus rubescens , Chlorella saccharophila , and Stichococcus bacillaris). They were exposed to EPS leachate for seven days and their photosynthetic activities were analyzed based on seven parameters. Overall, leachate exposure increased photosynthetic activity in all four species, albeit to different degrees and showing slightly different trends among the seven parameters. Based on chemical analysis, hexabromocyclododecane concentrations were higher in small-fragment leachate, whereas UV326 concentrations were higher in low-concentration-large-sphere leachate; bisphenol-A and total organic carbon showed no major differences among leachates. Thus, we speculate that exposure to trace chemicals influenced microalgal photosynthesis and overall growth. These results support further investigation of the impacts of plastic debris and chemical additives on marine ecosystems and organisms. • Four microalgae species were exposed to leachate from EPS fragments/spheres. • The leachates contained varying concentrations of chemical additives. • Leachate exposure for 7 days enhanced photosynthetic activity in all species. • Exposure to chemical additives likely resulted in the changes to photosynthesis. [ABSTRACT FROM AUTHOR]

Chae, Y., et al. (2019). "Effects of micro-sized polyethylene spheres on the marine microalga Dunaliella salina: Focusing on the algal cell to plastic particle size ratio." Aquatic Toxicology **216**: 105296.

There is increasing concern about how microplastics (MPs) are impacting marine ecosystems. In particular, studies on how MPs impact microalgae are required because of the abundance of MPs and importance of green microalgae as primary producers. This study investigated how MPs that are larger (200 mum) than algal cells impact them, using the marine microalga Dunaliella salina as the test species. The microalga was exposed to polyethylene MPs for 6 days. Of interest, the growth and photosynthetic activity of D. salina was enhanced with exposure to MPs, while cell morphology (size and granularity) was not impacted. This phenomenon might be explained by trace concentrations of additive chemicals (endocrine disruptors, phthalates, stabilizers) that possibly leached from MPs promoting the growth and photosynthetic activity of D. salina. We also confirmed that MP size contributes towards determining how plastics affect microalgae. Specifically, as MP size shrinks compared to algal cell size, MPs have increasingly adverse effects. MPs of very small size (like nanoplastics) induce particularly adverse effects on algae. Further studies are required to establish the relationship between algal cell size and MP size.

Chae, Y., et al. (2019). "Impact of nano-sized plastic on the nutritional value and gut microbiota of whiteleg shrimp Litopenaeus vannamei via dietary exposure." Environment International **130**: 104848.

Contamination of the world's oceans with plastic waste has attracted increasing attention in recent years. Whereas the ecological consequences of plastic pollution have been the focus of increasing research, the health-related implications of plastic pollution have been somewhat overlooked. In this study, we exposed whiteleg shrimp (Litopenaeus vannamei), a widely consumed marine species, to nano-sized plastic (polystyrene) via a simulated marine food chain in which mussel (Mytilus edulis) was the food source, and evaluated the effects of plastic contamination on shrimp physical, biochemical, and nutritional characteristics over a 21-day exposure period. We identified the changes in certain important biochemical and nutritional indicators, including changes in the gut microbiota and contents of amino acids and fatty acids. The biochemical analysis revealed that microbial activities in the intestine and the glutathione S-transferase and superoxide dismutase activities changed in L. vannamei exposed to nano-sized plastic. In these individuals, the levels of some essential amino acids and fatty acids also decreased. Overall, our findings indicate that plastic pollution can directly interfere with nutritional changes in marine food resources, thereby indirectly causing potential health implications for human consumers.

Chae, Y., et al. (2018). "Trophic transfer and individual impact of nano-sized polystyrene in a four-species freshwater food chain." Scientific Reports **8**(1).

This study investigated the trophic transfer, individual impact, and embryonic uptake of fluorescent nano-sized polystyrene plastics (nanoplastics) through direct exposure in a freshwater ecosystem, with a food chain containing four species. The alga Chlamydomonas reinhardtii, water flea Daphnia magna, secondary-consumer fish Oryzias sinensis, and end-consumer fish Zacco temminckii were used as test species. In the trophic transfer test, algae were exposed to 50 mg/L nanoplastics, defined as plastic particles <100 nm in diameter; higher trophic level organisms were exposed through their diet. In the direct exposure test, each species was directly exposed to nanoplastics. Microscopic analysis confirmed that the nanoplastics adhered to the surface of the primary producer and were present in the digestive organs of the higher trophic level species. Nanoplastics also negatively affected fish activity, as measured by distance traveled and area covered, and induced histopathological changes in the livers of fish that were directly exposed. Additionally, nanoplastics penetrated the embryo walls and were present in the yolk sac of hatched juveniles. These observations clearly show that nanoplastics are easily transferred through food chain, albeit because of high experimental dosages. Nevertheless, the results strongly point to the potential health risks of nanoplastic exposure.

Chagnon, C., et al. (2018). "Plastic ingestion and trophic transfer between Easter Island flying fish (Cheilopogon rapanouiensis) and yellowfin tuna (Thunnus albacares) from Rapa Nui (Easter Island)." Environmental Pollution **Part A. 243**: 127-133.

Millimetre-sized fragments have been documented in many fish species, but their transfer through food webs is still poorly understood. Here we quantified and described plastic fragments in the digestive tracts of 43 Easter Island flying fish (Cheilopogon rapanouiensis) and 50 yellowfin tunas (Thunnus albacares) from coastal waters around Rapa Nui (Easter Island) in the South Pacific subtropical gyre, and of fish preyed upon by T. albacares. Overall, seven C. rapanouiensis (16%) individuals had ingested microplastics, most of which resembled the common planktonic prey of the fish. One microplastic was found in the gut of a fish ingested by a tuna, which indicates that trophic transfer may occur between tuna and prey. A single T. albacares (2%) had ingested five mesoplastics (15.2-26.3 mm) that were probably not mistaken for prey items, but rather accidentally ingested during foraging on fish prey. The absence of microplastics in T. albacares suggests that such small particles, if transferred from the prey, do not accumulate in the relatively large digestive tract of large predators. On the other hand, larger plastic items may accumulate in the gut of tunas, to which they may induce deleterious effects that still need to be examined. However, only a small portion of the fish had ingested mesoplastics. The results of this study suggest that microplastic contamination is not an immediate threat to large predatory fish, such as T. albacares, along the coast of Easter Island within the South Pacific subtropical gyre. Microplastics may be transferred from fish prey to their predators, but do not remain in the predators' guts. Mesoplastics may accumulate in the guts of large predators, but are only ingested by few fish. Copyright © 2018 Elsevier Ltd

Chaidaroglou, A., et al. (2012). "Donor specific anti-HLA antibody detection in heart transplantation: Comparison of a donor-specific bead-based crossmatch technique with flow-crossmatch and single-antigen bead methodology." Journal of Heart and Lung Transplantation **1)**: S168-S169.

Purpose: In the present study we analyzed the efficiency of three different laboratory methodologies for the detection of donor-specific anti-HLA antibodies (DSA), their degree of correlation and their clinical relevance. Methods and Materials: The results of a Luminex donor-specific crossmatch (DSA-LX), in which donor-isolated HLA antigens are coated onto capture microbeads (Gen-Probe, USA), were compared with the results of a flow-cytometric crossmatch (FCM-X) and the results of a Luminex single-antigen bead methodology (SA-LX) (One Lambda, USA). A total of 46 sera samples obtained pre- (27 samples) and post-transplant (19 samples) were included in the study. All samples were tested with the DSA-LX and SA-LX methodology, while the 27 pre-transplant samples were also analyzed by FCM-X. Result(s): For the pre- transplant sera, the results of the three methods were in agreement for class I DSA in 21/27 (77.8%) samples and for class II DSA in 17/27 (63.0%) samples. When the results of the two bead-based methodologies were compared to the results of the FCM-X methodology, the SA-LX results showed better correlation with the FCM-X results than the DSA-LX results both for class I and class II antibodies. The results of SA-LX and DSA-LX, coincided for 40/46 (87.0%) and for 33/46 (71.7%) of sera tested for class I and class II HLA-DSA respectively. Furthermore, in the

group of transplanted patients the SA-LX results had more clinical relevance than the DSA-LX results. The methodology reproducibility score for both the SA-LX and the FCM-X was 100% whereas for DSA-LX the score was 88.9%. Conclusion(s): The results of DSA-LX do not have a good correlation with the results of FCM-X and SA-LX techniques for the detection of DSA, particularly as far as class II antibodies. Furthermore, DSA-LX has a lower reproducibility performance and a lower clinical relevance which renders it unsuitable for reliable graft allocation and patient monitoring.

Chakraborty, P., et al. (2019). "Organic micropollutants in the surface riverine sediment along the lower stretch of the transboundary river Ganga: Occurrences, sources and ecological risk assessment." Environmental Pollution **249**: 1071-1080.

The Hooghly River (HR) estuary is the first deltaic off-shoot of the perennial and transboundary river, Ganga, India. HR receives industrial and domestic waste along with storm-water run-off from Kolkata city and the adjoining districts. Organic micropollutants (OMPs) have been collectively termed for plasticizers, pharmaceuticals and personal care products, which are extensively consumed and disposed in the waste streams. Hence emerging OMPs were investigated to obtain the first baseline data from the Hooghly riverine sediment (HRS) along urban and suburban transects using gas chromatography mass spectrometry (GC-MS). The concentration range of OMPs in the HRS varied between 3 and 519 ng/g for carbamazepine, 5–407 ng/g for non-steroidal anti-inflammatory drugs (NSAIDs), 2–26 ng/g for musk ketone, 2–84 ng/g for triclosan, 2–199 ng/g for bisphenol A (BPA), 2–422 ng/g for plasticizers (phthalic acid esters (PAEs) and bis (2-ethylhexyl) adipate (DEHA)) and 87–593 ng/g for parabens. Carbamazepine concentration in sediment was an useful marker for untreated wastewater in urban waterways. High concentrations of BPA and PAEs in the suburban industrial corridor together with significant correlation between these two type of OMPs ($r2 = 0.5$; $p < 0.01$) likely reflect a common source, possibly associated with the plastic and electronic scrap recycling industries. Among all the categories of OMPs, plasticizers seems to exhibit maximum screening level ecological risk through out the study area. Image 1 • Carbamazepine can act as a possible marker for untreated wastewater. • Industrial sludge and burning of dumped plastic waste are potential sources of plasticizers. • Direct domestic discharge outlets might be a possible source for preservatives. Surveillance of microorganic pollutants in the Hooghly riverine sediment. [ABSTRACT FROM AUTHOR]

Chakraborty, R., et al. (2018). "A comparative study on the effect of polyethylene plastic waste on sandy soils." International Journal of Environment & Sustainable Development **17**(1): 56-69.

Plastic pollution is one of the major global issues. Engineering measures are being undertaken to harness the non-biodegradability of plastic by converting it to a vital part of built environment. A comparative study is undertaken to evaluate the effects of the waste plastic (polyethylene) on the geotechnical properties of two locally available sands viz. Brahmaputra sand and Kulsi sand by conducting a series of direct shear tests on the two sand samples reinforced with polyethylene plastic strips. The effect of varying concentration of plastics (0.10%, 0.20%, 0.30%, 0.45%, 0.60%, 0.70% and 0.75% by weight of the sand) using different dimensions of the plastic strips is investigated. The polyethylene plastic strips' length varied from 15 mm to 45 mm and width varied from 5 mm to 15 mm. The shear strength parameters which are obtained ultimately for the composite specimens on which analysis have been done, positively reflect soil improvement due to the inclusion of polyethylene plastic waste. [ABSTRACT FROM AUTHOR]

Chan, H. S. H., et al. (2019). "Evidence for non-selective ingestion of microplastic in demersal fish." Marine Pollution Bulletin **149**: 110523.

Microplastics have been observed in >100 species of fish, with considerable variability in levels of contamination in different species and different geographic locations. Here, we investigated the incidence of microplastic in five species of demersal fish (four wild-caught species and one from a mariculture business) in Hong Kong. We observed that 54% of fish stomachs contained microplastic (hard fragments and fibres) with no significant difference in the abundance of microplastic ingested between the species, between wild and commercial fish farms, or between locations. In addition, we observed no difference between the type of microplastics (shape or composition) ingested by fish. However, we did observe spatial variation, with fish closest to the Pearl River having higher frequency of occurrence of microplastics which reinforce the evidence that fish collected close to urban area are more likely to ingest microplastics.

Chan, R. W. S., et al. (2012). "The effect of macrophages on putative stem/progenitor cells in endometriosis." Human Reproduction. Conference: 28th Annual Meeting of the European Society of Human Reproduction and Embryology, ESHRE **27**(SUPPL. 2).

Introduction: Women with endometriosis have altered immunologic responses and defective immunosurveillance can lead to persistence and growth of menstrual debris at ectopic sites. Macrophages are key players of the natural immunity and are more activated in patients with endometriosis1. Stem cells have been found in human endometrium2 and ovarian endometrioma3 and they exhibit clonogenic activity3, 4 (ability to form large colony forming units, CFUs). Since the pathogenesis of endometriosis remains uncertain, we hypothesis that women with endometriosis are more likely to shed endometrial stem/progenitor cells during menses and these cells can rapidly grow at ectopic tissue upon exposure to a conducive environment. In this study, we examined: 1) the cloning efficiency of endometriotic cells when co-cultured with macrophages, 2) the invasiveness of endometriotic progenies after macrophage exposure, and 3) the cytokine profile of macrophages from women with/without endometriosis. Method(s): Ovarian endometriotic cysts were obtained from women undergoing laparoscopic ovarian cystectomy. Lesions were dissociated to achieve single cell suspensions. Stromal and epithelial cells were separated using CD326 microbeads and cultured at low seeding density (500 cells/cm2). Monocytes were isolated from venous blood samples from the same patients and co-culture in inserts with endometriotic cells for 14 days. Phorbol 12-myristate 13 acetate was used to induce differentiation of monocytes into macrophages. Condition medium (CM) was also collected after 72 hours and diluted with fresh culture medium at a ratio of 3:7 (CM/fresh medium, v/v) for culturing of endometriotic cells. The number of large CFUs was calculated. Endometriotic cells were then re-seeded onto matrigel invasion inserts to assess its invasion ability after 48 hours. Human cytokine antibody arrays containing 43 antibodies were

used to examine the differences in cytokine expression between macrophage CM from women with/without endometriosis. Result(s): Co-culture of macrophage significantly increased the cloning efficiencies (CE) of endometriotic epithelial cells (0.162 +/- 0.040%, n = 11) when compared to control (0.008 +/- 0.005%, P < 0.001, n = 11). The invasiveness of endometriotic epithelial cells increased by 2-fold when co-cultured with macrophages and 1.5-fold when cultured in macrophage CM. For endometriotic stromal cells, co-culture with macrophages (0.173 +/- 0.040%, P < 0.001, n = 16) and in macrophage CM (0.053 +/- 0.027%, P < 0.05, n = 16) also significantly increased the CE when compared to the control (0.003 +/- 0.002%, n = 16). The invasion ability of endometriotic stromal cells after co-cultured with macrophage increased by 1.5-fold. Forty-three cytokines were identified in the macrophage CM from women with/without endometriosis (n = 6). Macrophage colony stimulating factor was found to be up-regulated in endometriotic macrophage CM when compared to macrophage CM without endometriosis (P < 0.01). The up-regulated cytokine was also confirmed by ELISA. Conclusion(s): Our findings demonstrate that macrophages can increase the proliferation and the invasiveness of endometriotic cells from ovarian endometrioma. It is possible that macrophages and its secreted cytokines could stimulate the proliferation of stem/progenitor cells and be responsible for the development this gynecologic disease.

Chand, R. and S. Neethirajan (2017). "Microfluidic platform integrated with graphene-gold nano-composite aptasensor for one-step detection of norovirus." Biosensors & Bioelectronics **98**: 47-53.

Noroviruses are a foremost cause of gastroenteritis outbreaks throughout the world. On-site sample processing and detection of the viral clinical samples has always been a problem. This study reports an all-polydimethylsiloxane microfluidic chip integrated with screen-printed carbon electrode for the electrochemical detection of norovirus. The microfluidic chip contained packed silica microbeads zones to filter and enrich the norovirus infected clinical sample. Selective detection of norovirus was accomplished by functionalizing the graphene-gold nanoparticles composite modified carbon electrode with the viral capsid-specific aptamer. Norovirus specific aptamer was tagged with a ferrocene molecule, which acts a redox probe. The interaction of aptamer and norovirus resulted in a decrease in the electrochemical signal from ferrocene. The microfluidic chip and functionalized electrodes were characterized using several microscopic and electrochemical techniques. The optimized microfluidic aptasensor was employed to detect a range of norovirus concentration. Using differential pulse voltammetric analysis, a detection limit of 100 pM with a detection range from 100 pM to 3.5nM for norovirus was obtained. The application of aptasensor was also assessed by detecting norovirus in spiked blood samples. The aptasensor could easily discriminate between the target norovirus and other interfering molecules. The developed microfluidic aptasensor has the potential to be used for point-of-care one-step detection of norovirus in clinical samples.

Chang, A. B. (2014). "Advances in diagnosing the aetiology of childhood pneumonia." Pediatric Pulmonology **37)**: S15-S16.

Current studies determining the aetiology of childhood pneumonia vary substantially with respect to factors that influence the diagnosis and ascribed microbial etiology. These factors include variations in case definitions, use and interpretation of chest x-rays (CXRs), peripheral blood white cell counts and inflammatory markers, depth of investigations, facility type, and patient characteristics.1 While procalcitonin is a promising biomarker in adults with pneumonia, its diagnostic thresholds in childhood pneumonia are less defined and its usefulness and safety in guiding management has not been established.2 Also, ascribing definitive etiology with confidence is exceeding difficult unless lower airway specimens can be obtained and/or

concurrent systemic infection is identified. Consequently, it is not surprising that studies describe different frequency and types of pathogens associated with pneumonia. The Pneumonia Etiology Research for Child Health (PERCH) project is the largest multisite study (6000 children, 7 African and Asian countries) of childhood pneumonia. It seeks to address the aforementioned limitations by using case-control methodologies and adopting a protocol that has standardized enrollment criteria, specimen collection, laboratory testing and molecular detection techniques.3 Further, despite advances in identifying microorganisms using highly sensitive molecular techniques, ascribing causation may be problematic. Nucleic acid amplification (NAA) techniques, such as polymerase chain reaction (PCR) assays, identify genetic material, but the implicated microbe may no longer be viable or infectious and their presence may be from a recent, but unrelated respiratory illness. For example, the prevalence of respiratory viruses detected by molecular techniques in asymptomatic children is as high as 42%4 and strains of adenovirus C may remain latent in mucosal lymphocytes and be shed for months or even years.5 Even when the same molecular detection techniques for viruses are used, the site of specimen collection influences results. In paired comparisons of concurrently obtained upper and lower airway specimens for respiratory viruses in 75 children, we found significant discordance between nasopharyngeal aspirate and bronchoalveolar lavage (BAL) specimens.6 The discordancewas dependent on the virus type andmost marked for human rhinovirus (hRV) and adenoviruses. Nasopharyngeal aspirate (NPA) had a high sensitivity (92%) and low specificity (57%) for detecting hRV in BAL with poor kappa agreement value of 0.398 (95% CI 0.218-0.578, P<0.001). NPA had a fair sensitivity (69%) and good specificity (90.3%) for detecting adenovirus on BAL, kappa agreement was 0.561 (95%CI 0.32-0.80). Additionally, even when investigating viral infections from a single specimen collection site, detection of multiple viral types is common. This observation compounds the difficulty in determining the primary causative agent and presents new questions about the roles of these viruses in the aetiology of the disease. The ideal samples for determining etiologic agents in bacterial pneumonia are lower airway specimens. It is usually neither necessary nor feasible to obtain either BAL or needle lung aspirate specimens in acute pneumonia. Induced sputum is an alternative only in older children, and as potential respiratory bacterial pathogens commonly colonize the upper airways of healthy children, oropharyngeal contamination can complicate interpretation of culture results. Blood cultures are also infrequently (<10%) positive in children with pneumonia and as pneumococcal conjugate vaccines become incorporated into national immunization schedules their sensitivity is likely to be further reduced.2 PCR techniques have only modestly increased the yield of pathogen detection in blood samples,7 while with the exception of M. pneumoniae, serology is impractical in most clinical situations. Thus, it remains a challenge to determine the ideal, yet feasible, specimen for identifying the aetiological agent(s) in children with pneumonia. Increas ngly, viral-viral, viral-bacterial and bacterial-bacterial interactions in the pathogenesis of respiratory infections are recognized with in-vitro and in-vivo animal and human studies.8 Thus, although viruses may initiate the respiratory infection, secondary bacterial infection may occur and simply identifying a virus at presentation (leading to antibiotics being with-held) may not indicate the sole etiology of the child's acute clinical presentation or determine its long term outcomes. The complexity of the microbial contribution is further increased by introducing the world of '-omics' (e.g. metagenomics). While interest in this field is exploding, its use will likely further complicate ascribing etiology to a single organism. Microarray-based gene expression profiling (DNA microarray) i.e. comparing gene expression in infected to that in uninfected cells or tissues shows considerable promise for identifying causative pathogens of pneumonia.9 However, these and other nucleic acid amplification platforms (e.g. microbead arrays) are unlikely to be made available in the near future to resource-poor countries where the burden of

childhood pneumonia is greatest. Nevertheless there are promising signs of improved diagnostic yields for pneumococcal pneumonia when using molecular techniques to detect pneumococcal gene sequences in blood7 or by combining elevated serum biomarker results (eg. C-reactive protein; CRP) with rapid pneumococcal urinary antigen testing.10.

Chang, J., et al. (2013). "Does growing vegetables in plastic greenhouses enhance regional ecosystem services beyond the food supply?" Frontiers in Ecology and the Environment **11**(1): 43-49.
In recent years, plastic greenhouse vegetable cultivation (PGVC) has expanded worldwide, particularly in China, where it accounts for more than 90% of all global PGVC operations. As compared with conventional agricultural methods, PGVC has doubled crop yields by extending growing seasons and intensifying agriculture. PGVC also offers more ecosystem services relative to conventional approaches, including greater soil carbon sequestration, lower water consumption, and improved soil protection at regional scales. The economic benefits of this easily implemented agricultural method are attractive to small-holder farmers. However, greater environmental impacts (eg greenhouse-gas emissions, generation of large amounts of plastic waste) are associated with PGVC than with conventional approaches. Here, we review what is currently known about PGVC and identify future research priorities that will comprehensively assess the ecosystem services offered by this method of cultivation, as well as its environmental impacts and socioeconomic benefits.

Chang, M. (2015). "Reducing microplastics from facial exfoliating cleansers in wastewater through treatment versus consumer product decisions." Marine Pollution Bulletin **101**(1): 330-333.
Microplastics (<5mm) have been discovered in fresh and saltwater ecosystems, sediments, and wastewater effluent around the world. Their ability to persist and accumulate up food chains should be a concern as research is still experimenting with techniques to assess their long-term effects on the environment. I sought to characterize the microbeads found in facial exfoliating cleansers so as to better understand how to reduce this source of pollution through consumer use and wastewater treatment solutions. By sampling products from national-grossing cosmetic personal care brands, I was able to gather information on the size, color, volume, mass, and concentration of polyethylene beads in the cleansers. From that data, I modeled onto a consumer survey the estimated volume of microplastics entering a wastewater stream. Through inquiry, I learned the practices of two local wastewater treatment facilities. My findings show that consumer decisions and treatment protocols both play crucial parts in minimizing microplastic pollution.

Chang, X., et al. (2020). "Potential health impact of environmental micro- and nanoplastics pollution." Journal of Applied Toxicology **40**(1): 4-15.
Micro- and nanoplastics are generated from plastics and have negative impacts on the environment due to their high level of fragmentation. They can originate from various sources such as fragments, fibers and foams. The large proportion of the waste and resistance to degradation means micro- and nanoplastics have become a serious global environmental problem, but there are few studies on their potential toxicity for human health. In this review, we discussed routes of exposure and the potential effects of micro- and nanoplastics to human health. Human beings could mainly be exposed to micro- and nanoplastics orally and by inhalation. The possible toxic effects of plastic particles are due to the potential toxicity of plastics themselves, and their combined toxicity with leachable additives and adsorbed contaminants. The potential risks for human health focused on their gastrointestinal toxicity and liver toxicity. The toxic mechanisms could involve oxidative stress, inflammatory reactions and

metabolism disorders. More studies are needed to carry out and explore the potential toxicological mechanisms of micro- and nanoplastics and evaluate the combined toxicity of their adsorbed contaminants.

Chang-Bum, J., et al. (2016). "Microplastic Size-Dependent Toxicity, Oxidative Stress Induction, and p-JNK and p-p38 Activation in the Monogonont Rotifer (Brachionus koreanus)." Environmental Science & Technology **50**(16): 8849-8857.

In this study, we evaluated accumulation and adverse effects of ingestion of microplastics in the monogonont rotifer (Brachionus koreanus). The dependence of microplastic toxicity on particle size was investigated by measuring several in vivo end points and studying the ingestion and egestion using 0.05-, 0.5-, and 6-μm nonfunctionalized polystyrene microbeads. To identify the defense mechanisms activated in response to microplastic exposure, the activities of several antioxidant-related enzymes and the phosphorylation status of mitogen-activated protein kinases (MAPKs) were determined. Exposure to polystyrene microbeads of all sizes led to significant size-dependent effects, including reduced growth rate, reduced fecundity, decreased lifespan and longer reproduction time. Rotifers exposed to 6-μm fluorescently labeled microbeads exhibited almost no fluorescence after 24 h, while rotifers exposed to 0.05- and 0.5-μm fluorescently labeled microbeads displayed fluorescence until 48 h, suggesting that 6-μm microbeads are more effectively egested from B. koreanus than 0.05- or 0.5-μm microbeads. This observation provides a potential explanation for our findings that microbead toxicity was size-dependent and smaller microbeads were more toxic. In vitro tests revealed that antioxidant-related enzymes and MAPK signaling pathways were significantly activated in response to microplastic exposure in a size-dependent manner. [ABSTRACT FROM AUTHOR]

Chanhoun, M., et al. (2018). "Study of the implementation of waste wood, plastics and polystyrenes for various applications in the building industry." Construction and Building Materials **167**: 936-941.

This work enrolls in the context of sustainable development and protection of the immediate environment. It concerns a recycling study of wood waste, polystyrene waste and plastic waste. The objective of this study is to upgrade wood waste and plastic wastes (low and high density polyethylene) and expanded polystyrene in waste disposal in the developing countries of Africa. Two types of wood particle composites based on plastic and polystyrene polymers have been developed. The physical properties (density, water absorption and volumetric swelling) and mechanical properties (modulus of elasticity and modulus of rupture) required for their implementation are determined. The quantities found show that these composites can be used to produce self-adhesive sandwich panels or boards which will serve as a door core, false ceilings, formwork sandwich boards, interior and exterior flooring and furnishing materials.

Chao, Y., et al. (2011). "Amplification of Human Epidermal Cells by a Rotary Bioreactor in Vitro." Progress In Modern Biomedicine **11**(13): 2409-2412.

Objective: We attempted to produce human epidermal cells (hECs) on a large scale by Rotary Cell Culture System (RCCS). In this cultural system we used Cytodex-3 microbeads as microcarriers and high aspect ratio vessel RCCS as cultural system. Methods: The hECs were

obtained from human skin by using the method of digesting human foreskin with Dispase II and Trypsin-EDT and cultured in vitro and labeled with DIL, then combined with Cytodex-3 in RCCS. The characteristics of hECs combined with microcarriers were observed with Inverted microscope, and scanning electronic microscope (SEM). The proliferative capacities of microgravity cultivation and routine cultivation were compared by group doubling time. Results: Our results showed that hECs rapidly attached to the microcarriers in the RCCS, achieving high cell densities. hECs cultured on the microbeads in the RCCS remained actively proliferating potentials. Conclusion: Using biological reactor and microcarriers culture human epidermal cells is a kind of effective method for preparation a large number of seed cells for tissue engineering.

Chattopadhyay, S., et al. (2016). "Functionalized polymeric magnetic nanoconstructs for selective capturing and sensitive detection of Salmonella typhimurium." Analytica Chimica Acta **937**: 127-135.

Rapid detection and enumeration of pathogens is essential for monitoring contamination and spoilage of food products to ensure improved quality control management. Functionalized polymeric magnetic nanoconstructs (FPMNCs) were developed as an effective immunomagnetic separator and sensing platform for the selective capturing of Salmonella typhimurium. Novel FPMNCs were prepared in three stages involving synthesis of iron oxide (IO) dispersion, capping with sodium oleate and encapsulation of preformed IO nanoparticles by in-situ free radical emulsion polymerization of styrene (St), methyl methacrylate (MMA) and acetoacetoxy ethylmethacrylate (AAEM). PMMA improves the stability of FPMNCs by bridging extremely hydrophobic PS and hydrophilic PAAEM. Core-shell morphology of hydrophobic core of IO, PS & PMMA and hydrophilic shell of PAAEM was demonstrated by SEM, TEM and FTIR studies. FPMNCs with surface functionalized acetoacetoxy groups were covalently attached with polyclonal antibodies against Salmonella common structural antigen (CSA-1-Ab) without using any linker and catalyst. Colorimetric readout signal was acquired using CSA-1-Ab-HRP as secondary antibody after formation of sandwich immunocomplex with bacteria where the optical density of the samples were recorded using ELISA plate reader at 450 nm. The developed immunoassay was specific and selective which captures only targeted S. typhimurium with a detection limit of 10 cells/mL lower than infectious dose of salmonellosis infection. Minimal interference of food matrix with high signal to noise ratio was shown by various food samples. In addition, the performance of developed FPMNC based immunoassay was superior to commercially available immunomagnetic microbeads demonstrating undisputed advantage for capturing and detecting specific bacteria without any pre-enrichment of sample.

Chattopadhyay, S., et al. (2013). "Sensitive detection of food-borne pathogen Salmonella by modified PAN fibers-immunoassay." Biosensors & Bioelectronics **45**: 274-280.

Sensitive and rapid detection of Salmonella is a key to the prevention and identification of problems associated with human health and safety. Enzyme Linked Immunosorbent Assays (ELISAs) are popular and widely implemented technique to detect pathogenic bacteria in routine analysis but a typical ELISA yields a sensitivity of 10(6)-10(7)cfu/mL. The present study consecrates on the applicability of surface modified polyacrylonitrile (PAN) fibers as a novel matrix of immunoassay for the detection of Salmonella typhimurium in a sandwich ELISA format. Affinity purified antibody against Salmonella common structural antigen (CSA-1-Ab) was immobilized on modified PAN (mPAN) fibers using covalent immobilization via amine-glutaraldehyde chemistry and inactivated S. typhimurium were captured from various samples and detected colorimetrically using peroxidase-labelled common structural antibody (CSA-1-Ab-HRP) against Salmonella. The performance of the developed immunoassay was compared with commercially available immunomagnetic microbeads (Dynabeads()

anti-Salmonella), polystyrene (PS) microtitre plate and glutaraldehyde activated PS plate. Limit of detection (LOD) was found to be 10, 10(5), 10(6) and 10(7)cells/mL of bacteria for mPAN, Dynabeads(), glu-plate and PS plate respectively without any pre-enrichment step. The assay was specific for the targeted bacteria when investigated with other cross-reactant food and water-borne pathogens. The developed immunoassay offered undisputed advantages of being simple, sensitive and specific for the detection of S. typhimurium.

Chaturvedi, P. K., et al. (2011). "HPV neutralizing antibody detection in serum using liquid bead array system." International Journal of Gynecological Cancer **2)**: 27.

Detection of HPV (Human papillomavirus) DNA by nucleic acid hybridization is the method of choice for the diagnosis of HPV infection. Though DNA detection assays used, are highly sensitive, the data define only current HPV status, and previous transient infection may be missed. Numerous serologic studies using mainly HPV VLPs (virus like particles) have demonstrated that infection with HPVs follows a serologic immune response to viral capsid proteins and that anti-VLP antibodies can be an indicator of life-time exposure to HPV infection. It has been suggested that HPV VLP serologic assays may be a potential tool to identify women at risk for high-grade cervical intraepithelial neoplasia.In this study, we introduce a convenient method for investigating the seroresponse to HPV. By using multiplex luminex microbeads covalently coupled with HPV antigen, we can evaluate neutralizing antibodies and measure the titers of antibodies specific to each subtype. HPV 6, 11, 16 and 18 L1 genes were amplified by PCR, cloned into pGEX vector with GST tag and expressed in E.coli. Purified GST fusion proteins were coupled to respective microbeads and luminex assay was performed with patients' serum, collected 3 months after the final dose of quadrivalent HPV vaccine. The assay described in this study proved to be a robust, sensitive and high throughput assay to simultaneously measure antibodies to HPV type-specific, neutralizing epitopes against multiple HPV genotypes.

Chaudhary, A., et al. (2016). "Lightweight and Easily Foldable MCMB-MWCNTs Composite Paper with Exceptional Electromagnetic Interference Shielding." Acs Applied Materials & Interfaces **8**(16): 10600-10608.

Lightweight and easily foldable with high conductivity, multiwalled carbon nanotube (MWCNT)-based mesocarbon microbead (MCMB) composite paper is prepared using a simple, efficient, and cost-effective strategy. The developed lightweight and conductive composite paper have been reported for the first time as an efficient electromagnetic interference (EMI) shielding material in X-band frequency region having a low density of 0.26 g/cm(3). The investigation revealed that composite paper shows an excellent absorption dominated EMI shielding effectiveness (SE) of -31 to -56 dB at 0.15-0.6 mm thickness, respectively. Specific EMI-SE of as high as -215 dB cm(3)/g exceeds the best values of metal and other low-density carbon-based composites. Additionally, lightweight and easily foldable ability of this composite paper will help in providing stable EMI shielding values even after constant bending. Such intriguing performances open the framework to designing a lightweight and easily foldable composite paper as promising EMI shielding material, especially in next-generation devices and for defense industries.

Chaure, S., et al. (2010). "Spectroscopic investigation of sulfonate phthalocyanine to probe enzyme reactions for heavy metals detection." Journal of Hazardous Materials **173**(1-3): 253-257.

Optical absorption and Raman spectra of the sulfonated copper phthalocyanine (CuTsPc) layer were exploited for detection of cadmium (Cd) contaminants in water. Acetylcholine esterase was immobilized by freely suspending them in calcium alginate microbeads and this gel was

then spincoated on the drop cast sulfonated copper phthalocyanine film on a glass substrate to form a bilayer. The inhibition of catalytic reaction between acetylcholine chloride and enzyme due to Cd contaminants was monitored by recording changes in spectra of drop cast CuTsPc as an indicator. The detection limit of cadmium content in water was found to be 1 ppm.

Chavez, K., et al. (2016). "Gender biased immune-biomarkers in active tuberculosis and correlation of their profiles to efficacy of therapy." Tuberculosis **99**: 17-24.

Active pulmonary TB is an inflammatory disease and is increasingly viewed as an imbalance of immune responses to Mycobacterium tuberculosis (M. tb.) infection. In addition, this immune imbalance may be gender biased (males have a higher prevalence of TB) but reasons for such bias are uncertain. We hypothesized that studies on profiles of immune-biomarkers will not only provide insight into molecular basis of gender bias but may also help identify biomarkers to monitor efficacy of TB therapy. We examined 10 plasma cytokine/chemokine/growth-factor and 8 antibody (against 8 M. tb. antigens) biomarkers (elevated in TB patients) by multiplex microbead immunoassays. In addition, we examined these biomarkers in patients under anti-tuberculosis therapy (ATT). The results showed that female patients contained significantly higher levels of CXCL9 (MIG) and CXCL10 (IP-10), while males contained higher levels of PDGF-BB. In contrast, more males than females contained antibodies against several antigens. Our results also show that there are progressive and substantial decreases in plasma levels of CXCL9, CXCL10, PDGF-BB, IFNgamma, and IL-18, correlating with treatment success. Our results suggest that studies on gender bias in immunebiomarkers will enhance understanding of host responses in TB and would be valuable as biomarkers for monitoring efficacy of ATT.

Chawla, N., et al. (1998). "Effect of SiC volume fraction and particle size on the fatigue resistance of a 2080 Al/SiC sub p composite." Metallurgical and Materials Transactions A (USA) **29A**(11): 2843-2854A.

The effect of SiC volume fraction and particle size on the fatigue behavior of 2080 Al was investigated. Matrix microstructure in the composite and the unreinforced alloy was held relatively constant by the introduction of a deformation stage prior to aging. It was found that increasing volume fraction and decreasing particle size resulted in an increase in fatigue resistance. Mechanisms responsible for this behavior are described in terms of load transfer from the matrix to the high stiffness reinforcement, increasing obstacles for dislocation motion in the form of S' precipitates, and the decrease in strain localization with decreasing reinforcement interparticle spacing as a result of reduced particle size. Microplasticity was also observed in the composite, in the form of stress-strain hysteresis loops, and is related to stress concentrations at the poles of the reinforcement. Finally, intermetallic inclusions in the matrix acted as fatigue crack initiation sites. The effect of inclusion size and location on fatigue life of the composites is discussed.

Che, X., et al. (2013). "Improve effectivity of microbead biofilter by media motion." Transactions of the Chinese Society of Agricultural Engineering **29**(5): 194-198.

Conventional microbead biofilters are simple and reliable in form, but they possess certain limitations due to the thickness of the filter. Excessive filter thickness can cause channeling along the wall and even moderate to severe blockage. Water channeling detrimentally decreases the residing time of the reactants, thus leading to decreased nitrification activity. Sequencing microbead biofilter, in which the media keeps continuous "up and down" movement, is developed on the basis of the traditional microbead filters. The breaker bars are positioned in the bead bed volume in order to generate a relative displacement between microbeads, which enable the biofilter obtain the effect of self-cleaning. The investigation of effect of media layer reciprocating motion on nitritification efficiency and kinetics of this type of filter as a purpose, a pilot scale experiment was carried out in a recirculating aquaculture system. The experimental biofilter was divided into two chambers, designated A-chamber and B-chamber. The water flow through the filtration system was proceed by the electric control valve and water level switch in an alternating fashion, regularly switching between the vessels to enter the A-chamber or B-chamber. Each chamber of the experimental filter was 30 cm in diameter and 50 cm height. The filter used expanded polystyrene beads (microbead) approximately 3.0 mm in diameter, with a density of 28 kg/m³ and a specific surface area of 1160 m²/m³. The microbead packing layer was highly filled at 0.26 m, exhibiting a microbead packing volume of 0.037 m³. The filter used a pump to carry water, while the water trickles down the microbead packing due to gravity. The RAS test system consisting of a 1.3 m³ culture tank, a particle trap, swirl separators, a pump sump, a reuse pump, a sequencing microbead biofilter, and an air diffuser. The bulk water was pumped from a sump to the tested filter after removing solid wastes by the swirl separator, and then returned to culture tank. The total water volume of the system was about 1.6 m³. The reciprocating motion was suspended for six days. Then resume movement of the media and compare the ammonia removal rate and nitritification kinetics in two operation conditions. The result revealed that the movement enhanced the treatment performance greatly. Six days later, when the reciprocating motion was suspended, the ammonia removal efficiency exhibited a gradual decline of 27.1%. Then, the movement of the media was resumed. As a result biological filter ammonia removal efficiency increased rapidly to the level before the motion stops after two days. The results of nitritification kinetics indicate that the media movement changed the kinetics characteristics of filter. Compared with that in stationary state, the threshold value from zero-order to half-order kinetics decreased significantly. The media reciprocating movement and the cutting of the flow greatly improved the hydraulics on the surface of media the mass transfer efficiency. Thereby, the biofilm activity and nitrification the efficiency increased correspondingly.

Cheema, S. (2011). Metagenomic approach to study the polyhydroxyalkanoate genes in hydrocarbon contaminated site.

Plastics being xenobiotic are recalcitrant to microbial degradation. Plastic production also involves a number of harmful chemicals which pose environmental as well as human health risks. There is an obvious need to minimize the generation of plastic waste and to search for newer technologies that can play a vital role in mitigating these problems. Research has been going on for quiet some time with the idea of developing an alternate environment friendly product. Many biodegradable plastic materials have been exploited such as: 1) PHAs (polyhydroxyalkanoates), 2) polylactides, 3) aliphatic polyesters, 4) polysaccharides, 5) co-polymers and /or blends of above. Of these, PHAs have gained more and more importance the world over due to their structural diversity and close analogy to plastics. The other advantage which PHAs have is that they are biodegradable and environmental friendly. Many microorganisms have the ability to degrade these macromolecules enzymatically. PHAs are polyesters of various hydroxyalkanoates that are synthesized by many grampositive and gram-negative bacteria. It was in the last century (1926) when Lemoigne reported the formation of poly(3-hydroxbutyrate) (PHB) inside bacteria for the first time. Since then research in this field has developed considerably with the discovery of many more different PHAs from at least 75 different genera. This polymer is accumulated intracellularly to levels as high as 90% of the cell dry weight under conditions of nutrient stress and acts as a carbon and energy reserve. Research over the years has focused on the use of alternative substrates, novel extraction methods, genetically enhanced species and mixed cultures with a view to make PHAs more commercially attractive. Enormous advances in molecular analysis of PHA biosynthesis genes and PHA production have been well documented. Many strategies such as homologous or heterologous gene probes, short consensus oligonucleotide hybridization or PCR techniques have been employed for identifying PHA synthase genes and other genes involved in PHA biosynthesis. In Escherichia coli, a previous non-PHA producer, many strategies such as pathway engineering has been developed to set up microbial production by recombinant DNA technology. The sequence analysis of 89 complete and 34 partially sequenced genomes was done in an attempt to identify domains of PHA genes using RPSBLAST. Computer simulations of PHA granule formation in vivo are being done to help design strategies to optimize the fermentation process and achieve higher yields of PHA. Although PHA have been commercially developed and marketed, there are several important factors influencing the large scale commercial production. Efforts are being devoted with a renewed interest to increase PHA yield and productivity. A search is on to identify organisms capable of PHA production at higher levels. Conventional methods for searching microbes employ ineffective laboratory method with the result that a major portion of the bacteria remain largely untapped, unknown, and uncharacterized due to lack of proper culture conditions. On the other hand, Metagenomics represents a powerful tool to access the abundant microbial diversity of native environmental samples. It helps to effectively characterize the genetic diversity present in any samples regardless of the availability of laboratory culturing techniques. The term "metagenome" was first coined by Handelsman, 1998, as: The genomes of the total microbiota found in nature. Metagenomics, instead of removing microbes from their environment to isolate them, just directly isolates genomic DNA. This DNA is then cloned and environmental genetic libraries are constructed. Relevant clones from the libraries are sequenced or screened for the expression of gene products. Nucleotide-sequence based screening is highly efficient in comparison to enzyme-activity based screening. The success of metagenomic approach has already been demonstrated in identifying novel products ranging from small-sized genes conferring enzymatic activities suc as lipases, amylases. Reassembly of multiple genomes has provided insight into energy and nutrient cycling within the community, genome structure, gene function, population genetics and microheterogeneity, and lateral gene transfer among members of an uncultured community. The application of metagenomics to PHA will facilitate the trapping of those microbes that might have a better potential to produce PHA but are being missed out due to lack of proper culture techniques. This study is aimed at using metagenomics approach for bioprospecting of the PHA synthase gene in the environmental sample. Hydrocarbon contaminated sites are rich in carbon and have nutrient imbalance, providing excellent conditions for microbes to accumulate large amounts of PHA. And therefore are appropriate sources of sampling for our study. (Abstract shortened by UMI.)

Chen, B., et al. (2012). "Responsive polymer welds via solution casting for stabilized self-assembly." Acs Applied Materials & Interfaces **4**(12): 6911-6916.

We present a simple solution casting technique to apply polymer welds to stabilize capillary-force directed self-assembled systems including arrays of pillars and microbeads. The strength of the polymer welds can be enhanced by increasing either the polymer concentration or molecular weight. The use of responsive polymers to form the welds allow for the fabrication of hierarchical structures that actuate in response to external stimuli. For example, temperature-responsive and pH-responsive microstructures can be formed by solution casting poly(vinyl methyl ether) and poly(methacrylic acid), respectively. We demonstrate that polymer welds formed using biocompatible alginate allows for controllable release of microbeads in microfluidic channels, which has potential applications in drug delivery.

Chen, C., et al. (2019). "Organotin Release from Polyvinyl Chloride Microplastics and Concurrent Photodegradation in Water: Impacts from Salinity, Dissolved Organic Matter, and Light Exposure." Environmental Science & Technology **53**(18): 10741-10752.

Photochemical weathering leads to degradation of microplastics and releases chemical additives, polymeric fragments, and/or byproducts. This study evaluated the release kinetics of organotin compounds (OTCs) from three different sized (10-300 mum) polyvinyl chloride (PVC) microplastics under UV- and visible light irradiation. Four OTCs, dimethyltin (DMT), monomethyltin (MMT), dibutyltin (DBT), and monobutyltin (MBT), were found to release from PVC particles after 24 h leaching in darkness ranging from 2 to 20 mug.g-PVC⁻¹. Under UV/visible light irradiation, only DMT and DBT were detectable, whereas MMT and MBT were not detected due to rapid photodegradation. The total tin concentrations (including organic and inorganic tins) in the aqueous phase monotonically increased under light exposure. By contrast, they reached plateaus after 24 h in darkness, confirming the photodegradation of OTCs. A release kinetics model was established and correctly interpreted the microplastics size effect on the OTC release process. Finally, the impacts of salinity and dissolved organic matter (DOM) were investigated. The release and photodegradation of OTCs were both inhibited at high salinity conditions, probably due to the enhanced readsorption of OTCs on PVC microplastics and the formation of halogen radicals that were less reactive toward neutral OTCs. The presence of DOM, however, increased OTCs release probably because the excited state triplet DOM (³DOM*) formed and reacted with OTCs from PVC microplastics.

Chen, C., et al. (2018). "Aberrant expression of the innate restriction factor bone marrow stromal antigen-2 in primary Sjogren's syndrome." Clinical and Experimental Rheumatology **36 (3 Supplement 112)**: S277.

Background. Bone marrow stromal antigen-2 (BST-2) is a transmembrane innate immune protein that was detected to play important role in some autoimmune diseases. The objective of this study was to analyze BST-2 levels in labial glands, total peripheral blood mononuclear cells (PBMCs) and PBMC subpopulations from primary Sjogren's syndrome (pSS) patients and determine the correlation between BST-2 expression and clinical characteristics. Methods. PBMC subsets were positively separated using magnetic microbeads. BST-2 mRNA levels in labial glands, total PBMCs and PBMC subsets of 30 pSS and 16 healthy control (HC) subjects were investigated using real-time polymerase chain reaction (RT-PCR). Distribution of BST-2-positive cells in the labial glands was assessed by immunohistochemistry. Results. BST-2 was significantly increased in pSS labial glands and was positively correlated with the VAS value for parotid gland swelling and rheumatoid factor and beta2-microglobulin serum levels. BST-2 levels were statistically different between pSS patients with positive and negative expression of anti-SSA antibody. Positive glandular epithelial cells, ductal epithelial cells and adjacent infiltrating lymphocytes were observed in labial glands from pSS patients, while there were a few scattered positive ductal epithelial cells in controls. BST-2 was also up-regulated in CD19+ B cells and the remaining CD4-CD8-CD19-PBMCs. Conclusion. BST-2 was aberrantly expressed in pSS patients, and expression in labial glands was positively correlated with important clinical characteristics; thus, it may be a potential biomarker of pSS activity.

Chen, F., et al. (2013). "Inkjet nanoinjection for high-thoughput chemiluminescence immunoassay on multicapillary glass plate." Analytical Chemistry **85**(15): 7413-7418.

We report a novel chemiluminescence diagnosis system for high-throughput human IgA

detection by inkjet nanoinjection on a multicapillary glass plate. As proof-of-concept, microhole-based polydimethylsiloxane (PDMS) sheets were aligned on a multicapillary glass plate to form a microwell array as microreactors for enzyme-linked immunosorbent assay (ELISA). The multicapillary glass plate was utilized as a switch that controlled the holding/passing of the solution. Further, anti-IgA-labeled polystyrene (PS) microbeads was assembled into the microwell array, and an inkjet nanoinjection was specially used to distribute the sample and reagent solution for chemiluminescence ELISA, enabling high-throughput detection of human IgA. As a result, the performance of human IgA tests revealed a wider range for the calibration curve and a lower limit of detection (LOD) of 0.1 ng mL(-1) than the ELISA by a standard 96-well plate. The analysis time and reagent consumption were significantly decreased. The IgA concentrations in saliva samples were determined after 10000-fold dilution by the developed ELISA system showing comparable results by conventional immune assay with 96-wells. Thus, we believe that the inkjet nanoinjection for high-throughput chemiluminescence immunoassay on a multicapillary glass plate will be promising in disease diagnosis.

Chen, G., et al. (2020). "Mini-review of microplastics in the atmosphere and their risks to humans." Science of the Total Environment **703**: 135504.

Studies of microplastics (MPs) have highlighted their ubiquity in various environments. Recently, microplastics have been observed in atmospheric fallout collected from some cities. Although the studies are limited, some researches have shown that synthetic textiles are main source of airborne microplastics, and fibers are the dominant shape of microplastics in the atmosphere. Due to their small size, airborne microplastics can be directly inhaled posing health risks to humans, particularly to industry workers. Meteorological conditions and human activities affect the distribution and deposition of airborne microplastics. Furthermore, airborne microplastics are contributors to microplastic pollution in aquatic environments. We summarized the current knowledge and provide insights into further research to better understand airborne microplastics and their risks to human.

Chen, H., et al. (2015). "Crosslinking of Fc gamma-RLLb and Fc epsilon-RI binding peptides inhibits osteoclast formation in multiple myeloma through inactivation of the ITAM signaling pathway." Blood **126 (23)**: 2995.

Introduction: Overactivity of osteoclasts resulting in bone destruction is a hallmark of multiple myeloma (MM). Receptor for activation of NF-kB ligand (RANKL) and monocyte colony stimulating factor (MCSF) signaling pathways both promote proliferation and survival of the precursors of the osteoclast lineage, and have been widely investigated in MM. The third pathway involved in osteoclast differentiation is the immunoreceptor tyrosine-based activation motif (ITAM) with c-Fms signaling. ITAM and its inhibitor ITIM provide the basis for two opposed signaling modules that duel for control of osteoclast formation. Human monocyte/macrophage expresses the low-affinity FcgammaRIIb and high-affinity Fc? receptor 1 (Fc?RI). Both receptors mediate Syk phosphorylation to activate or inactivate downstream ITAM or ITIM signaling molecules. In this study, we determined the effects of an IgG(CH2-CH3) and IgE(CH2-CH3-CH4) fusion protein that activates the ITIM inhibitory pathway on downstream signaling of Syk and osteoclast formation in monocytes from MM patients. Method(s): We constructed IgG(CH2-CH3) with an IgE(CH2-CH3-CH4) fusion protein using standard cloning techniques. We evaluated the fusion protein on osteoclast formation using cells from either human monocytes isolated from MM patients' peripheral blood mononuclear cells (PBMCs) or bone marrow (BM) MCs with an anti-CD14 micro-bead affinity column and magnetic bead selection (Miltenyi Biotec, Auburn, CA). The monocytes were cultured on slide-culture dishes (2 X 105 cells/well).

The cells were treated with the fusion protein or with IgE or IgG and subsequently treated with 50ng/ml RANKL (receptor for activation of nuclear factor kB and 10ng/ml MCSF (monocyte colony stimulating factor) in order to stimulate osteoclast formation at the beginning of the culture and during a medium change after 3 days with the same amount of growth factors added. The cells were fixed for tartrate resistant acid phosphatase (TRAP)-staining assay on day 21. To investigate ITIM signaling pathway we determined Syk phosphorylation of monocytes treated or without treated with fusion protein by Western blot analysis. Result(s): We found that in a concentration-dependent fashion, the fusion protein inhibited osteoclast cell formation from CD14+ MCs from PB or BM exposed to RANKL and MCSF. We further analyzed the effects on the FcgammaRIIb-SHIP signaling pathway in monocytes induced with 50ng/ml RANKL and 10ng/ml MCSF following exposure to fusion protein or control IgG or IgE. The results showed that the monocytes showed markedly lower Syk phosphorylation following exposure to the fusion protein (100-200ng/ml). There was no change of Syk phosphorylationl in monocytes treated with IgG or IgE or IgG with IgE. Conclusion(s): The results of our study show that intact human IgG or IgE does not affect the ITAM or ITIM signaling pathways. However, a fusion protein consisting of IgG(CH2-CH3) with IgE(CH2-CH3-CH4) showed the ability to activate the ITIM inhibition pathway through FcgammaRIIb to reduce osteoclast formation. Thus, blockage of ITAM may be treating novel treatment for preventing bone loss for MM patients.

Chen, H., et al. (2019). "A nationwide assessment of litter on China's beaches using citizen science data." Environmental Pollution **258**: 113756.

China is the largest plastic consumer in the world. Despite its plastic waste import ban in 2017, this populous economy inevitably generates a large amount of waste, including plastic waste, a considerable part of which has become marine litter. Data from the 2018 National Coastal Cleanup and Monitoring Project, the largest beach litter monitoring activities using the citizen science approach in China, have been retrieved and analyzed to understand spatial patterns, composition, and original usage of marine litter. Within this project, 24 beaches were surveyed every two months. As a result, the mean density was 3.85 +/- 5.39 items m⁻², much higher than that reported by previous studies in China. There were great differences in the spatial distribution of litter. The highest densities appeared in the runoff-affected area of the Yangtze River, which was another difference from previous studies. Low-density, easy-to-transport foamed plastics were the major contributor to marine litter in these areas. Along China's coast, approximately 90% of litter was from land-based sources, and over half of that originated from domestic sources. Including foamed plastic products, plastic litter with low recycling value dominated. Both natural and human factors influencing the spatiotemporal distribution and composition of litter are discussed. Socioeconomic factors, such as the lifestyle and consumption levels of citizens and local waste management systems, are possible explanations for the low-value characteristic of marine litter. The deviation between previous data and citizen science data in this study may be caused by many factors. Based on the discussion on these factors, some suggestions for citizen science research in China are also put forward.

Chen, H., et al. (2019). "Mixing effect of polylactic acid microplastic and straw residue on soil property and ecological function." Chemosphere **243**: 125271.

Microplastics have become a contaminant of increasing concern in soils. Although biodegradable plastics were considered as alternatives of traditional plastics, some evidence showed that biodegradable plastics might produce more microplastics. Until now, the effect of biodegradable microplastics on soil functions and processes, as well as microbial communities is

uncertain. Based on high throughput sequencing, enzymatic activity assay and dynamic analysis of soil carbon and nitrogen, we investigated the effects of biodegradable polylactic acid microplastics (PLA MPs) on soil microbiota and related ecological processes under conditions of high or low carbon content. The results showed that PLA MPs had no significant effect on the overall diversity and composition of bacterial communities or related ecosystem functions and processes. However, co-occurrence network analysis revealed that PLA MPs impacted the interactions between constituent species, which might have legacy effect on soil bacterial communities and functions. Our data also revealed that PLA MPs could trade off the priming effect of carbon source. Our results provided an integrated picture in understanding the effects of PLA MPs on soil microbes, properties and ecological functions, which will help to further understand the effects of MPs on terrestrial ecosystems.

Chen, H. J., et al. (2018). "Anomalous dispersion of magnetic spiky particles for enhanced oil emulsions/water separation." Nanoscale **10**(4): 1978-1986.

In situ effective separation of oil pollutants including oil spills and oil emulsions from water is an emerging technology yet remains challenging. Hydrophobic micro- or nano-materials with ferromagnetism have been explored for oil removal, yet the separation efficiency of an oil emulsion was compromised due to the limited dispersion of hydrophobic materials in water. A surfactant coating on microparticles prevented particle aggregation, but reduced oil absorption and emulsion cleaning ability. Recently, polystyrene microbeads covered with nanospikes have been reported to display anomalous dispersion in phobic media without surfactants. Inspired by this phenomenon, here magnetic microparticles attached with nanospikes were fabricated for enhanced separation of oil emulsions from water. In this design, the particle surfaces were functionalized to be superhydrophobic/superoleophilic for oil absorption, while the surface of the nanospikes prevented particle aggregation in water without compromising surface hydrophobicity. The magnetic spiky particles effectively absorbed oil spills on the water surface, and readily dispersed in water and offered facile cleaning of the oil emulsion. In contrast, hydrophobic microparticles without nanospikes aggregated in water limiting the particle-oil contact, while surfactant coating severely reduced particle hydrophobicity and oil absorption ability. Our work provides a unique application scope for the anomalous dispersity of microparticles and their potential opportunities in effective oil-water separation.

Chen, K. J., et al. (2019). "Biotechnology to sustainability: Consumer preferences for food products grown on biodegradable mulches." Food Research International **116**: 200-210.

This study evaluates consumer preferences for an agricultural product grown on biodegradable mulch film, which is an environmentally friendly soil cover that sustains plant growth, but that avoids the environmental harm of plastic pollution from non-biodegradable mulches in the field or upon disposal. Using a dichotomous-choice contingent valuation method, we assessed the willingness to pay for strawberries grown on biodegradable mulch with a randomized information treatment on 1510 consumers across different regions of the United States. On average, consumers are willing to pay 10.3% more for food -strawberries in our case- grown on biodegradable mulches. Consumers who are female, earn a higher income, have stronger environment-friendly attitudes, or received the information treatment on the benefits of biodegradable mulches, also expressed more willingness to pay a premium price for strawberries grown on biodegradable mulches. Our findings support that consumers are willing to internalize a price premium for food products on biodegradable mulches, suggesting that agricultural producers could realize private benefits from price premiums that could, in turn, generate social benefits by increasing biodegradable mulch use, leading to a reduction of plastic pollution. By providing empirical evidence on the potential adoption of biotechnology in the food production system, our results allow agricultural crop producers to make more informed decisions on growing and pricing strategies. Our research will also facilitate agricultural scientists and policymakers to articulate industry-supporting policies for sustainable development.

Chen, K. S. and R. Z. Yeh (1996). "Pyrolysis kinetics of epoxy resin in a nitrogen atmosphere." Journal of Hazardous Materials **49**(2-3): 105-113.

Pyrolysis kinetics of epoxy resins are investigated under various heating conditions (2, 5, 10, and 20 K min⁻¹) in nitrogen by means of thermogravimetric measurements. Experimental initial reaction temperatures are within 531-552 K for each heating rate and the averaged apparent activation energy is 41.26 kcal mol⁻¹. The initial and final reaction temperatures, and thus the reaction range, all increase when the heating rate is increased. The overall rate equation can be modelled by an Arrhenius-type equation from which the kinetic parameters such as the activation energy, the pre-exponential factor, and the reaction order are determined by using the Friedman method. The results will be useful in developing pyrolysis or starved-air incineration systems for thermosetting plastic waste.

Chen, L., et al. (2018). "Curcumin attenuates sepsis-induced acute organ dysfunction by preventing inflammation and enhancing the suppressive function of Tregs." International Immunopharmacology **61**: 1-7.

Sepsis is characterized by the extensive release of cytokines and other mediators. It results in a dysregulated immune response and can lead to organ damage and death. Curcumin has anti-inflammatory properties and immunoregulation functions in various disorders such as sepsis, cancer, rheumatoid arthritis, cardiovascular diseases, lung fibrosis, gallstone formation, and diabetes. This paper investigates the effects of curcumin on immune status and inflammatory response in mice subjected to cecal ligation and puncture (CLP). Inflammatory tissue injury was evaluated by histological observation. Magnetic microbeads were used to isolate splenic CD4⁺CD25⁺regulatory T cells (Tregs), and phenotypes were then analyzed by flow cytometry. The levels of Foxp3 were detected by Western blot and real-time PCR and cytokine levels were determined by enzyme-linked immunosorbent assay. We found that the administration of curcumin significantly alleviated inflammatory injury of the lung and kidney in septic mice. The suppressive function of Treg cells was enhanced and the plasma levels of IL-10 increased after treatment with curcumin. Furthermore, the secretion of plasma TNF-alpha and IL-6 was notably inhibited in septic mice treated with curcumin and administration with curcumin could improve survival after CLP. These data suggest that curcumin could be used as a potential therapeutic agent for sepsis.

Chen, Q., et al. (2019). "Leaching of endocrine disrupting chemicals from marine microplastics and mesoplastics under common life stress conditions." Environment International **130**: 104938.

Microplastics (MPs) and mesoplastics are able to sorb harmful substances and often contain additives, e.g., endocrine disrupting chemicals (EDCs), that can cause adverse effects to organisms. The present study aims to determine EDC concentrations and their endocrine activities in leachates of field-collected marine MPs and mesoplastics under stress conditions that are known to occur during the plastic life cycle. Estrogens were the dominant EDCs on plastic particles and were either concentrated from the surrounding water or originated from plastic manufacturing. Bisphenol A had the highest detection frequency (75%) with an average concentration of 475+/-882mug/kg, followed by bisphenol S, octylphenol and nonylphenol.

Moreover, smaller marine MPs leached greater quantities of EDCs because the sorption from surrounding seawater is more efficient for smaller particles. It was found that normal life stresses such as microwaving (MW) and autoclaving (AC) can decrease EDC concentrations, but solar irradiation (solar) can increase EDC concentrations in leachates. Even though organisms with higher metabolic ability exhibited greater estrogenic effects, the comprehensive toxicity of plastic leachates after common life treatments was still limited (below the EC₁₀ value) if 0.1% is taken as the EDC uptake from plastic. In future studies, the accurate contribution of plastic bound EDCs needs to be further explored, and the monitoring of MPs and mesoplastics in the human diet remains important because the concentrations of these plastics may change in the future.

Chen, Q., et al. (2017). "Quantitative investigation of the mechanisms of microplastics and nanoplastics toward zebrafish larvae locomotor activity." Science of the Total Environment **584**(585): 1022-1031.

This study investigated the direct and indirect toxic effects of microplastics and nanoplastics toward zebrafish (Danio rerio) larvae locomotor activity. Results showed that microplastics alone exhibited no significant effects except for the upregulated zfrho visual gene expression; whereas nanoplastics inhibited the larval locomotion by 22% during the last darkness period, and significantly reduced larvae body length by 6%, inhibited the acetylcholinesterase activity by 40%, and upregulated gfap, alpha 1-tubulin, zfrho and zfblue gene expression significantly. When co-exposed with 2 micro g/L 17 alpha -ethynylestradiol (EE2), microplastics led to alleviation on EE2's inhibition effect on locomotion, which was probably due to the decreased freely dissolved EE2 concentration. However, though nanoplastics showed stronger adsorption ability for EE2, the hypoactivity phenomenon still existed in the nanoplastics co-exposure group. Moreover, when co-exposed with a higher concentration of EE2 (20 micro g/L), both plastics showed an enhanced effect on the hypoactivity. Principal component analysis was performed to reduce data dimensions and four principal components were reconstituted in terms of oxidative stress, body length, nervous and visual system related genes explaining 84% of total variance. Furthermore, oxidative damage and body length reduction were evaluated to be main reasons for the hypoactivity. Therefore, nanoplastics alone suppressed zebrafish larvae locomotor activity and both plastic particles can change the larvae swimming behavior when co-exposed with EE2. This study provides new insights into plastic particles' effects on zebrafish larvae, improving the understanding of their environmental risks to the aquatic environment.

Chen, Q., et al. (2012). "Haemodynamics-Driven Developmental Pruning of Brain Vasculature in Zebrafish." PLoS Biology **10**(8): e1001374.

Author Summary Although the brain comprises only 2% of body weight, it receives 15% of cardiac output and consumes 20% of total body oxygen delivered through its blood vasculature. The brain blood vasculature consists of a highly branched vessel network that is tailored to efficiently deliver oxygen and nutrients to each brain region. However, little is known about how the brain vasculature develops. Using in vivo long-term serial confocal imaging of zebrafish larvae, we analyze this process and find that the developing midbrain vasculature undergoes not only vessel growth but also blood flow-driven vessel pruning. We show that vessel pruning occurs preferentially at loop-shaped vessel segments via the migration of endothelial cells to adjacent unpruned segments; over time, such vessel pruning reduces the complexity of the early primitive midbrain vasculature. We also observe that pruned vessel segments exhibit a lower and more variable blood flow than do unpruned segments and that the local blocking of blood flow triggers vessel pruning. By contrast, increases in blood flow impair vessel pruning. Finally, we show that pruning events can be predicted using a haemodynamics based mathematical

model of the midbrain vasculature. These findings demonstrate the existence of brain vessel pruning during development and provide novel insights into the role of haemodynamics in brain vascular refinement.

Chen, Q., et al. (2020). "Is color a matter of concern during microplastic exposure to Scenedesmus obliquus and Daphnia magna?" Journal of Hazardous Materials **383**: 121224.

Toxicities of microplastics (MPs) on aquatic organisms have been widely investigated often by using white or transparent MPs. However, various colored MPs scatter in the real aquatic environment. Here we investigated four colored MPs' effects on Scenedesmus obliquus algal growth first. Under the light condition, algal growth increased initially due to hormesis stimulation and then decreased gradually at higher MP concentrations. Green colored MPs exhibited the lowest inhibition effect, probably due to their resemblance to algae; white MPs inhibited the algal growth significantly, which was attributed to the presence of ethanol. Turbulence condition seemed to diminish algal growth differences among groups, but it led to slight oxidative stress. Furthermore, we also tested MP effects on Daphnia magna feeding ability.

Chen, Q., et al. (2017). "Enhanced uptake of BPA in the presence of nanoplastics can lead to neurotoxic effects in adult zebrafish." Science of the Total Environment **609**: 1312-1321.

Plastic particles have been proven to be abundant in the aquatic environment, raising concerns about their potential toxic effects. In the present study, we determined the bioaccumulation potential of bisphenol A (BPA) in adult zebrafish (Danio rerio) in the absence and presence of nano-sized plastic particles (nanoplastics, NPPs). Results show that BPA can accumulate in the viscera, gill, head and muscle of zebrafish with 85, 43, 20, and 3 micro g/g ww after 1 d exposure. NPPs were also found to accumulate in different tissues of the fish. Relative equilibrium was reached after 1 d exposure in different tissues with 39 to 636 mg/kg ww. Co-exposure of NPPs and BPA led to a 2.2 and 2.6-fold significant increment of BPA uptake in the head and viscera, if compared with BPA alone treatment after 3 d exposure. As such, we further investigated several neurotoxic biomarker alterations in the fish head. It was found that either BPA or NPPs can cause myelin basic protein (MBP)/gene up-regulation in the central nervous system (CNS); meanwhile, both contaminants exhibited significant inhibition of acetylcholinesterase (AChE) activity, which is a well-known representative biomarker for neurotoxicity. Moreover, for the co-exposure treatment, biomarkers of myeline and tubulin protein/gene expressions, dopamine content, and the mRNA expression of mesencephalic astrocyte derived neurotrophic factor (MANF) were all significantly up-regulated, suggesting that an enhanced neurotoxic effects in both CNS and dopaminergic system occurred. However, AChE activity was no more inhibited in the co-exposure treatment, which implies that solely AChE measurement may not be sufficient to identify neurotoxic effects in the cholinergic system. Overall, the present study demonstrates that the presence of NPPs can increase BPA bioavailability and cause neurotoxicity in adult zebrafish.

Chen, Q., et al. (2019). "Marine microplastics bound dioxin-like chemicals: Model explanation and risk assessment." Journal of Hazardous Materials **364**: 82-90.

Microplastics have become one of the most pervasive emerging pollutants in the marine environment because of their wide occurrence and high sorption ability for hydrophobic organic contaminants (HOCs). Among the associated HOCs, dioxin-like chemicals (DLCs) can pose severe health risks; however, information on effects of microplastics bound DLCs is lacking. To fill this knowledge gap, this study integrated chemical analysis and in vitro bioassays to elucidate the

potential dioxin-like effects of microplastics bound DLCs. Chemical analysis results demonstrated that styrofoams possessed significantly greater DLCs than other coastal or open ocean plastic particles. This was probably due to the presence of additives and greater sorption ability of expanded polystyrene. However, styrofoams did not show as strong dioxin-like effects as predicted by the bioanalysis equivalent model in bioassays. This could be attributed to the decreased DLC bioavailability and increased competition with the presence of styrene oligomers. Besides, bioassay results also demonstrated that aging increased the associated DLC concentrations, since extra sorption from surrounding environment occurred during prolonged retention periods. Finally, it was estimated that the leaching of DLCs could induce dioxin-like effects in marine organisms under 100% (11/11) and 18% (2/11) scenarios for aged pellets and styrofoams through aqueous or dietary exposures.

Chen, S. and G. Cao (2002). "Photocatalytic oxidation of nitrite by sunlight using TiO_2 supported on hollow glass microbeads." Solar Energy **73**(1): 15-21.

The feasibility of photocatalytic oxidation of nitrite using TiO_2 supported on hollow glass microbeads as a photocatalyst by sunlight was studied. The results showed that $1.1x10^{-4}$mol/dm^3 of nitrite can be completely photocatalytically oxidized after 120-min illumination by sunlight. The conversion of nitrite was increased rapidly by adding a small amount of H_2O_2, Fe^{3+} and Pd^{2+}. The effects of parameters such as the amount of TiO_2/beads, air flow, initial pH, dichromate, SO_4^{2-}, NO_3^-, Cl^- and organic compounds on the photocatalytic oxidation of nitrite were also studied. The possible mechanisms of photocatalytic oxidation of nitrite were investigated. After 150-h illumination by sunlight, there was no significant loss of the photocatalytic activity of TiO_2/beads.

Chen, S., et al. (1997). "Photocatalytic degradation of dichlorvos using TiO sub(2) supported on hollow glass microbeads." Journal of Environmental Sciences (China) **9**(3): 278-282.

In this paper, a method for TiO sub(2) supported on hollow glass microbeads was described and the feasibility of photocatalytic degradation of dichlorvos using supported TiO sub(2)(TiO sub(2)/beads) was studied. The results showed that 1.0 x 10 super(-4) mol.dm super(-3) of dichlorvos could be completely photocatalytically degraded into PO sub(4) super(3-) after 120 min illumination with a 375 W medium pressure mercury lamp. The effects of the amount of TiO sub(2)/beads and concentration of Cu super(2+) on the photocatalytic degradation were also investigated. Some intermediate products of photocatalytic degradation of dichlorvos were detected.

Chen, S., et al. (2020). "Carbonization: A feasible route for reutilization of plastic wastes." Science of the Total Environment **710 (no pagination)**(136250).

Plastics not only bring convenience and color to human life, but also bring endless troubles and disaster to our environment. Reutilization of plastic wastes is in favor of energy conservation and emission reduction, thereby is a significant pathway of plastic wastes disposal. Carbonization is an effective way of converting polymer precursors to valuable carbon materials for use in fields of energy conversion and storage, environmental protection and restoration. Here, we present a systematic multi-perspective overview of carbonization as a feasible route of reutilization of plastic wastes. A brief summary of conventional routes for plastic wastes is followed by a brief introduction of carbonization for converting plastics to carbon materials. Special emphasis is paid on the carbonization pathways and mechanisms of common plastics. Finally, the feasibility, application prospect and challenge of carbonization as one method of reutilization of plastic wastes are proposed. By presenting a consolidated information source on

different carbonization mechanisms, this review provides a valuable guideline for reutilization of plastic wastes by carbonization. Copyright © 2018 Elsevier B.V.

Chen, S., et al. (1997). "Photocatalytic degradation of dichlorvos using TiO₂ supported on hollow glass microbeads." Journal of Environmental Sciences **9**(3): 278-282.

A method for TiO₂ supported on hollow glass microbeads was described and the feasibility of photocatalytic degradation of dichlorvos using supported TiO₂ (TiO₂/beads) was studied. The results showed that 1.0 x 10⁻⁴ mol/dmsuperscript 3 of dichlorvos could be completely photocatalytically degraded into PO³⁻₄ after 120 min illumination with a 375 W medium pressure mercury lamp. The effects of the amount of TiO₂/beads and concentration of Cu²⁺ on the photocatalytic degradation were also investigated. Some intermediate products of photocatalytic degradation of dichlorvos were detected.

Chen, S.-F. and X.-L. Cheng (1999). "Photocatalytic degradation of oil films floating on water by TiO sub(2) supported hollow glass microbeads." China Environmental Science **19**(1): 47-50.

The TiO sub(2)/beads photocatalyst was prepared by dip-coating technique using the hollow glass microbeads as a supporter. The feasibility of photocatalytic degradation of dodecane and toluene floating on water using TiO sub(2)/beads was studied. The results showed that 100% of toluene was photocatalytically degraded after 80 min illumination and 93.5% of dodecane degraded after 120 min illumination with a 375W medium pressure mercury lamp. Bubbling air was favourable for the photocatalytic removal of dodecane and toluene. The photocatalytic removal efficiency was increased rapidly by adding a trace amount of H sub(2)O sub(2) (5.0 mmol/L). Adding a small amount of Na super(+), no obviously effect for the photocatalytic removal of dodecane and toluene was observed.

Chen, T., et al. (1999). "Charged microbeads are not transported across the human stratum corneum in vitro by short high-voltage pulses." Bioelectrochemistry & Bioenergetics **48**(1): 181-192.

There have been several reports of particle transport due to high-voltage pulsing of human skin. Here, several different short, high-voltage pulsing protocols were used in vitro to study the possible transport of highly charged, fluorescent polystyrene particles (14 nm to 2.1 microns in diameter; surface charges of -4.05 x 10(3) e to -2.77 x 10(7) e) across the skin. Two different methods were used to trap and measure particles on the other side of the skin. The first used a polycarbonate membrane to trap the particles, determining the amount of transport by enumeration under a fluorescence microscope. The second used spectrofluorimetry to measure the amount of particles transported. After pulsing, particles were found in randomly distributed clusters on the surface of the skin. No detectable transport across the stratum corneum for any size particle was observed.

Chen, W., et al. (2013). "Surface-micromachined microfiltration membranes for efficient isolation and functional immunophenotyping of subpopulations of immune cells." Advanced Healthcare Materials **2**(7): 965-975.

An accurate measurement of the immune status in patients with immune system disorders is critical in evaluating the stage of diseases and tailoring drug treatments. The functional cellular immunity test is a promising method to establish the diagnosis of immune dysfunctions. The conventional functional cellular immunity test involves measurements of the capacity of peripheral blood mononuclear cells to produce pro-inflammatory cytokines when stimulated ex vivo. However, this "bulk" assay measures the overall reactivity of a population of lymphocytes and monocytes, making it difficult to pinpoint the phenotype or real identity of the reactive immune cells involved. In this research, we develop a large surface micromachined poly-dimethylsiloxane (PDMS) microfiltration membrane (PMM) with high porosity, which is integrated in a microfluidic microfiltration platform. Using the PMM with functionalized microbeads conjugated with antibodies against specific cell surface proteins, we demonstrated rapid, efficient and high-throughput on-chip isolation, enrichment, and stimulation of subpopulations of immune cells from blood specimens. Furthermore, the PMM-integrated microfiltration platform, coupled with a no-wash homogeneous chemiluminescence assay ("AlphaLISA"), enables us to demonstrate rapid and sensitive on-chip immunophenotyping assays for subpopulations of immune cells isolated directly from minute quantities of blood samples.

Chen, W., et al. (2013). "Microfluidic one-step synthesis of alginate microspheres immobilized with antibodies." Journal of the Royal Society Interface **10**(88): 20130566.

Micrometre- and submicrometre-size functionalized beads are frequently used to capture targets of interest from a biological sample for biological characterizations and disease diagnosis. The main challenge of the microbead-based assay is in the immobilization of probe molecules onto the microbead surfaces. In this paper, we report a versatile droplet microfluidics method to fabricate alginate microspheres while simultaneously immobilizing anti-Mycobacterium tuberculosis complex IgY and anti-Escherichia coli IgG antibodies primarily on the porous alginate carriers for specific binding and binding affinity tests. The binding affinity of antibodies is directly measured by fluorescence intensity of stained target bacteria on the microspheres. We demonstrate that the functionalized alginate microspheres yield specificity comparable with an enzyme-linked immunosorbent assay. The high surface area-to-volume ratio of the functionalized porous alginate microspheres improves the detection limit. By using the droplet microfluidics, we can easily modify the size and shape of alginate microspheres, and increase the concentration of functionalized alginate microspheres to further enhance binding kinetics and enable multiplexing.

Chen, W., et al. (2018). "Induced structural changes of humic acid by exposure of polystyrene microplastics: A spectroscopic insight." Environmental Pollution **233**: 1-7.

The occurrence of microplastics (MPs) as emerging contaminants in the environment may cause changes in water or sediment characteristics, and further affect their biogeochemical cycles. Thus, insights into the interactions between dissolved organic matter (DOM) and MPs are essential for the assessment of environmental impacts of MPs in ecosystems. Integrating spectroscopic methods with chemometric analyses, this work explored the chemical and microstructural changes of DOM-MP complex to reveal the mechanism of DOM-MP interaction at a molecular level. MPs were found to interact with the aromatic structure of DOM via pi-pi conjugation, then be entrapped in the DOM polymers by the carboxyl groups and C=O bonds, constituting a highly conjugated co-polymer with increased electron density. This induced the fluorescence intensity increase in DOM. The interaction affinity of DOM-MP was highly dependent on the MP size and solution pH. This work offers a new insight into the impact of MP discharge on environment and may provide an analytical framework for evaluating MP hetero-aggregation and the roles of MPs in the transportation of other contaminants. Furthermore, the integrated methods used in this work exhibit potential applications in exploring the fragmentation processes of MPs and formation of secondary MPs under natural conditions.

Chen, W., et al. (2020). "Single and combined effects of amino polystyrene and perfluorooctane sulfonate on hydrogen-producing thermophilic bacteria and the interaction mechanisms." Science of the Total Environment **703**: 135015.

As a carrier of perfluorooctane sulfonate, nano-plastics are ubiquitous and finally enriched in the sludge, which is widely used as a raw material for the production of bioenergy (hydrogen or methane) by anaerobic digestion. However, there are still many unknowns about their metabolic toxicity to functional microbes (e.g. hydrogen-producing thermophilic bacteria). Therefore, single and combined effects of amino polystyrene (NPS: 70nm; 0.2mg/L) and perfluorooctane sulfonate (PFOS: 0.1, 1 and 5mg/L) on hydrogen-producing thermophilic bacteria were investigated after exposure for 7days at 55degreeC and pH=5.7. Single NPS exhibited obvious interference to the metabolism of thermophilic bacteria, resulting in a 53.9% reduction in hydrogen production. However, the combined NPS+PFOS produced an antagonistic effect, leading to a 31.6% reduction in hydrogen production. Nonetheless, the single and combined exposure did not alter the type of hydrogen production (acetic acid-type hydrogen fermentation). Moreover, single NPS and combined NPS+PFOS not only induced the changes of the composition of extracellular polymers (EPSs) and pi bond structure of the protein in EPSs, but also decreased the activity of hydrolase in EPSs and surface charge of EPSs. Compared to single NPS exposure, NPS+PFOS-exposed thermophilic bacteria was less permeable to a semi-membrane permeable dye and produced less reactive oxygen species, but were still significantly higher than control group. In short, the main mechanisms of single NPS and combined NPS+PFOS were both to increase cell permeability and to induce oxidative stress. The addition of PFOS alleviated the toxic effect of NPS, but did not change its mechanism of toxicity.

Chen, X., et al. (2017). "Transport of biomolecules to binding partners displayed on the surface of microbeads arrayed in traps in a microfluidic cell." Biomicrofluidics **11**(1): 014101.

Arrays of probe molecules integrated into a microfluidic cell are utilized as analytical tools to screen the binding interactions of the displayed probes against a target molecule. These assay platforms are useful in enzyme or antibody discovery, clinical diagnostics, and biosensing, as their ultraminiaturized design allows for high sensitivity and reduced consumption of reagents and target. We study here a platform in which the probes are first grafted to microbeads which are then arrayed in the microfluidic cell by capture in a trapping course. We examine a course which consists of V-shaped, half-open enclosures, and study theoretically and experimentally target mass transfer to the surface probes. Target binding is a two step process of diffusion across streamlines which convect the target over the microbead surface, and kinetic conjugation to the surface probes. Finite element simulations are obtained to calculate the target surface concentration as a function of time. For slow convection, large diffusive gradients build around the microbead and the trap, decreasing the overall binding rate. For rapid convection, thin diffusion boundary layers develop along the microbead surface and within the trap, increasing the binding rate to the idealized limit of untrapped microbeads in a channel. Experiments are undertaken using the binding of a target, fluorescently labeled NeutrAvidin, to its binding partner biotin, on the microbead surface. With the simulations as a guide, we identify convective flow rates which minimize diffusion barriers so that the transport rate is only kinetically determined and measure the rate constant.

Chen, Y., et al. (2019). "Life cycle assessment of end-of-life treatments of waste plastics in China." Resources, Conservation and Recycling **146**: 348-357.

As the world's largest producer and consumer of plastics, China is also the largest producer and recycler of waste plastics. It is necessary to explore the environmental impacts of actual

end-of-life (EOL) treatments of waste plastics in China. In this study, a life cycle assessment (LCA) was conducted to evaluate the environmental impacts of mechanical recycling of waste plastics as well as incineration and landfilling with municipal solid waste in China. The results indicate the environmental benefits of current EOL treatments of waste plastics in China. Mechanical recycling was a negative and decisive contributor, with a minimum impact on terrestrial acidification potential (-83.4%) and a maximum impact on global warming potential (-165.8%). Incineration had negative contributions to 8 of the 12 environmental indicators, and landfilling was a positive contributor to all environmental impacts. Scenarios of treatment pattern, recycling technologies and import policy were set to analyze the potential reduction in environmental impacts of future EOL treatments of waste plastics. Increasing the proportion of mechanical recycling would reduce all environmental impacts, including up to 51.8% on particulate matter formation potential. Energy conservation and emission reduction in atmospheric pollutants would effectively reduce the environmental impacts of mechanical recycling. Banning waste plastics imports would decrease the transportation distances of waste plastics, thereby reducing the related environmental impacts, most notably a reduction of 84.8% for marine ecotoxicity potential. This study provides robust references for waste plastics management in China. Copyright © 2019 Elsevier B.V.

Chen, Y., et al. (2017). "Low cost smart phone diagnostics for food using paper-based colorimetric sensor arrays." Food Control **82**: 227-232.

There is a need for an accurate end-of-life indicator for packaged food (meat, seafood, dairy food etc.) beyond a simple "best use by" date on the food package. In this work, we propose a low cost solution by repurposing the food's barcode as a colorimetric sensor array to monitor food condition. A smart phone camera is used to read color information from the sensor barcode for quantitative estimate of the food aging and quality. The sensor is based on cross-reactive vapor sensitive dyes encapsulated in resin microbeads, which are impregnated onto a low cost paper substrate in a barcode pattern. The entire sensor platform is validated by accurately monitoring chicken aging and eventual spoilage under different temperature conditions. The proposed food diagnostics platform has the potential to reduce food waste and eliminate food-borne illness.

Chen, Y., et al. (2020). "Microplastic pollution in vegetable farmlands of suburb Wuhan, central China." Environmental Pollution **257 (no pagination)**(113449).

Microplastic pollution has become an emergency issue in the global environment. However, little is known about the occurrence and distribution of microplastics in agroecological system. In this study, we investigated the pollution of microplastics in vegetable farmlands in suburb of Wuhan, central China. Results showed that the abundance of microplastics ranged from 320 to 12,560 items/kg<inf>dw.</inf> Microplastic pollution adjacent to the suburban roads was about 1.8 times as serious as that in the residential areas. Microplastics with size less than 0.2 mm were dominated, reaching 70% in total. The main types of microplastics were fibers and microbeads. Moreover, polyamide (32.5%) and polypropylene (28.8%) were the main types of polymer. This study proclaims the occurrence and characteristics of microplastic pollution in typical farmland soils of suburb land. It may provide significant basis for subsequent research about microplastics contaminant in the terrestrial ecosystem. Microplastic pollution in agricultural soils from central China. Chen, Y., et al. (2016). "Establishment and clinical application of a liquid chip technology for high throughput screening pathogens of acute contagious respiratory disease." Chest **1)**: A94.

PURPOSE: To establish a liquid microarrays technology for the simultaneous, rapid, high throughput screening of 20 acute contagious respiratory disease pathogens. This technology can detect virus, atypical pathogens and bacteria simultaneously and rapidly. What more, This research was also designed investigate the clinical application value of this technology. METHOD(S): 1:Establishment of the liquid chip technology: First, we obtain pathogens gene sequence of bacteria and atypical pathogens. The primers and the probes were designed on conserved sequence. Then, Pathogens' gene was amplified. Amino-modified probes were spotted on encoding microbeads hybridized with the PCR amplicon. Finally, Liquid chip equipment get mean fluorescent intensity. As a result, The liquid chip technology can detecte the corresponding pathogens with these specific primers and the probes repeatedly and sensitivitily. 2: we used the liquid chip technology to screen 20 pathgens from 333 chinical speum samples, comparing with bacteria culture for bacteria and Real-time PCR assay for virus and atypical pathogens, so as to obtian the sensitivity and specificity of this method. RESULT(S): A liquid microarrays technology for high throughput screening of 20 contagious respiratory disease pathogens was establish sucessfully. Of 333 specimens, the positive rates of bacteria detection by liquid chip technology was significantly higherly than traditional bacteria culture (37.8%vs 10.8%) ($P<0.05$); The positive rates of atypical pathogens and viral detection by liquid chip technology and real-time PCR showed no significant differences (2.7%vs 3.0%) and (34.5% vs 31.2%) ($P>0.05$). comparing with standard methods, the sensitivity and specificity of liquid chip technology was 74.4% and 93.0% in bacteria detection, 50.0% and 99.4% in atypical pathogens detection, and 63.0% and 98.3% in viral detection. CONCLUSION(S): A liquid chip technology for high throughput screening of pathogens of acute contagious respiratory disease including bacteria, virus and atypical pathogens was established. This technology has a potential clinical application in high throughput screening multiple species of repiratory pathgens of the unexplained acute pneumonia comparing with other methods before which can only screen Single species. CLINICAL IMPLICATIONS: The liquid chip technology has a potential clinical application in high throughput screening multiple species of repiratory pathgens of the unexplained acute pneumonia comparing with other methods before which can only screen Single species.

Chen, Y., et al. (2020). "Defense responses in earthworms (Eisenia fetida) exposed to low-density polyethylene microplastics in soils." Ecotoxicology & Environmental Safety **187**: 109788.

The potential threats of microplastics to global health are a new problem. However, little is known about the influence of microplastics on soil organisms. Here, we investigated the effects of low-density polyethylene (LDPE, < 400mum) on earthworms (Eisenia fetida) under different concentrations (0.1, 0.25, 0.5, 1.0, 1.5g/kg dry) with three replicates in artificial soil.

Chen, Y., et al. (2013). "Multicompartmental Janus microbeads from branched polymers by single-emulsion droplet microfluidics." Langmuir **29**(41): 12657-12662.

We describe a versatile and facile route for the preparation of Janus microbeads using single emulsion droplet-based microfluidics, in which water droplets that contain a mixture of branched poly(N-isopropylacrylamide)-co-(poly(ethylene glycol)diacrylate)-co-(methacrylic acid) and colloidal particles form the basis of our approach. The colloidal particles, poly(methyl methacrylate) microspheres or titanium dioxide particles, and iron oxide nanoparticles are spatially positioned within the water droplets through gravity and an externally applied magnetic force, respectively. Evaporation of water leads to gel formation of the branched copolymer matrix as a result of physical cross-linking through hydrogen bond interactions, fixing the spatial position of the colloidal particles. The thermo- and pH-responsive nature of the branched poly(N-isopropylacrylamide) (PNIPAm)-based copolymer allows for the disintegration of the polymer network of the Janus microbeads and a triggered release of the colloidal content at temperatures below the lower critical solution temperature (LCST) and at increased pH values.

Chen, Y. C. (2018). "Effects of urbanization on municipal solid waste composition." Waste Management **79**: 828-836.

The generation of municipal solid waste (MSW) is related to various features of urbanization. In this study, a linear regression model was used to evaluate the effects of several urbanization indicators on the composition of MSW. Household population (P), area of urban planning (L), tap water penetration (W), electricity sold (El), number of operating factories (I), car density (T), education level (Ed), and annual revenue (R) were chosen as important indicators of urbanization. The five major categories of MSW-paper, food waste, plastic, metal, and glass-were also chosen for specific analysis, and MSW composition was found to be closely related to household population (P) (r²>0.8). The volume of one category of waste, food waste, was related to the industrialization indicator (r²>0.9). The total volume of MSW and the total volume of metal waste were linked with household population divided by tap water penetration (P/W) (r²=0.9903), and with annual revenue divided by tap water penetration (R/W) (r²=0.9364). The volume of plastic waste and glass waste generated, respectively, was related to annual revenue divided by education level (R/Ed) (r²=0.9814 vs. r²=0.9371). In addition, a case study of Taipei City indicated that MSW disposal fees should reflect not only household population (P) but also tap water penetration (W). This study provides valuable findings quantifying the effects of urbanization on MSW composition. The results will help governments and enterprises to efficiently evaluate and predict variation in MSW composition with reference to indicators of urbanization, thereby improving the management of waste.

Chen, Z., et al. (2005). "A practical approach to the detection of prognostically significant genomic aberrations in multiple myeloma." Journal of Molecular Diagnostics **7**(5): 560-565.

Multiple myeloma (MM) is a malignancy of differentiated B lymphocytes and has remained an incurable disease. Chromosomal abnormalities are among the most important prognostic parameters for MM. Cytoplasm immunoglobulin-enhanced interphase fluorescent in situ hybridization (FISH) has been a standard cell-targeting method for identifying genomic aberrations in MM. We have developed another cell-targeting approach by using CD138 magnetic microbeads to sort plasma cells for FISH analysis. The FISH panel consisted of four probes targeting RB-1, D13S319, immunoglobulin H, and p53 loci. We reviewed the FISH and conventional cytogenetic results of 60 patients with MM. The present cell-targeting approach in conjunction with the FISH probe panel was more sensitive than FISH performed on untargeted cells in detecting prognostically significant genomic aberrations (72 versus 24%, P = 0.0016). The frequencies of genomic abnormalities identified were similar to previously reported data obtained with the standard cell-targeting method. Therefore, our cell-targeting approach and FISH panel reliably detect prognostically important genomic abnormalities in MM and are potentially suitable for widespread use.

Chen, Z., et al. (2011). "Phase-separated chitosan-fibrin microbeads for cell delivery." Journal of Microencapsulation **28**(5): 344-352.

Matrix-enhanced delivery of cells is a promising approach to improving current cell therapies. Our objective was to create cell-laden composite microbeads that combine the attractive features of the natural polymers chitosan and fibrin. Liquid polydimethylsiloxane was used to emulsify a chitosanfibrinogen solution containing suspended human fibroblast cells, followed by initiation of thrombin-mediated polymerization of fibrin and thermal/pH-mediated gelation of chitosan. Chitosan/fibrin weight percent (wt%) ratios of 100/0, 75/25, 50/50 and 25/75 were investigated. Microbead diameters ranged from 275?+/- ?99?mum to 38?+/- ?10?mum using impeller speeds from 600 to 1400?rpm. Fibroblasts remained viable on day 1 post-fabrication in all matrices, but cell viability was markedly higher in high-fibrin microbeads by day 8 post-fabrication. Cell spreading and interaction with the extracellular matrix was also markedly increased in high-fibrin matrices. Such composite microbeads containing viable entrapped cells have potential for minimally invasive delivery of cells for a variety of tissue repair applications. © 2011 Informa UK Ltd All rights reserved.

Chen, Z., et al. (2020). "Enhanced in situ biodegradation of microplastics in sewage sludge using hyperthermophilic composting technology." Journal of Hazardous Materials **384**: 121271.

Land spreading of sewage sludge is a major source of environmental microplastics (MPs) contamination. However, conventional sludge treatments are inefficient at removing sludge-based MPs. Herein, hyperthermophilic composting (hTC) technology is proposed and demonstrated in full-scale (200t) for in situ biodegradation of sludge-based MPs. After 45 days of hTC treatment, 43.7% of the MPs was removed from the sewage sludge, which is the highest value ever reported for MPs biodegradation. The underlying mechanisms of MPs removal were investigated in lab-scale polystyrene-microplastics (PS-MPs) biodegradation experiments. The hTC inoculum degraded 7.3% of the PS-MPs at 70degreeC in 56 days, which was about 6.6 times higher than that of the conventional thermophilic composting (cTC) inoculum at 40degreeC. Analyses of the molecular weight and physicochemical properties of the PS-MPs residuals indicated that hyperthermophilic bacteria in hTC accelerated PS-MPs biodegradation through excellent bio-oxidation performance. High-throughput sequencing suggested that Thermus, Bacillus, and Geobacillus were the dominant bacteria responsible for the highly efficient biodegradation during hTC. These results reveal the critical role of hyperthermophilic bacteria in MPs biodegradation during hTC, highlighting a promising strategy for sludge-based MPs removal from the real environment.

Cheng, D., et al. (2018). "A simple microdevice for single cell capture, array, release, and fast staining using oscillatory method." Biomicrofluidics **12**(3): 034105.

Microchips that perform single cell capture, array, and identification have become powerful tools for single cell studies, which can reveal precise underlying mechanisms among bulk cell populations. However, current single cell capture and on-chip immunostaining methods consume more time and reagent than desired. To optimize this technology, we designed a novel trap structure for single cell capture, array, and release, and meanwhile an oscillatory method was used to perform rapid on-chip cell immunostaining. The trap structure array used equal distribution of lateral flow to achieve single cell array in high velocity flows and decrease the risk of clogging. A length of glass capillary with a sealed bubble was inserted into the outlet so that it could act in a manner analogous to that of a capacitor in an RC circuit. By applying one periodic air pressure to the inlet, oscillation motion was generated, which significantly enhanced the on-chip reaction efficiency. In addition, the oscillation performance could be easily regulated by changing the length of the capillary. The trapped cells could maintain their positions during oscillation; hence, they were able to be tracked in real time. Through our trap microchip, 12 mum microbeads were successfully trapped to form a microarray with a capture efficiency of ~92.7% and 2 mum microbeads were filtered. With an optimized oscillation condition

(P_{push} = 0.03 MPa, f = 1 Hz, L = 3 cm), fast on-chip immunostaining was achieved with the advantages of less time (5 min) and reagent (2 mul) consumption. The effectiveness of this method was demonstrated through quantitative microbead and qualitative Caco-2 cell experiments. The device is simple, flexible, and efficient, which we believe provides a promising approach to single cell heterogeneity studies, drug screening, and clinical diagnosis.

Cheng, L., et al. (2019). "Silica microbeads capture fetal nucleated red blood cells for noninvasive prenatal testing of fetal ABO genotype." Electrophoresis **04**: 04.

ABO hemolytic disease of the newborn (ABO-HDN), which may cause neonatal jaundice and polycythemia, or even stillbirth or neonatal death, is widespread in China. Prenatal testing for the fetal ABO blood group can reduce unnecessary concerns or ensure prompt treatment. Herein, we presented a method to employ high-density silica microbeads (SiO₂ MBs) for capturing fetal nucleated red blood cells (fnRBCs) in maternal peripheral blood, and we detected the ABO genotype of the fetus using these captured cells. We evaluated 52 patients using the SiO₂ MBs. Among 26 pregnant women with type O blood, 8 (30.8%) of the fetuses had type A blood, 5 (19.2%) had type B blood, and 13 (50%) had type O blood. SRY genes were detected in all 27 male fetuses. This study represents a simple and effective method for noninvasive prenatal detection of the fetal ABO genotype. We believe that this method has great potential for noninvasive prenatal testing of the fetal Rh blood group and other fetal diseases as well.

Cheng, S. H., et al. (2001). "The use of microangiography in detecting aberrant vasculature in zebrafish embryos exposed to cadmium." Aquatic toxicology (Amsterdam, Netherlands) **52**(1): 61-71.

Embryonic vascular patterns in zebrafish (Danio rerio) could be visualised by confocal microscopy coupled with microinjected fluorescent microbeads. This microangiographic technique was adopted here, for the first time, to study the effects of cadmium on cardiovascular development in zebrafish embryos. Zebrafish embryos were incubated in culture medium containing 100 microM cadmium from 5 h post fertilisation (hpf) to 48 hpf. At 48 hpf, embryos were examined for viability and occurrence of malformations. The 100 microM cadmium caused 32.21 +/- 3.65% mortality and 20.33 +/- 4.04% visible malformations in surviving embryos. In the remaining embryos with no visible signs of malformations, further assessments for less obvious abnormalities were performed. Assessments on craniofacial development were made by digital measurements on areas of brains and eyes. Cardiac development was assessed by immunostaining the heart with the antibody MF20 specific for myosin heavy chain. Body lengths of the embryos were also measured. Embryonic development of brains, eyes, hearts and body lengths of visibly healthy embryos in the cadmium treatment group showed no significant difference from the controls. Embryonic vasculature of these visibly healthy embryos was then studied by microinjecting fluorescent microbeads of diameter 0.02 microm into the circulation. All the cadmium treated embryos showed localised vascular defects in the dorsal aortae, segmental and cranial vessels while none of the control embryos showed any aberrant patterns in the networking of the vasculature. Improved image analyses on the anterior regions revealed that cadmium treated embryos had markedly less complex networks of cranial vessels with fewer vessels perfusing the craniofacial regions. The number of branch points in the vascular network was counted. In untreated embryos, there were 135.6 +/- 51 branches in the vasculature in entire body. In the cadmium treated embryos, there were 64.5+/-31 branches. The difference was significant when assessed with Student's t-test. It appeared that although cadmium did not cause any signs of external malformations in these visibly healthy embryos, nonetheless induced impaired branching and anastomsis of the cranial

vessels. This study revealed, for the first time, that vital vascular structures in fish embryos could be affected by exposure to cadmium. This technique allowed visualisation of vascular anomalies in embryos showing no external signs of malformations. The impairment of anatomical features during embryonic development might serve as meaningful health endpoints in ecotoxicological studies and in risk assessment.

Cheng, W., et al. (2013). "Organophosphorus esters in the oceans and possible relation with ocean gyres." Environmental Pollution **180**: 159-164.

Abstract: Four organophosphorus esters (OPEs) were detected in aerosol samples collected in the West Pacific, the Indian Ocean and the Southern Ocean from 2009 to 2010, suggesting their circumpolar and global distribution. In general, the highest concentrations were detected near populated regions in China, Australia and New Zealand. OPE concentrations in the Southern Ocean were about two orders of magnitude lower than those near major continents. Additionally, relatively high OPE concentrations were detected at the Antarctic Peninsula, where several scientific survey stations are located. The four OPEs investigated here are significantly correlated with each other, suggesting they may derive from the same source. In the circumpolar transect, OPE concentrations were associated with ocean gyres in the open ocean. Their concentrations were positively related with average vorticity in the sampling area suggesting that a major source of OPEs may be found in ocean gyres where plastic debris is known to accumulate. Cheng, Y., et al. (2016). "A bubble- and clogging-free microfluidic particle separation platform with multi-filtration." Lab on a Chip **16**(23): 4517-4526.

Microfiltration is a compelling method to separate particles based on their distinct size and deformability. However, this approach is prone to clogging after processing a certain number of particles and forming bubbles in the separation procedure, which often leads to malfunctioning of devices. In this work, we report a bubble-free and clogging-free microfluidic particle separation platform with high throughput. The platform features an integrated bidirectional micropump, a hydrophilic microporous filtration membrane and a hydrophobic porous degassing membrane. The bidirectional micropump enables the fluid to flow back and forth repeatedly, which flushes the filtration membrane and clears the filtration micropores for further filtration, and to flow forward to implement multi-filtration. The hydrophobic porous membrane on top of the separation channel removes air bubbles forming in the separation channel, improving the separation efficiency and operational reliability. The microbead mixture and undiluted whole blood were separated using the microfluidic chip. After 5 cycles of reverse flushing and forward re-filtration, a 2857-fold enrichment ratio and an 89.8% recovery rate of 10 mum microbeads were achieved for microbead separation with 99.9% removal efficiency of 2 mum microbeads. After 8 cycles, white blood cells were effectively separated from whole blood with a 396-fold enrichment ratio and a 70.6% recovery rate at a throughput of 39.1 mul min⁻¹, demonstrating that the platform can potentially be used in biomedical applications.

Chengaiah, B., et al. (2011). "Self emulsifying drug delivery system: A novel approach for drug delivery." Research Journal of Pharmacy and Technology **4**(2): 175-181.

The oral delivery of hydrophobic drugs presents a major challenge because of the low aqueous solubility of such compounds. Self-emulsifying drug delivery systems (SEDDS) are mixtures of oils and surfactants, ideally isotropic, sometimes including co-solvents, which emulsify under conditions of gentle agitation, similar to those which would be encountered in the gastrointestinal tract. Recently, much attention has been focused on SEDDS to improve the oral bioavailability of poorly aqueous soluble drugs. The sole objective of pharmaceutical science is to design successful dosage forms which fulfill the therapeutic needs of the patients effectively. SEDDS are liquid to semisolid in nature, but it has drawbacks as formulation development, quality control, stability etc. These liquid SEDDS can be converted into solid dosage forms such as pellets, tablets, capsules, microspheres, micro-beads, nanoparticles etc without affecting drug release property. After administering the drug gets released and self emulsify in the GI tract. This article gives an overview of the new excipients used in SEDDS, types of formulations and SE dosage forms with characterization methods and pharmaceutical applications of SEDDS. © RJPT All right reserved.

Cheremisinoff, N. P. and P. N. Cheremisinoff (1989). "The Plastics Waste Problem." Pollution Engineering **21**(8): 58.

Plastics disposal has reached crisis proportions and resolution of the disposal problem is necessary. This crisis is expected to impact on industry in three ways: increased direct costs, reduced price competitiveness, and reduced plastic uses. Sources of plastic waste are identified. In 1980 plastics constituted only 2-3% of municipal waste. This amount has increased steadily and will reach 10-15% by the year 2000. Separation methods for municipal refuse applicable to plastics, such as air classification, shredders, and hammermills, are discussed, as are primary recycling and disposal options.

Chersi, A., et al. (2004). "Responses of peptide-specific T cells to stimulation with polystyrene beads carrying HLA class I molecules loaded with single peptides." Journal of Immunological Methods **291**(1-2): 79-91.

Cell-sized microbeads carrying single peptide-loaded HLA class I molecules were prepared for HLA-A2 and HLA-B7 by a simple procedure which transfers single peptide-loaded HLA class I molecules from cultured cells to polystyrene beads using anti-peptide antibodies directed to an intracellular segment of HLA-A alpha chains. The surface density of peptide-loaded HLA class I molecules on beads was comparable to that on the peptide-loaded cells. HLA-A2 beads loaded with an HCV peptide HCV1073 were tested for stimulation activity on an HCV1073-specific CD8+ T cell clone NS3-1. A substantial level of gamma-IFN production was induced. The stimulation was peptide-specific. The efficiency was dependent on the bead concentration and the surface HLA class I density on beads and enhanced significantly by co-coupling of anti-CD28 to peptide-loaded beads. The peptide-loading efficiency on HLA class I molecules and the transfer efficiency of HLA class I molecules to polystyrene beads were reasonably high for HLA-A2 and HLA-B7. Thus, polystyrene beads carrying these single peptide-loaded HLA class I molecules are potentially useful in further analysis of the co-stimulatory or inhibitory factors involved in CD8+ T cell responses and eventually in detection of cytotoxic T cells in PBLs.

Chesler, N. C., et al. (2011). "Acute thromboembolic pulmonary hypertension in a dog model - Correlation of right ventricular ejection fraction and pulmonary arterial distensibility measured by MRI." American Journal of Respiratory and Critical Care Medicine. Conference: American Thoracic Society

International Conference, ATS **183**(1 MeetingAbstracts).

Introduction: The hemodynamic mechanisms of heart failure in pulmonary arterial hypertension (PAH) are not well understood. Non-invasive imaging techniques offer many advantages for diagnosis and prognosis of PAH as well as quantification of cardiopulmonary status changes during disease progression. We hypothesized that large pulmonary artery (PA) stiffening impairs right ventricular (RV) function in PAH, and that magnetic resonance imaging (MRI) could be effectively used to demonstrate this relationship in a dog model of disease. To provide an initial test of our hypothesis, we created an acute model of PAH by embolizing dog lungs with micro-beads. Success was confirmed by high-resolution digital subtraction angiography (DSA). Method(s): Four adult female beagles were induced with propofol and maintained under anesthesia with isoflurane. Baseline pulmonary arterial pressures (PAP) were measured by right heart catheterization (RHC). Baseline DSA and MRI were performed to assess a) the pulmonary vasculature, b) RV function, and c) PA distensibility via the relative area change (RAC) between systole and diastole. PAH was induced by injecting micro-beads (150-500mm) into the right atrium and ventricle. Post-embolization, MRI, DSA and RHC were repeated. RV ejection fraction (RVEF) was quantified from CINE MR images per clinical standard. PA RAC was determined from phase contrast MR images of the PA cross-sectional area at peak systole and end-diastole. Three dogs were humanely euthanized with pentobarbital intravenously after the procedures; one dog died of presumed worsening PH before post-embolization tests could be performed. High quality MR images could not be obtained in one dog at baseline. Result(s): DSA revealed multiple wedge-shaped areas indicative of acute embolism. Mean PAP was higher in the embolized dogs (38.6 +/- 2.5 mmHg vs. 21 +/- 6.5 mmHg, p = 0.01) (Fig. 1); PA RAC and RVEF tended to decrease. A good correlation (R2 = 0.64) was found between RVEF and PA RAC, which supports our hypothesis. (Figure presented) Conclusion(s): and RVEF were not Acute PAH was successfully induced in dogs by micro-bead embolization. While the decreases in RAC Conclusion(s): and RVEF were not significant, both decreased and a positive correlation was found between RVEF and PA RAC, which is in agreement with our previously reported human data. Future work will focus on larger number of animals and expanding this initial work to a chronic model. This approach may provide valuable insights into the mechanisms of RV failure in acute and chronic PAH in patients.

Cheung, A. K., et al. (2015). "Quantitative detection of eryptosis in human erythrocytes using tunable resistive pulse sensing and annexin-V-beads." Analyst **140**(4): 1337-1348.

Toxicological assessments of human red blood cells (RBCs) are important in human health because RBCs are the most abundant cell type in our body. Erythrotoxicology testing guidelines using hemolysis have been established as a standard (e.g. by the ASTM International). However, many xenobiotics promote eryptosis (apoptosis in human RBCs) without causing hemolysis. Based on the major features of eryptosis, i.e. cell shrinkage and translocation of phosphatidylserine (PS) to the outer lipid bilayer of the plasma membrane, we report here a novel approach utilizing the quantitative tunable resistive pulse sensing (TRPS) technology, a widely adopted technique for characterizing nanoparticles in the field of nanotechnology, to measure the degree of eryptosis in a non-optical manner. With the TRPS system, we were able to determine PS externalization with microbeads functionalized with annexin-V for PS binding, cell swelling and shrinkage in physiological buffers (cell volume: 86 +/- 12 fL) and solutions of different osmolarities with or without apoptotic trigger. After setting these standards, we then evaluated the toxicity of Polyphyllin D (PD), a potential anti-cancer drug that kills more liver cancer cells with multi-drug resistance, in erythrocytes to prove our concept. Data revealed that PD induced PS externalization and shrinkage in RBCs in a dose-dependent manner. Moreover, another feature of eryptosis, as small as 5 fL, was detected thus showing the PD-induced erythrotoxicity in human cells. Taken together, our results indicate that our approach using annexin-V-beads and TRPS is simple, safe and convenient, using only a small volume (35 muL) to evaluate the erythrotoxicity of xenobiotics.

Cheung, L. T. O., et al. (2018). "Microplastic Contamination of Wild and Captive Flathead Grey Mullet (Mugil cephalus)." International Journal of Environmental Research and Public Health **15**(4): 597.

A total of 60 flathead grey mullets were examined for microplastic ingestion. Thirty wild mullets were captured from the eastern coast of Hong Kong and 30 captive mullets were obtained from fish farms. Microplastic ingestion was detected in 60% of the wild mullets, with an average of 4.3 plastic items per mullet, while only 16.7% of captive mullets were found to have ingested microplastics, with an average of 0.2 items per mullet. The results suggested that wild mullets have a higher risk of microplastic ingestion than their captive counterparts. The most common plastic items were fibres that were green in colour and small in size (<2 mm). Polypropylene was the most common polymer (42%), followed by polyethylene (25%). In addition, the abundance of microplastics was positively correlated with larger body size among the mullets.

Cheung, P. K. and L. Fok (2016). "Evidence of microbeads from personal care product contaminating the sea." Marine Pollution Bulletin **109**(1): 582-585.

Plastic microbeads in personal care products have been identified as a source of marine pollution. Yet, their existence in the environment is rarely reported. During two surface manta trawls in the coastal waters of Hong Kong, eleven blue, spherical microbeads were captured. Their sizes (in diameters) ranged from 0.332 to 1.015mm. These microbeads possessed similar characteristics in terms of colour, shape and size with those identified and extracted from a facial scrub available in the local market. The FT-IR spectrum of the captured microbeads also matched those from the facial scrub. It was likely that the floating microbeads at the sea surface originated from a facial scrub and they have bypassed or escaped the sewage treatment system in Hong Kong. Timely voluntary or legislative actions are required to prevent more microbeads from entering the aquatic environment.

Cheung, P. K. and L. Fok (2017). "Characterisation of plastic microbeads in facial scrubs and their estimated emissions in Mainland China." Water Research **122**: 53-61.

Plastic microbeads are often added to personal care and cosmetic products (PCCPs) as an abrasive agent in exfoliants. These beads have been reported to contaminate the aquatic environment and are sufficiently small to be readily ingested by aquatic organisms. Plastic microbeads can be directly released into the aquatic environment with domestic sewage if no sewage treatment is provided, and they can also escape from wastewater treatment plants (WWTPs) because of incomplete removal. However, the emissions of microbeads from these two sources have never been estimated for China, and no regulation has been imposed on the use of plastic microbeads in PCCPs. Therefore, in this study, we aimed to estimate the annual microbead emissions in Mainland China from both direct emissions and WWTP emissions. Nine facial scrubs were purchased, and the microbeads in the scrubs were extracted and enumerated. The microbead density in those products ranged from 5219 to 50,391 particles/g, with an average of 20,860 particles/g. Direct emissions arising from the use of facial scrubs were estimated using this average density number, population data, facial scrub usage rate, sewage treatment rate, and a few conservative assumptions. WWTP emissions were calculated by multiplying the annual treated sewage volume and estimated microbead density in treated sewage. We estimated that, on average, 209.7 trillion microbeads (306.9 tonnes) are emitted

into the aquatic environment in Mainland China every year. More than 80% of the emissions originate from incomplete removal in WWTPs, and the remaining 20% are derived from direct emissions. Although the weight of the emitted microbeads only accounts for approximately 0.03% of the plastic waste input into the ocean from China, the number of microbeads emitted far exceeds the previous estimate of plastic debris (>330 mum) on the world's sea surface. Immediate actions are required to prevent plastic microbeads from entering the aquatic environment.

Cheung, P. K., et al. (2018). "Spatio-temporal comparison of neustonic microplastic density in Hong Kong waters under the influence of the Pearl River Estuary." Science of the Total Environment **628-629**: 731-739.

Rivers are recognised as an important source of plastic debris in the open sea. The Pearl River in China is estimated to transport 0.1milliontonnes of plastic waste to the open sea annually. However, no empirical study has been conducted to assess the plastic contamination levels in the Pearl River Estuary. Hong Kong is situated in the east of the Pearl River Estuary; its western waters are strongly influenced by river discharge, whereas the eastern waters are unaffected by the freshwater plume. In this study, we quantified the neustonic plastic debris density in the western and eastern waters of Hong Kong. The mean microplastic (0.355-4.749mm) and large plastic debris (>=4.75mm) densities in the western side were 3.627 and 0.758n/m³, respectively. Seasonal comparisons indicated that both size classes of plastic debris were significantly more abundant by number in the rainy season than the dry season (p<0.001). However, the influence of rivers on plastic density at the sea surface may be highly restricted to the estuarine delta, as no significant spatial difference was found between the western and eastern waters.

Chi, W., et al. (2011). "CD4+ T cells from behcet patients produce high levels of IL-17." Eye Science **26**(2): 65-69.

PURPOSE: To investigate the role of interleukin (IL)-17-producing CD4+ T cells in Behcet disease (BD).

METHODS: Blood samples were drawn from eight BD patients with active uveitis, eight BD patients with inactive uveitis and eight normal controls, respectively. PBMCs were prepared from heparinized blood by Ficoll-Hypaque density-gradient centrifugation. Peripheral CD4+ T cells were purified by Human CD4 Microbeads (MACS). The purity rate of CD4+ T cells was detected using flow cytometry. Purified CD4+ T cells were stimulated with or without anti-CD3 and anti-CD28 antibodies in the presence or absence of recombinant-IL-23 (rIL-23) or recombinant-IL-12 (rIL-12) for 72 hours. The concentrations of IL-17, IFN-gamma and IL-4 in the collected supernatants from CD4+ T cells were measured using a Duoset ELISA Development kit.

RESULTS: The results showed that the levels of IL-17 and IFN-gamma observed in active BD patients were significantly higher as compared with those in inactive patients and normal controls. There was no significant difference concerning IL-4 production between BD patients and normal controls. rIL-23 significantly augmented the production of IL-17 by CD4+ T cells from both BD patients and normal controls. Both rIL-23 and rIL-12 could increase IFN-gamma production by CD4+ T cells from BD patients and normal controls. Moreover, the effect of rIL-12 was more robust compared with that of rIL-23. Neither rIL-23 nor rIL-12 exerted any effect on IL-4 production.

CONCLUSION: rIL-23 can promote the production of IL-17 by CD4+ T cells in BD patients. The upregulated IL-17 levels may be related with the intraocular inflammation of Behcet patients.

Chi, W., et al. (2019). "Research of Cu-Doped Hydroxyapatite Microbeads Fabricated by Pneumatic Extrusion Printing." Materials **12**(11): 31.

Copper is an indispensable micronutrient in human health, which has important effects on the promotion of angiogenesis and thus contributes to bone formation and antimicrobial activity. We used ion exchange and pneumatic printing methods to prepare hydroxyapatite (HA) microspheres with different copper content. The microspheres were characterized by scanning electron microscope (SEM), X-ray diffractometry (XRD) and X-Ray photoelectron spectroscopy (XPS). Considering the resistance of hydroxyapatite to biodegradation in vivo, the degradation rate of microspheres in modified simulated body fluids was studied. In addition, cell proliferation and antibacterial experiments were carried out to study the biological properties of microspheres. HA-1.5MCu microbeads treated by 1.5 mol/L CuSO₄ curing solution have good performance on degradation, antibacterial properties and cell survival rate on day 7. The results showed that HA-1.5MCu microbeads may be used as a good repair material for bone defects.

Chi, Y., et al. (2013). "Cytokine and chemokine levels in patients infected with the novel avian influenza A (H7N9) virus in China." Journal of Infectious Diseases **208**(12): 1962-1967.

H7N9 avian influenza is an emerging viral disease in China caused by avian influenza A (H7N9) virus. We investigated host cytokine and chemokine profiles in serum samples of H7N9 patients by multiplex-microbead immunoassays. Statistical analysis showed that IP-10, IL-6, IL-17, and IL-2 were increased in H7N9 infected patients. Furthermore, IL-6 and the chemokine IP-10 were significantly higher in severe H7N9 patients compared to nonsevere H7N9 cases. We suggest that proinflammatory cytokine responses, characterized by a combined Th1/Th17 cytokine induction, are partially responsible for the disease progression of patients with H7N9 infection.

Chiang, C. T. and L. J. Huang The utilization and preparation of soil conditioner from plastic waste materials. Technical Bulletin, Taiwan Fertilizer Company; 1977. (54):23 pp.

In pot experiments with wheat, an application of PVC charcoal (a soil conditioner obtained by heating PVC at 350 deg C) increased grain yields by 30%. This conditioner (which contains humic substances) was more effective under upland conditions than under lowland (paddy) conditions. An improvement in soil properties was apparent at an application rate as low as 0.05%. Nitrification treatment of the conditioner did not significantly change its effects on the contents of exchangeable nitrogen, available phosphorus, exchangeable potassium in the soil or on the percentage of water stable aggregates.

Chiang, W. L., et al. (2014). "Injectable microbeads with a thermo-responsive shell and a pH-responsive core as a dual-switch-controlled release system." SMALL **10**(20): 4100-4105.

Treating inflammation with a dual-switch-controlled release system: The release of a drug from the developed microbead system occurs only in response to both an increase in local temperature and an acidic environmental pH. This dual-switch-controlled release system has the advantages of distinguishing between inflamed and healthy tissues to improve treatment efficacy.

Chib, A., et al. (2009). "[minus]plastic: influencing pro-environmental attitudes among Singaporean youth." Environmental Education Research **15**(6): 679-696.

Plastics have much to offer as a modern convenience, but lack of responsible plastic waste management habits can lead to potentially harmful environmental effects. Past environmental initiatives revealed a lack of understanding about youth attitudes towards pro-environmental

issues. [minus]plastic, an online public environmental promotional campaign, encouraged Singaporean youth to recognize the importance of, adopt positive attitudes towards and subsequently adopt the practice of responsible plastic management. We propose the Temporal Incentives Model of Social Influence, based on Prochaska and DiClemente's stages of change model, to guide social campaign design. A pre-post quantitative research design showed that the pre-contemplation, contemplation and preparation stages progressed significantly after the campaign. The findings suggest that stimuli incorporating specialized information and small action steps allow migration to successive stages. With the strong presence of internet culture among Singaporean youth, the online medium was found effective in altering the attitudes of the campaign target audience, while exposure to the campaign messages proved useful in encouraging environmental learning among youth. Chidi Onyema, E., et al. (2018). "Feasting on microplastics: ingestion by and effects on marine organisms." Aquatic Biology **27**: 93-106.
Ingestion of microplastics by marine organisms is a common occurrence in marine ecosystems, but the experimental demonstration of the effects of ingested microplastics on marine organisms has only recently become an important subject of research. In this review, the ingestion of microplastics by marine organisms, its attendant potential consequences and specific hypothetical questions for further studies are discussed. The formation of heteroaggregates in the gut of prey organisms may delay microplastic clearance, potentially increasing the chances of microplastic trophic transfer to predators. Also, the survival and energetics of keystone species at lower trophic levels are negatively affected by ingestion of microplastics, thereby raising questions about the transfer of energy and nutrients to organisms at higher trophic levels. Further, since microplastics are able to adsorb and concentrate organic pollutants up to 1 million times more than the pollutant concentration in ambient waters, the ingestion of such small plastic fragments is, a probable route for the entrance and biomagnification of toxic chemicals in the marine food web. However, the equilibrium state between pollutant concentration in marine organisms and that of surrounding waters makes it unclear whether the ingestion of microplastics actually increases the pollutant load of organisms. Finally, microplastic ingestion can cause endocrine disorders in adult fish, which could result in neoplasia via epigenetic programming. Therefore, microplastic pollution may be a contributory cause of increased incidents of neoplasia in marine animals. The amount of microplastics in marine waters will steadily rise, and questions about their impact on marine ecosystems will linger.

Chilvers, R. A., et al. (2010). "Development of a novel protocol for isolation and purification of human granulosa cells." Fertility and Sterility **1)**: S185.
OBJECTIVE: To develop an optimal method to purify human granulosa cells and a method to account for red blood cell (RBC) contamination in samples. DESIGN: Prospective experimental study. MATERIALS AND METHODS: Follicular fluid was collected from 25 patients after oocyte retrieval. A series of experimental granulosa isolation and purifying techniques was performed with adjustments after determination of results from former sample collections. The techniques

include: 1) density gradient (DG) centrifugation with colloidal silica, 2) DG centrifugation with a polymer of sucrose, 3) negative selection of RBCs using primary antibody (Ab) to glycophorin A and secondary Ab connected to spherical, paramagnetic, epoxy beads, 4) positive selection of granulosa cells using primary Ab to mullerian inhibiting substance receptor II (MISRII) and secondary Ab coupled to irregular, superparamagnetic (SPM) beads, 5) positive selection of granulosa cells using primary Ab to MISRII and secondary Ab coupled to biodegradable, SPM microbeads, 6) dilution of follicular fluid samples with buffer before DG centrifugation. In addition, Western blotting was used to analyze samples for relative amounts of hemoglobin A (HgbA) as compared to a standard curve of blood samples. RESULT(S): The procedure that resulted in the largest increase in purity of usable granulosa cells is dilution of the follicular fluid with buffer, then use of DG centrifugation using colloidal silica, then positive selection of granulosa cells using MISRII and secondary Ab coupled to biodegradable, SPM microbeads. Western blotting with staining of samples for HgbA provided visible quantification of RBCs. CONCLUSION(S): A novel protocol has been developed yielding granulosa cell samples that are largely free of nondesirable cells. This technique provides a solution for patient samples that have heavy RBC contamination and uniquely involves a primary Ab against the MISRII. Western blotting with HbgA antibody is an effective means of comparing patient sample purity.

Chimenti, M. S., et al. (2013). "Multiplatform metabolomic study of CD4+ cells after methotrexate and infliximab treatment: Focus on safety and tolerability profiles." Annals of the Rheumatic Diseases. Conference: Annual European Congress of Rheumatology of the European League Against Rheumatism, EULAR **72**(SUPPL. 3).

Background Activated CD4+ cells comprise a large proportion of inflammatory cells involved in the development of rheumatoid arthritis (RA). Inflammatory cytokines, as tumor necrosis factor-a (TNFa), have also been implicated in the establishment and progression of joint destruction. Treatments for RA include synthetical and biological disease modifying anti-rheumatic drugs (DMARDs), as methotrexate (MTX) and TNFa-inhibitors, as infliximab. Cellular effects can be evaluated by metabolomics with measurement of ideally all endogenous metabolites. Objectives Evaluation in CD4+ cells, from a multiplatform metabolomic study, of MTX and infliximab treatment in order to investigate the metabolomic features. Methods Blood samples from 5 healthy controls were collected for metabolomic study. CD4+ cells were isolated by magnetic separation using CD4 MicroBeads from peripheral blood mononuclear cells, divided in 5 different groups and cultured for 24 hours: 1. CD4+ T cells as control, 2. CD4+ T cells treated with MTX at the dosage of 0.01 mM, 3. CD4+ T cells treated with MTX at the dosage of 0.1mM, 4. CD4+ T cells treated with infliximab at the dosage of 1 mug/ml, 5. CD4+ T cells treated with IgG1k at the dosage of 1mug/ml as control of Infliximab. A total of 25 cell samples were analysed using Metabolon's standard extraction method. Results Ribulose was reduced with decrease in glycolysis and inhibition of phosphofructose kinase 1 (PFK1) by MTX ($p<0.05$). This reflects CD4+ cells effort to increase the production of cellular reducing power (NADPH) to offset stress exerted by MTX. Isovalerylcarnitine, linked to proteolytic enzymes and calpain system, was increased by MTX ($p<0.05$). Both calpain and caspase systems lead to cytochrome activation and promote early apoptosis. Hypotaurine, an antioxidants in vivo, was increased by both MTX and Infliximab ($p<0.05$). Glutarate (pentanedioate) was reduced by infliximab($p<0.05$). This agent is linked to oxidized phospholipids and proteins; measurement of protein-bound phosphate and long-chain fatty acids may be useful for assessing long-term lipid peroxidative damage to proteins in vivo. Methylphosphate was increased by MTX and infliximab ($p<0.05$): It reduce transcription of inflammatory genes and decrease RNAs affinity to nuclear phosphoprotein. 7 beta-hydroxycholesterol was reduced by infliximab ($p<0.05$). It is present at

elevated concentrations in inflammatory lesions, strongly cytotoxic and pro-oxidative. Its effect is relevant on cell death and oxidative DNA damage. Conclusions Biochemicals involved in a number of pathways showed some promising and subtle trends and better elucidate the pathogenetic mechanisms of the disease and response to treatments. MTX and Infliximab treatment of CD4+ cells had an impact on inflammation and cellular defence. This is the first demonstration of metabolites that can be monitored for treatment efficacy and tolerability. These observations provide some insights into the potential mechanisms involved in mediating the anti-inflammatory and the immunomodulation effects of MTX and infliximab.

Chindavijak, S., et al. (2018). "Effect of therapeutic vaccine on CTLA4 and tumor debulking response in recurrent and metastatic HNSCC." Journal of Clinical Oncology. Conference **36**(5 Supplement 1).

Background: Head and Neck Squamous Cell Carcinoma (HNSCC) is associated with multiple immune suppression and avoidance mechanisms . Blocking the PD-1 signal axis in second line provides a significant survival advantage compared to chemotherapy. However, checkpoint blockade efficacy is limited to the subset of patients that present with tumors highly infiltrated with effector immune cells. We investigated a novel vaccine designed to increase the infiltration of tumor-specific effector cells and counter-regulate the suppressive tumor microenvironment. Method(s): Pre-treated r/m HNSCC patients with externally visible tumors were accrued. Tumor biopsy samples were processed at baseline to purify endogenous chaperones with calreticulin, hsp70, hsp90 and gr94/gp96 (CRCL) as a source of tumor neoantigen. Exvivo differentiated, allogeneic Th1 memory cells with CD3/CD28-coated microbeads attached (aTh1) expressing CD40L and IFNgamma served as adjuvant. Subjects were primed with 4 weekly aTh1 ID injections to increase allo-specific Th1 memory titer. Primed subjects were provided 3 weekly ID injections of CRCL + aTh1 to increase tumor-specific Th1 memory titer followed by intravenous aTh1 in the 4th week to activate circulating memory cells through CD40-CD40L, causing their extravasation and trafficking to tumor lesions. Allo-rejection response produces a sustained Type 1 cytokine release which dys-regulates suppressor circuits. The ID/IV cycle was then repeated. Result(s): 10 subjects with recurrent or metastatic disease were accrued. All with prior radiochemotherapy. 50% (5/10) had clinical response with visible reduction in tumor burden. Vaccine was well tolerated. Debulking response correlated with increased CD3+ immune cell infiltration and decreased CTLA-4 expression. Conclusion(s): This individualized vaccine caused increased immune cell infiltration in tumors, downregulation of CTLA4 and visible tumor debulking in a heavily pretreated, chemotherapy-refractory population. These results provide rationale for further evaluation of this vaccine in a first-line setting with and without PD1/L1 blockade.

Chisada, S., et al. (2019). "Ingestion of polyethylene microbeads affects the growth and reproduction of medaka, Oryzias latipes." Environmental Pollution **254**(Part B).

Research using various species of wild and cultured fish has identified negative effects of short-term exposure to microbeads. Although wild animals might be contaminated with microbeads and/or other pharmaceuticals, data regarding the long-term effects remain limited. To clearly elucidate the effects of microbeads, studies of long-term exposure using animal models are necessary. Our aim was to elucidate the effects of microbeads alone on the growth and fecundity of medaka following long-term exposure (12 weeks). In experiment 1, fish groups (except controls) were temporarily exposed to polyethylene microbeads (10-63 micro m diameter) a low dose of 0.065 microbeads-mg/L and high dose of 0.65 microbeads-mg/L. In experiment 2, see-through medaka and fluorescent polyethylene microbeads (10-45 micro m diameter) were used to estimate the retention time of ingested microbeads in the digestive

tract, which was 4-9 days. The low dose of microbeads did not affect growth but did decrease the number of eggs and the hatching rate. The high dose decreased growth, the number of eggs, and hatching rate. Growth differences were recognized for the first time at 7 weeks, and differences in the number of eggs at 12 weeks. Thus, long-term tests using medaka indicated that microbeads per se exhibit growth inhibition and reproductive toxicity. These effects could be associated with nutritional factors resulting from the long retention time of microbeads in the digestive tract. We also determined the dose that affects only fecundity. This suggests that normal growth of medaka in the wild does not mean the environment is free from microbead contamination. We are thus attempting to identify new biological indexes for monitoring the status of microbead contamination using our system.

Chitaka, T. Y. and H. von Blottnitz (2019). "Accumulation and characteristics of plastic debris along five beaches in Cape Town." Marine Pollution Bulletin **138**: 451-457.

Beach accumulation surveys can be used as a proxy to estimate litter flows into the marine environment. However, litter loads can be influenced by various factors including catchment area characteristics, weather conditions and ocean water movements. This complexity is evidenced by the results of five beach surveys conducted in Cape Town in 2017. Observed average litter accumulation rates across the beaches ranged from 36 to 2961items.day⁻¹.100m⁻¹. Item mass ranged from 0.01-367g, with items weighing <1g contributing 61-85% of count. Plastic items accounted for 94.5-98.9% of total count and this prevalence appears to have increased relative to older data (1989-1994). The top ten identifiable items accounted for 40-57% of plastic debris. Nine of these were associated with foods commonly consumed on-the-go, including polystyrene packaging, snack packets and straws. A mitigation approach focused on these items may address one third to one half of marine litter sources in Cape Town.

Cho, H. M., et al. (2015). "Microcalcification detectability using a bench-top prototype photon-counting breast CT based on a Si strip detector." Medical Physics **42**(7): 4401-4410.

PURPOSE: To investigate the feasibility of detecting breast microcalcification (muCa) with a dedicated breast computed tomography (CT) system based on energy-resolved photon-counting silicon (Si) strip detectors.

METHODS: The proposed photon-counting breast CT system and a bench-top prototype photon-counting breast CT system were simulated using a simulation package written in matlab to determine the smallest detectable muCa. A 14 cm diameter cylindrical phantom made of breast tissue with 20% glandularity was used to simulate an average-sized breast. Five different size groups of calcium carbonate grains, from 100 to 180 mum in diameter, were simulated inside of the cylindrical phantom. The images were acquired with a mean glandular dose (MGD) in the range of 0.7-8 mGy. A total of 400 images was used to perform a reader study. Another simulation study was performed using a 1.6 cm diameter cylindrical phantom to validate the experimental results from a bench-top prototype breast CT system. In the experimental study, a bench-top prototype CT system was constructed using a tungsten anode x-ray source and a single line 256-pixels Si strip photon-counting detector with a pixel pitch of 100 mum. Calcium carbonate grains, with diameter in the range of 105-215 mum, were embedded in a cylindrical plastic resin phantom to simulate muCas. The physical phantoms were imaged at 65 kVp with an entrance exposure in the range of 0.6-8 mGy. A total of 500 images was used to perform another reader study. The images were displayed in random order to three blinded observers, who were asked to give a 4-point confidence rating on each image regarding the presence of muCa. The muCa detectability for each image was evaluated by using the average area under the receiver operating characteristic curve (AUC) across the readers.

RESULTS: The simulation results using a 14 cm diameter breast phantom showed that the proposed photon-counting breast CT system can achieve high detection accuracy with an average AUC greater than 0.89 +/- 0.07 for muCas larger than 120 mum in diameter at a MGD of 3 mGy. The experimental results using a 1.6 cm diameter breast phantom showed that the prototype system can achieve an average AUC greater than 0.98 +/- 0.01 for muCas larger than 140 mum in diameter using an entrance exposure of 1.2 mGy.

CONCLUSIONS: The proposed photon-counting breast CT system based on a Si strip detector can potentially offer superior image quality to detect muCa with a lower dose level than a standard two-view mammography.

Cho, M., et al. (2014). "Combination of biobarcode assay with on-chip capillary electrophoresis for ultrasensitive and multiplex biological agent detection." Biosensors & Bioelectronics **61**: 172-176.

Early diagnosis of biological agents is of paramount importance to prevent the casualties and fatal disease in human during bioterrorism or biological warfare. In this study, we reported an efficient and sensitive multiplex biological agent detection method based on the DNA biobarcode assay and the micro-capillary electrophoresis (muCE) technology. Monoplex as well as multiplex pathogen identification was performed using five targets including Bacillus anthracis, Francisella tularensis, Yersinia pestis, Vaccinia virus and Botulinum toxin A. Through the DNA biobarcode assay process, the magnetic microparticle-pathogen-polystyrene microbead complexes were formed, and the FAM labeled single stranded barcode DNA could be released from the complexes upon denaturation. Different lengths of a barcode DNA were designed to designate each pathogen, so that the specific peak elution time in the capillary electrophoresis on a chip allows us to distinguish the target with high accuracy within 3 min. We improved the assignment accuracy of the peak in the electropherogram by adding two bracket ladders. Owing to the abundant amount of barcode DNAs, the presence of B. anthracis, F. tularensis, Y. pestis, Vaccinia virus was confirmed with a limit of detection of 50CFU/mL, while Botulinum toxin A was analyzed even at a concentration of 12.5 ag/mL. Multiple pathogen detection was also successfully conducted in a phosphate buffered saline (PBS) as well as a serum medium with background of other pathogens. Thus, our analytical platform based on the biobarcode assay and on-chip CE analysis provides rapid, sensitive, multiplex, and accurate biological agent identification.

Cho, M.-H., et al. (2015). "Air gasification of PVC (polyvinyl chloride)-containing plastic waste in a two-stage gasifier using Ca-based additives and Ni-loaded activated carbon for the production of clean and hydrogen-rich producer gas." Energy **87**: 586-593.

A plastic waste containing polyvinyl chloride was gasified in a two-stage gasifier consisting of a fluidized bed reactor and tar-cracking zone to produce a hydrogen-rich producer gas with low tar and HCl contents. In particular, this study investigated the effects of calcined Ca-based additives, especially oyster shells, and a Ni-loaded activated carbon on the chlorine and tar removal. Additionally, a ~3 h gasification of the plastic waste was performed using a distributor with a large hole size to confirm the gasification stability. In the experiments, where 900 g activated carbon was applied, all the producer gases were free of tar. The maximum H sub(2) content (30 vol.%) in the producer gas was obtained with 900 g of Ni-loaded activated carbon. Chlorine in the feed material was mainly distributed in char and condensate liquid. The HCl contents in the producer gases obtained with the calcined Ca-based additives including oyster shells were under 1 ppm. The ~3 h gasification revealed that the gasification was stable in terms of tar content in producer gas and producer gas composition.

Cho, M.-H., et al. (2014). "Two-stage air gasification of mixed plastic waste: Olivine as the bed material and effects of various additives and a nickel-plated distributor on the tar removal." Energy **70**: 128-134.

Air gasification of mixed plastic waste was conducted in a two-stage gasifier. The effects of the combination of olivine as the fluidized bed material and activated carbon with or without other additives for tar cracking, as well as a Ni-plated distributor, the use of steam as a gasifying agent, and the calcination of olivine on the producer gas compositions and tar production, were also investigated. The maximum Hz concentration (27.3 vol%) was obtained with 900 g of activated carbon in the tar-cracking zone, and through the use of calcined olivine as the bed material. In the experiments, the maximum tar removal efficiency calculated using a base case reached 98.2%. The LHVs of the producer gases were in the range of 6.1-9.0 MJ/Nm super(3). The increase in the activated carbon amount led to an enhanced H sub(2) production, as well as a decrease in tar production. The Ni-plated distributor was found to be effective for tar removal. In the application of dolomite in the tar-cracking zone and the use of steam as a fluidizing medium resulted in a high rate of HCl removal. The minimum HCl concentration in the producer gases was under 1 ppm.

Cho, M.-H., et al. (2013). "Production of low-tar producer gas from air gasification of mixed plastic waste in a two-stage gasifier using olivine combined with activated carbon." Energy **58**: 688-694.

A fraction of mixed plastic waste was gasified using olivine as a bed material and activated carbon as a tar-cracking additive in a two-stage gasifier. The effects of the amount of activated carbon, the use of an activated carbon filter, and the removal of an EP (electrostatic precipitator) from the process on the gas composition and tar amount generated were investigated. The effects of the ER (equivalence ratio), the type of distributor, the use of steam and the use of a wire mesh basket for activated carbon on the coke removal were also examined. As a result, H2 concentrations of around 30 vol% were obtained with 1500 g of activated carbon. The tar removal efficiency was maximized at about 98% with the application of 1500 g of activated carbon and steam. The LHVs (lower heating values) of the producer gases obtained with the two additives at ERs of about 0.31 were in the range of 5.3a6.2 MJ/Nm3.

Cho, M. K. and H. S. Shin (2016). "Mechanotransduction-Induced Lipid Production System with High Robustness and Controllability for Microalgae." Scientific Reports **6**: 32860.

Microalgae lipids are a promising energy source, but current biochemical methods of lipid-inductions such as nitrogen deprivation have low process robustness and controllability. Recently, use of mechanotransduction based membrane distortion by applying compression stress in a 2D-microsystem was suggested as a way to overcome these limitations of biochemical induction. However, reproduction in large numbers of cells without cell death has been difficult to overcome because compression for direct membrane distortion reduces culture volume and leads to cell death due to nutrient deprivation. In this study, a mechanotransduction-induced lipid production (MDLP) system that redirects elastic microbeads to induce membrane distortion of microalgae with alleviating cell death was developed. This system resulted in accumulation of lipid in as little as 4 hr. Once compressed, porous microbeads absorb media and swell simultaneously while homogeneously inducing compression stress of microalgae. The absorbed media within beads could be supplied to adjacent cells and could minimize cell death from nutrient deficiency. All mechanotransduction was confirmed by measuring upregulation of calcium influx and Mat3 genes. The microbeads ensured robustness and controllability in repeated compression/de-compression processes. Overall, the MDLP system has potential for use as a fundamental biodiesel process that requires robustness and controllability.

Cho, S., et al. (2004). "Microbead-based affinity chromatography chip using RNA aptamer modified with photocleavable linker." Electrophoresis **25**(21-22): 3730-3739.

A microbead-based affinity chromatography chip (micro-BACC) controlling hundreds of nanoliters of reaction volume was developed to separate and analyze hepatitis C virus (HCV) RNA polymerase protein by immobilization of an RNA aptamer on beads. A photocleavable linker was conjugated in between the beads and the aptamer to elute the bound RNA polymerase from the RNA aptamer in one step by UV irradiation, resulting in an efficient method to elute and identify the target molecule bound on RNA using a mass spectrometer. This linker showed a cleavage activity over 70% upon UV irradiation at 1050 mW/cm2 for more than 5 min. The photoelution method could prevent the target molecule from contaminations in affinity chromatography caused by elution solutions of high salt concentration, extreme pH and detergent, respectively. In this chip, sample reagents up to 800 nL could be metered quantitatively into the bead chamber using a nanoliter dispenser working, based on surface-guided flow control and pneumatic control by external air pressure on the chip. RNA polymerase eluted after UV irradiation was successfully analyzed by trypsin treatment without additional purification. As a result, using the aptamer, we could detect RNA polymerase from 800 nL hepatitis C patient serum containing 96 fmol HCV RNA polymerase. The detection limit of this system was estimated to be 9.6 fmol HCV RNA polymerase.

Cho, Y., et al. (2019). "Abundance and characteristics of microplastics in market bivalves from South Korea." Environmental Pollution **245**: 1107-1116.

Microplastic contamination in marine organisms is a growing environmental issue with implications for seafood safety. Among marine organisms, shellfish are considered to be an important route of human exposure to microplastics because they filter a large volume of seawater while feeding and, thus, accumulate microplastics from seawater; furthermore, they are consumed whole, without gut removal. In this study, a market survey was carried out to understand microplastic contamination in domestic bivalves sold in fishery markets in three major cities of South Korea. Four popular bivalve species, oyster (Crassostrea gigas), mussel (Mytilus edulis), Manila clam (Tapes philippinarum) and scallop (Patinopecten yessoensis), were selected as monitoring species, which together account for 79-84% of total shellfish consumption in Korea. The mean concentration of microplastics in these four species was 0.15+/-0.20 n/g and 0.97+/-0.74 n/individual. Fragments and particles smaller than 300mum were dominant shape and size, accounting for 76% and 65% of total microplastics, respectively. Polyethylene (PE), polypropylene (PP), polystyrene (PS), and polyester were the major polymer types. Interestingly, differing polymer compositions were observed according to the culture methods and habitat characteristics of each species. PS was found in high proportions in oysters and mussels cultured in the upper layer of the water column, while the proportions decreased and those of polyester increased in Manila clams and scallops that were cultured in intertidal sediments or the middle and bottom layers of the water column. The annual dietary intake of microplastics by the Korean population via shellfish consumption was estimated as 212 n/person.year. Our results suggested that microplastic pollution is widespread in commercial bivalves and we recommend a systematic and integrative market-basket survey to clarify the current status of human exposure to microplastics.

Choi, D., et al. (2014). "A prototype of time temperature integrator (TTI) with microbeads-entrapped microorganisms maintained at a constant concentration." Journal of Food Engineering **120**: 118-123.

The existing microbial TTIs based on lactic acid production have some weakness that their

kinetics includes both the microbial growth and the lactic acid production. Such weakness was improved by applying SPG (Shirasu porous glass) membrane emulsification to produce microbeads entrapping microorganisms, resulting in maintaining constant microbial levels throughout the use periods and considering only lactic acid production in kinetics. The TTIs containing the microbeads with the initial concentration of 10.7 log CFU/g of Weissella cibaria CIFP 009 maintained the microbial level constant during the use, while the TTIs with less initial levels (6.2 and 9.3 log CFU/g) showed a slight increase. A wide range of TTI response (pH) rates in zero-order reaction were obtained by varying the amounts of the microbeads in TTI formulations. In addition, the lag phase common to microbial growth was not manifested in the pH change, which facilitates an immediate TTI response after activation. In conclusion, the application of the microbeads to microbial TTI could provide the wide response rates in zero-order and the absence of lag phase favorable to an ideal microbial TTI.

Choi, E. S., et al. (2015). "Haploidentical hematopoietic stem cell transplantation in pediatric patients: Comparison of depletion efficacy and engraftment according to in vitro T cell depletion method." Bone Marrow Transplantation **1)**: S327.

Introduction: We compared the efficacy of CD3 depletion with TCRalphabeta depletion in haploidentical stem cell transplantation (HHCT) for children and adolescents with malignant or non-malignant diseases. Materials (or patients) and methods: Sixty-seven HHCTs were performed in 57 patients (SAA 19, MDS 7, AML 17, ALL 7, NBL 1, NHL 2, CDA 1, Rhabdomyosarcoma 1, Ewing's sarcoma 1, WAS 1) using CD3-depleted (HHCT-CD3, n=38) or TCRalphabeta-depleted (HHCT-TCRalphabeta, n=29) grafts from haploidentical family donors between 2008 and 2014 at AMCCH. A total of 67 graft manipulations were done with anti-CD3 (n=38) or anti-TCRalphabeta (n=29) microbeads (CliniMACS, MiltenyiBiotec). Donors included mother (n=36), sibling (n=18) and father (n=13). We sought toobtain at least 4x10⁶ CD34⁺ cells/kg of recipient. MMF and cyclosporine or FK506 were used for GVHD prophylaxis. Result(s): As for 67 graft manipulations, mean recovery of CD34⁺ stem cells after CD3 depletion and TCRalphabeta depletion were 82.4% and 89.8% (P=0.04), respectively. Mean depletion efficacy of CD3⁺ Tcells after CD3 depletion was 3.1 log and that of alphabeta⁺ Tcells after TCRalphabeta depletion was 3.6 log (P=0.01). Of a total of 67 HHCTs, 3 (4.5%) experienced primary graft failure(GF) and additional 6 (8.9%) experienced graft rejection(GR) after HHCT-CD3. All 9 GF/GR were rescued with a second HHCT. There were neither GF nor GR in HHCT-TCRalphabeta. The median day of neutrophil engraftment was 10 days (range, 9-15) post-transplant which was not different according to depletion methods (P>0.05). However, platelet engraftment was faster in HHCT-TCRalphabeta compared to HHCTCD3 (median 16 days; 17 days for HHCT-TCRalphabeta vs 31 days for HHCT-CD3, P=0.03). Conclusion(s): TCRalphabeta depletion is a highly effective method to deplete T cells along with enrichment of CD34⁺ stem cells. Given the high engraftment rate, HHCT using TCRalphabeta depletion is a promising approach in children and adolescents who lack a suitable donor.

Choi, J. S., et al. (2019). "Evaluation of microplastic toxicity in accordance with different sizes and exposure times in the marine copepod Tigriopus japonicus." Marine Environmental Research: 104838.

The indiscriminate use of plastic has greatly increased microplastic contamination risk in the marine environment. Microplastics can affect all marine life via the food web, from primary producers (e.g., microalgae) to final consumers (e.g., carnivorous fish). Thus, several studies have attempted to evaluate microplastic toxicity, but information about the underlying mechanisms of their effect is limited. Therefore, in this study, we examined multiple factors that

could contribute to microplastic-induced toxicity. We investigated the potential molecular effects of microplastic size and exposure time. We exposed the marine copepod Tigriopus japonicus to 50nm and 10mum polystyrene microbeads. We found that both size and exposure time increased intracellular levels of reactive oxygen species. In addition, antioxidant-related gene expression was modulated and antioxidant enzyme activities were changed significantly. The results of this study provide important insights into the molecular mechanisms of microplastic-induced toxicity in a marine organism.

Choi, J. S., et al. (2018). "Toxicological effects of irregularly shaped and spherical microplastics in a marine teleost, the sheepshead minnow (Cyprinodon variegatus)." Marine Pollution Bulletin **129**: 231.
The increasing global contamination of plastics in marine environments is raising public concerns about the potential hazards of microplastics to environmental and human health. Microplastics formed by the breakdown of larger plastics are typically irregular in shape. The objective of this study was to compare the effects of spherical or irregular shapes of microplastics on changes in organ distribution, swimming behaviors, gene expression, and enzyme activities in sheepshead minnow (Cyprinodon variegatus). Both types of microplastics accumulated in the digestive system, causing intestinal distention. However, when compared to spherical microplastics, irregular microplastics decreased swimming behavior (i.e., total distance travelled and maximum velocity) of sheepshead minnow. Both microplastics generated cellular reactive oxygen species (ROS), while ROS-related molecular changes (i.e., transcriptional and enzymatic characteristics) differed. This study provides toxicological insights into the impacts of environmentally relevant (fragmented) microplastics on fish and improves our understanding of the environmental effects of microplastics in the ecosystem.

Choi, S., et al. (2017). "Inhibition by miR-410 facilitates direct retinal pigment epithelium differentiation of umbilical cord blood-derived mesenchymal stem cells." Journal of Veterinary Science **18**(1): 59-65.
Retinal pigment epithelium (RPE) is a major component of the eye. This highly specialized cell type facilitates maintenance of the visual system. Because RPE loss induces an irreversible visual impairment, RPE generation techniques have recently been investigated as a potential therapeutic approach to RPE degeneration. A microRNA-based technique is a new strategy for producing RPE cells from adult stem cell sources. Previously, we identified that antisense microRNA-410 (anti-miR-410) induces RPE differentiation from amniotic epithelial stem cells. In this study, we investigated RPE differentiation from umbilical cord blood-derived mesenchymal stem cells (UCB-MSCs) via anti-miR-410 treatment. We identified miR-410 as a RPE-relevant microRNA in UCB-MSCs from among 21 putative human RPE-depleted microRNAs. Inhibition of miR-410 induces overexpression of immature and mature RPE-specific factors, including MITF, LRAT, RPE65, Bestrophin, and EMMPRIN. The RPE-induced cells were able to phagocytize microbeads. Results of our microRNA-based strategy demonstrated proof-of-principle for RPE differentiation in UCB-MSCs by using anti-miR-410 treatment without the use of additional factors or exogenous transduction.

Choi, S. W., et al. (2015). "miR-410 Inhibition Induces RPE Differentiation of Amniotic Epithelial Stem Cells via Overexpression of OTX2 and RPE65." Stem Cell Reviews & Reports **11**(3): 376-386.
The retinal pigment epithelium (RPE) is a highly specialized cell type located between the choroid and neural retina of the eye. RPE degeneration causes irreversible visual impairment, extending to blindness. Cell therapy has recently emerged as a potential therapeutic approach for retinal degeneration. MicroRNA-based differentiation of stem cells is a new strategy for producing tissue-specific cell types. In this study, we developed a novel microRNA-based

strategy for RPE induction from human amniotic epithelial stem cells (AESCs). We identified microRNAs involved in RPE development in AESCs. Of 29 putative human RPE-relevant microRNAs, microRNA-410 (miR-410) was predicted to target multiple RPE development-relevant genes. Inhibition of miR-410 induces overexpression of immature and mature RPE-specific factors, including OTX2, RPE65, Bestrophin and EMMPRIN. These RPE-like cells were morphologically altered toward a cobblestone-like shape and were able to phagocytize microbeads. We showed that miR-410 directly regulates predicted target genes OTX2 and RPE65. Our microRNA-based strategy demonstrated RPE differentiation in AESCs by treatment of an antisense microRNA-410 (anti-miR-410), without the use of additional factors or exogenous transduction. These findings suggest that miR-410 inhibition can be a useful tool for directed cell differentiation and an attractive method for cell therapy in human retinal degenerative diseases.

Chon, J. W. and M. Gu (2004). "Scanning total internal reflection fluorescence microscopy under one-photon and two-photon excitation: image formation." Applied Optics **43**(5): 1063-1071.

We propose a new type of total internal reflection fluorescence microscopy (TIRFM) called scanning TIRFM (STIRFM) that uses a focused ring-beam illumination and a high-numerical-aperture objective (NA = 1.65). The evanescent field produced by the STIRFM is focused laterally, producing a small excitation volume that can induce a nonlinear effect such as two-photon absorption. Experimental images of CdSe quantum dot nanocrystals and Rhodamine 6G-doped microbeads show that good lateral and axial resolutions are achieved with the current setup. The theoretical simulation of the focal spot produced in STIRFM geometry shows that the focused evanescent field is split into two peaks because of the depolarization effect of a high numerical-aperture objective lens. However, the point-spread function analysis of both one-photon and two-photon excitation cases shows that the detection of the focus-splitting effect is dependent on the detection pinhole size. The effect of pinhole size on image formation is theoretically investigated and confirmed experimentally with the nanocrystal images.

Chong, J., et al. (2019). "Two-stage cultivation of the marine microalga Chlorella salina for starch and carbohydrate production." Aquaculture International **27**(5): 1269-1288.

Growing concern and awareness towards environmental issues, such as plastic pollution, have encouraged scientific focus on microalgae as a potential feedstock for thermoplastic starch production. Given their unique ability to utilize wastewater nutrients, microalgae are suitable to be used in wastewater treatment. In first-stage cultivation, Chlorella salina was grown in a Conway medium at 30 degrees C and exposed to red light under a photoperiod of 24:0 h light-dark cycle to maximize biomass production. The microalgal biomass harvested from the first stage was used as the inoculum for second-stage cultivation. The effects of photoperiod, CO₂ concentration, and nutrient limitation were investigated. Cultivation using wastewater was compared with the synthetic medium for starch and carbohydrate accumulation. C. salina cultivated under 12:12 h light-dark cycle significantly accumulated the highest starch and carbohydrate with respective concentrations of 16.769 and 70.850 mg L⁻¹. Under 5% (v/v) CO₂, C. salina significantly accumulated starch and carbohydrate with respective concentrations of 13.699 and 58.910 mg L⁻¹. The combination of nitrogen and sulfur limitation significantly triggered the highest starch (30.505 mg L⁻¹) and carbohydrate (145.994 mg L⁻¹) accumulation. Under optimized 5% v/v CO₂ supply, the concentrations of starch and carbohydrate accumulated by C. salina using wastewater were 24.971 and 110.756 mg L⁻¹, respectively, which were approximately twice higher compared with the synthetic medium. The

usage of wastewater aerated with 5% v/v CO₂ would be a more sustainable and economical strategy for high starch and carbohydrate accumulation in C. salina compared with the combination of nitrogen with sulfur limitation.

Chong, S., et al. (2017). "Physical Characterization and Pre-assessment of Recycled High-Density Polyethylene as 3D Printing Material." Journal of Polymers & the Environment **25**(2): 136-145.

3D printing has received lots of attention due to its limitless potential and advantages in comparison to traditional manufacturing processes. This study focuses on the most popular type of home 3D printers, namely fused filament fabrication (FFF) printers, which use plastic filaments as the feedstock. The rather high material cost and large amount of plastic waste generated by FFF 3D printers have driven the need for plastic filaments produced from recycled plastic waste. This study evaluates, in terms of physical characterization, the feasibility of using recycled high-density polyethylene (HDPE), one of the most commonly used plastics, as the feedstock for 3D printers, in comparison with the common acrylonitrile butadiene styrene plastic pellets. In-house extrusion using recycled HDPE pellets and flakes is possible. The diameter consistency and extrusion rate results, along with other physical characterization results, including differential scanning calorimetry, thermogravimetric analysis, Fourier transform infrared spectroscopy, Raman spectroscopy, and water absorption, suggest that making filaments from recycled HDPE pellets is a viable option, as the obtained filament has favorable water rejection and comparable extrusion rate and thermal stability. Existing methods for overcoming the warping and adhesion problems in 3D printing with HDPE were also reviewed. In order to increase the market competitiveness of waste-derived filaments, optimization of the extrusion process, studies on the mechanical and aging properties, and development of a standard characterization methodology and database are crucial. [ABSTRACT FROM AUTHOR]

Chou, J., et al. (2012). "Modeling Analyte Transport and Capture in Porous Bead Sensors." Analytical Chemistry **84**(5): 2569.

Porous agarose microbeads, with high surface to volume ratios and high binding densities, are attracting attention as highly sensitive, affordable sensor elements for a variety of high performance bioassays. While such polymer microspheres have been extensively studied and reported on previously and are now moving into real-world clinical practice, very little work has been completed to date to model the convection, diffusion, and binding kinetics of soluble reagents captured within such fibrous networks. Here, we report the development of a three-dimensional computational model and provide the initial evidence for its agreement with experimental outcomes derived from the capture and detection of representative protein and genetic biomolecules in 290 µm porous beads. We compare this model to antibody-mediated capture of C-reactive protein and bovine serum albumin, along with hybridization of oligonucleotide sequences to DNA probes. These results suggest that, due to the porous interior of the agarose bead, internal analyte transport is both diffusion and convection based, and regardless of the nature of analyte, the bead interiors reveal an interesting trickle of convection-driven internal flow. On the basis of this model, the internal to external flow rate

ratio is found to be in the range of 1:170 to 1:3100 for beads with agarose concentration ranging from 0.5% to 8% for the sensor ensembles here studied. Further, both model and experimental evidence suggest that binding kinetics strongly affect analyte distribution of captured reagents within the beads. These findings reveal that high association constants create a steep moving boundary in which unbound analytes are held back at the periphery of the bead sensor. Low association constants create a more shallow moving boundary in which unbound analytes diffuse further into the bead before binding. These models agree with experimental evidence and thus serve as a new tool set for the study of bioagent transport processes within a new class of medical microdevices. [PUBLICATION ABSTRACT]

Choudhary, S., et al. (2018). "Hypoxic Three-Dimensional Cellular Network Construction Replicates Ex Vivo the Phenotype of Primary Human Osteocytes." Tissue engineering. Part A. **24**(5-6): 458-468.

Osteocytes are deeply embedded in the mineralized matrix of bone and are nonproliferative, making them a challenge to isolate and maintain using traditional in vitro culture methods without sacrificing their inimitable phenotype. We studied the synergistic effects of two microenvironmental factors that are vital in retaining, ex vivo, the phenotype of primary human osteocytes: hypoxia and three-dimensional (3D) cellular network. To recapitulate the lacunocanalicular structure of bone tissue, we assembled and cultured primary human osteocytic cells with biphasic calcium phosphate microbeads in a microfluidic perfusion culture device. The 3D cellular network was constructed by the following: (1) the inhibited proliferation of cells entrapped by microbeads, biomimetically resembling lacunae, and (2) the connection of neighboring cells by dendrites through the mineralized, canaliculi-like interstitial spaces between the microbeads. We found that hypoxia synergistically and remarkably upregulated the mature osteocytic gene expressions of the 3D-networked cells, SOST (encoding sclerostin) and FGF23 (encoding fibroblast growth factor 23), by several orders of magnitude in comparison to those observed from two-dimensional and normoxic culture controls. Intriguingly, hypoxia facilitated the self-assembly of a nonproliferating, osteoblastic monolayer on the surface of the 3D-networked cells, replicating the osteoblastic endosteal cell layer found at the interface between native bone and bone marrow tissues. Our ability to replicate, with hypoxia, the strong expressions of these mature osteocytic markers, SOST and FGF23, is important since these (1) could not be significantly produced in vitro and (2) are new important targets for treating bone diseases. Our findings are therefore expected to facilitate ex vivo studies of human bone diseases using primary human bone cells and enable high-throughput evaluation of potential bone-targeting therapies with clinical relevance.

Choudhury, P. K., et al. (2010). "Design, development and evaluation of frusemide loaded micropellets prepared by ionotropic gelation method." International Journal of PharmTech Research **2**(1): 420-426.

Frusemide is a representative of loop diuretics, which is commonly indicated for acute or chronic renal failure. In low dose it is also used for the treatment of chronic hypertension. It has got pH independent solubility behavior. The half life of Frusemide is 1.5 hr and it is predominantly metabolized in kidney. The micro beads were prepared by the ionotropic gelation of sodium alginate in calcium chloride solution, which were further made sustained by using different acrylic polymers namely Eudragit NE30D, Eudragit S100. The prepared micro beads were evaluated mainly for the sustain release of the drug and the effect of these polymers on the release profile of the drug has been reported in this study. Different formulations were prepared using Eudragit NE30D (F1, F2); and Eudragit S100 (F3, F4) at concentration 2%, 4%w/w. The final formulations were subjected to several characterization studies like, general appearance, particle size determination, rheological studies, Scanning

Electron Microscopy, moisture content, loose surface crystals study, drug content and % drug encapsulation efficiency and in vitro drug release study. The method had resulted in good encapsulation efficiency and micron sized alginate spheres. The drug release was found to be sustained as only 72 % to 90 % of the cumulative drug release were observed in all formulations after 9 hours, which found to follow the Higuchi's diffusion model. Among all formulations, the formulation F2 with Eudragit NE30D 4%w/w showed high encapsulation efficiencies and maximum prolongation of drug release.

Chow, C.-f., et al. (2016). "Research and development of a new waste collection bin to facilitate education in plastic recycling." Applied Environmental Education and Communication **15**(1): 45-57.

Plastic recycling has been an alternative method for solid waste management apart from landfill and incineration. However, recycling quality is affected when all plastics are discarded into a single recycling bin that increases cross contaminations and operation cost to the recycling industry. Following the engineering design process, a new eight-compartment plastic waste collection bin is designed to facilitate plastic recycling and sorting at source, which also provides insight to educators about problem solving on environmental issues. The volumes of plastic wastes collected match the design dimensions well. Further education about plastic recycling is required to improve the recycling quality.

Christiansen, K. (2014). Mind the gap: lost opportunities. **203:** 16-18.

An interview with Kim Christiansen, the northern region director of the trade association PlasticsEurope is presented, in which he discusses the findings of a study of post-consumption plastic waste management across the continent. Christiansen reveals that the rates of plastic recycling and energy recovery have grown considerably from 2006 to 2012, yet the European plastics industry must do more to achieve its goal of reducing the amount of plastic waste going into landfill to zero by 2020.

Chu, J. H., et al. (2012). "Dynamic network connectivity mapping of T-cell activation in Caucasians and African Americans identifies a common set of asthma-associated hub genes." American Journal of Respiratory and Critical Care Medicine. Conference: American Thoracic Society International Conference, ATS **185**(MeetingAbstracts).

Background: CD4+ T-cell activation represents a sentinel event in the expression of allergic and asthmatic responses. Though individual molecular components of this process have been characterized, more holistic, system-wide descriptions using transcriptome network mapping in large populations has not been performed. Objective(s): We set out to characterize and compare the gene networks in resting and stimulated human CD4+ peripheral blood lymphocytes, and define those focal modules most radically altered upon activation. Method(s): A subset of subjects participating in the Asthma BRIDGE initiative from six clinical centers provided whole blood samples, from which PBMCs were isolated and plated in split samples. 25ul of PHA (@5ug/ml) was added to 50% of wells (stimulated samples). At 24 hours, cells were harvested and CD4+ cells were isolated using CD4 Microbeads (Miltenyi); RNA was isolated using the QIAGEN AllPrep DNA/RNA extraction protocol. Expression profiling was performed using the Illumina Human HT12 array. Following data QC and preprocessing procedures, we used differential connectivity mapping procedures (Chu et al. BMC Systems Biology 2011) and compared the transcriptome networks of the stimulated and unstimulated samples to define regulatory modules that undergo restructuring during T-cell activation. Result(s): Expression data from 98 non-Hispanic whites and 157 African Americans were available for analysis. We noted widespread differences in the topographical landscape of the CD4+ lymphocyte

transcriptome following stimulation, identifying 216 gene hubs that each demonstrated differential connectivity to no fewer than 50 genes. In comparisons across ethnic groups, the correlation of observed differential connectivity was high (0.68). 86 genes were identified in both the white and African American samples, representing a reproducible set of regulatory modules with altered topography (i.e. altered gene-gene co-expression patterns) upon T-cell activation. These 86 genes are enriched for genes involved in antigen processing and presentation (p=3.0E-04) and those with genetic variants associated with immune-related diseases. As proof of concept that detection of these hubs can define potential disease-susceptibility targets, we found that among the most differentially connected genes were UTS2, GSTM1, HLA-C, ARG1 and HLA-DRB1, all of which have been implicated in the genetics of asthma. Conclusion(s): We have described the network topography underlying T-cell activation, and have identified a reproducible set of 86 gene hubs with substantially altered connectivity upon stimulation. As many of the genes on this list are known asthma genes, the remainder should be prioritized for further evaluation as therapeutic targets in the treatment of allergic and autoimmune disease.

Chu, S., et al. (2015). "Perfluoroalkyl sulfonates and carboxylic acids in liver, muscle and adipose tissues of black-footed albatross (Phoebastria nigripes) from Midway Island, North Pacific Ocean." Chemosphere **138**: 60-66.

The Great Pacific Garbage Patch (GPGP) is a gyre of marine plastic debris in the North Pacific Ocean, and nearby is Midway Atoll which is a focal point for ecological damage. This study investigated 13 C 4 –C 16 perfluorinated carboxylic acids (PFCAs), four (C 4 , C 6 , C 8 and C 10) perfluorinated sulfonates and perfluoro-4-ethylcyclohexane sulfonate [collectively perfluoroalkyl acids (PFAAs)] in black-footed albatross tissues (collected in 2011) from Midway Atoll. Of the 18 PFCAs and PFSAs monitored, most were detectable in the liver, muscle and adipose tissues. The concentrations of PFCAs and PFSAs were higher than those in most seabirds from the arctic environment, but lower than those in most of fish-eating water birds collected in the U.S. mainland. The concentrations of the PFAAs in the albatross livers were 7-fold higher than those in Laysan albatross liver samples from the same location reported in 1994. The concentration ranges of PFOS were 22.91–70.48, 3.01–6.59 and 0.53–8.35 ng g −1 wet weight (ww), respectively, in the liver, muscle and adipose. In the liver samples PFOS was dominant, followed by longer chain PFUdA (8.04–18.70 ng g −1 ww), PFTrDA, and then PFNA, PFDA and PFDoA. Short chain PFBA, PFPeA, PFBS and PFODA were below limit of quantification. C 8 –C 13 PFCAs showed much higher composition compared to those found in other wildlife where PFOS typically predominated. The concentrations of PFUdA in all 8 individual albatross muscle samples were even higher than those of PFOS. This phenomenon may be attributable to GPGP as a pollution source as well as PFAA physicochemical properties. [ABSTRACT FROM AUTHOR]

Chua, E. M., et al. (2014). "Assimilation of Polybrominated Diphenyl Ethers from Microplastics by the Marine Amphipod, Allorchestes Compressa." Environmental Science & Technology **48**(14): 8127-8134.

Microplastic particles (MPPs; <5 mm) are found in skin cleansing soaps and are released into the environment via the sewage system. MPPs in the environment can sorb persistent organic

pollutants (POPs) that can potentially be assimilated by organisms mistaking MPPs for food. Amphipods (Allorchestes compressa) exposed to MPPs isolated from a commercial facial cleansing soap ingested ⩽45 particles per animal and evacuated them within 36 h. Amphipods were exposed to polybrominated diphenyl ether (PBDEs) congeners (BDE-28, -47, -99, -100, -153, -154, and -183) in the presence or absence of MPPs. This study has demonstrated that PBDEs derived from MPPs can be assimilated into the tissue of a marine amphipod. MPPs reduced PBDE uptake compared to controls, but they caused greater proportional uptake of higher-brominated congeners such as BDE-154 and -153 compared to BDE-28 and -47. While MPPs in the environment may lower PBDE uptake compared to unabsorbed free chemicals, our study has demonstrated they can transfer PBDEs into a marine organism. Therefore, MPPs pose a risk of contaminating aquatic food chains with the potential for increasing public exposure through dietary sources. This study has demonstrated that MPPs can act as a vector for the assimilation of POPs into marine organisms. [ABSTRACT FROM AUTHOR]

Chui, C. Y., et al. (2019). "Atomic force microscopy-indentation demonstrates that alginate beads are mechanically stable under cell culture conditions." Journal of the Mechanical Behavior of Biomedical Materials **93**: 61-69.

Alginate microbeads are extensively used in tissue engineering as microcarriers and cell encapsulation vessels. In this study, we used atomic force microscopy (AFM) based indentation using 20micro m colloidal probes to assess the local reduced elastic modulus (E*) using a novel method to detect the contact point based on the principle of virtual work, to measure microbead mechanical stability under cell culture conditions for 2 weeks. The bead diameter and swelling were assessed in parallel. Alginate beads swelled up to 150% of their original diameter following addition of cell culture media. The diameter eventually stabilized from day 2 onwards. This behaviour was mirrored in E*where a significant decrease was observed at the start of the culture period before stabilization was observed at ~ 2.1kPa. Furthermore, the mechanical properties of freeze dried alginate beads after re-swelling them in culture media were measured. These beads displayed vastly different structural and mechanical properties compared those that did not go through the freeze drying process, with around 125% swelling and a significantly higher E*at values over 3kPa.

Chui, C. Y., et al. (2018). "Direct electrospinning of poly(vinyl butyral) onto human dermal fibroblasts using a portable device." Biotechnology Letters **40**(4): 737-744.

OBJECTIVE: To demonstrate that uniform poly(vinyl butyral) (PVB) fibres can be safely electrospun onto a monolayer of human dermal fibroblasts using a portable device.

RESULTS: PVB in solvent mixtures containing various amounts of ethanol and water was electrospun. Six percent (weight-to-volume ratio) PVB in a 9:1 ethanol:water ratio was the solution with the highest content in water that could be electrospun into consistent fibres with an average diameter of 0.9 mum (+/- 0.1 mum). Four and five percent PVB solutions created beaded fibres. A 8:2 ethanol:water solution lead to microbead formation while a 7:3 ethanol:water mix failed to fully dissolve. The selected solution was successfully electrospun onto a monolayer of human dermal fibroblasts and the process had no significant effect ($p < 0.05$) on cell viability compared

to the control without fibres.
CONCLUSIONS: PVB-ethanol-water solutions could be electrospun without damaging the exposed cell layer. However, further work is required to demonstrate the long-term effect of PVB as a wound healing material.

Chung, S., et al. (2015). "The microfluidic chip module for the detection of murine norovirus in oysters using charge switchable micro-bead beating." Biosensors & Bioelectronics **67**: 625-633.

Sample preparation has recently been an issue in the detection of food poisoning pathogens, particularly viruses such as norovirus (NoV), in food because of the complexity of foods and raw fresh materials. Here, we demonstrate a total analytical microfluidic chip module to automatically perform a series of essential processes (cell concentration, lysis (RNA extraction), nucleic acid amplification, and detection) for the fast but sensitive detection of norovirus in oysters. The murine NoV spiked oyster was stomached using a standard method. The supernatant was first loaded into a shape switchable sample preparation chamber consisting of charge switchable micro-beads. Murine NoV, which was adsorbed on microbeads by electrostatic physisorption, was lysed using bead beating. The extracted RNA was transferred to the detection chamber to be amplified using Nucleic Acid Sequence Based Amplification (NASBA). The optimal surface functionality, size, and number of microbeads were achieved for the virus concentration and the stable RNA extraction in the shape-switchable micro-channel. As a result, murine NoV in a single oyster was successfully detected within 4 h by the microfluidic chip developed here, and could be directly applied to the large volume environmental sample as well as the food sample.

Chung, S., et al. (2018). "Nicotine activates epithelial trpa1 receptors to cause mucociliary dysfunction." American Journal of Respiratory and Critical Care Medicine. Conference: American Thoracic Society International Conference, ATS **197**(MeetingAbstracts).

RATIONALE: Widespread e-cigarette use, touted as a 'safer' form of nicotine delivery, is confounded by high-dose nicotine deposition onto the airway epithelium. Historically, nicotine was studied for its properties on excitable systems (e.g., central nervous system), where nicotineinduced calcium (Ca2+) signaling is highly variable due to differential expression of nicotinic receptors. TRPA1, a Ca2+-selective ionophore receptor, was also reported to be nicotinesensitive in chemosensory neurons. Here, we investigated whether TRPA1 is expressed and functional in the less excitable ciliated airway epithelia and whether TRPA1 contributes to effects of nicotine on mucociliary function. METHOD(S): Primary normal human bronchial epithelial (NHBE) cells, isolated from appropriately consented donors whose lungs were found unsuitable for transplantation, were expanded and then re-differentiated at the air-liquid interface (ALI) on collagen-coated Transwell inserts. For Ca2+ measurements, GCaMP6s was transduced into NHBE cells. GCaMP6s emissions (Ex 495 nm) were recorded using MetaFluor software. Aerosolized treatments for assessing mucociliary parameters were deposited via a mesh nebulizer. Airway surface liquid (ASL) volume was measured by meniscus scanning. Ciliary beat frequency (CBF) was recorded and analyzed by SAVA software. Mucociliary transport (MCT) was assessed by recording movement of fluorescent micro-beads. RESULT(S): TRPA1 mRNA and protein were consistently expressed in low but detectable quantities in ALI-differentiated NHBE cells isolated from lungs of young non-smokers. A plasmid encoding a characterized human TRPA1 orthologue was used as a positive control for primer and antibody validation. TRPA1 function was probed by perfusing cultures with the TRPA1 agonist cinnamaldehyde, which caused robust Ca2+ influx in NHBE cells that was significantly reduced by the TRPA1 antagonist A967079. Nicotine induced a similar Ca2+ response that was also reduced by A967079 and

HC030031, both TRPA1 antagonists. To assess Ca2+ signaling contributions from ER stores, experiments were repeated in the presence of thapsigargin: similar but smaller Ca2+ responses were again observed with nicotine but reduced with TRPA1 antagonists. Lastly, nicotine exposure via nebulization caused ASL volume loss, reduced CBF, and impaired MCT as early as 1 hr and up to 24 hrs post-exposure. Again, these parameters of mucociliary function were partially protected by pre-treatment with A967079. CONCLUSION(S): Low but functional TRPA1 expression occurs in NHBE cells of non-smokers. Its expression is relevant since it contributes to nicotine signaling, which triggers a series of events that causes mucociliary dysfunction. Future studies will investigate how Ca2+ influx through TRPA1 impairs various molecular mechanisms related to airway hydration.

Chung, S. S. and C. S. Poon (2001). "Characterisation of municipal solid waste and its recyclable contents of Guangzhou." Waste Management and Research **19**(6): 473-485.

Waste characteristics are essential data for waste disposal facilities planning and waste management policy formulation. However, waste composition studies are rarely carried out in mainland Chinese cities and even when it does, the methodologies used are not stringent. A year-long field survey on the physical components of waste and the recyclable in the waste stream has been conducted in Guangzhou to fill the information gap and to provide further experience for waste characterization study in mainland China. It was found that the ash content in the waste stream has decreased considerably. But the proportion of plastic materials in the waste stream has increased and is now comparable to its more urbanized cities. Although this lends support to the recent controls on expanded polystyrene food containers implemented by the Guangzhou environmental protection bureau, more detailed analysis shows that the focus should not only be on disposable food containers, but also on film plastic waste. Furthermore, the abundance of composite materials in the waste stream solicits attention from the waste management authority to step up the monitoring of their generation pattern and to consider imposing control measures.

Ciechomska, M., et al. (2012). "Toll-like receptor-mediated expression of profibrotic tissue-inhibitor of metalloproteinase-1 by circulating monocytes in Systemic sclerosis." European Journal of Clinical Investigation **1)**: 57.

Background: Systemic sclerosis (SSc) is an autoimmune disease characterised by fibrosis, vascular dysfunction and abnormal activation of immune cells including monocytes. Substantial evidence indicates that SSc monocytes overexpress interferon-regulated genes in response to certain toll-like receptor (TLR) stimulation. Therefore, we aim to test weather circulating monocytes from SSc patients produce tissue-inhibitor of metalloproteinase-1 (TIMP-1) following TLR activation, which contributes to excessive matrix deposition and consequently disease progression. Material(s) and Method(s): 23 patients with SSc and 16 HC were included in this study. Peripheral blood monocytes were further separated by CD14+ microbeads. Production of TIMP-1 by monocytes was determined by ELISA, qRT-PCR or functional assay in response to either panel of TLR agonists or patient's sera. Result(s): TIMP-1 produced by monocytes was elevated in SSc patients compared to HC as measured by qRT-PCR (fold increase 3.1, P = 0.03) and ELISA (fold increase 3.2, P = 0.02). Also, TIMP-1 expression was significantly stronger when SSc and HC monocytes were stimulated with TLR4 (LPS) or TLR8 (ss-RNA) agonists, but the response was more pronounced in SSc monocytes (Fig. 1). Agonists against other TLRs were less effective in the induction of TIMP-1. Matrix assay of TLR8 stimulated monocytes also confirmed functional TIMP-1 secretion, as matrix metalloproteinase-1 activity was significantly inhibited. Furthermore, HC monocytes co-cultured with sera from (Figure Presented) SSc patients induce elevated level of TIMP-1 compare to HC sera (Fig. 2). However, pre-treatment with Myd88 inhibitors attenuated TIMP-1 production, but not when incubated with control peptides, confirming the specificity of the agonists. Conclusion(s): This study indicates a potential link between TLR signaling and excessive TIMP-1 secretion in circulating monocytes from SSc patients, supporting an important role of monocytes in production of pro-fibrotic factors.

Ciechomska, M., et al. (2013). "The role of serum factors and toll-like receptor signaling in the induction of profibrotic TIMP-1 by monocytes in systemic sclerosis." Annals of the Rheumatic Diseases **1)**: A11-A12.

Background and Objectives Systemic sclerosis (SSc) is an autoimmune disease characterised by fibrosis, vascular dysfunction and abnormal activation of immune cells including monocytes. Monocytes along with fibroblasts play an important role in the production of profibrotic factors such as IL-6 and TIMP-1 (tissue-inhibitor of metalloproteinase-1). TIMPs are specific inhibitors of matrix metalloproteinases (MMPs) regulating extracellular matrix (ECM) turnover. Importantly, the balance between TIMPs and MMPs is altered in most pathological stages including SSc and is associated with abnormal ECM formation. However, the exact factors which drive both profibrotic TIMP-1 secretion are not fully defined. We aim to test whether circulating monocytes from SSc patients produce TIMP-1 in response to TLR activation and serum factors, which contributes to excessive matrix deposition and consequently disease progression. Materials and Methods 25 patients with SSc, one IRAK4 deficient patient and 20 HC (healthy control) were included in this study. Peripheral blood monocytes were further separated by CD14+ microbeads. Production of TIMP-1, IL-6 by monocytes was determined by ELISA, qRT-PCR or functional assay in response to either panel of conventional TLR agonists or HC and SSc sera. Skin section from SSc patient was stained with CD14+ and TIMP-1 antibodies and further analysed by confocal microscopy. Results TIMP-1 production by monocytes was observed in the SSc skin section and was upregulated in SSc patients compared to HC. Incubation of HC monocytes with SSc sera resulted in functionally active TIMP-1 production. However, pre-treatment with MyD88 inhibitor, but not control peptide, decreased TIMP-1 secretion. Furthermore, SSc-mediated TIMP-1 induction by monocytes was attenuated when FcgammaR was blocked and also when SSc sera were treated with DNA/RNA endonuclease prior to stimulation. This indicates that SSc sera contain RNA/DNA agonists inducing TIMP-1 production. Indeed, direct treatment of HC and SSc monocytes with a panel of TLR ligands demonstrated strong TIMP-1 and IL-6 production following triggering with TLR8 agonists (ssRNA). TLR8-mediated TIMP-1 production was reduced in monocytes from a patient with a genetic TLR signalling defect or HC monocytes cultured with MyD88 inhibitory peptide. Furthermore, matrix assay of TLR8 stimulated monocytes also confirmed functional TIMP-1 secretion, as matrix metalloproteinase-1 activity was significantly inhibited. Conclusions This study indicates a potential link between SSc serum factors and TLR signalling resulting in excessive TIMP-1 secretion by circulating monocytes from SSc patients.

Ciechomska, M., et al. (2012). "Toll-like receptor-mediated expression of profibrotic mediators by circulating monocytes in systemic sclerosis." Annals of the Rheumatic Disease. Conference: Annual European Congress of Rheumatology of the European League Against Rheumatism, EULAR **71**(SUPPL. 3).

Background Systemic sclerosis (SSc) is an autoimmune disease characterised by fibrosis, vascular dysfunction and abnormal activation of immune cells including monocytes. It was suggested that monocytes along with fibroblasts play an important role in the production of profibrotic factors such as IL-6 and TIMP-1 (tissue-inhibitor of metalloproteinase-1). TIMPs are specific inhibitors of matrix metalloproteinases (MMPs) regulating extracellular matrix (ECM) turnover.

Importantly, the balance between TIMPs and MMPs is altered in most pathological stages including SSc and is associated with abnormal ECM formation. However, the exact factors which drive both profibrotic TIMP-1 and IL-6 secretion have not been fully established. Objectives We aim to test whether circulating monocytes from SSc patients and dermal fibroblasts produce TIMP-1 and IL-6 in response to TLR activation, which contributes to excessive matrix deposition and consequently disease progression. Methods 23 patients with SSc and 19 HC (healthy control) were included in this study. Peripheral blood monocytes were further separated by CD14+ microbeads. Production of TIMP-1, IL-6 by monocytes and dermal fibroblasts was determined by ELISA, qRT-PCR or functional assay in response to either panel of conventional TLR agonists or Danger Associated Molecular Patterns (DAMPs) such as High-Mobility Group Box-1 protein (HMGB-1) and hyaluronic acid (HA). Results TIMP-1 produced by monocytes was elevated in SSc patients compared to HC as measured by qRT-PCR (fold increase 3.1, p=0.03) and ELISA (fold increase 3.2, p=0.02). The level of TIMP-1 present in SSc sera patients was also higher than in the HC (fold increase 1.8, p<0.001). In addition, IL-6 and TIMP-1 expression was significantly stronger when SSc and HC monocytes were stimulated with TLR4 (LPS) or TLR8 (ss-RNA) agonists, but the response was more pronounced in SSc monocytes. Agonists against other TLRs were less effective in the induction of TIMP-1 and IL-6. Furthermore, SSc and HC monocytes stimulated with HMGB-1 alone did not induce the secretion of profibrotic factors. However, combination of HMGB-1 and LPS upregulated the expression of both IL-6 and TIMP-1. These results suggest that there is the synergic effect between LPS and HMGB-1 on monocytes and fibroblasts activation. Interestingly, HC and SSc monocytes stimulated with HA alone or in the combination with LPS upregulated TIMP-1 and IL-6 at the same level as HA stimulation only. Furthermore, matrix assay of TLR8 stimulated monocytes also confirmed functional TIMP-1 secretion, as matrix metalloproteinase-1 activity was significantly inhibited. Conclusions This study indicates a potential link between TLR signaling and excessive TIMP-1 and IL-6 secretion in circulating monocytes from SSc patients and activated dermal fibroblasts, supporting an important role of these cells in production of pro-fibrotic factors.

Ciechomska, M. and J. Van Laar (2013). "Role of FRA-2 in TLR8-mediated TIMP-1 production in systemic sclerosis." Annals of the Rheumatic Diseases. Conference: Annual European Congress of Rheumatology of the European League Against Rheumatism, EULAR **72**(SUPPL. 3).

Background Systemic sclerosis (SSc) is an autoimmune connective tissue disease characterised by fibrosis, vascular dysfunction and abnormal activation of immune cells. We and others have shown that monocytes along with fibroblasts play an important role in the production of pro-fibrotic factors such as IL-6 and TIMP-1 (tissue-inhibitor of metalloproteinase-1). Importantly, the balance between TIMP-1 and MMPs is altered in SSc leading to abnormal ECM formation. However, the exact factors which drive pro-fibrotic TIMP-1 in monocytes have not been fully established. Previous studies showed that AP-1 transcription factors including Fra-2 and JunD are involved in TIMP-1 gene expression in hepatic stellate cells contributing to liver fibrosis. Also Fra-2 transgenic mice develop a proliferative vasculopathy of the lung and skin fibrosis resembling similar disease manifestations seen in SSc patients. Objectives The aim of this study is to determine the role of Fra-2 in TIMP-1 production. We also plan to determine if TIMP-1 is a direct target gene of Fra-2 upon TLR8 stimulation in SSc monocytes. Additionally, we want to investigate if altered Fra-2 signalling results in enhanced TIMP-1 production thus contributing to ECM deposition and fibrosis development observed in systemic sclerosis. Methods 20 patients with SSc, one IRAK4 deficient patient and 20 HC (healthy control) were included in this study. Peripheral blood monocytes were further separated by CD14+ microbeads. Expression of TIMP-1 and Fra-2 by monocytes was determined by ELISA, qRT-PCR in

response toTLR8 agonists (ssRNA). Results The results from our group demonstrated that circulating monocytes from SSc patients contribute to the imbalance between TIMP-1 and MMPs and to an increased pro-fibrotic IL-6 production upon TLR8 agonist stimulation (ssRNA). Interestingly, monocytes from an IRAK-4 (a key kinase in TLR-signalling) deficient patient did not produce IL-6 and TIMP-1. In addition, the results showed that the basal gene expression level of Fra-2 in SSc monocytes is higher than in healthy or IRAK-4 deficient monocytes. Interestingly, TLR8 activation induced even stronger Fra-2 gene expression and correlated with increased expression of TIMP-1 in SSc monocytes, suggesting that the TLR signalling pathway may be involved in Fra-2 mediated TIMP-1 induction and therefore promotes fibrosis. Also, we plan to pre-treat monocytes with the chemical AP-1 inhibitor (T-5224) and assess both gene and protein level of TIMP-1 upon TLR8 activation. Conclusions This study helps to understand the molecular mechanisms of Fra-2 mediated fibrogenesis in SSc.

Cinar, U., et al. (2019). "INVESTIGATION OF USABILITY OF RECYCLED MATERIALS IN PROTECTIVE EARMUFFS." Fresenius Environmental Bulletin **28**(10): 7282-7286.

Exposure to high volume for long periods of time can cause hearing loss for workers. Furthermore, in the case of intermittent exposure to loudly noise may lead to hearing damage, irritability, decreased concentration and even occupational accidents. Passive protective earmuffs are highly preferred because of its cost and durability. It is generally mandatory to use earmuffs, which must be renewed at certain times, during the heavy industrial works. A new earmuff model that complies the principles of EN 352-1 standard is proposed. It is made of materials which can be recycled from paper, glass and plastic waste. This fact will also be beneficial in terms of environmental and economic aspects. The outer part of the earmuff consists of recycled polymers and inner part consists of materials which are combined differently with egg tray, recycled fibers, bondex foam, melamine foam, glass wool and corkboard. Depending on the results of the studies performed, it was determined that all passive noise cancelling earmuffs containing recyclable materials in certain layers were usable and all combinations other than the combination consisting of egg tray and recycled fibers were detected to have a better noise damping property compared to conventional earmuffs. Cincinelli, A., et al. (2019). "A potpourri of microplastics in the sea surface and water column of the Mediterranean Sea." TrAC - Trends in Analytical Chemistry **110**: 321-326.

This review provides insight into the abundance, origin, distribution and composition of MPs in the sea surface and water column of the Mediterranean Sea. Literature data on MP particles on the sea surface showed an evident heterogeneous distribution and composition, with marked geographical differences between Mediterranean sub-basins. A standardized protocol for water sampling, extraction and detection of plastic debris is strongly recommended. The heterogenicity of MPs distribution and its concentration levels could be related to several factors, such as the different methodological approaches. In addition, the influence of hydrodynamic features such as currents, up and down-welling, gyres and fronts could also be responsible for this heterogeneity in concentrations. Marine litter modelling studies have been applied to understand litter sources, fate, transport and accumulation in oceans. Recent studies focused on the "plastisphere" in order to better understand the potential risk of pathogen dispersion with plastic transport in the Mediterranean Sea. Copyright © 2018 Elsevier B.V.

Cincinelli, A., et al. (2017). "Microplastic in the surface waters of the Ross Sea (Antarctica): Occurrence, distribution and characterization by FTIR." Chemosphere **175**: 391-400.

This is the first survey to investigate the occurrence and extent of microplastic (MPs) contamination in sub surface waters collected near-shore and off-shore the coastal area of the Ross Sea (Antarctica). Moreover, a non-invasive method to analyze MPs, consisting in filtration after water sampling and analysis of the dried filter through Fourier Transform Infrared Spectroscopy (FTIR) 2D Imaging, using an FPA detector, was proposed. The non-invasiveness of analytical set-up reduces potential bias and allows subsequent analysis of the filter sample for determination of other classes of contaminants. MPs ranged from 0.0032 to 1.18 particle per m³ of seawater, with a mean value of 0.17 +/- 0.34 particle m⁻³, showing concentrations lower than those found in the oceans worldwide. MPs included fragments (mean 71.9 +/- 21.6%), fibers (mean 12.7 +/- 14.3%), and others (mean 15.4 +/- 12.8%). The presence of different types of MPs was confirmed by FTIR spectroscopy, with predominant abundance of polyethylene and polypropylene. The potential environmental impact arising from scientific activities, such as marine activities for scientific purposes, and from the sewage treatment plant, was also evidenced.

Civancik-Uslu, D., et al. (2019). "Life cycle assessment of carrier bags and development of a littering indicator." Science of the Total Environment **685**: 621-630.

Increased plastic consumption has resulted in high amounts of plastic waste ending up in the environment. Recently, the European Commission (EC) has identified a list of single-use plastics, including plastic bags, most commonly found in the European beaches. As a response, alternatives for plastic carrier bags have been more of a concern. Many life cycle assessment (LCA) studies have been performed to evaluate the environmental profile of different carrier bags; however, without considering the possibility of contribution to the littering problem. Therefore, in this study, an indicator has been introduced, based on an LCA study of carrier bags which was performed in Spain. The indicator is influenced by parameters such as: number of bags to fulfill the functional unit, weight, surface, fee, and biodegradability. In this paper, a comparative LCA of HDPE, LDPE, PP, paper and biodegradable plastic bags is presented. Following that, a littering indicator is introduced to allow a comparison of the risk of littering of the different carrier bags in marine environment. The results given by the Littering Potential indicator rank the bags oppositely to the results given by the LCA as usual. Further research is needed to refine the model and include additional contributing variables.

Civancik-Uslu, D., et al. (2019). "Improving the production chain with LCA and eco-design: application to cosmetic packaging." Resources, Conservation & Recycling **151**: N.PAG-N.PAG.

One of the main drivers for companies to perform environmental improvements is economic benefit, either by obtaining a more valuable product or gaining new customers. Circular economy combines environmental improvements with these drivers to achieve higher and quicker benefits. This paper is a case study on packaging eco-design aligned with circular economy strategy along the production chain. Life cycle assessment (LCA) was used to identify the product life cycle stages where the application of eco-design strategies would be more efficient (in this case, raw materials production from virgin petrochemicals). To improve the environmental profile of this packaging, virgin petrochemicals were partially replaced by mineral

fillers (calcium carbonate based) or/and post-consumer recycled plastics. Different technically compliant cosmetic tubes were produced by collaboration between a company producing the plastic granulates with mineral fillers and a company producing the cosmetic tubes and cradle-to-gate LCA were performed. The replacement of virgin petrochemicals by mineral fillers helped to reduce the environmental impacts by an average of 12% and the use of post-consumer recycled plastic further decreased emissions up to 29% for 6 out of the 9 evaluated impact categories. The option with better environmental performance was also the one with lower economic costs. According to the involved companies, LCA combined with ecodesign helped to achieve efficient environmental and economic savings. The findings are important for the plastic packaging sector because they tackle with prime concerns, like plastic debris, climate change and resource depletion. They are of main interest for industrial activities where brand positioning is a priority (i.e. cosmetics). [ABSTRACT FROM AUTHOR]

Claessens, M., et al. (2011). "Occurrence and distribution of microplastics in marine sediments along the Belgian coast." Marine Pollution Bulletin **62**(10): 2199-2204.

Plastic debris is known to undergo fragmentation at sea, which leads to the formation of microscopic particles of plastic; the so called 'microplastics'. Due to their buoyant and persistent properties, these microplastics have the potential to become widely dispersed in the marine environment through hydrodynamic processes and ocean currents. In this study, the occurrence and distribution of microplastics was investigated in Belgian marine sediments from different locations (coastal harbours, beaches and sublittoral areas).Particles were found in large numbers in all samples, showing the wide distribution of microplastics in Belgian coastal waters. The highest concentrations were found in the harbours where total microplastic concentrations of up to 390particleskg⁻¹ dry sediment were observed, which is 15-50 times higher than reported maximum concentrations of other, similar study areas.The depth profile of sediment cores suggested that microplastic concentrations on the beaches reflect the global plastic production increase. © 2011 Elsevier Ltd.

Claessens, M., et al. (2013). "New techniques for the detection of microplastics in sediments and field collected organisms." Marine Pollution Bulletin **70**(1-2): 227-233.

Microplastics have been reported in marine environments worldwide. Accurate assessment of quantity and type is therefore needed. Here, we propose new techniques for extracting microplastics from sediment and invertebrate tissue. The method developed for sediments involves a volume reduction of the sample by elutriation, followed by density separation using a high density NaI solution. Comparison of this methods' efficiency to that of a widely used technique indicated that the new method has a considerably higher extraction efficiency. For fibres and granules an increase of 23% and 39% was noted, extraction efficiency of PVC increased by 100%. The second method aimed at extracting microplastics from animal tissues based on chemical digestion. Extraction of microspheres yielded high efficiencies (94-98%). For fibres, efficiencies were highly variable (0-98%), depending on polymer type. The use of these two techniques will result in a more complete assessment of marine microplastic concentrations.

Clauss, M., et al. (2011). "The effect of size and density on the mean retention time of particles in the reticulorumen of cattle (Bos primigenius f. taurus), muskoxen (Ovibos moschatus) and moose (Alces alces)." British Journal of Nutrition **105**(4): 634-644.

Particle passage from the reticulorumen (RR) depends on particle density and size. Forage particle density and size are related and change over time in the RR. Particle density mainly influences sorting in the reticulum, whereas particle size influences particle retention in the fibre mat of stratified rumen contents ('filter-bed' effect). We investigated these effects independently, by inserting plastic particles of different sizes (1, 10 and 20 mm) and densities (1.03, 1.20 and 1.44 mg/ml) in the RR of cattle (Bos primigenius f. taurus) as a pilot study, and of muskoxen (Ovibos moschatus; n 4) and moose (Alces alces; n 2) both fed two diets (browse and grass). Faeces were analysed for plastic residues for 13 d after dosing to calculate mean retention times (MRT). The results confirmed previous findings of differences in absolute MRT between species. Comparing muskoxen with moose, there was no difference in the effect of particle density on the MRT between species but particle size had a more pronounced effect on the MRT in muskoxen than in moose. This indicated a stronger 'filter-bed effect' in muskoxen, in accord with the reports of stratified RR contents in this species v. the absence of RR content stratification in moose. Low-density particles were retained longer in both species fed on grass diets, indicating a contribution of forage type to the 'filter-bed effect'. The results indicate that retention based on particle size may differ between ruminant species, depending on the presence of a fibre mat in the RR, whereas the density-dependent mechanism of sedimentation in the RR is rather constant across species.

Clegg, C. D., et al. (1996). "Biophysical processes affecting the transit of a genetically-modified Pseudomonas fluorescens through the gut of the woodlouse Porcellio scaber." Soil Biology & Biochemistry **28**(8): 997-1004.

The effect was determined of gut transit retention time of genetically-modified bacteria ingested by Porcellio scaber. The experimental animals were supplied ash leaf litter inoculated with the genetically-modified bacterium Pseudomonas fluorescens KTG and bacteria in food and faeces were counted using selective plating and immunofluorescent techniques. The bacteria were also detected using the polymerase chain reaction (PCR). Plate counts of P. fluorescens KTG in fresh faeces were lower than those in the litter when the genetically modified microorganism (GEMMO) was supplied to animals at five different population densities, suggesting that a proportion of the GEMMO population was lost during gut transit. There was no significant difference in the survival of freshly cultured and starved cultures of P. fluorescens KTG on gut transit through Porcellio scaber as determined by plate counts in fresh faeces. Retention time of Pseudomonas fluorescens KTG in the wood louse gut was longer than that of the food bolus. The passage of bacteria through the gut was modelled and tracked using microbeads of a size similar to bacteria. Fluorescent microbeads added to food litter were detected within the anterior chamber, papillate region and rectum of the wood louse for at least 17 days after ingestion. Beads were retained within the cuticular structure of the digestive tract and also within mucopolysaccharide produced within the gut. Immunofluorescent observations of washed hindgut samples provided little evidence to suggest P. fluorescens KTG had become attached to the hindgut wall during transit. Very few colonies of the GEMMO and indigenous bacteria were detected from homogenised hepatopancreas samples. P. fluorescens KTG was however detected in the hepatopancreas of Porcellio scaber using PCR. It is suggested that the retention of bacteria within the guts of woodlice is by physical rather than biological mechanisms such as growth or attachment.

Clemente, T. M., et al. (2010). SUPER HI-CAT: Survey of Underwater Plastic and Ecosystem Response between Hawaii and California, American Geophysical Union, 2000 Florida Ave., N.W. Washington DC 20009 USA, [URL:http://www.agu.org].

Microbes are the most abundant organisms in the oceans and are vital to the Earths habitability. Marine microbes produce the oxygen we breathe, form the base of the marine food web and help regulate the Earths climate. Marine debris has become a serious issue concerning the health of todays oceans. Plastic debris in particular is known to have negative impacts on marine organisms through ingestion and entanglement by seabirds and large marine fauna; however, little is known about its influence on microbial communities. The objective of the SUPER HI-CAT cruise was to locate and sample microbial communities and biogeochemical properties associated with the so-called Pacific plastic patch between Honolulu, HI and Port Hueneme, CA. Sampling was conducted from the R/V Kilo Moana between 25 August - 5 September 2008. During the transit a total of 15 CTD/Trawl/Optics stations and 15 underway stations were occupied. Hydrographic and biogeochemical data were collected to characterize the upper 150m water column and a Manta Trawl was used to map the surface distribution of plastic. Plastic samples were size fractioned into the following size classes; 5mm and larger, 2- 5mm size classes ranged from 0.35-3.71 pieces m-3 across all sampling stations. Integrated over the top 0.5m of the ocean, the particle concentrations along the transect ranged from 0.17-1.85 x 106 plastic fragments km-2. Total microbial biomass, as measured by ATP content and Chlorophyll were measured for a range of plastic types and size categories. ATP and Chlorophyll concentrations were highly variable across the transect (100 to 1000 fold range, respectively), but provided proof that microorganisms colonized the plastic particles and occasionally achieved significant enrichments relative to their distributions in seawater. Total particle abundance and particle size distributions, as determined by a forward scattering measurement, were not correlated with measured abundance of size-fractionated plastic in the surface waters along our transect. Rather total particle distributions tracked phytoplankton biomass, as chlorophyll or particulate carbon. Measurements of Gross Primary Production (GPP), Net Community Production (NCP) and Respiration (R) revealed high community metabolic rates on plastic particles in the two larger size classes. More importantly, whereas rates of NCP in the seawater were close to zero (GPP=R), microbial assemblages associated with the plastic debris were demonstrably net auto-trophic suggesting the presence of phytoplankton enriched biofilms.

Clotilde, L. M., et al. (2011). "Microbead-based immunoassay for simultaneous detection of Shiga toxins and isolation of Escherichia coli O157 in foods." Journal of Food Protection **74**(3): 373-379.

Shiga toxin-producing Escherichia coli (STEC) is a significant foodborne pathogen with great economic consequences. There has been an increased food safety concern with this organism since outbreaks of human illnesses caused by this pathogen were first reported in 1982. Therefore, developing a reliable, sensitive, and rapid assay capable of detecting E. coli O157 and the main toxins produced by STEC (i.e., Shiga toxins 1 [Stx(1)] and 2 [Stx(2)]) will directly benefit regulatory agencies by minimizing analysis time. Here, we use Luminex technology to detect multiple analytes in a single 50-ml sample. Using commercially available monoclonal antibodies coupled to carboxylated magnetic microbeads, we developed an immunoassay capable of simultaneously serotyping E. coli O157 and detecting Stx(1) and/or Stx(2). The specificity and sensitivity of this immunoassay was tested against a collection of 34 E. coli isolates belonging to various O serogroups phenotypically different for Stx. The results were compared with microplate sandwich enzyme-linked immunosorbent assay (ELISA), and no cross-reactivity was

observed for any of the monoclonal antibodies used. An increased sensitivity up to 1,000 times was observed in the microbead-based immunoassay when compared with the microplate sandwich ELISA. The results indicate that Luminex technology has the potential to simultaneously detect multiple targets without loss of specificity and/or sensitivity. A blind experiment was conducted with 48 samples of ground beef, lettuce, and milk spiked with <=2 CFU/g E. coli. All the samples were correctly identified, with no false positives or false negatives. This microbead-based immunoassay could be extended to simultaneously detect additional foodborne pathogens and their toxic markers.

Clotilde, L. M., et al. (2015). "Comparison of multiplex immunochemical and molecular serotyping methods for Shiga toxin-producing Escherichia coli." Foodborne Pathogens and Disease **12**(2): 118-121.

Traditionally, serotyping of Escherichia coli has been performed via slide agglutination methods using antisera. More recently, multiplex immunoassays and "molecular serotyping" via polymerase chain reaction (PCR) have been validated for this purpose. In this study, the serogroups of 161 Shiga toxin-producing Escherichia coli (STEC) strains isolated from fecal samples of California cattle were typed by conventional methods using antisera as well as two newly developed multiplex PCR- and antibody-based microbead assays using the Luminex technology. Using the Luminex assays, we were capable of serotyping 11 STEC isolates that were previously determined untypeable for the O antigen by conventional methods using antisera. Except for 14 isolates, results from the 2 Luminex assays agreed.

Clukey, K. E., et al. (2018). "Persistent organic pollutants in fat of three species of Pacific pelagic longline caught sea turtles: Accumulation in relation to ingested plastic marine debris." Science of the Total Environment **610/611**: 402-411.

In addition to eating contaminated prey, sea turtles may be exposed to persistent organic pollutants (POPs) from ingesting plastic debris that has absorbed these chemicals. Given the limited knowledge about POPs in pelagic sea turtles and how plastic ingestion influences POP exposure, our objectives were to: 1) provide baseline contaminant levels of three species of pelagic Pacific sea turtles; and 2) assess trends of contaminant levels in relation to species, sex, length, body condition and capture location. In addition, we hypothesized that if ingesting plastic is a significant source of POP exposure, then the amount of ingested plastic may be correlated to POP concentrations accumulated in fat. To address our objectives we compared POP concentrations in fat samples to previously described amounts of ingested plastic from the same turtles. Fat samples from 25 Pacific pelagic sea turtles [2 loggerhead (Caretta caretta), 6 green (Chelonia mydas) and 17 olive ridley (Lepidochelys olivacea) turtles] were analyzed for 81 polychlorinated biphenyls (PCBs), 20 organochlorine pesticides, and 35 brominated flame-retardants. The olive ridley and loggerhead turtles had higher ΣDDTs (dichlorodiphenyltrichloroethane and metabolites) than ΣPCBs, at a ratio similar to biota measured in the South China Sea and southern California. Green turtles had a ratio close to 1:1. These pelagic turtles had lower POP levels than previously reported in nearshore turtles. POP concentrations were unrelated to the amounts of ingested plastic in olive ridleys, suggesting that their exposure to POPs is mainly through prey. In green turtles, concentrations of ΣPCBs were positively correlated with the number of plastic pieces ingested, but these findings were confounded by covariance with body condition index (BCI). Green turtles with a higher BCI had eaten more plastic and also had higher POPs. Taken together, our findings suggest that sea turtles accumulate most POPs through their prey rather than marine debris. Clunies-Ross, P. J., et al. (2016). "Synthetic shorelines in New Zealand? Quantification and characterisation of microplastic pollution on Canterbury's coastlines." New Zealand Journal of Marine and Freshwater Research **50**(2): 317-325.

Microplastics are persistent environmental contaminants found in marine environments worldwide. Microplastic particles isolated from coastlines in the Canterbury region of New Zealand were quantified and characterised. Sediment samples were collected from 10 locations representing exposed-beach, estuarine and harbour environments in both urban and non-urban settings. Particles were isolated from sediments using an NaCl density-separation procedure and quantified and characterised with a combination of optical/fluorescence imaging and micro-Raman spectroscopy. Microplastics were detected at eight out of 10 locations, at concentrations ranging from 0-45.4 particles kg-1 of dry sediment. The majority of microplastics were identified as polystyrene (55%), polyethylene (21%) and polypropylene (11%). Microplastic concentrations in exposed-beach environments were significantly greater than in harbour and estuarine environments.

Cluzard, M., et al. (2015). "Intertidal Concentrations of Microplastics and Their Influence on Ammonium Cycling as Related to the Shellfish Industry." Archives of Environmental Contamination & Toxicology **69**(3): 310-319.

Microplastics are ubiquitous within the marine environment. The last 10 years have seen research directed at understanding the fate and effect of microplastics within the marine environment; however, no studies have yet addressed how concentrations of these particles could affect sedimentary processes such as nutrient cycling. Herein we first determine the concentration and spatial distribution of microplastics within Baynes Sound, a key shellfish-growing area within coastal British Columbia (BC). We also determined sediment grain size and % organic matter (OM) such that we could relate spatial patterns in sediment microplastic concentrations to sedimentary processes that determine zones of accretion and erosion. Using field-determined concentrations of microplastics, we applied laboratory microcosms studies, which manipulated sediment concentrations of microplastics, OM, and bivalves to determine the influence of sediment microplastics on ammonium cycling within intertidal sediments. Concentrations of microplastics determined within the intertidal sediment varied spatially and were similar to those found in other coastal regions of high urban use. Concentrations were independent of grain size and OM suggesting that physical processes other than those that govern natural sediment components determine the fate of microplastics within sediments. Under laboratory conditions, concentrations of ammonium were significantly greater in the overlying water of treatments with microplastics, clams, and OM compared with treatments without microplastics. These preliminary studies suggest that high concentrations of microplastics have the potential to alter key sedimentary processes such as ammonium flux. This could have serious implications, for example, contributing to eutrophication events in regions of the coast that are highly urbanized.

Coburn, C. (2019). "Microplastics and gastrointestinal health: how big is the problem?" The Lancet. Gastroenterology & Hepatology **4**(12): 907-908.

Coburn, R. (2010). "Crafting for a Greener World." Natural Life(136): 12-15.

The article offers the author's insights regarding the growing concern on plastics and industrial wastes that are accumulated in oceans and the use of recycled plastics as a craft material. It mentions the Plastiki, a sailing boat made from gas filled polyethylene terephthalate (PET) soda bottles, which sails from San Francisco, California to Australia to address the problem of plastic waste. Furthermore, it explores the potential impact of plastic materials on ocean organisms at various levels.

Coda, B., et al. (2001). "Behavior of Chlorine and Enrichment of Risky Elements in Bubbling Fluidized Bed Combustion of Biomass and Waste Assisted by Additives." Energy & Fuels **15**(3): 680-690.

High contents of chlorine and alkalies restrict the use of biomass in energy production. Alkali chlorides vaporize during combustion. Chlorine tends to produce corrosive deposits and unacceptably high emissions of HCl and dioxins. Chlorine recovery and enrichment of Cl, Na, K, Ca, Al, and Si in coarse and fine fly ash were studied experimentally with two electrically stabilized bubbling fluidized bed (BFB) reactors capable of reproducing the particle residence times existing in full-scale BFB plants. Feedstocks were fir (mixture of heartwood and bark), paper sludge, and blends of fir with agricultural waste or plastic waste. Sulfur concentrations of feed components were low (<0.5 wt %), while chlorine and potassium concentrations ranged widely (0.02-3.2 wt % for Cl and 0.07-3.1 wt % for K). Aluminum-containing additives (kaolin, bauxite and fly ash from a pulverized coal plant) and limestone were added to the feedstocks at various dosages to evaluate their influence on Cl behavior and enrichment of the elements of interest. HCl was measured by FTIR and wet-absorption methods. Different ash samples (bed, cyclone and filter ash) were characterized for their Cl content and the major ash-forming constituents. Cl was completely volatilized from bed ash and recovered only in coarse (cyclone) and fine (filter) fly ash fractions. Al-containing additives increased HCl formation and decreased Cl concentration in the fly ash. In the case of Al-Si based additives, evidence was found of the formation of alkali aluminum silicates from alkali chlorides. The aluminum silicates were transferred mainly to the coarse fly ash fraction. Al-based additives also seemed to liberate Cl from alkali chlorides with reactions forming water-soluble alkali compounds. Limestone had the opposite effect to the Al-containing additives by binding Cl from gas phase to fly ash, but mainly to the coarse fly ash fraction. The results will be useful in optimizing the behavior of chlorine in bubbling bed combustion of Cl- and alkali-containing biomass.

Codina-Garcia, M., et al. (2013). "Plastic debris in Mediterranean seabirds." Marine Pollution Bulletin **77**(1/2): 220-226.

Plastic debris is often ingested by marine predators and can cause health disorders and even death. We present the first assessment of plastic ingestion in Mediterranean seabirds. We quantified and measured plastics accumulated in the stomach of 171 birds from 9 species accidentally caught by longliners in the western Mediterranean from 2003 to 2010. Cory's shearwaters (Calonectris diomedea) showed the highest occurrence (94%) and large numbers of small plastic particles per affected bird (on average N=15.3+or-24.4 plastics and mass=23.4+or-49.6 mg), followed by Yelkouan shearwaters (Puffinus yelkouan, 70%, N=7.0+or-7.9, 42.1+or-100.0 mg), Balearic shearwaters (Puffinus mauretanicus, 70%, N=3.6+or-2.9, 5.5+or-9.7 mg) and the rest of species (below 33%, N=2.7, 113.6+or-128.4 mg). Plastic characteristics did not differ between sexes and were not related to the physical condition of the birds. Our results point out the three endemic and threatened shearwater species as being particularly exposed to plastic accumulation.

Coffin, S., et al. (2018). "Comparisons of analytical chemistry and biological activities of extracts from North Pacific gyre plastics with UV-treated and untreated plastics using in vitro and in vivo models." Environment International **121**: 942-954.

Plastic debris is an emerging worldwide threat to marine biota. Marine species may face unique challenges in low-flow estuarine systems with a high abundance of "macro-sized" (>4.75 mm) plastic due to the leaching of constituents and adsorbed contaminants. To simulate this leaching process, plastic samples recovered from the North Pacific Gyre along with corresponding UV-irradiated virgin plastic and non-irradiated virgin plastic counterparts were incubated in saltwater for 30 days at ambient temperatures ranging from 17 to 25 °C. Following solid-phase extraction, water samples were fractionated with sequential methanol elution from 10 to 100% and evaluated using in vitro assays assessing estrogen receptor (ER) and aryl hydrocarbon receptor (AhR) activities. In vivo responses (vitellogenin [vtg] and cytochrome p 450 1A [cyp1a] mRNA) were measured following 5-day exposures in Japanese medaka (Oryzias latipes) larvae (3 days post hatch). Estrogenic plasticizers, co-planar PCBs and PAHs were quantified in the extracts using targeted GC–MS/MS and UPLC-MS/MS. In vitro estrogenicity showed highest activity in the 70% methanol fraction for all plastic leachate exposures. Whole extract in vitro estradiol equivalent (EEQ) values were 4.34 ± 2.65, 8.79 ± 2.09 and 13.78 ± 3.64 ng/L, for virgin plastic, UV-irradiated virgin plastic and North Pacific Gyre-recovered plastic, respectively (mean ± SD). Significant vtg induction was observed in medaka larvae exposed to leachate extracts from North Pacific Gyre-recovered plastic and UV-irradiated virgin plastic (9.9-fold, $p = 0.039$ and 10.1-fold, $p = 0.042$, respectively). Chemically-determined EEQ values were also localized in the 70% methanol fraction. Whole leachate extract chemical EEQ values were 0.33 ± 0.07, 1.64 ± 0.62 and 11.4 ± 2.13 ng/L, for virgin plastic, UV-irradiated virgin plastic and North Pacific Gyre-recovered plastic, respectively. In-vitro AhR activity was highest in the 70% methanol elution with greater activity in North Pacific Gyre-recovered plastic than in virgin plastic and UV-irradiated virgin plastic (toxic equivalency [TEQ] = 1.06 ± 0.54, 0.38 ± 0.07 and 0.71 ± 0.47 ng/L, respectively). CYP1A mRNA was significantly induced in larval medaka exposed to North Pacific Gyre-recovered plastic leachates (17.8-fold, $p = 0.02$) while exposure to virgin plastic and UV-irradiated virgin plastic leachates caused no significant change. Chemically-determined TEQ analysis for AhR indicated highest activity in the 90% methanol fraction for all leachates, with whole extract in vitro TEQs being 1.47 ± 0.87, 0.03 ± 0.05 and 0.42 ± 0.38 ng/L for North Pacific Gyre-recovered plastic, virgin plastic and UV-irradiated virgin plastic, respectively. These results indicate that weathering and UV radiation release estrogenic plasticizers and demonstrate the ability for plastics to transport adsorbed persistent organic pollutants at eco-toxicologically relevant concentrations. Graphical abstract Unlabelled Image Highlights • North Pacific Gyre plastic leached higher in vitro and chemical EEQ and TEQ than "virgin" and irradiated "virgin" plastic. • North Pacific Gyre plastic leachates significantly induced cyp1a and VTG mRNA in Oryzias latipes. • UV radiation enhanced desorption of BPA, OP and PCBs from virgin plastic and induced VTG mRNA in Oryzias latipes. [ABSTRACT FROM AUTHOR]

Coffin, S., et al. (2019). "Simulated digestion of polystyrene foam enhances desorption of diethylhexyl

phthalate (DEHP) and In vitro estrogenic activity in a size-dependent manner." Environmental Pollution **246**: 452-462.

Marine polychaetes and fish are known to ingest polystyrene microparticles in the environment. Laboratory microplastic feeding experiments have demonstrated that plastic may release endocrine-disrupting compounds such as diethylhexyl phthalate (DEHP), which can cause adverse effects in both vertebrates and invertebrates. In order to determine the influence of size and digestive conditions on the desorption of DEHP and other plasticizers to polychaetes and fish, we exposed polystyrene particles of various sizes under invertebrate and vertebrate digestive conditions (vertebrate mimic; pepsin, pH = 2.0, 24 degreeC, invertebrate mimic; Na taurocholate pH = 7, 18 degreeC). Estrogen receptor activation and concentrations of 12 plasticizers were measured in the extracts. DEHP, bisphenol S and 4-tert-octylphenol were the only compounds detected. Simulated vertebrate gut digestion did not significantly enhance the release of chemicals nor estrogenic activity. However, a 6.3 +/- 2.0-fold increase in the concentration of DEHP was observed in extracts from invertebrate gut conditions (Mean +/- SD; N = 24, p < 0.0001). Additionally, estimated particle surface area was positively correlated with estrogenic activity across all treatment types (r = 0.85, p < 0.0001). Overall, these data indicate an elevated bioaccessibility of DEHP may occur in invertebrates, and size-dependent desorption of uncharacterized estrogenic compounds from plastic suggest additional complexity when considering the risks of MP to aquatic organisms. This study concludes that polystyrene particles release more biologically-active estrogenic chemicals with decreasing size, and releases DEHP at higher quantities under invertebrate gut conditions. Coghlan, A. (2018). "Plastic in bottled water shouldn't be a worry." New Scientist(3170): 25-25.

The article discusses microplastic contamination in bottled water, which the author maintains is not a health risk, referencing a study by the global consortium Orb Media.

Cohen, D. (2019). "Towards a Plastic-Free Future." Earth Island Journal **34**(1): 56-56.

The article offers information on the views of author towards several initiatives such as Plastic Pollution Coalition which provides tools and share best practices to empower people to reduce their own plastic footprint, and to help their families, friends, towns, states, and countries do the same. Topics include details on toxic chemicals such as phthalates and bisphenols that leach into the food and beverages and impacts the bodies and the environment.

Cohen, J. H., et al. (2019). "Observations and Simulations of Microplastic Debris in a Tide, Wind, and Freshwater-Driven Estuarine Environment: the Delaware Bay." Environmental Science & Technology **53**(24): 14204-14211.

Microplastic (MP) in estuarine and coastal environments remains poorly characterized, despite the importance of these physically dynamic regions as a buffer between land, freshwater environments, and the open ocean where plastic debris accumulates. We sampled MP particles to determine concentration, size, and type in Delaware Bay and numerically simulated transport and distribution at a high spatiotemporal resolution of positively buoyant particles, representing common MP types. Baywide MP concentrations averaged between 0.19 and 1.24 pieces m⁻³ depending on size fraction (300-1000 and 1000-5000 mum) and sampling month (April and June 2017). Upper bay stations, which are located in or near the estuarine turbidity maximum, had higher MP concentrations than lower bay and New Jersey shore stations. Fragments were predominately polyethylene, and filaments predominately polypropylene. Model results suggest that buoyant particles quickly (i.e., within hours) organize in patchy, highly inhomogeneous distributions, creating "hot spots" of MP. In the presence of variable currents driven by buoyancy, wind, and tides, we predict high spatial and temporal variability of MP distributions in Delaware Bay; MP concentrations could vary by a factor of 1000 within a tidal cycle at our sample locations. Collectively, these observations and simulations provide a baseline of MP concentrations in Delaware Bay along with broader, contextual understanding for how measurements reflect MP concentrations in a dynamic estuarine system.

Colabuono, F. I., et al. (2009). "Plastic ingestion by Procellariiformes in Southern Brazil." Marine Pollution Bulletin **58**(1): 93-96.

The Procellariiformes are the birds most affected by plastic pollution. Plastic fragments and pellets were the most frequent items found in the digestive tract of eight species of Procellariiformes incidentally caught by longline fisheries as well as beached birds in Southern Brazil. Plastic objects were found in 62% of the petrels and 12% of the albatrosses. The Great shearwater, Manx shearwater, Cory's shearwater and Antarctic fulmar were found to have greater quantities and frequencies of occurrence of plastic. There was no significant difference in the number of plastics between the birds from longline fisheries and beached birds. No correlation was found between the number of prey and number of plastics in the digestive tract of the birds analyzed, but this does not discard the hypothesis that, in some cases, the presence of plastic in the digestive tract has a negative effect on the feeding efficiency of these birds.

Colabuono, F. I., et al. (2010). "Polychlorinated biphenyls and organochlorine pesticides in plastics ingested by seabirds." Marine Pollution Bulletin **60**(4): 630-634.

The occurrence of plastic objects in the digestive tract was assessed in eight species of Procellariiformes collected in southern Brazil and the occurrence of polychlorinated biphenyls (PCBs) and organochlorine pesticides (OCPs) in the ingested plastics pellets and plastic fragments was evaluated. PCBs were detected in plastic pellets (491 ng g⁻¹) and plastic fragments (243-418 ng g⁻¹). Among the OCPs, p,p'-DDE had the highest concentrations, ranging from 68.0 to 99.0 ng g⁻¹. The occurrence of organic pollutants in post-consumer plastics supports the fact that plastics are an important source carrying persistent organic pollutants in the marine environment. Although transfer through the food chain may be the main source of exposure to POPs to seabirds, plastics could be an additional source for the organisms which ingest them, like Procellariiformes which are the seabirds most affected by plastic pollution.

Colangelo, F., et al. (2013). "Experimental and Numerical Analysis of Thermal and Hygrometric Characteristics of Building Structures Employing Recycled Plastic Aggregates and Geopolymer Concrete." Energies **6**(11): 6077-6101.

The correct estimation of building energy consumptions is assuming an always increasing importance, and a detailed reproduction of building structures, with all the single components involved, is necessary to achieve this aim. In addition, the current ecological development tries to limit the use of natural raw materials as building components, in favor of alternative (waste) materials, which ensure significant advantages from the economic, energetic and environmental point of views. In this work, dynamic heat and vapor transport in a typical three-dimensional (3D) building structure, involving different types of environmental-friendly concrete mixtures, have been simulated by using finite elements. In particular, the authors propose to substitute part of the aggregates with plastic waste and to use a fly ash based geopolymeric binder for the production of low conductivity concrete, to be employed in eco-efficient buildings. Concrete produced with natural limestone aggregates has been considered as the reference benchmark. The whole characterization of the different types of concrete tested in the present work has

been obtained through laboratory experiments. The structure taken into account in the simulations is a 3D thermal bridge, typical of building envelopes. The thermal and hygrometric transient behavior of this structure, employing plastic waste in different percentages and geopolymer concrete, has been analyzed by the authors.

Cole, M., et al. (2019). "Effects of Nylon Microplastic on Feeding, Lipid Accumulation, and Moulting in a Coldwater Copepod." Environmental Science & Technology **53**(12): 7075.

Microplastic debris is a pervasive environmental contaminant that has the potential to impact the health of biota, although its modes of action remain somewhat unclear. The current study tested the hypothesis that exposure to fibrous and particulate microplastics would alter feeding, impacting on lipid accumulation, and normal development (e.g., growth, moulting) in an ecologically important coldwater copepod Calanus finmarchicus. Preadult copepods were incubated in seawater containing a mixed assemblage of cultured microalgae (control), with the addition of ~50 microplastics mL–1 of nylon microplastic granules (10–30 μm) or fibers (10 × 30 μm), which are similar in shape and size to the microalgal prey. The additive chemical profiles showed the presence of stabilizers, lubricants, monomer residues, and byproducts. Prey selectivity was significantly altered in copepods exposed to nylon fibers (ANOVA, $P < 0.01$) resulting in a nonsignificant 40% decrease in algal ingestion rates (ANOVA, $P = 0.07$), and copepods exposed to nylon granules showed nonsignificant lipid accumulation (ANOVA, $P = 0.62$). Both microplastics triggered premature moulting in juvenile copepods (Bernoulli GLM, $P < 0.01$). Our results emphasize that the shape and chemical profile of a microplastic can influence its bioavailability and toxicity, drawing attention to the importance of using environmentally relevant microplastics and chemically profiling plastics used in toxicity testing.

Cole, M. and T. S. Galloway (2015). "Ingestion of Nanoplastics and Microplastics by Pacific Oyster Larvae." Environmental Science & Technology **49**(24): 14625-14632.

Plastic debris is a prolific contaminant effecting freshwater and marine ecosystems across the globe. Of growing environmental concern are "microplastics"and "nanoplastics" encompassing tiny particles of plastic derived from manufacturing and macroplastic fragmentation. Pelagic zooplankton are susceptible to consuming microplastics, however the threat posed to larvae of commercially important bivalves is currently unknown. We exposed Pacific oyster (Crassostrea gigas) larvae (3-24 d.p.f.) to polystyrene particles spanning 70 nm-20 μm in size, including plastics with differing surface properties, and tested the impact of microplastics on larval feeding and growth. The frequency and magnitude of plastic ingestion over 24 h varied by larval age and size of polystyrene particle (ANOVA, $P < 0.01$), and surface properties of the plastic, with aminated particles ingested and retained more frequently (ANOVA, $P < 0.01$). A strong, significant correlation between propensity for plastic consumption and plastic load per organism was identified (Spearmans, $r = 0.95$, $P < 0.01$). Exposure to 1 and 10 μm PS for up to 8 days had no significant effect on C. gigas feeding or growth at <100 microplastics mL1. In conclusion, whil micro- and nanoplastics were readily ingested by oyster larvae, exposure to plastic concentrations exceeding those observed in the marine environment resulted in no measurable effects on the development or feeding capacity of the larvae over the duration of the study. [ABSTRACT FROM AUTHOR]

Cole, M., et al. (2015). "The Impact of Polystyrene Microplastics on Feeding, Function and Fecundity in the Marine Copepod Calanus helgolandicus." Environmental Science & Technology **49**(2): 1130-1137.

Microscopic plastic debris, termed "microplastics", are of increasing environmental concern. Recent studies have demonstrated that a range of zooplankton, including copepods, can ingest microplastics. Copepods are a globally abundant class of zooplankton that form a key trophic link between primary producers and higher trophic marine organisms. Here we demonstrate that ingestion of microplastics can significantly alter the feeding capacity of the pelagic copepod Calanus helgolandicus. Exposed to 20 μm polystyrene beads (75 microplastics mL-1) and cultured algae ([250 μg C L-1) for 24 h, C. helgolandicus ingested 11% fewer algal cells (P = 0.33) and 40% less carbon biomass (P < 0.01). There was a net downward shift in the mean size of algal prey consumed (P < 0.001), with a 3.6 fold increase in ingestion rate for the smallest size class of algal prey (11.6-12.6 μm), suggestive of postcapture or postingestion rejection. Prolonged exposure to polystyrene microplastics significantly decreased reproductive output, but there were no significant differences in egg production rates, respiration or survival. We constructed a conceptual energetic (carbon) budget showing that microplastic-exposed copepods suffer energetic depletion over time. We conclude that microplastics impede feeding in copepods, which over time could lead to sustained reductions in ingested carbon biomass. [ABSTRACT FROM AUTHOR]

Cole, M., et al. (2013). "Microplastic Ingestion by Zooplankton." Environmental Science & Technology **47**(12): 6646-6655.

Small plastic detritus, termed "microplastics", are a widespread and ubiquitous contaminant of marine ecosystems across the globe. Ingestion of microplastics by marine biota, including mussels, worms, fish, and seabirds, has been widely reported, but despite their vital ecological role in marine food-webs, the impact of microplastics on zooplankton remains under-researched. Here, we show that microplastics are ingested by, and may impact upon, zooplankton. We used bioimaging techniques to document ingestion, egestion, and adherence of microplastics in a range of zooplankton common to the northeast Atlantic, and employed feeding rate studies to determine the impact of plastic detritus on algal ingestion rates in copepods. Using fluorescence and coherent anti-Stokes Raman scattering (CARS) microscopy we identified that thirteen zooplankton taxa had the capacity to ingest 1.7-30.6 μm polystyrene beads, with uptake varying by taxa, life-stage and bead-size. Post-ingestion, copepods egested faecal pellets laden with microplastics. We further observed microplastics adhered to the external carapace and appendages of exposed zooplankton. Exposure of the copepod Centropages typicus to natural assemblages of algae with and without microplastics showed that 7.3 μm microplastics (>4000 mL-1) significantly decreased algal feeding. Our findings imply that marine microplastic debris can negatively impact upon zooplankton function and health. [ABSTRACT FROM AUTHOR]

Cole, M., et al. (2011). "Microplastics as contaminants in the marine environment: A review." Marine Pollution Bulletin **62**(12): 2588-2597.

Since the mass production of plastics began in the 1940s, microplastic contamination of the marine environment has been a growing problem. Here, a review of the literature has been conducted with the following objectives: (1) to summarise the properties, nomenclature and sources of microplastics; (2) to discuss the routes by which microplastics enter the marine environment; (3) to evaluate the methods by which microplastics are detected in the marine environment; (4) to assess spatial and temporal trends of microplastic abundance; and (5) to discuss the environmental impact of microplastics. Microplastics are both abundant and widespread within the marine environment, found in their highest concentrations along coastlines and within mid-ocean gyres. Ingestion of microplastics has been demonstrated in a range of marine organisms, a process which may facilitate the transfer of chemical additives or hydrophobic waterborne pollutants to biota. We conclude by highlighting key future research areas for scientists and policymakers. © 2011 Elsevier Ltd.

Cole, M., et al. (2016). "Microplastics Alter the Properties and Sinking Rates of Zooplankton Faecal Pellets." Environmental Science & Technology **50**(6): 3239-3246.

Plastic debris is a widespread contaminant, prevalent in aquatic ecosystems across the globe. Zooplankton readily ingest microscopic plastic (microplastic, < 1 mm), which are later egested within their faecal pellets. These pellets are a source of food for marine organisms, and contribute to the oceanic vertical flux of particulate organic matter as part of the biological pump. The effects of microplastics on faecal pellet properties are currendy unknown. Here we test the hypotheses that (l) faecal pellets are a vector for transport of microplastics, (2) polystyrene microplastics can alter the properties and sinking rates of zooplankton egests and, (3) faecal pellets can facilitate the transfer of plastics to coprophagous biota. Following exposure to 20.6 µm polystyrene microplastics (1000 microplastics mL-1) and natural prey (~1650 algae mL-1) the copepod Calanus helgolandkxis egested faecal pellets with significantly (P < 0.001) reduced densities, a 2.25-fold reduction in sinking rates, and a higher propensity for fragmentation. We further show that microplastics, encapsulated within egests of the copepod Centropages typicas, could be transferred to C. helgolandicus via coprophagy. Our results support the proposal that sinking faecal matter represents a mechanism by which floating plastics can be vertically transported away from surface waters. [ABSTRACT FROM AUTHOR]

Cole, M., et al. (2014). "Isolation of microplastics in biota-rich seawater samples and marine organisms." Scientific Reports **4**(1).

Microplastic litter is a pervasive pollutant present in aquatic systems across the globe. A range of marine organisms have the capacity to ingest microplastics, resulting in adverse health effects. Developing methods to accurately quantify microplastics in productive marine waters, and those internalized by marine organisms, is of growing importance. Here we investigate the efficacy of using acid, alkaline and enzymatic digestion techniques in mineralizing biological material from marine surface trawls to reveal any microplastics present. Our optimized enzymatic protocol can digest >97% (by weight) of the material present in plankton-rich seawater samples without destroying any microplastic debris present. In applying the method to replicate marine samples from the western English Channel, we identified 0.27 microplastics m⁻³. The protocol was further used to extract microplastics ingested by marine zooplankton under laboratory conditions. Our findings illustrate that enzymatic digestion can aid the detection of microplastic debris within seawater samples and marine biota.

Colic, M., et al. (2010). "Production of IL-10 and IL-12 by antigen-presenting cells in periapical lesions." Journal of Oral Pathology and Medicine **39**(9): 690-696.

Background: Interferon-gamma (IFN-gamma) plays an important role in the pathogenesis of periapical lesions. Its expression is up-regulated by interleukin (IL)-12) and down-regulated by IL-10. The aim of this work was to study the cellular source of these cytokines and their mutual interactions in human periapical lesions. Method(s): Mononuclear cells, macrophages and dendritic cells were isolated from periapical lesions using plastic adherence and osmotic gradients. Cytokines were measured in culture supernatants by a microbeads fluorescence assay. Phenotypic characteristics of cells were studied by immunocytochemistry, whereas allostimulatory activity of antigen-presenting cells was tested using a mixed leukocyte reaction. Result(s): We observed the positive correlations between the levels of IL-12 and IFN-gamma as well as IL-12 and IL-10 in cultures of mononuclear cells. As IL-10 and IL-12 are produced by dendritic cells and activated macrophages, we examined their contribution to the production of these cytokines. Macrophages, CD14⁺ adherent cells, produced high levels of IL-10 and very low levels of IL-12. In contrast, non-adherent, strongly HLA-DR⁺ dendritic cells, potent stimulators of the alloreactive T-cell response, produced low levels of IL-10 and moderate levels of IL-12. Dendritic cells stimulated the production of IFN-gamma by allogeneic CD4⁺ T cells. In contrast, the level of IFN-gamma was significantly decreased and the production of IL-10 was enhanced by addition of macrophages to the culture system. Conclusion(s): Our results suggest that a fine balance between the production of IL-10 and IL-12 by different antigen-presenting cells, through IFN-gamma, may control the course of chronic inflammation in periapical lesions. © 2010 The Authors. Collard, F., et al. (2019). "Plastic Particle Ingestion by Wild Freshwater Fish: A Critical Review." Environmental Science & Technology **53**(22): 12974.

Plastic pollution, especially microplastics (MP) pollution, is a hot topic in both mainstream media and scientific literature. Although rivers are potentially the major transport pathway of this pollution to the sea, plastic contamination in freshwater bodies is comparatively understudied. Microplastic pollution in freshwater fish is of growing interest, and while few studies exist, discrepancies do occur in the sampling, extraction, and identification of MP and in the expression of the results. Even though those differences hamper comparisons between some studies, a comparative work has been performed to identify the factors influencing MP ingestion by fish and consequently to target potential ecological traits that can be used to monitor species. Monitoring plastic ingested by fish will give relevant ecological information on MP pollution. This review focuses on MP ingestion by wild freshwater and estuarine fish. In addition to providing an overview of the existing data concerning contamination levels in wild freshwater

fish, we aimed to (1) propose several overall recommendations on the methodologies applicable to all biota, (2) compare MP contamination levels in fish and in their environment, and (3) determine which parameters could help to define fish species for monitoring.

Collard, F., et al. (2018). "Anthropogenic particles in the stomach contents and liver of the freshwater fish Squalius cephalus." Science of the Total Environment **643**: 1257-1264.

Anthropogenic particles (APs) are a very broad category of particles produced directly or indirectly by human activities. Their ingestion by biota is well studied in the marine environment. In contrast, studies on AP ingestion in wild freshwater organisms are scarce despite high contamination levels in some rivers and lakes. In this study, we aimed to evaluate the ingestion of APs and the possible occurrence of APs in the liver and muscle of a freshwater fish, Squalius cephalus, from the Parisian conurbation. After isolation, the particles were analyzed using Raman spectroscopy. In sixty stomachs, eighteen APs were found, half of which were plastics and the other half were dyed particles. Twenty-five percent of sampled individuals had ingested at least one AP. The mean length of the APs was 2.41 mm. No significant difference was found between the sites upstream and downstream of Paris. Additionally, 5% of sampled livers contained one or more APs, which were characterized as microplastics (MPs). No APs were found in the muscle tissue. The majority of APs isolated from stomach contents were fibers, which is similar to the findings of a previous river contamination study. This highlights that fish could be more exposed to fibers than previously thought and that more studies on the impacts of fiber ingestion are required. Despite their low occurrence, MPs are reported, for the first time, in the liver of a wild freshwater fish species. While the pathways and impacts are still unknown, MPs also occur in liver of marine mollusks and fish. Physiological in vitro studies are needed to better evaluate the impacts of such phenomena.

Collard, F., et al. (2017). "Microplastics in livers of European anchovies (Engraulis encrasicolus, L.)." Environmental Pollution **229**: 1000-1005.

Microplastics (MPs) are thought to be ingested by a wide range of marine organisms before being excreted. However, several studies in marine organisms from different taxa have shown that MPs and nanoplastics could be translocated in other organs. In this study, we investigated the presence of MPs in the livers of commercial zooplanktivorous fishes collected in the field. The study focuses mainly on the European anchovy Engraulis encrasicolus but concerns also the European pilchard Sardina pilchardus and the Atlantic herring Clupea harengus. Two complementary methodologies were used to attest the occurrence of MPs in the hepatic tissue and to exclude contamination. (1) MPs were isolated by degradation of the hepatic tissue. (2) Cryosections were made on the livers and observed in polarized light microscopy. Both methods separately revealed that MPs, mainly polyethylene (PE), were translocated into the livers of the three clupeid species. In anchovy, 80 per cent of livers contained relatively large MPs that ranged from 124 micro m to 438 micro m, showing a high level of contamination. Two translocation pathways are hypothesized: (i) large particles found in the liver resulted from the agglomeration of smaller pieces, and/or (ii) they simply pass through the intestinal barrier. Further studies are however required to understand the exact process.

Collard, F., et al. (2015). "Detection of Anthropogenic Particles in Fish Stomachs: An Isolation Method Adapted to Identification by Raman Spectroscopy." Archives of Environmental Contamination & Toxicology **69**(3): 331-339.

Microplastic particles (MP) contaminate oceans and affect marine organisms in several ways. Ingestion combined with food intake is generally reported. However, data interpretation often is

circumvented by the difficulty to separate MP from bulk samples. Visual examination often is used as one or the only step to sort these particles. However, color, size, and shape are insufficient and often unreliable criteria. We present an extraction method based on hypochlorite digestion and isolation of MP from the membrane by sonication. The protocol is especially well adapted to a subsequent analysis by Raman spectroscopy. The method avoids fluorescence problems, allowing better identification of anthropogenic particles (AP) from stomach contents of fish by Raman spectroscopy. It was developed with commercial samples of microplastics and cotton along with stomach contents from three different Clupeiformes fishes: Clupea harengus, Sardina pilchardus, and Engraulis encrasicolus. The optimized digestion and isolation protocol showed no visible impact on microplastics and cotton particles while the Raman spectroscopic spectrum allowed the precise identification of microplastics and textile fibers. Thirty-five particles were isolated from nine fish stomach contents. Raman analysis has confirmed 11 microplastics and 13 fibers mainly made of cellulose or lignin. Some particles were not completely identified but contained artificial dyes. The novel approach developed in this manuscript should help to assess the presence, quantity, and composition of AP in planktivorous fish stomachs. [ABSTRACT FROM AUTHOR]

Collard, F., et al. (2017). "Morphology of the filtration apparatus of three planktivorous fishes and relation with ingested anthropogenic particles." Marine Pollution Bulletin **116**(1/2): 182-191.

Anthropogenic particles (APs), including microplastics, are ingested by a wide variety of marine organisms. Exposure of Clupeiformes (e.g. herrings, anchovies, sardines) is poorly studied despite their economic and ecological importance. This study aims to describe the morphology of the filtration apparatus of three wild-caught Clupeiformes (Sardina pilchardus, Clupea harengus and Engraulis encrasicolus) and to relate the results to ingested APs. Consequently, the species with the more efficient filtration apparatus will be more likely to ingest APs. We hypothesized that sardines were the most exposed species. The filtration area and particle retention threshold were determined in the three species, with sardines displaying the highest filtration area and the closest gill rakers. Sardines ingested more fibers and smaller fragments, confirming that it is the most efficient filtering species. These two results lead to the conclusion that, among the three studied, the sardine is the species most exposed to APs.

Collicutt, B., et al. (2019). "Microplastics in juvenile Chinook salmon and their nearshore environments on the east coast of Vancouver Island." Environmental Pollution **244**: 135-142.

Microplastics are a significant issue in the world's oceans. These small plastic particles (<5 mm in size) are becoming globally ubiquitous in the marine environment and are ingested by various fish species. Here we investigate the incidence of microplastics in juvenile Chinook salmon and their nearshore marine environments on the east coast of Vancouver Island, British Columbia. We completed a series of beach seines, plankton tows and sediment cores in nearshore areas of importance to juvenile salmon. Microplastics were extracted from fish, water and sediment samples and concentrations were quantified. Microplastics analysis, consisting predominantly of fibrous plastics, showed juvenile Chinook salmon contained 1.2+or-1.4 (SD) microplastics per individual while water and sediment samples had 659.9+or-520.9 microplastics m⁻³

and 60.2+or-63.4 microplastics kg⁻¹ dry weight, respectively. We found no differences in microplastic concentrations in juvenile Chinook and water samples among sites but observed significantly higher concentrations in sediment at the Deep Bay site compared to Nanaimo and Cowichan Bay sites. Chinook microplastic concentrations were relatively low compared to literature values and, given the size and type of microplastics we observed, are unlikely to represent an immediate threat to fish in this area. However, microplastics less than 100 micro m in size were not included in the study and may represent a greater threat due to their ability to translocate through tissues.

Collignon, A., et al. (2014). "Annual variation in neustonic micro- and meso-plastic particles and zooplankton in the Bay of Calvi (Mediterranean-Corsica)." Marine Pollution Bulletin **79**(1-2): 293-298.

The annual variation in neustonic plastic particles and zooplankton was studied in the Bay of Calvi (Corsica) between 30 August 2011 and 7 August 2012. Plastic particles were classified into three size classes, small microplastics (0.2-2. mm), large microplastics (2-5. mm) and mesoplastics (5-10. mm).74% of the 38 samples contained plastic particles of varying composition: e.g. filaments, polystyrene, thin plastic films. An average concentration of 6.2particles/100m² was observed. The highest abundance values (69 particles/100m²) observed occurred during periods of low offshore wind conditions. These values rose in the same order of magnitude as in previous studies in the North Western Mediterranean.The relationships between the abundance values of the size classes between zooplankton and plastic particles were then examined. The ratio for the intermediate size class (2-5. mm) reached 2.73. This would suggest a potential confusion for predators regarding planktonic prey of this size class. © 2013 Elsevier Ltd.

Collignon, A., et al. "Neustonic microplastic and zooplankton in the North Western Mediterranean Sea." Marine Pollution Bulletin.

Neustonic microplastic and zooplankton abundance was determined in the North Western Mediterranean Sea during a summer cruise between July 9th and August 6th 2010, with a break between July 22th and 25th due to a strong wind event. Ninety percent of the 40 stations contained microplastic particles (size 0.3-5 mm) of various compositions: e.g., filaments, polystyrene, thin plastic films. An average concentration of 0.116 particles/m² was observed. The highest abundances (>0.36 particles/m²) were observed in shelf stations. The neustonic plastic particles concentrations were 5 times higher before than after the strong wind event which increased the mixing and the vertical repartition of plastic particles in the upper layers of the water column. The values rise in the same order of magnitude than in the North Pacific Gyre. The average ratio between microplastics and mesozooplankton weights was 0.5 for the whole survey and might induce a potential confusion for zooplankton feeders. © 2012 Elsevier Ltd. Collins, E., et al. (2014). "Effects of mesenchymal stem cells on human B cell proliferation." Arthritis and Rheumatology **10)**: S854.

Background/Purpose: Human mesenchymal stem cells (MSC) are progenitor cells that have immunomodulatory properties. MSCs have been used to treat a variety of autoimmune diseases, including lupus. However, literatures have reported conflicting results of MSC function in regards to B cell biological behaviors. We tested the ability of MSCs from umbilical cords, and MSCs from healthy and lupus bone marrow in modulating the B cell functions of healthy and lupus patients. Method(s): Human MSCs were isolated from umbilical cords (UC), healthy bone marrow (HBM), and lupus patient bone marrow (LBM). Passages between 4 and 7 were used for these assays. B cells were isolated from peripheral blood of healthy and lupus donors using CD19 micro-beads, then labeled with CFSE for detection of proliferation. B cells were plated at 5x10⁴ per well in 96-well plates, with or without pre-plated MSCs, at the same number, within 24 hours. The cells were incubated at 37degreeC and 5% CO<inf>2</inf> for 96 hours +/- stimulation (CpG, CD40L, IL2, and anti-human IgG/IgA/ IgG). B cells were then collected and analyzed for proliferation by flow cytometry. Supernatants were collected for detection of antibodies and cytokines via ELISA. Result(s): When co-cultured, UC-MSC and HBM-MSC inhibited healthy B cell proliferation better than LBM-MSC. However, only UC-MSC appeared to reduce the proliferation of lupus patient B cells. Regardless of proliferation, healthy B cells cultured in the presences of MSCs experienced increased IgM and IgG production. Supernatants of healthy B cells cocultured with MSCs also presented increased the levels of IL-6 while having decreased amounts TNF-alpha when compared to the supernatants of wells with B cells alone. Conclusion(s): In our experiments, MSCs obtained from umbilical cords exhibited strong activity in suppressing both healthy and lupus B cell proliferation while MSCs from healthy bone marrow suppressed healthy, but not lupus B cell proliferation. Lupus patient derived MSCs were unable to significantly suppress B cell proliferation from healthy or lupus patients. Furthermore, MSCs from all sources did not inhibit healthy B cell IgG or IgM secretion. These studies aim to improve our understanding of the in vitro effects of MSCs on B cell function in order to predict in vivo efficacy of MSCs to be used in the treatment of SLE.

Colomer, J., et al. (2019). "Mediated food and hydrodynamics on the ingestion of microplastics by Daphnia magna." Environmental Pollution **251**: 434-441.

There is consensus on the need to study the potential impact microplastics (MP) have on freshwater planktonic organisms. It is not yet fully understood how MP enter the aquatic food web or the effect they have on all the trophic levels. As a result of the potential for MP to accumulate throughout food webs, there is increasing interest in evaluating their fate in a variety of environmental conditions. This study investigated the variability in the ingestion of MP to food ratios and the exposed time of MP to Daphnia magna in non-sheared and sheared conditions. The sheared environment provided Daphnia magna with the conditions for optimal filtering capacity. Regardless of the ratios of MP concentration to food concentration (MP:Food), the filtration capacity of the Daphnia magna was enhanced in the sheared experiments. In both the sheared and non-sheared experiments, filtration capacity decreased when the ratios of MP to food concentration and the exposure times to MP were increased. Mortality was mainly enhanced in the non-sheared conditions at higher MP concentrations and exposure times to MP. No mortality was found in the sheared conditions for the exposure times studied. Therefore, in aquatic systems that undergo constant low sheared conditions, Daphnia magna can survive longer when exposed to MP than in calm conditions, provided food concentrations do not limit their capacity to filter.

Colton Jr, J. B., et al. (1974). "Plastic particles in surface waters of the Northwestern Atlantic." Science **185**(4150): 491-497.

The occurrence of plastic particles has recently been reported in the Sargasso Sea and in coastal waters of southern New England. These reports were based on a small number of samples within limited geographic areas, but the observers suggested that plastics might be more widely distributed. In this study the authors confirm, after examination of neuston (surface) net samples taken in July and August 1972, that plastic particles do occur over a wide area of the North Atlantic. These samples were collected on the first multiship MARMAP ichthyo plankton survey of coastal and oceanic waters from Cape Cod to the North Caribbean. Three National

Oceanic and Atmospheric Administration vessels participated in the survey. The type and characteristics of the plastic particles were as follows: white opaque polystyrene spherules; translucent to clear polystyrene spherules containing gaseous voids; opaque to translucent polyethylene cylinders or disks; pieces of Styrofoam; sheets of thin, flexible wrapping material; and pieces of hard and soft, clear and opaque plastics of various thicknesses which appear to be parts of plastic containers, toys, and so forth. It is concluded that the widespread distribution of polystyrene spherules and polyethylene disks in rivers, estuaries, and the open ocean suggests that improper waste water disposal is common practice in the plastics industry. Strong federal, state, and municipal pollution control and monitory programs are necessary to prevent the emission of plastic beads into the waste water systems of plastic producing and plastic processing plants.

Comăniță, E.-D., et al. (2016). "OCCURRENCE OF PLASTIC WASTE IN THE ENVIRONMENT: ECOLOGICAL AND HEALTH RISKS." Environmental Engineering & Management Journal (EEMJ) **15**(3): 675-685.

Environmental threats posed in the environment by plastic production and plastic wastes continue to be a major problem today, closely connected with the increase of plastics consumption by the population. Moreover, little efforts are involved in some parts of the world associated to plastic waste collection, recycling and reuse. Considering all these prerequisites, the identification and discussion of risks generated by plastic production and waste in the environment are performed in this paper and some measures for plastic waste reduction were proposed. Although plastic polymers are not considered toxic, some residual monomers contained in the materials can be hazardous. Also, many chemical compounds used in the plastics manufacturing as additives, in particular plasticizers are dangerous to human health and the environment, along with some degradation products that may be released during the plastic life cycle. Bearing in mind the potential impacts and risks generated by these products in the environment and for humans, the paper highlights that the current requirements and tendencies are to reduce the need for plastic, the enhancement of recycling and recovering the waste, simultaneously with the replacement of plastic from fossil fuel with a continuous widening spectrum of biodegradable polymers. Bioplastics began to be recognized as a positive and important invention of chemical and plastics industry, providing many and varied opportunities for environmental impacts and risks abatement. Comella, K., et al. (2001). "Effects of antibody concentration on the separation of human natural killer cells in a commercial immunomagnetic separation system." Cytometry **45**(4): 285-293.

BACKGROUND: The magnetic separation of a cell population based on cell surface markers is a critical step in many biological and clinical laboratories. In this study, the effect of antibody concentration on the separation of human natural killer cells in a commercial, immunomagnetic cell separation system was investigated.

METHODS: Specifically, the degree of saturation of antibody binding sites using a two-step antibody sandwich was quantified. The quantification of the first step, a primary anti-CD56-PE antibody, was achieved through fluorescence intensity measurements using a flow cytometer. The quantification of the second step, an anti-PE-microbeads antibody reagent, was achieved

through magnetophoretic mobility measurements using cell tracking velocimetry.

RESULTS: From the results of these studies, two different labeling protocols were used to separate CD56+ cells from human, peripheral blood by a Miltenyi Biotech MiniMACS cell separation system. The first of these two labeling protocols was based on company recommendations, whereas the second was based on the results of the saturation studies. The results from these studies demonstrate that the magnetophoretic mobility is a function of both primary and secondary antibody concentrations and that mobility does have an effect on the performance of the separation system.

CONCLUSIONS: As the mobility increased due to an increase in bound antibodies, the positive cells were almost completely eliminated from the negative eluent. However, with an increase in bound antibodies, and thus mobility, the total amount of positive cells recovered decreases. It is speculated that these cells are irreversibly retained in the column. These results demonstrate the complexity of immunomagnetic cell separation and the need to further optimize the cell separation process.

Comini, M., et al. (2016). "Evaluation of chimerism in the CD34+ sorted cells with the STR-PCR method." Bone Marrow Transplantation **1)**: S445.

Introduction: Analysis of donor chimerism is an important diagnostic tool to assess the risk of relapse after Hematopoietic Stem Cell Transplantation (HSCT), especially in patients lacking a specific marker suitable for monitoring of minimal residual disease. We investigated the predictive role of donor chimerism analysis in sorted CD34+ bone marrow (BM) cells patients (pts) with hematological disease. Material (or patients) and methods: We analyzed 25 pts affected by ALL (n = 8), CML (n = 1), AML (n = 14), MDS (n=1) and Myelofibrosis (n = 1). Fresh mononuclear cells (MNC) were isolated from anticoagulated BM using Ficoll-Paque density gradient centrifugation. CD34+ cells were selected using a CD34 MicroBeads Kit and the AutoMACS automated selection device (MiltenyiBiotec, Bergisch Galdbach, Germany) according to the manufacturer's instructions. STR amplifcation: PCR was performed using the AmpFlSTR Profiler Plus Kit Amplification as recommended by the manufacture. Result(s): We sorted CD34+ cells from BM and we performed STR-PCR in order to detect host cells in all fractions. Sorted CD34+ cells STR analysis showed a complete donor chimerism (CC) in 17 pts: 7 ALL, 7 AML, 1 CML, 1 MDS and 1 Myelofibrosis, while the CD34+ fraction from 1 ALL and 7 AML showed a mixed donor chimerism (MC). In samples with MC <90% of donor there is correlation with molecular MRD (Table 1). In pt 4 the analysis of CD34+ sorted cells showed MC (98,49% of donor) corresponding with the presence of a complex karyotype clone, with no molecular evidences and after chemotherapy treatment we observed a conversion from MC to CC. Instead pt 5 showed a spontaneous conversion from MC to CC. Conclusion(s): The STR-PCR based on CD34+ cells sorted could be used as an useful diagnostic tool, providing to clinicians additional informations, specially when MRD is not available in patients who lack specific molecular markers. This method could be an accurate alternative approach in the evaluation of chimerism, suggesting the possible persistence of disease: in fact our preliminary data indicate that decrease of CD34+ chimerism of less than 90% is a strong evidence of relapse. (Table presented).

Commendatore, C. ISRI Focuses on Safety, Design for Recycling at 2019 Convention.

The article focuses on the Institute of Scrap Recycling Industries' (ISRI) 2019 Convention & Exposition held in Los Angeles, California on April 11, 2019. It refers to a presentation by by ISRI Chairman Brian Shineon ISRI's Design for Recycling Award to Nestle Waters North America and Circle of Safety Excellence (COSE) initiative.

Commendatore, C. (2019). "Study Links Consumer Choice Modification to Plastic Straw Reduction." Waste360: N.PAG-N.PAG.

The article discusses the study "Assessing the Use of Default Choice Modification to Reduce Consumption of Plastic Straws" in San Luis Obispo, California by co-author Travis Wagner of University of Southern Maine to address plastic marine debris. Topics mentioned include the focus of the study on the city's ordinance plastic straw upon request only, survey of restaurants covered by the ordinance, and the reduction in straw consumption following the ordinance.

Comnea-Stancu, I. R., et al. (2017). "On the Identification of Rayon/Viscose as a Major Fraction of Microplastics in the Marine Environment: Discrimination between Natural and Manmade Cellulosic Fibers Using Fourier Transform Infrared Spectroscopy." Applied Spectroscopy **71**(5): 939-950.

This work was sparked by the reported identification of man-made cellulosic fibers (rayon/viscose) in the marine environment as a major fraction of plastic litter by Fourier transform infrared (FT-IR) transmission spectroscopy and library search. To assess the plausibility of such findings, both natural and man-made fibers were examined using FT-IR spectroscopy. Spectra acquired by transmission microscopy, attenuated total reflection (ATR) microscopy, and ATR spectroscopy were compared. Library search was employed and results show significant differences in the identification rate depending on the acquisition method of the spectra. Careful selection of search parameters and the choice of spectra acquisition method were found to be essential for optimization of the library search results. When using transmission spectra of fibers and ATR libraries it was not possible to differentiate between man-made and natural fibers. Successful differentiation of natural and man-made cellulosic fibers has been achieved for FT-IR spectra acquired by ATR microscopy and ATR spectroscopy, and application of ATR libraries. As an alternative, chemometric methods such as unsupervised hierarchical cluster analysis, principal component analysis, and partial least squares-discriminant analysis were employed to facilitate identification based on intrinsic relationships of sample spectra and successful discrimination of the fiber type could be achieved. Differences in the ATR spectra depending on the internal reflection element (Ge versus diamond) were observed as expected; however, these did not impair correct classification by chemometric analysis. Moreover, the effects of different levels of humidity on the IR spectra of natural and man-made fibers were investigated, too. It has been found that drying and re-humidification leads to intensity changes of absorption bands of the carbohydrate backbone, but does not impair the identification of the fiber type by library search or cluster analysis.

Compa, M., et al. (2019). "Risk assessment of plastic pollution on marine diversity in the Mediterranean Sea." Science of the Total Environment **678**: 188-196.

Plastic marine pollution is an increasing threat to global marine diversity. Quantifying this threat is particularly difficult and complex, especially when evaluating multiple species with different ecological requirements. Here, we examine the semi-enclosed basin of the Mediterranean Sea where the inputs of plastic pollution and its impact on marine diversity are still widely unknown. Eighty-four species from six taxonomic classes were evaluated to assess the risk of ingesting plastic marine debris, integrating inter-specific factors such as plastic exposure rates and life history traits (e.g., motility, habitat, and body size). Species were modelled within a spatial context to identify and estimate their exposure to plastic ingestion across the Mediterranean Sea using literature data, species distribution maps and plastic dispersion models. Our approach identified hotspots for the risk of plastic ingestion across multiple taxa in the Mediterranean Sea, highlighting that coastal species are at higher risk of ingesting plastic in the marine environment than open-sea species. The plastic exposure analysis indicated that species with larger home ranges were more at risk of exposure with increased distances while local species were more likely to be exposed to plastic closer to the centre of their home range location. The approach used in this study can be applied to support management and mitigation efforts throughout the Mediterranean Sea and in other geographic regions to minimize the impact of plastic pollution on marine diversity. Copyright © 2019 Elsevier B.V.

Compa, M., et al. (2018). "Ingestion of microplastics and natural fibres in Sardina pilchardus (Walbaum, 1792) and Engraulis encrasicolus (Linnaeus, 1758) along the Spanish Mediterranean coast." Marine Pollution Bulletin **128**: 89-96.

The ingestion of microplastics and natural fibres (<5 mm) was assessed for two commercial fish species in the western Mediterranean Sea: Sardina pilchardus and Engraulis encrasicolus. Gastrointestinal tracts from 210 individuals from 14 stations were examined with 14.28-15.24% of the small pelagic fish S. pilchardus and E. encrasicolus having ingested microplastics and natural fibres. A latitudinal increase in condition index (Fulton's K) of S. pilchardus gave an indication that larger individuals with better physical condition are less likely to ingest microplastics and natural fibres. Fibres were the most frequent particle type (83%) and Fourier Transform Infrared spectroscopy (FT-IR) analysis indicated polyethylene terephthalate was the most common microplastics material (30%). Results from this study show that both microplastics and natural fibres of anthropogenic origin are common throughout the pelagic environment along the Spanish Mediterranean coast.

Comte, J., et al. (2006). "Microbial Community Structure and Dynamics in the Largest Natural French Lake (Lake Bourget)." Microbial Ecology **52**(1): 72-89.

We investigated the dynamics and diversity of heterotrophic bacteria, autotrophic and heterotrophic flagellates, and ciliates from March to July 2002 in the surface waters (0-50 m) of Lake Bourget. The heterotrophic bacteria consisted mainly of "small" cocci, but filaments (>2 µm), commonly considered to be grazing-resistant forms under increased nanoflagellate grazing, were also detected. These elongated cells mainly belonged to the Cytophaga-Flavobacterium (CF) cluster, and were most abundant during spring and early summer, when mixotrophic or heterotrophic flagellates were the main bacterial predators. The CF group strongly dominated fluorescent in situ hybridization-detected cells from March to June, whereas clear changes were observed in early summer when Beta-proteobacteria and Alpha-proteobacteria increased concomitantly with maximal protist grazing pressures. The analysis of protist community structure revealed that the flagellates consisted mainly of cryptomonad forms. The dynamics of Cryptomonas sp. and Dinobryon sp. suggested the potential importance of mixotrophs as consumers of bacteria. This point was verified by an experimental approach based on fluorescent microbeads to assess the potential grazing impact of all protist taxa in the epilimnion. From the results, three distinct periods in the functioning of the epilimnetic microbial loop were identified. In early spring, mixotrophic and heterotrophic flagellates constituted the main bacterivores, and were regulated by the availability of their resources mainly during April (phase 1). Once the "clear water phase" was established, the predation pressure of metazooplankton represented a strong top-down force on all microbial compartments. During this period only mixotrophic flagellates occasionally exerted a significant bacterivory pressure (phase 2). Finally, the early summer was characterized by the highest protozoan grazing impact and by a rapid shift in the carbon pathway transfer, with a fast change-over of the main predators contribution, i.e., mixotrophic, heterotrophic flagellates and ciliates in bacterial mortality. The high abundance of ciliates during this period was consistent with the high densities of resources (heterotrophic nanoflagellates, algae, bacteria) in deep layers containing the most chlorophyll. Bacteria, as ciliates, responded clearly to increasing phytoplankton abundance, and although bacterial grazing impact could vary largely, bacterial abundance seemed to be primarily bottom-up regulated (phase 3).[PUBLICATION ABSTRACT]

Cong, Y., et al. (2019). "Ingestion, egestion and post-exposure effects of polystyrene microspheres on marine medaka (Oryzias melastigma)." Chemosphere **228**: 93-100.

Microplastics (MPs) are of environmental concern due to their bioavailability and potential impacts on a wide range of marine biota. In this study, we investigated the ingestion, bioaccumulation and egestion of fluorescent polystyrene (PS) micospheres (10 micro m) in both larvae and adults of marine medaka (Oryzias melastigma), with or without food supply. The post-exposure effects of non-fluorescent PS (10 micro m) on the survival, growth and reproduction of medaka larvae were also explored. Results showed that the PS microspheres could be ingested by both larvae and adults during the 48 h-exposure. Notably, feeding status was found to significantly affect the ingestion in medaka adults, which was not observed in the larvae. The egestion process of PS was rapid during the first recovery day but there was still certain percent of particles retained in digestive tracts at the end of 7 d recovery for either larvae or adults. After a 14 d pre-exposure with the non-fluorescent PS microspheres, the subsequent survival, growth and reproduction of medaka larvae were all significantly affected at the end of 120 d of experiment without PS. Overall, these results indicate that fishes might ingest or retain more MPs if the environmental abundance of MPs continues to increase while the available food decreases. Medaka fishes in larval stage have no capacity to select natural food sources like the adults. The chronic and "legacy effect" of MPs might also be a problem worthy paid more attention in future research instead of acute and immediate effect studies.

Cong, Y., et al. (2019). "Ingestion, egestion and toxic effects of fluorescent polystyrene microspheres on the Polychaete, Perinereis aibuhitensis." Haiyang Huanjing Kexue = Marine Environmental Science(2): 161.

Marine microplastic(MP) pollution has become a global concern. It was reported that the content of MPs in intertidal zone was relatively high. However,relatively few studies have been conducted on the effects of MPs on organisms inhabiting intertidal zones. In this study,we investigated the ingestion,bioaccumulation and egestion processes of fluorescent polystyrene microspheres(PS,10 μm) in sediment-dwelling organism,Perinereis aibuhitensis,through seawater exposure pathway. The impacts of PS on the burrowing behavior and subcellular structure alteration of worms were also explored after a 14 d of sediment exposure. Results showed that the ingested PS microspheres in worms increased with time within 48 h,and the retained PS percentage decreased after transferring to clean seawater,which reached to only 2. 2 % after depuration of 96 h. However,the burrowing time of worms in clean sediment was significantly prolonged after 14 d of sediment exposure,and epithelia apoptosis of worm body wall and mitochondria edema of worm myocytes were observed. The impairment of worm burrowing behavior was possibly related to the dysfunction of mitochondria. This study emphasized the sensitivity of behavior indicator when assessing the toxicity of MPs on sediment-dwelling organisms. Findings are expected to provide a basis for exploration of mechanisms of MPs and their ecological risk assessment.

Conkle, J. L., et al. (2018). "Are We Underestimating Microplastic Contamination in Aquatic Environments?" Environmental Management **61**(1): 1-8.

Plastic debris, specifically microplastic in the aquatic environment, is an escalating environmental crisis. Efforts at national scales to reduce or ban microplastics in personal care products are starting to pay off, but this will not affect those materials already in the environment or those that result from unregulated products and materials. To better inform future microplastic research and mitigation efforts this study (1) evaluates methods currently used to quantify microplastics in the environment and (2) characterizes the concentration and size distribution of microplastics in a variety of products. In this study, 50 published aquatic surveys were reviewed and they demonstrated that most (~80%) only account for plastics >= 300 mum in diameter. In addition, we surveyed 770 personal care products to determine the occurrence, concentration and size distribution of polyethylene microbeads. Particle concentrations ranged from 1.9 to 71.9 mg g⁻¹ of product or 1649 to 31,266 particles g⁻¹ of product. The large majority (> 95%) of particles in products surveyed were less than the 300 mum minimum diameter, indicating that previous environmental surveys could be underestimating microplastic contamination. To account for smaller particles as well as microfibers from synthetic textiles, we strongly recommend that future surveys consider methods that materials < 300 mum in diameter.

Conley, K. R. and K. R. Sutherland (2017). "Particle shape impacts export and fate in the ocean through interactions with the globally abundant appendicularian Oikopleura dioica." PLoS ONE **12**(8).

Marine microbes exhibit highly varied, often non-spherical shapes that have functional significance for essential processes, including nutrient acquisition and sinking rates. There is a surprising absence of data, however, on how cell shape affects grazing, which is crucial for predicting the fate of oceanic carbon. We used synthetic spherical and prolate spheroid microbeads to isolate the effect of particle length-to-width ratios on grazing and fate in the ocean. Here we show that the shape of microbe-sized particles affects predation by the appendicularian Oikopleura dioica, a globally abundant marine grazer. Using incubation experiments, we demonstrate that shape affects how particles are retained in the house and that the minimum particle diameter is the key variable determining how particles are ingested. High-speed videography revealed the mechanism behind these results: microbe-sized spheroids oriented with the long axis parallel to fluid streamlines, matching the speed and tortuosity of spheres of equivalent width. Our results suggest that the minimum particle diameter determines how elongated prey interact with the feeding-filters of appendicularians, which may help to explain the prevalence of ellipsoidal cells in the ocean, since a cell’s increased surface-to-volume ratio does not always increase predation. We provide the first evidence that grazing by appendicularians can cause non-uniform export of different shaped particles, thereby influencing particle fate.

Connor, T. H. and J. P. Smith (2016). "New approaches to wipe sampling methods for antineoplastic and other hazardous drugs in healthcare settings." Pharmaceutical Technology in Hospital Pharmacy **1**(3): 107-114.

PURPOSE: At the present time, the method of choice to determine surface contamination of the workplace with antineoplastic and other hazardous drugs is surface wipe sampling and subsequent sample analysis with a variety of analytical techniques. The purpose of this article is to review current methodology for determining the level of surface contamination with hazardous drugs in healthcare settings and to discuss recent advances in this area. In addition it will provide some guidance for conducting surface wipe sampling and sample analysis for these

drugs in healthcare settings.

METHODS: Published studies on the use of wipe sampling to measure hazardous drugs on surfaces in healthcare settings drugs were reviewed. These studies include the use of well-documented chromatographic techniques for sample analysis in addition to newly evolving technology that provides rapid analysis of specific antineoplastic.

RESULTS: Methodology for the analysis of surface wipe samples for hazardous drugs are reviewed, including the purposes, technical factors, sampling strategy, materials required, and limitations. The use of lateral flow immunoassay (LFIA) and fluorescence covalent microbead immunosorbent assay (FCMIA) for surface wipe sample evaluation is also discussed.

CONCLUSIONS: Current recommendations are that all healthcare settings where antineoplastic and other hazardous drugs are handled include surface wipe sampling as part of a comprehensive hazardous drug-safe handling program. Surface wipe sampling may be used as a method to characterize potential occupational dermal exposure risk and to evaluate the effectiveness of implemented controls and the overall safety program. New technology, although currently limited in scope, may make wipe sampling for hazardous drugs more routine, less costly, and provide a shorter response time than classical analytical techniques now in use.

Connors, E. J. (2017). "Distribution and biological implications of plastic pollution on the fringing reef of Mo'orea, French Polynesia." PeerJ **5**: e3733.

Coral reef ecosystems of the South Pacific are extremely vulnerable to plastic pollution from oceanic gyres and land-based sources. To describe the extent and impact of plastic pollution, the distribution of both macro- (>5 mm) and microplastic (plastic < 5 mm) of the fringing reef of an isolated South Pacific island, Mo'orea, French Polynesia was quantified. Macroplastic was found on every beach on the island that was surveyed. The distribution of this plastic was categorized by site type and by the presence of Turbinaria ornata, a common macroalgae on Mo'orea. Microplastics were discovered in the water column of the fringing reef of the island, at a concentration of 0.74 pieces m⁻². Additionally, this study reports for the first time the ingestion of microplastic by the corallimorpha Discosoma nummiforme. Microplastics were made available to corallimorph polyps in a laboratory setting over the course of 108 h. Positively and negatively buoyant microplastics were ingested, and a microplastic particle that was not experimentally introduced was also discovered in the stomach cavity of one organism. This study indicates that plastic pollution has the potential to negatively impact coral reef ecosystems of the South Pacific, and warrants further study to explore the broader potential impacts of plastic pollution on coral reef ecosystems.

Connors, K. A., et al. (2017). "Advancing the quality of environmental microplastic research." Environmental Toxicology and Chemistry **36**(7): 1697-1703.

Investigations into the environmental fate and effects of microplastics have been gaining momentum. Small, insoluble polymeric particles are implicated by scientists in a wide variety of studies that are used to suggest a potential for widespread impacts in freshwater and marine pelagic and sediment environments. An exponential growth in scientific publications and an increase in regulatory attention have occurred. However, despite these efforts, the environmental hazard of these particles is still unknown. To evaluate the hazard of microplastics within a risk assessment context, we need a way to evaluate the quality of experimental studies. We performed a thorough review of the quality and focus of environmental microplastic research, to understand the methodologies employed and how this may assist or distract from the ability of environmental risk assessors to evaluate microplastics. We provide guidance to improve the reliability and relevance of ecotoxicological studies for regulatory and broader

environmental assessments. Nine areas of needed improvement are identified and discussed. Important data gaps and experimental limitations are highlighted. Environ Toxicol Chem 2017;36:1697-1703. © 2017 SETAC.

Constant, M., et al. (2019). "Beached microplastics in the Northwestern Mediterranean Sea." Marine Pollution Bulletin **142**: 263.

Microplastics are small (<5 mm) fragments of plastic debris that are ubiquitous in coastal areas and in open ocean. We have investigated the occurrence and composition of microplastics in beach sediments from the micro-tidal Northwestern Mediterranean Sea. Samples were collected on two beaches (northern and southern site) of the western Gulf of Lion showing markedly different characteristics. Sampling was performed along depositional lower, mid and upper beaches and repeated after 1 month. Concentrations of microplastics in the northern and southern site were highly variable, ranging from 33 to 798 and from 12 to 187 microplastics per kg of dry sediment, respectively. Highest concentrations were found at three specific locations: nearby a local river mouth, within an accretionary area and in a depositional upper beach. The spatial and temporal distribution of beached microplastics seems to be directly dependent on external forcing such as wind, swell, precipitation, outflow and river mouth proximity.

Constantino, P. J., et al. (2016). "Simulation of enamel wear for reconstruction of diet and feeding behavior in fossil animals: A micromechanics approach." BioEssays **38**(1): 89-99.

The deformation and wear events that underlie microwear and macrowear signals commonly used for dietary reconstruction in fossil animals can be replicated and quantified by controlled laboratory tests on extracted tooth specimens in conjunction with fundamental micromechanics analysis. Key variables governing wear relations include angularity, stiffness (modulus), and size of the contacting particle, along with material properties of enamel. Both axial and sliding contacts can result in the removal of tooth enamel. The degree of removal, characterized by a "wear coefficient," varies strongly with particle content at the occlusal interface. Conditions leading to a transition from mild to severe wear are discussed. Measurements of wear traces can provide information about contact force and particle shape. The potential utility of the micromechanics methodology as an adjunct for investigating tooth durability and reconstructing diet is explored. Microindentation and wear tests on human enamel are used to simulate microwear and macrowear patterns in fossil teeth. Characteristic "pit" and "scratch" traces associated with axial and sliding loading are quantified using micromechanics analysis. Mild and severe wear states identify with microplastic and microfracture modes, respectively. Copyright © 2015 WILEY Periodicals, Inc.

Contado, C., et al. (2007). "Sedimentation field flow fractionation of immunoglobulin A coated polystyrene beads. Influence of carrier composition on complex characterization." Journal of Chromatography. A **1169**(1-2): 158-174.

The amount of immunoglobulin A (IgA) adsorbed on the surface of two different samples of polystyrene (PS) microbeads was evaluated using differential sedimentation field flow fractionation (SdFFF) analyses. For the first time, the SdFFF separations obtained by using, as mobile phase, solutions common to many biochemical procedures and applications have been compared and discussed. Good separation results were achieved in the different carriers, and the SdFFF gave equivalent mass per particle values in all carriers provided that the pH and ionic strength conditions of the eluents were well controlled. The IgA adsorption process onto PS occurred by maintaining unaltered the capacity of the PS-IgA substrate to selectively recognize anti-IgA (aIgA), as proven by elution of the ternary complex PS-IgA-aIgA and from the monitored

lack of reaction when the PS-IgA was placed in contact with aIgE.

Contessi Negrini, N., et al. (2019). "Tissue-mimicking gelatin scaffolds by alginate sacrificial templates for adipose tissue engineering." Acta Biomaterialia **87**: 61-75.

When adipose tissue (AT) is impaired by trauma or disease, AT engineering could provide a shelf-ready structural and functional restoration as alternative to current clinical treatments, which mainly aim at aesthetic replacement. Yet, the lack of an efficient vascular network within the scaffolds represents a major limitation to their translation application in patients. Here, we propose the use of microstructured crosslinked gelatin hydrogels with an embedded prevascular channel as scaffolding materials for AT engineering. The scaffolds are fabricated using - simultaneously - alginate-based microbeads and 3D printed filaments as sacrificial material encapsulated in gelatin at the point of material fabrication and removed post-crosslinking. This method yields the formation of microstructures that resemble the micro-architecture of physiological human fat tissue and of microvessels that can facilitate vascularization through anastomosis with patients' own blood vessels. The cytocompatible method used to prepare the gelatin scaffolds showed structural stability over time while allowing for cell infiltration and protease-based remodeling/degradation. Scaffolds' mechanical properties were also designed to mimic the one of natural breast adipose tissue, a key parameter for AT regeneration. Scaffold's embedded channel (=300-400micro m) allowed for cell infiltration and enabled blood flow in vitro when an anastomosis with a rat blood artery was performed using surgical glue. In vitro tests with human mesenchymal stem cells (hMSC) showed colonization of the porous structure of the gelatin hydrogels, differentiation into adipocytes and accumulation of lipid droplets, as shown by Oil Red O staining. STATEMENT OF SIGNIFICANCE: The potential clinical use of scaffolds for adipose tissue (AT) regeneration is currently limited by an unmet simultaneous achievement of adequate structural/morphological properties together with a promoted scaffold vascularization. Sacrificial materials, currently used either to obtain a tissue-mimicking structure or hollow channels to promote scaffold' vascularization, are powerful versatile tools for the fabrication of scaffolds with desired features. However, an integrated approach by means of sacrificial templates aiming at simultaneously achieving an adequate AT-mimicking structure and hollow channels for vascularization is missing. Here, we prove the suitability of crosslinked gelatin scaffolds obtained by using sacrificial alginate microbeads and 3D printed strands to achieve proper features and hollow channels useful for scaffolds vascularization.

Conti, B., et al. (2013). "Adhesive microbeads for the targeting delivery of anticaries agents of vegetable origin." Food Chemistry **138**(2-3): 898-904.

The formulation of quinic acid, a food constituent demonstrating potential anticaries and antigingivitis properties, was investigated in an adhesive microparticulate delivery system with the goal of improving its effect by prolonging its residence time at the site of action. Alginate and chitosan were selected as mucoadhesive polymers. The microspheres were prepared by coacervation. Different types of alginates, polymers blends and crosslinking agent concentrations were considered and evaluated. The best results in terms of encapsulation efficiency, in vitro active agent release profile and in vitro adhesive properties, both to oral mucosa and to teeth surface, were obtained with a blend of Alginate Protanal LF200S: Alginate Protanal LF120LS 1:1.5 w/w, 0.1 M CaCl<inf>2</inf>, and chitosan coating, prepared by a one-step complex coacervation method. This microparticulate delivery system showed prolonged release of quinic acid, and could be used as an active component in chewing gums or mouthwashes for both caries and gingivitis prevention. © 2012 Elsevier Ltd. Cooper, J. (2019). "Tackling Packaging Waste Through Public/Private Partnerships." Food Technology **73**(9): 71.

Institute of Food Technologists (IFT) and author Dale Buss (July) are to be commended for prominently bringing the plastic waste "tsunami" issue to the attention of IFT members. A PPP board would be able to secure research funding and establish research priorities and application procedures. Engagement with a spectrum of industry, academic, consumer, regulatory, and public stakeholders could best address and balance inherent food safety, integrity, and quality requirements as well as the environmental, infrastructure, and financial considerations involved in what should be a united priority effort to discover new food packaging materials.

Coppock, R. L., et al. (2017). "A small-scale, portable method for extracting microplastics from marine sediments." Environmental Pollution **230**: 829-837.

Microplastics (plastic particles, 0.1 mum-5 mm in size) are widespread marine pollutants, accumulating in benthic sediments and shorelines the world over. To gain a clearer understanding of microplastic availability to marine life, and the risks they pose to the health of benthic communities, ecological processes and food security, it is important to obtain accurate measures of microplastic abundance in marine sediments. To date, methods for extracting microplastics from marine sediments have been disadvantaged by complexity, expense, low extraction efficiencies and incompatibility with very fine sediments. Here we present a new, portable method to separate microplastics from sediments of differing types, using the principle of density floatation. The Sediment-Microplastic Isolation (SMI) unit is a custom-built apparatus which consistently extracted microplastics from sediments in a single step, with a mean efficiency of 95.8% (+/-SE 1.6%; min 70%, max 100%). Zinc chloride, at a density of 1.5 g cm⁻³, was deemed an effective and relatively inexpensive floatation media, allowing fine sediment to settle whilst simultaneously enabling floatation of dense polymers. The method was validated by artificially spiking sediment with low and high density microplastics, and its environmental relevance was further tested by extracting plastics present in natural sediment samples from sites ranging in sediment type; fine silt/clay (mean size 10.25 +/- SD 3.02 mum) to coarse sand (mean size 149.3 +/- SD 49.9 mum). The method presented here is cheap, reproducible and is easily portable, lending itself for use in the laboratory and in the field, eg. on board research vessels. By employing this method, accurate estimates of microplastic type, distribution and abundance in natural sediments can be achieved, with the potential to further our understanding of the availability of microplastics to benthic organisms.

Coppock, R. L., et al. (2019). "Microplastics alter feeding selectivity and faecal density in the copepod, Calanus helgolandicus." Science of the Total Environment **687**: 780-789.

Microplastics (1 micro m-5 mm) are a ubiquitous marine contaminant of global concern, ingested by a wide range of marine taxa. Copepods are a key component of marine food webs, providing a source of food for higher trophic levels, and playing an important role in marine nutrient cycling. Microplastic ingestion has been documented in copepods, but knowledge gaps remain over how this affects feeding preference and faecal density. Here, we use exposure studies incorporating algal prey and microplastics of varying sizes and shapes at a concentration of 100 microplastics mL⁻¹ to show: (1) prey selection by the copepod Calanus helgolandicus was affected by the size and shape of microplastics and algae they were exposed to; Exposure to nylon fibres resulted in a 6% decrease in ingestion of similar shaped chain-forming algae, whilst exposure to nylon fragments led to an 8% decrease in ingestion of a unicellular algae that were similar in shape and size. (2) Ingestion of microplastics with different densities altered the sinking rates of faecal pellets. Faeces containing low-density polyethylene sank significantly more slowly than controls, whilst sinking rates increased when faeces contained high-density polyethylene terephthalate. These results suggest that C. helgolandicus avoid ingesting algae that are similar in size and/or shape to the microplastic particles they are exposed to, potentially in a bid to avoid consuming the plastic.

Corbi, F., et al. (2011). "Point mutations in kinase and pseudokinase domains of JAK1 gene do not seem to be responsible for activation of JAK/STAT pathway in multiple myeloma." Haematologica **2)**: 528.

Background: JAK/STAT pathway, which can be persistently activated in multiple myeloma (MM) patients due to constant stimulation by IL- 6, was recently explored by Burger et al (2009) as potential therapeutic target in this still incurable disease: Janus Kinase (JAK) inhibitor INCB20 presented antiproliferative and apoptotic effects on human myeloma cells in vitro and in vivo. Aims. To search for point mutations in JAK1 gene kinase and pseudokinase domains in an attempt to define any critical and recurrent alteration that could be used as therapeutic target for MM. Patients and Methods. We obtained RNA from purified CD138-positive cells from MM bone marrow samples using microbeads conjugated to monoclonal anti-human CD138 (sydecan-1) by the MACS methodology - Magnetic Cell Sorting of Human Cells (Miltenyi Biotec, Bergisch Gladbach, Germany) from 21 newly diagnosed patients MM, four healthy controls (one peripheral blood and three reactive tonsils) and four MM cell lines (U266, Sko-007, SKMM-2, RPMI). After amplification of of JAK1 pseudokinase (exons 12-18) and kinase (exons 19-24) domains in cDNA samples, we performed automatic sequencing of fragments using forward and reverse primers. Result(s): 15 of the 21 (71%) MM cases showed at least one polymorphism, all synonymous SNPs, being: 12/15 in codon 733 (CCA>CCG), 6/15 in codon 683 (AGC>AGT), 4/15 in codons 1032 (AAG>AAA) and 659 (CGC>CGT), and 3/15 in codon 699 (GCC>GCG). All the four cell lines also presented only synonymous SNP: 4/4 in codon 683 (AGC>AGT) and 1/4 in codon 733 (CCA>CCG). Among the four controls, one showed synonymous SNP in codon 733 (CCA>CCG), one in codon 683 (AGC>AGT) and one in codon 1032 (AAG>AAA). Conclusions. Mutations in kinase and pseudokinase domains of JAK1 gene do not seem to be important for activation of JAK/STAT pathway in multiple myeloma and other underlying mechanisms, besides IL-6 stimulation, must be investigated.

Corcoran, P. L., et al. (2009). "Plastics and beaches: a degrading relationship." Marine Pollution Bulletin **58**(1): 80-84.

Plastic debris in Earth's oceans presents a serious environmental issue because breakdown by chemical weathering and mechanical erosion is minimal at sea. Following deposition on beaches, plastic materials are exposed to UV radiation and physical processes controlled by wind, current, wave and tide action. Plastic particles from Kauai's beaches were sampled to determine relationships between composition, surface textures, and plastics degradation. SEM images indicated that beach plastics feature both mechanically eroded and chemically weathered surface textures. Granular oxidation textures were concentrated along mechanically weakened fractures and along the margins of the more rounded plastic particles. Particles with oxidation textures also produced the most intense peaks in the lower wavenumber region of FTIR spectra. The textural results suggest that plastic debris is particularly conducive to both chemical and mechanical breakdown in beach environments, which cannot be said for plastics in other natural settings on Earth.

Corcoran, P. L., et al. (2015). "Hidden plastics of Lake Ontario, Canada and their potential preservation in the sediment record." Environmental Pollution **204**: 17-25.

Microplastics are a source of environmental pollution resulting from degradation of plastic products and spillage of resin pellets. We report the amounts of microplastics from various sites of Lake Ontario and evaluate their potential for preservation in the sediment record. A total of 4635 pellets were sampled from the Humber Bay shoreline on three sampling dates. Pellet colours were similar to those from the Humber River bank, suggesting that the river is a pathway for plastics transport into Lake Ontario. Once in the lake, high density microplastics, including mineral-polyethylene and mineral-polypropylene mixtures, sink to the bottom. The minerals may be fillers that were combined with plastics during production, or may have adsorbed to the surfaces of the polymers in the water column or on the lake bottom. Based on sediment depths and accumulation rates, microplastics have accumulated in the offshore region for less than 38 years. Their burial increases the chance of microplastics preservation. Shoreline pellets may not be preserved because they are mingled with organic debris that is reworked during storm events. [ABSTRACT FROM AUTHOR]

Cordier, M. and T. Uehara (2019). "How much innovation is needed to protect the ocean from plastic contamination?" Science of the Total Environment **670**: 789-799.
Plastics are non-biodegradable, and increasing accumulation of plastic debris in the ocean is a major cause for concern. The World Economic Forum, Ellen MacArthur Foundation, and McKinsey & Company claimed in 2016 that technological innovations can solve the plastic problem. Such a claim raises an as yet unanswered question: how much technological innovation is needed and is it economically feasible? We offer answers to this question via a system dynamics model that we developed to simulate different scenarios aimed at controlling plastic debris entering the global ocean. Our results show that ocean cleanup technologies could achieve a 25% reduction in the level of plastic debris in the ocean below 2010 levels in 2030. However, this would require removing 15% of the stock of plastic debris from the ocean every year over the period 2020-2030, which equates to 135 million tons of plastic in total (metric tons). The implementation cost of such an ocean cleanup effort would amount to 492 billion-708 billion, which represents 0.7%-1.0% of the world GDP in 2017 - this calculation is based on unit costs in /kg estimated in The Ocean Cleanup project feasibility study. The Ocean Cleanup project alone is designed to collect 70,320 tons of plastic debris over a 10year period. Removing 135 million tons of plastic debris would require investing in 1924 similar cleanup projects. These results help to assess the economic feasibility of removing such large volume of plastics. Moreover, our results provide quantitative confirmation that technological solutions alone are not sufficient to solve plastic pollution issues. A portfolio of diverse solutions - not only technological ones - is likely to have greater technical, political and economic feasibility. Our model shows that such a combined portfolio implemented over the period 2020-2030 could reduce the ocean plastic stock to 2013 levels (94 million tons) by 2030.

Cordova, M. R., et al. (2018). "Occurrence and abundance of microplastics in coral reef sediment: a case study in Sekotong, Lombok-Indonesia." AES Bioflux **10**(1): 23-29.
Microplastics are categorized as less than 5 mm in length - sized plastics. Lombok is located in Indonesia, part of the coral triangle region, and one of the out flow locations of the Indonesian

Through Flow (ITF). There is likelihood that microplastics would flow across the ITF and would be accumulated in the coral reef ecosystem, especially in biota and sediment. To improve the knowledge of microplastics pollution in Indonesia, we analyzed sediment samples from 10 stations at coral reef habitats in Sekotong, Lombok - Indonesia. The microplastics concentration in Sekotong varied from 35 to 77 particles per-kg, with average 48.3+or-13.98 (SD) particles per-kg, found in all ten sampling location. The highest concentration was found in the south-west of Gili Gede Island (77 particles per-kg). All of the microplastics collected were foam (41.20%), fragment (32.51%), granule (22.77%) and fiber (3.52%). Microplastic with size more than 1000 micro m found at most, followed by size range of 500-1000 micro m, 200-500 micro m and particle size less than 200 micro m in length. Polystyrene was the most abundant type of plastic polymer identified, followed by polyethylene and polypropylene. This type of polymers indicates that the primary source of microplastics in the Sekotong's coral reef sediment was from the usage of styrofoam, food and beverage packages, also fishing devices. It is strongly suggested that the management of plastic waste to be improved and it is essential to develop an environmentally friendly substance to replace plastics in near future.

Cormier, B., et al. (2019). "Multi-Laboratory Hazard Assessment of Contaminated Microplastic Particles by Means of Enhanced Fish Embryo Test With the Zebrafish (Danio rerio)." Frontiers in Environmental Science.

As wide-spread pollutants in the marine environment, microplastics (MPs) have raised public concern about potential toxic effects in aquatic organisms, and, among others, MPs were suspected to act as a vector for organic pollutants to biota. The purpose of the present study was to investigate effects by three model pollutants, oxybenzone (BP3), benzo[a]pyrene (BaP) and perfluorooctane sulfonate (PFOS) adsorbed to polyethylene MPs on the basis of a standard assay, the acute fish embryo toxicity test (FET; OECD TG 236) with zebrafish (Danio rerio) supplemented by additional endpoints such as induction of ethoxyresorufin-O-deethylase (EROD) activity, modification of cyp1a gene transcription and changes in larval swimming behavior. FET assays were performed in three laboratories using slightly different husbandry and exposure conditions, which, however, were all fully compatible with the limits defined by OECD TG 236. This allowed for testing of potential changes in the FET assay due to protocol variations. The standard endpoints of the FET (acute embryotoxicity) did not reveal any acute toxicity for both virgin MPs and MPs spiked with BP3, BaP and PFOS. With respect to sublethal endpoints, EROD activity was increased after exposure to MPs spiked with BP3 (3 h pulse) and MPs spiked with BaP (96 h continuous exposure). Cyp1a transcription was increased upon exposure to MPs spiked with BP3 or BaP. For the selected combination of MPs particles and contaminants, the basic FET proved not sensitive enough to reveal effects of (virgin and spiked) MPs. However, given that the FET can easily be supplemented by a broad variety of more subtle and sensitive endpoints, an enhanced FET protocol may provide a relevant approach with developmental stages of a vertebrate animal model, which is not protected by current EU animal welfare legislation (Directive EU 2010/63).

Cornejo-D'Ottone, M., et al. (2019). "Greenhouse gas cycling by the plastisphere: The sleeper issue of plastic pollution." Chemosphere **246**: 125709.

Plastic is an allochthonous material to marine ecosystems but is rapidly colonized by marine microbial communities, with an as yet unclear contribution to biogeochemical cycles. In this study, we investigated the influence of an active microbial community grown on microplastic particles (the plastisphere) on CO₂ and N₂O recycling and its potential role in greenhouse gas inventories and air-sea exchange. Microplastics were collected during two cruises (Cimar 21 and FIP Montes Submarinos) from the surface layer (5 m depth) from several contrasting trophic regions of the South Pacific Ocean, i.e., from a transition zone off the eutrophic coastal upwelling of Chile, to a mesotrophic transition area of oceanic seamounts and, finally, to an oligotrophic zone in the South Pacific Subtropical Gyre. . Experiments were carried out onboard to evaluate CO₂ and N₂O production/consumption by the plastisphere. The active microbial community and its specific quantification were determined for Cimar 21 using iTag 16 S rRNA. The experiments showed that the plastisphere generally contributed to CO₂ and N₂O production/consumption, with rates ranging from -20.5 (consumption) to +4.5 (production) mumol/m²/d. The seamounts and the transition zone presented the highest production/consumption rates. The experiments performed in the two seamount stations showed that production and consumption of CO₂ were related to the environmental nutrient concentration. Both stations presented N₂O consumption that was associated with the high nitrogen deficit of the subantarctic water mass. The transition zone presented CO₂ and N₂O production in a plastisphere dominated by heterotrophic communities. The plastisphere in oligotrophic waters was diverse and active. The experiments, however, presented low or no production of greenhouse gases. Our results show a contribution of CO₂ and N₂O to the global gas surface inventories and air-sea exchange is lower than 1% of the global sources. These results highlight different critical impacts of plastic pollution on the environment that have, until now, not been considered.

Corradini, F., et al. (2019). "Predicting soil microplastic concentration using vis-NIR spectroscopy." Science of the Total Environment **650**(Pt 1): 922-932.

Microplastic accumulation in soil may have a detrimental impact on soil biota. The lack of standardized methods to identify and quantify microplastics in soils is an obstacle to research. Existing techniques are time-consuming and field data are seldom collected. To tackle the problem, we explored the possibilities of using a portable spectroradiometer working in the near infrared range (350-2500nm) to rapidly assess microplastic concentrations in soils without extraction. Four sets of artificially polluted soil samples were prepared. Three sets had only one polymer polluting the soil (low-density polyethylene (LDPE), polyethylene terephthalate (PET), or polyvinyl chloride (PVC)). The fourth set contained random amounts of the three polymers (Mix). The concentrations of microplastics were regressed on the reflectance observed for each of the 2150 wavelengths registered by the instrument, using a Bayesian approach. For a measurement range between 1 and 100gkg⁻¹, results showed a root-mean-squared-deviation (RMSD) of 8, 18, and 10gkg⁻¹ for LDPE, PET, and PVC. The Mix treatment presented an RMSD of 8, 10, and 5gkg⁻¹ for LDPE, PET, and PVC. The repeatability of the proposed method was 0.2-8.4, 0.1-5.1, and 0.1-9.0gkg⁻¹ for LDPE, PET, and PVC, respectively. Overall, our results suggest that vis-NIR techniques are suitable to identify and quantify LDPE, PET, and PVC microplastics in soil samples, with a 10gkg⁻¹ accuracy and a detection limit=15gkg⁻¹. The method proposed is different than other approaches since it is faster because it avoids extraction steps and can directly quantify the amount of plastic in a sample. Nevertheless, it seems to be useful only for pollution hotspots.

Corradini, F., et al. (2019). "Evidence of microplastic accumulation in agricultural soils from sewage sludge disposal." Science of the Total Environment **671**: 411-420.

Microplastics are emerging as a steadily increasing environmental threat. Wastewater treatment plants efficiently remove microplastics from sewage, trapping the particles in the sludge and preventing their entrance into aquatic environments. Treatment plants are essentially taking the microplastics out of the waste water and concentrating them in the sludge, however. It has become common practice to use this sludge on agricultural soils as a fertilizer. The aim of the current research was to evaluate the microplastic contamination of soils by this practice, assessing the implications of successive sludge applications by looking at the total count of microplastic particles in soil samples. Thirty-one agricultural fields with different sludge application records and similar edaphoclimatic conditions were evaluated. Field records of sludge application covered a ten year period. For all fields, historical disposal events used the same amount of sludge (40tonha⁻¹ dry weight). Extraction of microplastics was done by flotation and particles were then counted and classified with the help of a microscope. Seven sludge samples were collected in the fields that underwent sludge applications during the study period. Soils where 1, 2, 3, 4, and 5 applications of sludge had been performed had a median of 1.1, 1.6, 1.7, 2.3, and 3.5 particles g⁻¹ dry soil, respectively. There were statistical differences in the microplastic contents related to the number of applications that a field had undergone (1, 2, 3<4, 5). Microplastic content in sludge ranged from 18 to 41 particles g⁻¹, with a median of 34 particles g⁻¹. The majority of the observed microplastics were fibers (90% in sludge, and 97% in soil). Our results indicate that microplastic counts increase over time where successive sludge applications are performed. Microplastics observed in soil samples stress the relevance of sludge as a driver of soil microplastic contamination.

Corrales Escobosa, A. R., et al. (2015). "Effect of different glycation agents on Cu(II) binding to human serum albumin, studied by liquid chromatography, nitrogen microwave-plasma atomic-emission spectrometry, inductively-coupled-plasma mass spectrometry, and high-resolution molecular-mass spectrometry." Analytical and bioanalytical chemistry **407**(4): 1149-1157.

Issue Title: A different way of looking at vibrational hyperspectral data/Micellar extraction for the analysis of Alzheimer's disease brain proteome/Quantification of polyolefin microplastics in personal-care products/Removal of Triton X-100 by microdialysis The ability of human serum albumin to capture unbound copper under different clinical conditions is an important variable potentially affecting homeostasis of this element. Here, we propose a simple procedure based on size-exclusion chromatography with on-line UV and nitrogen microwave-plasma atomic-emission spectrometry (MP-AES) for quantitative evaluation of Cu(II) binding to HSA upon its glycation in vitro. The Cu-to-protein molar ratio for non-glycated albumin was 0.98±0.09; for HSA modified with glyoxal (GO), methylglyoxal (MGO), oxoacetic acid (GA), and glucose (Glc), the ratios were 1.30±0.22, 0.72±0.14, 0.50±0.06, and 0.95±0.12, respectively. The results were confirmed by using ICP-MS as an alternative detection system. A reduced ability of glycated protein to coordinate Cu(II) was associated with alteration of the N-terminal metal-binding site during incubation with MGO and GA. In contrast, glycation with GO seemed to generate new binding sites as a result of tertiary structural changes in HSA. Capillary reversed-phase liquid chromatography with electrospray-ionization quadrupole-time-of-flight tandem mass spectrometry enabled detection and identification of Cu(II) coordinated to the N-terminal metal-binding site (Cu(II)-DAHK) in all tryptic digests analyzed. This is the first report confirming Cu(II)-DAHK species in HSA by means of high-resolution tandem mass spectrometry, and the first report on the use of MP-AES in combination with chromatographic separation. [Figure not available: see fulltext.]

Correa, C. A., et al. (2019). "Green-PVC with full recycled industrial waste and renewably sourced content." Journal of Cleaner Production **229**: 1397-1411.

Polyvinyl Chloride (PVC) resins and their compounds are very versatile materials with applications ranging from flexible packaging to rigid building products, such as extruded pipes, profiles and injection moulded electrical/plumbing fittings. Nowadays, large amounts of industrial waste resulting from PVC processing must be handled in order to comply with enacted environmental and health hazards legislations concerning plastic waste disposal. Nonetheless, provided the waste contamination is controlled at its source, PVC waste is potentially recyclable and can be compounded with thermoplastic starches leading to reprocessed formulations with renewable content. These formulations can be reengineered onto injection moulded appliances within a closed-loop manufacturing framework. Starches can be gelatinized by heat, pressure and shearing with glycerol, and in the present work, a by-product of the biodiesel manufacturing was used for this purpose. The main aspects related to cascaded recycling of PVC waste from pipe processors are discussed, in regard to challenges for developing alternative green markets for plastic products in terms of recycling technology and properties compliance for using reprocessed plastic plumbing waste on electrical fittings. Coping with hygroscopic nature of glycerol plasticized starch was the main challenge and many bioderived plasticizers have been tested to overcome this drawback. The research on Green PVC implied that eco-innovation in the conventional plastic industry requires "drop-in" solution regardless of their renewably or fossil sourced feedstock. Furthermore, the green value is not clearly perceived as marketing advantage by plastic processors and consumers and a green-premium associated with production costs tend to hinder a pervading market. 2019 Elsevier Ltd

Correia, M. and K. Loeschner (2018). "Detection of nanoplastics in food by asymmetric flow field-flow fractionation coupled to multi-angle light scattering: possibilities, challenges and analytical limitations. (Special Issue: Food safety analysis.)." Analytical and bioanalytical chemistry **410**(22): 5603-5615.

We tested the suitability of asymmetric flow field-flow fractionation (AF4) coupled to multi-angle light scattering (MALS) for detection of nanoplastics in fish. A homogenized fish sample was spiked with 100 nm polystyrene nanoparticles (PSNPs) (1.3 mg/g fish). Two sample preparation strategies were tested: acid digestion and enzymatic digestion with proteinase K. Both procedures were found suitable for degradation of the organic matrix. However, acid digestion resulted in large PSNPs aggregates/agglomerates (>1 micro m). The presence of large particulates was not observed after enzymatic digestion, and consequently it was chosen as a sample preparation method. The results demonstrated that it was possible to use AF4 for separating the PSNPs from the digested fish and to determine their size by MALS. The PSNPs could be easily detected by following their light scattering (LS) signal with a limit of detection of 52 micro g/g fish. The AF4-MALS method could also be exploited for another type of nanoplastics in solution, namely polyethylene (PE). However, it was not possible to detect the PE particles in fish, due to the presence of an elevated LS background. Our results demonstrate that an analytical method developed for a certain type of nanoplastics may not be directly applicable to other types of nanoplastics and may require further adjustment. This work describes for the first time the detection of nanoplastics in a food matrix by AF4-MALS. Despite the current limitations, this is a promising methodology for detecting nanoplastics in food and in experimental studies (e.g., toxicity tests, uptake studies).

Corrigan, O. I., et al. (2003). "Influence of dissolution medium buffer composition on ketoprofen release from ER products and in vitro-in vivo correlation." International Journal of Pharmaceutics **254**(2): 147-154.

The purpose of this work was to investigate the influence of dissolution medium composition on the in vitro release of ketoprofen from a series of ER products and the impact of the different

buffer media on the in vivo-in vitro (IVIV) relationship. The products investigated were coated micro bead preparations having increasing levels of coating to retard drug release. Four common dissolution media; USP phosphate buffers of pH 7.2 and 6.8, phosphate (modified isotonic) buffer pH 6.8 and a fasted state simulated intestinal fluid without lipid components (FaSSIFLF) of pH 6.5, were employed in the USP 2 apparatus. Release profiles were compared to the corresponding in vivo release profiles, obtained following deconvolution of the plasma level versus time profiles obtained from a 10-subject five-period cross-over study. Despite the relative similarity in composition of the media employed, significant differences in release profiles were observed reflecting media differences in buffer capacity, ionic strength and pH. As a consequence, the quality and shape of the IVIV relationship changed significantly, the only apparent IVIVC incorporating all four ER products, which was non-linear, was obtained using the phosphate (modified isotonic) buffer of pH 6.8. This data was fitted, using a non-linear least squares method, by the equation of Polli et al. [J. Pharm. Sci. 85 (1996) 753] and gave an alpha parameter estimate of 2, consistent with initial dissolution being more rapid in vitro than in vivo. The systematic shift in profiles, particularly with buffer capacity, underlines the sensitivity of IVIV relationship to medium composition and hence the current difficulties in making a rational choice of an appropriate single dissolution medium.

Cortina, M. E., et al. (2016). "Electrochemical magnetic microbeads-based biosensor for point-of-care serodiagnosis of infectious diseases." Biosensors & Bioelectronics **80**: 24-33.

Access to appropriate diagnostic tools is an essential component in the evaluation and improvement of global health. Additionally, timely detection of infectious agents is critical in early diagnosis and treatment of infectious diseases. Conventional pathogen detection methods such as culturing, enzyme linked immunosorbent assay (ELISA) or polymerase chain reaction (PCR) require long assay times, and complex and expensive instruments making them not adaptable to point-of-care (PoC) needs at resource-constrained places and primary care settings. Therefore, there is an unmet need to develop portable, simple, rapid, and accurate methods for PoC detection of infections. Here, we present the development and validation of a portable, robust and inexpensive electrochemical magnetic microbeads-based biosensor (EMBIA) platform for PoC serodiagnosis of infectious diseases caused by different types of microorganisms (parasitic protozoa, bacteria and viruses). We demonstrate the potential use of the EMBIA platform for in situ diagnosis of human (Chagas disease and human brucellosis) and animal (bovine brucellosis and foot-and-mouth disease) infections clearly differentiating infected from non-infected individuals or animals. For Chagas disease, a more extensive validation of the test was performed showing that the EMBIA platform displayed an excellent diagnostic performance almost indistinguishable, in terms of specificity and sensitivity, from a fluorescent immunomagnetic assay and the conventional ELISA using the same combination of antigens. This platform technology could potentially be applicable to diagnose other infectious and non-infectious diseases as well as detection and/or quantification of biomarkers at the POC and primary care settings.

Costa, E., et al. (2020). "Microplastics ingestion in the ephyra stage of Aurelia sp. triggers acute and behavioral responses." Ecotoxicology & Environmental Safety **189**: 109983.

For the first time, we report a correspondence between microplastics (MP) ingestion and ecotoxicological effects in gelatinous zooplankton (Cnidarian jellyfish). The ephyra stage of the jellyfish Aurelia sp. was exposed to both environmental and high concentrations of fluorescent 1-4 mum polyethylene MP (0.01-10 mg/L). After 24 and 48 h, MP accumulation, acute (Immobility) and behavioral (Frequency pulsation) endpoints were investigated. MP were detected by confocal and tomographic investigations on gelatinous body and mouth, either attached on the surface or ingested. This interaction was responsible for impairing ephyrae survival and behavior at all tested concentrations after 24 h. Acute and behavioral effects were also related to mechanical disturbance, caused by MP, triggering a loss of radial symmetry. Contaminated ephyrae exposed to clean seawater showed full recovery after 72 h highlighting the organisms without the microspheres, attached on body jellyfish surface around the mouth and lappets. In conclusion, short-term exposure to MP affects ephyrae jellyfish health, impairing both their survival and behavior. Polyethylene MP temporarily affect both Immobility and Frequency of pulsation of Aurelia sp. jellyfish. This study provides a first step towards understanding and clarifying the potential impacts of MP contamination in gelatinous zooplankton.

Costa, E., et al. (2012). "Tuning smart microgel swelling and responsive behavior through strong and weak polyelectrolyte pair assembly." Langmuir **28**(26): 10082-10090.

The layer-by-layer (LbL) assembly of polyelectrolyte pairs on temperature and pH-sensitive cross-linked poly(N-isopropylacrylamide)-co-(methacrylic acid), poly(NIPAAm-co-MAA), microgels enabled a fine-tuning of the gel swelling and responsive behavior according to the mobility of the assembled polyelectrolyte (PE) pair and the composition of the outermost layer. Microbeads with well-defined morphology were initially prepared by synthesis in supercritical carbon dioxide. Upon LbL assembly of polyelectrolytes, interactions between the multilayers and the soft porous microgel led to differences in swelling and thermoresponsive behavior. For the weak PE pairs, namely poly(L-lysine)/poly(L-glutamic acid) and poly(allylamine hydrochloride)/poly(acrylic acid), polycation-terminated microgels were less swollen and more thermoresponsive than native microgel, whereas polyanion-terminated microgels were more swollen and not significantly responsive to temperature, in a quasi-reversible process with consecutive PE assembly. For the strong PE pair, poly(diallyldimethylammonium chloride)/poly(sodium styrene sulfonate), the differences among polycation and polyanion-terminated microgels are not sustained after the first PE bilayer due to extensive ionic cross-linking between the polyelectrolytes. The tendencies across the explored systems became less noteworthy in solutions with larger ionic strength due to overall charge shielding of the polyelectrolytes and microgel. ATR FT-IR studies correlated the swelling and responsive behavior after LbL assembly on the microgels with the extent of H-bonding and alternating charge distribution within the gel. Thus, the proposed LbL strategy may be a simple and flexible way to engineer smart microgels in terms of size, surface chemistry, overall charge and permeability.

Costa, E., et al. (2018). "Development of an artifact to attenuate whole-body vibration in agricultural tractors." Energia na Agricultura **33**(1): 22-26.

The use of tractors in agriculture is a key element in increasing productivity and quality of agricultural production, as it is able to perform operations in less time, more efficiently and decrease production costs. Although tractors provide increased productivity, their use can damage the machine operator health, that is exposed to problems such as vibration when using the tractor. Over the years, the weight of agricultural tractors without ballast has decreased due to the development of lighter materials and increase in displacement speeds, what can cause vibration and increase operator health problems. The objective of the work was to develop an artifact to attenuate the whole body vibrations (VCI) to which the agricultural tractor operator is exposed. The experimental design was completely randomized, in which three treatments were evaluated, using two attenuating materials on the seat (viscoelastic foam and polystyrene microbeads) and one without attenuation (control treatment). Readings were taken with 3 min of duration, and every 10 s a sample was collected totaling 18 samples collected for each repetition, with 5 replicates for each treatment. Statistical analysis of the data was performed using ASSISTAT statistical software. To verify the normality of the data, the Anderson-Darling test was performed. After the normality of the data was confirmed, they were submitted to analysis of variance by the F test, and when significant, the means were compared by the Tukey test, at 5% significance. According to the results obtained, the viscoelastic foam and the polystyrene micro-beads presented VDVR and lower area values, within the acceptable level established by the NR-15, which characterizes the materials used as good alternative attenuation. Both materials used showed similar attenuation.

Costa, L. L., et al. (2019). "Can the Atlantic ghost crab be a potential biomonitor of microplastic pollution of sandy beaches sediment?" Marine Pollution Bulletin **145**: 5-13.

The objective of the present study was to test whether the Atlantic ghost crab Ocypode quadrata is a reliable biomonitor of microplastic (MP) pollution of beach sediments. To test the hypothesis (H1) that the sediment is the main source of MP ingestion, the proportion of MP types (hard plastic, microfibers, pellet, soft plastic, and extruded polystyrene foam) in the gut content was compared with that on the strandline. The types of MPs in the gut content and sediment had similar proportions; black (~49%) and blue (~45%) microfibers were responsible for this similarity (55%), hence confirming H1. However, the second hypothesis (H2) that prevalence of MP in the gut content is related to its density on beach with distinct urbanization degree was not accepted. These results indicate that high trophic plasticity of the ghost crab and, consequently, multiple-sources of contamination may interfere with its use as a biomonitor of MP pollution. Costa, M. F. and M. Barletta (2015). "Microplastics in coastal and marine environments of the western tropical and sub-tropical Atlantic Ocean." Environmental Science. Processes & Impacts **17**(11): 1868-1879.

Microplastic pollution is a global issue. It is present even in remote and pristine coastal and marine environments, likely causing impacts of unknown scale. Microplastics are primary- and secondary-sourced plastics with diameters of 5 mm or less that are either free in the water column or mixed in sandy and muddy sediments. Since the early 1970s, they have been reported to pollute marine environments; recently, concern has increased as soaring amounts of microplastics in the oceans were detected and because the development of unprecedented processes involving this pollutant at sea is being unveiled. Coastal and marine environments of the western tropical and sub-tropical Atlantic Ocean (WTAO) are contaminated with microplastics at different quantities and from a variety of types. The main environmental compartments (water, sediments and biota) are contaminated, but the consequences are still poorly understood. Rivers and all scales of fishery activities are identified as the most likely sources of this pollutant to coastal waters; however, based on the types of microplastics observed, other maritime operations are also possible sources. Ingestion by marine biota occurs in the vertebrate groups (fish, birds, and turtles) in these environments. In addition, the presence of microplastics in plankton samples from different habitats of estuaries and oceanic islands is confirmed. The connectivity among environmental compartments regarding microplastic pollution is a new research frontier in the region.

Costa, M. F., et al. (2010). "On the importance of size of plastic fragments and pellets on the strandline: A snapshot of a Brazilian beach." Environmental Monitoring and Assessment **168**(1-4): 299-304.

Virgin plastic pellets and plastic fragments are reported as ubiquitous beach contaminants in the peer-reviewed literature. A surface density of 0.3 virgin plastic pellets and plastic fragments per square centimeter of the strandline area was registered on an urban beach of the northeast of Brazil. This beach is presently not affected by petrochemical facilities or pellet processing plants. The main source of fragments (96.7%) was attributed to the breaking down of larger plastic items deposited on the beach. In the case of virgin plastic pellets (3.3%), the main sources were the marine environment and possibly nearby port facilities. This category of plastic pollutant offers particular threats to the marine environment and to beach users. © 2009 Springer Science+Business Media B.V.

Costiuc, L., et al. (2015). "EXPERIMENTAL INVESTIGATION ON THE HEAT OF COMBUSTION FOR SOLID PLASTIC WASTE MIXTURES." Environmental Engineering & Management Journal (EEMJ) **14**(6): 1295-1302.

The aim of this paper is to determine the heat of combustion of plastic wastes resulted from municipal solid waste, automotive shredder facility waste and building and construction waste. The plastic wastes have been separated by flotation technique using as flotation media: water, ethanol, their mixtures and magnetic fluid. Resulted fractions have been analyzed aiming to determine the most effective fraction from the heat of combustion point of view. The obtained results have been compared to those reported in the literature, with those calculated by oxygen consumption method and those proposed in this paper and calculated by weighted sum of combustion heat of components, aiming to allow its approximation for different fractions of polymeric wastes with known composition, avoiding the experimental measurements. Deviations of measured values of the heat of combustion from those obtained by theoretical calculation have been explained by the polymer degradation during their life cycle. The most effective fraction from calorific point of view is that containing polyolefins, but this fraction could be mechanically recycled. The present study evidenced that the heat of combustion of the plastic waste decreases after polyolefin extraction and the remaining density fractions can be effectively used for energy recovery of the plastic waste by incineration. Cotruvo, J. P. B. (2019). Managing plastic microparticles in water. Water Technology. Latham, National Trade Publications Incorporated. **42:** 8.

Cotruvo focuses on the management of plastic microparticles in water. More recently, microplastic particles have been detected in seawater, freshwaters and drinking waters, including bottled waters and foods. Environmental plastics are a risk to aquatic organisms from ingestion; they are unsightly and indicative of gross mismanagement of disposal of plastic wastes. For perspective, the maximum contaminant level (MCL) for asbestos microparticles in drinking water is 7,000,000 fibers per liter longer than 10 µm. Ingested plastic microparticles have not yet been shown to produce adverse human health effects.

Coudron, L., et al. (2019). "Fully integrated digital microfluidics platform for automated immunoassay; A versatile tool for rapid, specific detection of a wide range of pathogens." Biosensors & Bioelectronics **128**: 52-60.

With the tangible threat posed by the release of chemical and biological warfare (CBW) agents, detection of airborne pathogens is a critical military and security concern. Recent air sampling techniques developed for biocollection take advantage of Electrowetting on Dielectric (EWOD) to recover material, producing highly concentrated droplet samples. Bespoke EWOD-based digital microfluidics platforms are very well suited to take full advantage of the microlitre concentrated droplet resulting from this recovery process. In this paper we present a free-standing, fully automated DMF platform for immunoassay. Using this system, we demonstrate the automated detection of four classes of CBW agent simulant biomolecules and organisms each representing credible threat agents. Taking advantage of the full magnetic separation process with antibody-bound microbeads, rapid and complete separation of specific target antigen can be achieved with minimal washing steps allowing for very rapid detection. Here, we report clear detection of four categories of antigens achieved with assay completion times of between six and ten minutes. Detection of HSA, Bacillus atrophaeus (BG spores), MS2 bacteriophage and Escherichia coli are demonstrated with estimated limit of detection of respectively 30ngml⁻¹, 4x10⁴ cfuml⁻¹, 10⁶ pfuml⁻¹ and 2x10⁷ cfuml⁻¹. The fully-integrated portable platform described in this paper is highly compatible with the next generation of electrowetting-coupled air samplers and thus shows strong potential toward future in-field deployable biodetection systems and could have key implication in life-changing sectors such as healthcare, environment or food security.

Courtene-Jones, W., et al. (2019). "Consistent microplastic ingestion by deep-sea invertebrates over the last four decades (1976–2015), a study from the North East Atlantic." Environmental Pollution **244**: 503-512.

Although evidence suggests the ubiquity of microplastics in the marine environment, our knowledge of its occurrence within remote habitats, such as the deep sea, is scarce. Furthermore, long term investigations of microplastic abundances are even more limited. Here we present a long-term study of the ingestion of microplastics by two deep-sea benthic invertebrates (Ophiomusium lymani and Hymenaster pellucidus) sampled over four decades. Specimens were collected between the years 1976–2015 from a repeat monitoring site >2000 m deep in the Rockall Trough, North East Atlantic. Microplastics were identified at a relatively consistent level throughout and therefore may have been present at this locality prior to 1976. Considering the mass production of plastics began in the 1940s - 50s our data suggest the relatively rapid occurrence of microplastics within the deep sea. Of the individuals examined (n = 153), 45% had ingested microplastics, of which fibres were most prevalent (95%). A total of eight different polymer types were isolated; polyamide and polyester were found in the highest concentrations and in the majority of years, while low-density polystyrene was only identified in 2015. This study provides an assessment of the historic occurrence of microplastics on the deep seafloor and presents a detailed quantification and characterisation of microplastics ingested by benthic species. Furthermore these data advance our knowledge on the long-term fate of microplastic in marine systems. Graphical abstract Image 1 Highlights • First long-term study of microplastic pollution in the deep sea. • Ingested microplastic abundance remained relatively consistent 1976–2015. • Data indicate microplastics may have been present at this location prior to 1976. • No trends were observed in polymer type or overall abundance across years. • Eight polymers were identified of which polyamide and polyester dominated. This unique dataset reveals consistent levels of microplastics were ingested by deep-sea invertebrates since 1976, indicating the long-term occurrence of microplastic pollution in this region. [ABSTRACT FROM AUTHOR]

Courtene-Jones, W., et al. (2017). "Microplastic pollution identified in deep-sea water and ingested by benthic invertebrates in the Rockall Trough, North Atlantic Ocean." Environmental Pollution **Part 1. 231**: 271-280.

Microplastics are widespread in the natural environment and present numerous ecological threats. While the ultimate fate of marine microplastics are not well known, it is hypothesized that the deep sea is the final sink for this anthropogenic contaminant. This study provides a quantification and characterisation of microplastic pollution ingested by benthic macroinvertebrates with different feeding modes (Ophiomusium lymani, Hymenaster pellucidus and Colus jeffreysianus) and in adjacent deep water > 2200 m, in the Rockall Trough, Northeast Atlantic Ocean. Despite the remote location, microplastic fibres were identified in deep-sea water at a concentration of 70.8 particles m⁻³, comparable to that in surface waters. Of the invertebrates examined (n = 66), 48% ingested microplastics with quantities enumerated comparable to coastal species. The number of ingested microplastics differed significantly between species and generalized linear modelling identified that the number of microplastics ingested for a given tissue mass was related to species and not organism feeding mode or the length or overall weight of the individual. Deep-sea microplastics were visually highly degraded with surface areas more than double that of pristine particles. The identification of synthetic polymers with densities greater and less than seawater along with comparable quantities to the upper ocean indicates processes of vertical re-distribution. This study presents the first snapshot of deep ocean microplastics and the quantification of microplastic pollution in the Rockall Trough. Additional sampling throughout the deep-sea is required to assess levels of microplastic pollution, vertical transportation and sequestration, which have the potential to impact the largest global ecosystem. Microplastics were identified in deep-sea benthic invertebrates and adjacent water >2200 m deep in the Rockall Trough with quantities comparable to surface concentrations. Cousin, H. R., et al. (2015). "The frequency of ingested plastic debris and its effects on body condition of Short-tailed Shearwater (Puffinus tenuirostris) pre-fledging chicks in Tasmania, Australia." Emu - Austral Ornithology **115**(1): 6-11.

In recent years, there have been increasing reports of ingestion of marine plastic debris in seabirds. Our aim was to assess the frequency and effects of ingested plastic debris in pre-fledging Short-tailed Shearwaters (Puffinus tenuirostris) in Tasmania. We conducted necropsies of 171 Shearwater chicks, confiscated after illegal poaching, to determine the presence of plastic debris in the proventriculus and ventriculus. We also examined whether there was a correlation between body condition (based on body mass and fat-scores) and quantity of plastic ingested (by count and weight). We recorded 1032 ingested plastic particles, consisting of industrial plastic (31%) and user plastic (69%). Most of the Shearwater chicks (96%) contained plastic debris with a mean of 148.1 mg per bird (s.e. 8.1). Most plastic was found in the ventriculus. Light-coloured plastic dominated (63.8%), with the rest medium (22.1%) and dark (14.1%) plastics. We found that total mass of ingested plastic was not significantly related to body condition, or fat-scores or mass individually. Our study highlights the prevalence of

plastic pollution in apparently healthy Shearwater chicks and underscores concern regarding the effects of increasing marine pollution on a global scale. Additional keywords: industrial plastic, marine debris, nurdles, plastic colour, plastic pollution, user plastic.

Cousins, D. (2009). "Untitled." Farmers Weekly: 98-98.
The article features a dog-kennel, which is one of the latest additions to products to be created using recycled farm plastic waste collected from farms by the National Farmers Recycling Service in Dumfries, Scotland in 2009. Other products to be made using such materials are cited, including chicken cages.

Couto, J. A., et al. (2017). "Somatic PIK3CA mutations are present in multiple tissues of facial infiltrating lipomatosis." Pediatric Research **82**(5): 850-854.
BackgroundFacial infiltrating lipomatosis (FIL) is a congenital disorder that causes overgrowth of one side of the face. The purpose of this study was to determine whether PIK3CA mutations are present in tissues outside of the subcutaneous adipose.

Couture, O., et al. (2006). "A model for reflectivity enhancement due to surface bound submicrometer particles." Ultrasound in Medicine & Biology **32**(8): 1247-1255.
Submicrometer particles filled with liquid perfluorocarbon have been shown to increase the ultrasound reflectivity of surfaces onto which they bind and, consequently, are seen as potential targeted contrast agents. The objective of this study is to explain the reflectivity enhancement as a result of the presence of randomly distributed particles on a surface. A model is presented where the diffraction-weighted scattering of all particles is summed over the exposed surface. Experiments were performed at frequencies ranging from 15 MHz to 60 MHz, with glass microbeads and perfluorohexane particles deposited on the surface of agar and Aqualene, a rubber closely matched to water, to confirm the validity of the model.

Covernton, G. A., et al. (2019). "Microplastics in bivalves and their habitat in relation to shellfish aquaculture proximity in coastal British Columbia, Canada." Aquaculture Environment Interactions **11**: 357.
Shellfish aquaculture often uses large amounts of plastic equipment and has been suggested as a potential source of microplastic contamination in the marine environment. To determine the influence of shellfish aquaculture on microplastic concentrations in bivalves and their environment, we compared microplastic particle (MP) concentrations in Manila clams Venerupis philippinarum and Pacific oysters Crassostrea gigas grown on commercial shellfish beaches with those in individuals of the same species grown on nearby non-aquaculture beaches in 6 regions of coastal British Columbia, Canada. MP concentrations did not differ between shellfish aquaculture and non-aquaculture sites for either bivalve species, sediment, or water samples. Plastic presence differed by site and oysters on sites with many synthetic anti-predator nets contained significantly, yet marginally, more MPs than those on sites without (0.05 vs. 0.03 g^{-1} dry-tissue weight on average). However, analysis of suspected MPs using Fourier-transform infrared spectroscopy indicated a predominance of fibres from textiles (including nylon and polyester), which are not typically used in shellfish aquaculture, suggesting that this may be caused by the larger average body weight of oysters grown at non-aquaculture sites rather than by the degradation of aquaculture infrastructure.

Covernton, G. A. and K. Cox (2019). "Commentary on: Abundance and distribution of microplastics within surface sediments of a key shellfish growing region of Canada." PLoS ONE [Electronic Resource]

14(12): e0225945.

This formal comment is in response to "Abundance and distribution of microplastics within surface sediments of a key shellfish growing region of Canada" written by Kazmiruk and colleagues in 2018. This article presents microplastics concentrations in sediment, primarily microbeads, within Baynes Sound, British Columbia, which are some of the highest that have been reported anywhere in the world. The authors cite the local shellfish industry as the likely source of this high degree of contamination and present the industry as a substantial risk to the environment. However, the authors do not sufficiently justify the efficacy of their methodology, and there are several flaws which call into question the legitimacy of their findings. In this commentary, we address the microplastic abundances reported by the authors, and methodological concerns. Furthermore, we provide additional data to elucidate some of this study's more contentious findings. Specifically, we seek to clarify the visual identification of microbeads and microfibres, and the microplastic concentration within shellfish populations, water, and sediment, within the Baynes Sound shellfish growing region.

Covernton, G. A., et al. (2019). "Size and shape matter: A preliminary analysis of microplastic sampling technique in seawater studies with implications for ecological risk assessment." Science of the Total Environment **667**: 124-132.

Microplastic particles (MPs) are widely distributed in seawater. Fibrous MPs (microfibres) are often reported as the most commonly encountered shape of particle. To estimate MP concentrations in seawater, samples are often collected using towed nets (generally 300-350-mum mesh) and may underestimate the amount of microfibres present, which may pass through the mesh due to their narrow width. We compared the potential microplastic particle (PMP) concentration estimates provided by two different seawater sampling methods conducted at three commercial shellfish farms and three unfarmed sites in Baynes Sound, British Columbia, Canada. The methods were: 10-L bucket samples sieved through 63-mum mesh in situ and subsequently filtered through an 8-mum polycarbonate membrane; and 1-L bulk samples collected in jars and subsequently filtered to 8mum. The jar samples yielded PMP concentrations averaging approximately 8.5 times higher than the bucket samples per L of water (at the site level), largely driven by differences in the number of microfibres. There was no significant difference in PNP concentration between shellfish farms and unfarmed sites. An analysis of MP concentrations and mesh sizes reported in the literature suggests that using a 300-350-mum mesh may underestimate total MP concentrations by one to four orders of magnitude compared with samples that are filtered through much smaller mesh sizes (e.g. <100mum), despite the effect of sample volume. Particles <300mum in diameter make up a large component of MPs commonly found in fish and invertebrates. As such, common sampling practices fail to adequately measure a biologically relevant class of MPs, thereby undermining the ability to quantify ecological risk. We suggest that seawater sampling methods be designed to filter to <10mum (the approximate width of many microfibres), either using pressurized pumps for large-volume samples, or by using sufficient replication of small-volume discrete samples.

Cowger, W., et al. (2019). "Anthropogenic litter cleanups in Iowa riparian areas reveal the importance of near-stream and watershed scale land use." Environmental Pollution **250**: 981-989.

Volunteer cleanup operations collect large datasets on anthropogenic litter that are seldom analyzed. Here we assess the influence of land use in both near-stream and watershed scale source domains on anthropogenic litter concentration (standing stock, kg km⁻¹) in riparian zones of Iowa, USA. We utilized riparian litter concentration data on four classes of

anthropogenic litter (metal, recyclable, garbage, and tires) from volunteer cleanup operations. Anthropogenic litter data were tested for correlation with near-stream and watershed scale land uses (developed, road density, agricultural, and open lands). Road density (road length/area) and developed land use (% area) were significantly correlated to anthropogenic litter, but agricultural (% area) and open lands (% area) were not. Metal objects correlated to near-stream road density (r=0.79, p=0.02), while garbage and recyclable materials correlated to watershed scale road density (r=0.69, p=0.06 and r=0.71, p=0.05 respectively). These differences in the important spatial scales of land use may be related to differences in transport characteristics of anthropogenic litter. Larger, denser metal objects may be transported more slowly through the watershed/channelized system and thus, dependent on more proximal sources, whereas smaller, less dense garbage and recyclable material are likely transported more rapidly, resulting in concentrations that depend more on watershed scale supply. We developed a linear regression model that used near-stream road density and the total amount of observed litter to predict an average anthropogenic litter density of 188kgkm⁻¹ and a standing stock of 946t in all Iowa streams (>4th Strahler order). The techniques employed in this study can be applied to other professional and volunteer litter datasets to develop prevention and cleanup efforts, inform investigations of process, and assess management actions.

Cox, J. A., et al. (2014). "Woodchip or weedmat? A comparative study on the effects of mulch on soil properties and blueberry yield." Acta Horticulturae.

Blueberry growers in northern New South Wales, Australia, wanted to replace black plastic weedmat with woodchip fines mulch to reduce plastic waste and improve soil condition. Experiments were established to compare the effects of two mulch treatments on berry yield, plant size, soil compaction and soil microbial activity over three years. Southern highbush Vaccinium x corymbosum 'Star' seedlings were planted on three soil types, with 5 cm of woodchip or plastic weedmat applied to each plot. After three years, woodchip treatment increased berry yield by 81% on one soil type (grey gravelly silty loam), but was not significant on two other soil types (red loam, red silty loam). Canopy volume also increased with woodchip at the grey silty loam site, for a six month period in the red silty loam but not at the red loam site. Soil compaction (bulk density) was reduced with woodchip treatments in two of the three soil types. There was no difference in soil microbial activity. The improvements after woodchip application were most beneficial to compacted soils.

Cox, K. D., et al. (2019). "Human Consumption of Microplastics." Environmental Science & Technology **53**(12): 7068-7074.

Microplastics are ubiquitous across ecosystems, yet the exposure risk to humans is unresolved. Focusing on the American diet, we evaluated the number of microplastic particles in commonly consumed foods in relation to their recommended daily intake. The potential for microplastic inhalation and how the source of drinking water may affect microplastic consumption were also explored. Our analysis used 402 data points from 26 studies, which represents over 3600 processed samples. Evaluating approximately 15% of Americans' caloric intake, we estimate that annual microplastics consumption ranges from 39000 to 52000 particles depending on age and sex. These estimates increase to 74000 and 121000 when inhalation is considered. Additionally, individuals who meet their recommended water intake through only bottled sources may be ingesting an additional 90000 microplastics annually, compared to 4000 microplastics for those who consume only tap water. These estimates are subject to large amounts of variation; however, given methodological and data limitations, these values are likely underestimates.

Cox, T. (2014). "Introducing the Good Scrub Guide." Oryx **48**(1): 13-13.

The article reports on the challenges confronting marine conservation which focuses on plastic pollution. Noted in the 2012 Convention on Biological Diversity is the ingestion of marine debris of 247 species. Highlighted is the merging area of research in micropasltic pollution wherein plastic particles have been found to have implications for the health of oceans. Indicated is the Good Scrub Guide by the Fauna and Flora International (FFI) marine program which addresses microplastic pollution.

Coyne, K. (2010). "Beyond the bottle for better recovery rates." Local Authority Waste & Recycling **18**(11): 18-19.

The article focuses on the state of plastic recovery plants in Great Britain based on the Waste & Resources Action Programme report "Realising the Value of Recovered Plastics - An Update."The report states that plastic usage has grown by 1 percent a year to 5 million tonnes per annum, wherein over half of the consumption is meant for packaging. The report adds that 590,000 tonnes of plastics packaging were processed in 2010, although most of them are plastics recycled by businesses all over Great Britain.

Cózar, A., et al. (2014). "Plastic debris in the open ocean." Proceedings of the National Academy of Sciences of the United States of America **111**(28): 10239.

There is a rising concern regarding the accumulation of floating plastic debris in the open ocean. However, the magnitude and the fate of this pollution are still open questions. Using data from the Malaspina 2010 circumnavigation, regional surveys, and previously published reports, we show a worldwide distribution of plastic on the surface of the open ocean, mostly accumulating in the convergence zones of each of the five subtropical gyres with comparable density. However, the global load of plastic on the open ocean surface was estimated to be on the order of tens of thousands of tons, far less than expected. Our observations of the size distribution of floating plastic debris point at important size-selective sinks removing millimeter-sized fragments of floating plastic on a large scale. This sink may involve a combination of fast nano-fragmentation of the microplastic into particles of microns or smaller, their transference to the ocean interior by food webs and ballasting processes, and processes yet to be discovered. Resolving the fate of the missing plastic debris is of fundamental importance to determine the nature and significance of the impacts of plastic pollution in the ocean.

Cozar, A., et al. (2015). "Plastic accumulation in the Mediterranean sea." PLoS ONE [Electronic Resource] **10**(4): e0121762.

Concentrations of floating plastic were measured throughout the Mediterranean Sea to assess whether this basin can be regarded as a great accumulation region of plastic debris. We found that the average density of plastic (1 item per 4 m2), as well as its frequency of occurrence (100% of the sites sampled), are comparable to the accumulation zones described for the five subtropical ocean gyres. Plastic debris in the Mediterranean surface waters was dominated by millimeter-sized fragments, but showed a higher proportion of large plastic objects than that present in oceanic gyres, reflecting the closer connection with pollution sources. The accumulation of floating plastic in the Mediterranean Sea (between 1,000 and 3,000 tons) is likely related to the high human pressure together with the hydrodynamics of this semi-enclosed basin, with outflow mainly occurring through a deep water layer. Given the biological richness and concentration of economic activities in the Mediterranean Sea, the affects of plastic pollution on marine and human life are expected to be particularly frequent in this plastic accumulation region.

Crecea, V., et al. (2014). "High Resolution Phase-Sensitive Magnetomotive Optical Coherence Microscopy for Tracking Magnetic Microbeads and Cellular Mechanics." IEEE Journal of Selected Topics in Quantum Electronics **20**(2).

We present a real-time multimodal near-infrared imaging technology that tracks externally induced axial motion of magnetic microbeads in single cells in culture. The integrated multimodal imaging technique consists of phase-sensitive magnetomotive optical coherence microscopy (MM-OCM) and multiphoton microscopy (MPM).MPMis utilized for the visualization of multifunctional fluorescent and magnetic microbeads, while MM-OCM detects, with nanometer-scale sensitivity, periodic displacements of the microbeads induced by the modulation of an external magnetic field. Magnetomotive signals are measured from mouse macrophages, human breast primary ductal carcinoma cells, and human breast epithelial cells in culture, and validated with full-field phase-sensitive microscopy. This methodology demonstrates the capability for imaging controlled cell dynamics and has the potential for measuring cell biomechanical properties, which are important in assessing the health and pathological state of cells.

Crestani, S., et al. (2016). "Enhanced target-specific signal detection using an Escherichia coli lysate in multiplex microbead immunoassays with E. coli-derived recombinant antigens." Journal of Immunological Methods **435**: 17-26.

Diverse techniques have been developed to analyze antibody-mediated responses to infections. However, the most common tests, i.e., enzyme-linked immunosorbent assays, require separate reactions for each antigen and consequently necessitate large sample volumes. Luminex technology allows the detection of multiple antibodies in a single experiment, but nonspecific binding can impair the results. Therefore, we examined the use of Escherichia coli lysates to reduce nonspecific binding and improve the results of liquid microarrays based on Luminex technology. Anti-bacteria antibodies were detected in human serum samples, as evidenced by high median fluorescence intensity (MFI) in assays performed with paramagnetic microspheres coupled with E. coli lysates. Moreover, the addition of an E. coli lysate as a blocker reduced the nonspecific binding of antigens produced by E. coli in a concentration-dependent manner. Tris-HCl reduced MFI values in negative samples, but did not affect MFI for positive samples. For microspheres coupled with different antigens, an E. coli lysate blocker significantly improved the fluorescence signals from positive samples. The addition of Tris-HCl and the E. coli lysate induced antigen-specific differences in MFI. This combination of the E. coli lysate blocker and Tris-HCl yielded a statistically significant improvement in MFI in the assays for Chagas disease and hepatitis C virus samples. However, for the Treponema pallidum p47 antigen improvement in MFI was only observed for the preparation with the E. coli blocker at a concentration of 3%. In conclusion, the addition of an E. coli lysate and Tris-HCl to the microarray assay reduced the nonspecific binding of human anti-bacteria antibodies and, therefore, increased the specific MFI.

Cribb, J., et al. (2015). "A high throughput array microscope for the mechanical characterization of biomaterials." Review of Scientific Instruments **86**(2): 023711.

In the last decade, the emergence of high throughput screening has enabled the development of novel drug therapies and elucidated many complex cellular processes. Concurrently, the mechanobiology community has developed tools and methods to show that the dysregulation of biophysical properties and the biochemical mechanisms controlling those properties contribute significantly to many human diseases. Despite these advances, a complete understanding of the connection between biomechanics and disease will require advances in instrumentation that enable parallelized, high throughput assays capable of probing complex signaling pathways, studying biology in physiologically relevant conditions, and capturing specimen and mechanical heterogeneity. Traditional biophysical instruments are unable to meet this need. To address the challenge of large-scale, parallelized biophysical measurements, we have developed an automated array high-throughput microscope system that utilizes passive microbead diffusion to characterize mechanical properties of biomaterials. The instrument is capable of acquiring data on twelve-channels simultaneously, where each channel in the system can independently drive two-channel fluorescence imaging at up to 50 frames per second. We employ this system to measure the concentration-dependent apparent viscosity of hyaluronan, an essential polymer found in connective tissue and whose expression has been implicated in cancer progression.

Crichton, E. M., et al. (2017). "A novel, density-independent and FTIR-compatible approach for the rapid extraction of microplastics from aquatic sediments. (Special Issue: Microplastics in the environment.)." Analytical Methods **9**(9): 1419-1428.

Microplastics have been detected in aquatic sediments around the world, highlighting the propensity of this matrix to serve as a sink for these structural pollutants. More reliable and reproducible extraction protocols for microplastics would facilitate comparisons across studies. A number of different extraction techniques are currently used to separate microplastics from sediment and almost exclusively employ density-based separations, which take advantage of the inherent densities of plastic particles. Some of these techniques are cost-effective but fail to fully recover all plastic types. Other techniques may recover most plastic types, but are more costly and/or hazardous to human or environmental health. We present here a novel, cost-effective oil extraction protocol (OEP) that provides an alternative to density-based approaches by taking advantage of the oleophilic properties of microplastics. Using this technique, we counted microplastic particles in spiked sediment samples using light microscopy and observed 96.1%+or-7.4 recovery for total microplastics, with recovery rates of 92.7%+or-4.3 for fibers and 99%+or-1.4 for particles. Subsequent analysis with Fourier-Transform Infrared Spectrometry (FTIR) revealed that the oil interfered with the FTIR spectrum of microplastics, but that an additional, post-extraction clean-up step using ethyl alcohol (90%) removed residual traces of oil and eliminated the FTIR spectral interference. The application of this new technique to shoreline sediment samples collected from sites in urban Vancouver, British Columbia, Canada, and a remote beach on Vancouver Island, as well as bulk seawater, demonstrated that the oil extraction protocol is effective for environmental samples. This novel OEP represents a cost-effective and reliable alternative to leading density-based techniques.

Critchell, K., et al. (2019). "Predicting the exposure of coastal species to plastic pollution in a complex island archipelago." Environmental Pollution **252**(Part B): 982-991.

Plastic pollution in the marine environment is a pervasive and increasing threat to global biodiversity. Prioritising management actions that target marine plastic pollution require spatial information on the dispersal and settlement of plastics from both local and external sources. However, there is a mismatch between the scale of most plastic dispersal studies (regional, national and global) and the scale relevant to management action (local). We use a fine-resolution hydrodynamic model to predict the potential exposure of coastal habitats and species (mangroves, coral reefs and marine turtles) to plastic pollution at the local scale of a management region (the 1,700 km² Whitsunday Islands, Queensland, Australia). We assessed the potential exposure of mangroves, coral reefs and marine turtles to plastics during the two dominant wind conditions of the region; the trade wind and monsoon wind seasons. We found that in the trade wind season (April to September) all habitats and species had lower exposure than during the monsoon wind season (October to March). In both wind seasons we found a small proportion of coral reef habitat and large area of turtle habitat were in high potential exposure categories. Unlike coral reefs or marine turtles, mangroves had consistent hotspots of high exposure across wind seasons. Local scale management requires data at fine resolution to capture the variability that occurs at this scale. The outputs of our study can inform the development of conservation resources and local scale management action.

Critchell, K. and J. Lambrechts (2016). "Modelling accumulation of marine plastics in the coastal zone; what are the dominant physical processes?" Estuarine, Coastal and Shelf Science **171**: 111-122.

Anthropogenic marine debris, mainly of plastic origin, is accumulating in estuarine and coastal environments around the world causing damage to fauna, flora and habitats. Plastics also have the potential to accumulate in the food web, as well as causing economic losses to tourism and sea-going industries. If we are to manage this increasing threat, we must first understand where debris is accumulating and why these locations are different to others that do not accumulate large amounts of marine debris. This paper demonstrates an advection-diffusion model that includes beaching, settling, resuspension/re-floating, degradation and topographic effects on the wind in nearshore waters to quantify the relative importance of these physical processes governing plastic debris accumulation. The aim of this paper is to prioritise research that will improve modelling outputs in the future. We have found that the physical characteristic of the source location has by far the largest effect on the fate of the debris. The diffusivity, used to parameterise the sub-grid scale movements, and the relationship between debris resuspension/re-floating from beaches and the wind shadow created by high islands also has a dramatic impact on the modelling results. The rate of degradation of macroplastics into microplastics also have a large influence in the result of the modelling. The other processes presented (settling, wind drift velocity) also help determine the fate of debris, but to a lesser degree. These findings may help prioritise research on physical processes that affect plastic accumulation, leading to more accurate modelling, and subsequently management in the future.

Critchfield, A., et al. (2012). "Permeability properties of cervical mucus in women at high risk for preterm birth." American Journal of Obstetrics and Gynecology **1)**: S207.

OBJECTIVE: Cervical mucus is an important defensive barrier to ascending infection during pregnancy. Our OBJECTIVE was to study permeability properties of cervical mucus from women at high risk of preterm birth. STUDY DESIGN: Cervical mucus samples were aspirated from the external cervical os and flash frozen or used fresh (within 4 hours). Two assays were performed: bead permeability and bioinfectivity. For bead permeability, mucus samples were applied to streptavidin coated glass slides. Biotin-labeled, fluorescent polystyrene microbeads (0.2 micron Fluorospheres, 25,000 beads/well) were applied to the mucus samples. After two hours, beads passing through the mucus and bound to the bottom of the slide were visualized with fluorescence microscopy (10x). Controls included mucus samples from women at low risk for preterm birth. For bioinfectivity, mucus samples (50 uL) were applied to 96 well plates pre-plated with HeLa cells. Human Papilloma Virus (HPV) particles containing green fluorescent protein (GFP) reporter vectors were applied the mucus samples. Virus particles passing through the mucus samples infected the HeLa cells. Infected cells expressed GFP which was detected with flow cytometry. RESULT(S): Mucus samples were collected from 25 women with singleton pregnancies (20 - 34 wks) at high risk (n=11) and low risk (n=14) for preterm birth. Mean volume of cervical mucus obtained was 220 uL. Cervical mucus from high risk subjects showed increased permeability to microbeads compared to low risk subjects (5.8 beads/field vs 2.2 beads/field, p = 0.03). The bioinfectivity assay showed no significant difference in GFP expression in HeLa cells exposed to frozen vs fresh cervical mucus (5.3% vs 4.2%, p=0.3). Significantly fewer HeLa cells expressed GFP when exposed to mucus compared to buffer (4.6% vs 73.3%, p = 0.001). CONCLUSION(S): Our results suggest increased permeability of cervical mucus from women at high risk for preterm birth compared to low risk women. Investigation of cervical mucus permeability properties could improve our understanding of cervical barrier function during pregnancy.

Critchfield, A. S., et al. (2013). "Cervical Mucus Properties Stratify Risk for Preterm Birth." PLoS ONE **8 (8) (no pagination)**(e69528).

Background:Ascending infection from the colonized vagina to the normally sterile intrauterine cavity is a well-documented cause of preterm birth. The primary physical barrier to microbial ascension is the cervical canal, which is filled with a dense and protective mucus plug. Despite its central role in separating the vaginal from the intrauterine tract, the barrier properties of cervical mucus have not been studied in preterm birth.Methods and Findings:To study the protective function of the cervical mucus in preterm birth we performed a pilot case-control study to measure the viscoelasticity and permeability properties of mucus obtained from pregnant women at high-risk and low-risk for preterm birth. Using extensional and shear rheology we found that cervical mucus from women at high-risk for preterm birth was more extensible and forms significantly weaker gels compared to cervical mucus from women at low-risk of preterm birth. Moreover, permeability measurements using fluorescent microbeads show that high-risk mucus was more permeable compared with low-risk mucus. Conclusion(s):Our findings suggest that critical biophysical barrier properties of cervical mucus in women at high-risk for preterm birth are compromised compared to women with healthy pregnancy. We hypothesize that impaired barrier properties of cervical mucus could contribute to increased rates of intrauterine infection seen in women with preterm birth. We furthermore suggest that a robust association of spinnbarkeit and preterm birth could be an effectively exploited biomarker for preterm birth prediction. © 2013 Critchfield et al.

Crowther, D. C., et al. (2014). "Anassay for seeded proteinaggregation detects abeta seeds in serum." Alzheimer's and Dementia **4)**: P271.

Background: Many common neurodegenerative disorders are characterised by progressive protein aggregation. In Alzheimer's disease the principal pathologies of interest are amyloid plaques composed of the amyloid-beta peptide (Abeta) and tangles comprised of tau. The spread of pathology within the brain is thought to be mediated by a prionlike seeding process that accelerates the aggregation of susceptible polypeptides in the neighbourhood of existing deposits. Soluble seeds of Abeta may travel widely: between neurones or even to the CSF and peripheral circulation. Method(s): We measure seeded Abeta aggregation in brain and blood extracts from animal models of Alzheimer's disease. Firstly we examine brains from Drosophila melanogaster expressing the Abeta peptide versus non-expressing controls. Secondly we assess brain and serum from aged CRND8 mice and compare them to their non-transgenic littermate controls. Brains are homogenised in PBS followed by dilution to give a protein concentration of 3 mg/ml. Serum is diluted to 3 mg/ml in PBS.Our assay uses microfluidic apparatus to compartmentalise these crude biological extracts into aqueous droplets (50 mm diameter) containing fluorescent-labelled Abeta42 peptide along with molten agarose (37degreeC). The droplets are cooled to room temperature, whereupon the agarose forms a gel, and are then incubated for up to 3 hr. Following this incubation the oil phase is removed and the uncoated agarose microbeads are washed to remove unincorporated fluorescent peptide. Result(s): Seeded aggregates are marked by their having incorporated fluorescent- labelled Abeta during the incubation step. Aggregates that are larger than MW 1000 kDa are retained within the agarose matrix and are detected and quantified by fluorescence activated cytometry (FACS). Over 10,000 beads are assessed for each assay.In the brain extracts we see significantly higher fluorescence signals in microbeads derived from AD-affected organisms as compared to controls. Remarkably this higher fluorescence signal is also seen in the serum samples from affected mice. Conclusion(s): These data indicate that Abeta-seeding activity can be detected in the brain and serum of models of Alzheimer's disease.We are now testing human clinical samples as this assay may provide novel prognostic and/or diagnostic tools in humans.

Cruickshank, G., et al. (2018). "Local delivery of irinotecan to recurrent glioblastoma at reoperation offers a safe therapeutic advantage over systemic delivery." Neuro-Oncology **20 (Supplement 1)**: i1.

Direct drug delivery to a brain tumours offers the surety of access, together with the potential to realise at least therapeutic concentrations. With previously used systemic drugs toxicity and removal mechanisms are avoided. With new formulations drug activation and duration can be explored for low local toxicity, and tumour impact with sequential imaging. In this early study Irinotecan a drug with known efficacy against glioma but with limiting systemic toxicity has been incorporated into biodegradeable hydrogel microspheres and injected into the post-surgical cavity wall in patients with recurrent glioblastoma. 10 patients with focally recurrent GBM were recruited with 9 undergoing injection with up to 3mls of microbeads in alginate suspension in up to 60 ~ 8mm injection tracks after surgical resection (100mg). Patients were assessed for immediate (72hrs) toxicity with clinical assessment and imaging. Pharmacokinetic determination of Irinotecan and SN 38 active metabolite allowed confirmation of activation and comparator with known plasma toxicity profiles. Follow-up was planned for a minimum of 6/12 for SAE but continued to allow overall survival estimation. No overt SAE were determined for this group of patients with imaging and steroid use indicating less local swelling and wound healing issues than have been demonstrated for Carmustine wafers despite early offloading. Phamacokinetic measures (SN38 plasma curves) indicate a much higher activation of Irinotecan (>90%) than expected but shorter period of exposure. Survival curves suggest clinical benefit with 4/9 patient living longer than 8 months warranting further exploration of this safe approach.

Cruz-Aldaco, K., et al. (2014). "Surface adhesion fermentation for lipase production by Mucor griseocyanus." Micologia Aplicada International **26**(1): 9-16.

The lipase production by Mucor griseocyanus was evaluated using surface adhesion fermentation. Plastic particles, covered with fungal biomass, were produced in the first experimental step. Erlenmeyer flasks (250 ml) were used with whey as culture medium, polystyrene foam as support for fungal growth, and olive oil as inducer for lipase activity. Kinetics were monitored during 72 h of culture time. In a second experimental step, an airlift bioreactor was packed with the plastic particles covered with fungal biofilm and used for production of lipases in batch conditions employing whey supplemented with olive oil. Evaluation of operational conditions indicated that the maximum level of activity was obtained at 60 C and at pH 6.0. It was demonstrated that the fungus grown by adhesion on plastic particles produced the highest activity level (133 U L⁻¹) at 60 h, however, fungal biofilms obtained at 72 h of surface adhesion fermentation had a lipolytic activity at 94 U L⁻¹. For this reason, under these culture conditions, the fungal particles were

produced and then packed into the airlift bioreactor where the lipase activity was enhanced. Two sequential batches were evaluated using the same particles of polystyrene foam covered by fungal biomass. The fungal covered particles can be used and reused to produce lipases.

Cruz-Campos, A., et al. (2019). "Performance Evaluation of the Noveos Specific Ige D001 and D002* (House Dust Mite) Assays." Annals of Allergy, Asthma and Immunology **123 (5 Supplement)**: S21.

Introduction: Determination of allergen-specific IgE (sIgE) is beneficial for the evaluation and diagnosis of various hypersensitivity disorders. The NOVEOSTM Immunoassay Analyzer is a novel, high throughput automated platform that utilizes magnetic microbeads in combination with fluorescence and chemiluminescence signals to quantify allergen-sIgE present in human serum. The analytical performance of the NOVEOS devices was evaluated with the NOVEOS sIgE D001, D. pteronyssinus, and D002, D. farinae, assays. Method(s): The NOVEOS sIgE assay precision and functional sensitivity were evaluated in accordance with CLSI EP05-A3. Limit of Blank (LoB) and Limit of Detection (LoD) were estimated in accordance with CLSI EP17-A2. Assay linearity was assessed in accordance with CLSI I/LA20-A3. Cross reactivity of non-IgE immunoglobulin isotypes, endogenous, and exogenous interferences were evaluated in accordance with CLSI EP07-A2. Method comparison of NOVEOS and ImmunoCAPTM assay results was performed in accordance with CLSI EP09-A3 and CLSI EP24-A2. Result(s): The NOVEOS immunoassay analyzer produced overall repeatability <9%CV and within-lab precision <12%CV for the sIgE assay. Functional sensitivity was determined at 0.17 kU/L, while LoB/LoD measured <0.08kU/L. The performance for both allergens exhibited good linearity across the reportable range of the NOVEOS sIgE assay. No significant reactivity was observed for cross reactive, endogenous, and exogenous interferents. The system produced excellent clinical sensitivity to skin prick testing and generated acceptable agreement when compared to a commercially available device on over 100 human serum samples. Conclusion(s): The NOVEOS sIgE D001 and D002 assay on the NOVEOS immunoassay analyzer exhibited strong analytical performance for the determination of sIgE in human serum. Copyright © 2019

Cruz-Rodriguez, N., et al. (2016). "Gene expression signature predicts induction treatment response and clinical outcome in adult Colombian patients with acute lymphoblastic leukemia." Cancer Research. Conference: 107th Annual Meeting of the American Association for Cancer Research, AACR **76**(14 Supplement).

Background. In Colombia ALL in adults represents a public health problem because its incidence and mortality increase annually. Only 61% of Colombian adult patients with ALL achieve complete remission. The median overall survival to the disease is less than 11.3 months and the eventfree survival is 7.34 months. Identification of prognostic factors in patients with ALL is crucial for the proper planning of treatment strategies and the optimal results of therapy. Our goal was to determine gene expression signatures correlated with response to therapy and to evaluate the utility of these expression patterns as predictors of risk prior to therapy of adult Colombian patients with BALL. Methods. This study included 43 adult patients newly diagnosed with Bcell precursor or common BALL. Patients were recruited at the Colombian National Cancer Institute and Hospital Universitario San Ignacio, both in Bogota, Colombia. The leukemic blast population from diagnostic samples was separated with magnetic microbeads coated with either antiCD19 or anti-CD34 antibodies followed by column enrichment using standard procedures and MACS (Miltenyi, Bergisch Gladbach,Germany). Total RNA from purified leukemic cells was isolated using the RNeasy Mini Kit (Qiagen) according to the manufacturer's protocols. We used microarray analysis to identify genes that distinguish poor from good response to induction treatment using differential gene expression analysis and the response group as reference and the Illumina Custom algorithm embedded in the GenomeStudio software (Illumina). The expression profile was validated by realtime PCR (RTPCT) using TaqMan probes. The 2DELTADELTACT method was used to estimate the fold induction of each gene using GAPDH and an internal calibrator as controls. Assays were done in triplicate. Results. We identified 442 genes differentially expressed between 22 leukemia patients who responded and 5 who did not respond to induction chemotherapeutic treatment. Hierarchical analysis with the 99 most differentially expressed genes between the two groups revealed 3 sets of patients that differed in their clinical characteristics giving these genes high prognostic clinical outcome impact capacity. We validated the expression of 7 genes by RT PCR in 43 patients and, in addition to finding a correlation with gene expression profiles, we established correlations with good and poor prognosis from the time of diagnosis. Conclusions. Our study suggests that the response to induction treatment and clinical outcome of patients can be predicted from the onset of the disease and that gene expression profiles can be used to stratify patient risk adequately and accurately. The present study represents the first showing that gene expression profiling could become a clinically relevant tool for stratification in the early course of disease of Colombian adults BALL.

Csaszar, E., et al. (2014). "Real-time monitoring and control of soluble signaling factors enables enhanced progenitor cell outputs from human cord blood stem cell cultures." Biotechnology & Bioengineering **111**(6): 1258-1264.

Monitoring and control of primary cell cultures is challenging as they are heterogenous and dynamically complex systems. Feedback signaling proteins produced from off-target cell populations can accumulate, inhibiting the production of the desired cell populations. Although culture strategies have been developed to reduce feedback inhibition, they are typically optimized for a narrow range of process parameters and do not allow for a dynamically regulated response. Here we describe the development of a microbead-based process control system for the monitoring and control of endogenously produced signaling factors. This system uses quantum dot barcoded microbeads to assay endogenously produced signaling proteins in the culture media, allowing for the dynamic manipulation of protein concentrations. This monitoring system was incorporated into a fed-batch bioreactor to regulate the accumulation of TGF-beta1 in an umbilical cord blood cell expansion system. By maintaining the concentration of TGF-beta1 below an upper threshold throughout the culture, we demonstrate enhanced ex vivo expansion of hematopoietic progenitor cells at higher input cell densities and over longer culture periods. This study demonstrates the potential of a fully automated and integrated real-time control strategy in stem cell culture systems, and provides a powerful strategy to achieve highly regulated and intensified in vitro cell manufacturing systems.

Cseplak, G. (1966). "A new procedure for the recording of the superficial relations of the skin and the relative size of, alterations projecting from the skin. [Czech]." Borgyogyaszati es Venerologia Szemle **42**(6): 257-260.

A dermato-microplastic method is described which makes it possible to take impressions of any given number of superficial alterations of the healthy or diseased skin. The essential procedure is the making of a negative of the surface of the prepared skin by means of the quickly polymerizing substance 'Renit' which is used in dentistry and by taking plaster impressions from the negative which are examined with a strongly magnifying glass. The method is also suitable for medicolegal purposes.

Csizmadia, Z., et al. (2018). "Comparison of chemiluminescent and conventional ELISA techniques in autoantibody detection." Clinical Chemistry and Laboratory Medicine **56 (9)**: eA159.

Because of the presence of high amounts of interfering antibodies, it is important to choose the most accurate immunoserological assay for autoantibody detection to support the diagnosis of autoimmune diseases. The chemiluminescent immunoassay (CIA) is a recent alternative to conventional ELISA tests, allowing highly sensitive, more specific, and less time-consuming parallel autoantibody measurements. We compared our well-established ELISA tests with the new CIA, where antigens are immobilized on magnetic microbeads instead of polystyrene plate wells, enabling a several fold higher surface to give a more sensitive detection of antibody titers. For simple test comparison samples were chosen from our routine diagnostic laboratory serum-bank (n>500), while for clinical confirmation of the CIA anti-dsDNA antibody measurements, we used sera from patients (n>80) with established SLE clinical diagnosis. There was a high concordance between results obtained by ELISA and CIA: anti-dsDNA 75%, anti-Cardiolipin 90%, anti-B2GP 82%, anti-MPO 98%, anti-PR3 91%, anti-tTG 86%. Comparing anti-dsDNA measurements, the CIA laboratory data showed a better correlation with the clinical history of the patients (p-value<0.0001, alpha=0.05). In summary, CIA enables fast, parallel autoantibody measurements with continuous loading of samples, without need of pre-dilution, and repeated measurement of standards. Although ELISA tests and the new CIA method showed high agreement, further clinical evidence based confirmation of the CIA test is needed for the full implementation of the test, and method changes.

Cui, X., et al. (2018). "A fluorescent microbead-based microfluidic immunoassay chip for immune cell cytokine secretion quantification." Lab on a Chip **18**(3): 522-531.

Quantitative and dynamic analyses of immune cell secretory cytokines are essential for precise determination and characterization of the "immune phenotype" of patients for clinical diagnosis and treatment of immune-related diseases. Although multiple methods including the enzyme-linked immunosorbent assay (ELISA) have been applied for cytokine detection, such measurements remain very challenging in real-time, high-throughput, and high-sensitivity immune cell analysis. In this paper, we report a highly integrated microfluidic device that allows for on-chip isolation, culture, and stimulation, as well as sensitive and dynamic cytokine profiling of immune cells. Such a microfluidic sensing chip is integrated with cytometric fluorescent microbeads for real-time and multiplexed monitoring of immune cell cytokine secretion dynamics, consuming a relatively small extracted sample volume (160 nl) without interrupting the immune cell culture. Furthermore, it is integrated with a Taylor dispersion-based mixing unit in each detection chamber that shortens the immunoassay period down to less than 30 minutes. We demonstrate the profiling of multiple pro-inflammatory cytokine secretions (e.g. interleukin-6, interleukin-8, and tumor necrosis factors) of human peripheral blood mononuclear cells (PBMCs) with a sensitivity of 20 pg ml⁻¹ and a sample volume of 160 nl per detection. Further applications of this automated, rapid, and high-throughput microfluidic immunophenotyping platform can help unleash the mechanisms of systemic immune responses, and enable efficient assessments of the pathologic immune status for clinical diagnosis and immune therapy.

Cujic, N., et al. (2016). "Spray drying influence on encapsulation of chokeberry (aronia melanocarpa L.) extract." Arhiv za Farmaciju **ISS)**: 123-124.

INTRODUCTION Chokeberry (Aronia melanocarpa) is a rich source of polyphenols with confirmed health benefits. Nowdays there is increasing interest for chokeberry extracts, very rich sources of antioxidant phenolics, especially anthocyanins, which could be useful in prevention and treatment of cardiovascular diseases, diabetes and many other chronic diseases.

Problem with instability of polyphenols in extracts could be solved using the microencapsulation technology. The main goal of microencapsulation are stability enhancement of bioactive compounds, protection from harmful environmental conditions, shelf life extension, controlled delivery, covering unpleasant taste (bitter taste of polyphenols), and circumvention the damaging effects of gastrointestinal tract. Spray drying is simple, low cost and one of the most convenient microencapsulation method for controlled production of small particles with uniform and desirable size. Encapsulation of 50% chokeberry ethanolic extracts, one prepared from dried berries-CE and one after juice production-CWE, with different carriers were employed. Encapsulation systems were examined and compared in order to choose the optimal one. MATERIALS AND METHODS Spray drying method was applied for microencapsulation of 50% ethanolic chokeberry extracts-CE (2.52mg GAE/ml) and 50% ethanolic chokeberry extract from waste-CWE (4.11mg GAE/ml) (with prior ethanol evaporation) under the below-stated spray-drying conditions. Two different biopolymers: maltodextrin and summed milk, in same concentration (20%, w/v) were used for microencapsulation. They prepared by dissolving a required amount of each encapsulant in previously prepared extracts at 40 degreeC. The resulting solutions were mixed, homogenized prior to spray drying. A spray dryer (Buchi mini B-290, Buchi Labortechnik AG, Switzerland) with a 0.7-mm standard diameter nozzle was used with inlet (130+/-3degreeC) and outlet (56+/-2degreeC) temperatures. Relatively low spraying air flow rate (536 L/h), liquid feed (8 mL/min rate), atomization pressure (6 psi) and low inlet temperature were chosen in order to ensure a good atomization along the liquid feed rate and to obtained a stable powder (especially to ensure anthocyanins stability) with high actual loading. The release profiles for the polyphenols and anthocyanis from microbeads in water were investigated determining the total polyphenol content-TP using Folin-Ciocalteau method and total anthocyanins content-TA using the procedure described in European Pharmacopoeia 6.0. (2008) with slight modifications. Transmission spectra of of obtained spraydried powders were recorded using a IRAffinity-1 Fourier transform infrared spectrophotometer (Schimadzu, Japan) and applying the KBr disc method. Microbeads were mixed with KBr powder and compressed to pastilles. Infrared spectra over the wavelength range 4000 to 600 cm⁻¹ were recorded and the resolution was 4 cm⁻¹. The size of the encapsulated microbeads was deter-mined using Mastersizer 2000 (Malvern Instruments, Worcester-shire, UK). The mean diameter over volume (also called DeBroukere mean) was used as representative diameter. RESULTS AND DISCUSSION Influence of matrix and different extracts on the active compounds stability in obtained microparticles were evaluated. The impact of different type of carriers on phenolics and anthocyanins realise has been observed. For both extracts, better TP realise was achieved with summed milk as a carrier (1.79 mg GAE/g for CE, 2.56 mg GAE/g for CWE, respectively) in comparasion with encapsulated maltodextrin (1.20 mg GAE/g for CE, 2.07 mg GAE/g for CWE, respectively). Better realise of TA was achieved with maltodextrin (0.031% for CE, 0.5663% for CWE, respectively) than with skimmed milk (0.022% for CE, 0.3611% for CWE, respectively). Phenolis and anthocyanins compounds were released very rapidly from spray dried microbeads. Particle size for obtained microparticles ranged from 4.72-11.01mum for both carriers and extracts, which confirmed that spray drying is suitable method for pr duction of small particles with uniform size. In the case with both extracts, microbeads obtained with maltodextrin were smaller (4.27mum for CE, 5.12mum for CWE, respectively) in comparation with skimmed powders (8.50mum for CE, 11.01mum for CWE, respectively). Deserable particle size depends on future application. Larger particles provide more extended realise of encapsulated compounds, while smaller beads have better organoleptic charateristics, which is important for application in food or pharmaceutical products. Optimization of process parameters, spraying air flow rate, rate of liquid speed, atomization process, could provide microbeads with uniform size, desired diameter and high uniformity. FTIR spectrum of encapsulated CE and CWE in maltodextrin and skimmed milk showed several relevant picks. Picks in range about 1000cm⁻¹ could be attributed to the-C-O of cyclic ether and alcoholic groups from polyphenols, especially in the case of maltodextrin. FTIR analysis showed that CE and CWE were successfully incorporated into the particles and it could be concluded that used matrixes are compatible materials for extracts encapsulation. CE and CWE bioactive molecules were incorporated in the biopolymer matrix by intermolecular interactions, they integrity were preserved after spray drying process. CONCLUSIONS This study demonstrates the potential of spray dried microbeads for encapsulation of chokeberry and chokeberry waste polyphenols in order to improve their functionality, stability and bioavailability. Our result showed that stability of polyphenols, especially anthocyanins might be improved using spray drying as microencapsulation tehnology. Chokeberry polyphenol microbeads, due to their antioxidant potential, represent a promising food additive for incorporation into dietary suplements, functional food or pharmaceutical and cosmetic preparations.

Cujic, N., et al. (2016). "Chokeberry (Aronia melanocarpa L.) extract loaded in alginate and alginate/inulin system." Industrial Crops and Products **86**: 120-131.

Chokeberry (Aronia melanocarpa) is a rich source of polyphenols with confirmed health benefits. Microencapsulation tehnique is a promising tool for improving its polyphenols functionality, stability and bioavailability. Electrostatic extrusion process was carried out to obtain microbeads with encapsulated chokeberry extract. The effects of the carrier type (alginate of low and medium viscosity), addition of inulin as filler, and the needle diameter (18, 20, 22 gauges) on the morphological characteristics and release properties of the microbeads were studied. Particles obtained with medium viscosity alginate carrier (1.5% w/v), using inulin as filler (5% w/v) and medium needle size (20 gauges) showed the best results in the release studies. Drying process affected the encapsulation efficiency, the amount of encapsulated polyphenols increased from 0.24 mg GAE/g in hydrogel beads to 3.57 mg GAE/g in freeze dried beads, and the release profile of encapsulated extracts was prolonged to 40 min. SEM micrographs confirmed that the addition of inulin as filler improved the final properties of the microbeads, while FTIR analysis showed that the extract was successfully incorporated into the particles. Due to the extended storage and stability, dry microbeads showed the best potential as a delivery system suitable for pharmaceutical or functional food industry.

Culin, J. and T. Bielic (2016). "Plastic Pollution from Ships." Pomorski Zbornik **51**(1): 57.

The environmental impact of shipping on marine environment includes discharge of garbage. Plastic litter is of particular concern due to abundance, resistance to degradation and detrimental effect on marine biota. According to recently published studies, a further research is required to assess human health risk. Monitoring data indicate that despite banning plastic disposal at sea, shipping is still a source of plastic pollution. Some of the measures to combat the problem are discussed.

Cummings, R. D. (2017). "Glycan functions in development and glycan recognition by lectins and antibodies." Glycoconjugate Journal **34 (Supplement 1)**: S12.

Glycans in human and animal glycoconjugates are bound by a wide variety of glycan-binding proteins (GBPs), including animal cell receptors, microbial adhesins lectins and toxins, as well as functioning indirectly in glycoproteins to facilitate intra-and intermolecular interactions that maintain homeosta-sis and biological integrity. But glycans are also recognized by a wide variety of antibodies in human serum and other fluids, including saliva and cerebrospinal fluid. We have taken a multifaceted approach to explore glycan functions using human and mouse biology and genetics, and to explore protein-glycan interactions using a variety of technologies including shotgun glycomics and glycan microarray and glycans derivatized to microbeads. Our studies show that extended O-glycans are required for recognition by many types of GBPs and that loss of extended O-glycans due to engineered and acquired mutations in the molecular chaperone Cosmc lead to loss of function in almost all cell types, but we have identified many specific changes in lymphocyte function as-sociated with normal O-glycans. In addition, we have identified many antibodies in animals and people that bind to simple or complex glycans, including microbial glycans, and the antisugar antibody repertoire (ASAR) is extensive but unique for each individual and indicates their history of exposure to different types of pathogens and commensal organisms. Overall, these studies reveal the complex recognition of gly-cans by endogenous GBPs and antibodies and the complex ways in which cellular glycans regulate many aspects of development and immunity.

Cunha, C., et al. (2019). "Marine vs freshwater microalgae exopolymers as biosolutions to microplastics pollution." Environmental Pollution **249**: 372-380.

Microalgae can excrete exopolymer substances (EPS) with a potential to form hetero-aggregates with microplastic particles. In this work, two freshwater (Microcystis panniformis and Scenedesmus sp.) and two marine (Tetraselmis sp. and Gloeocapsa sp.) EPS producing microalgae were exposed to different microplastics. In this study, the influence of the microplastic particles type, size and density in the production of EPS and hetero-aggregates potential was studied. Most microalgae contaminated with microplastics displayed a cell abundance decrease (of up to 42%) in the cultures. The results showed that the formed aggregates were composed of microalgae and EPS (homo-aggregates) or a combination of microalgae, EPS and microplastics (hetero-aggregates). The hetero-aggregation was dependent on the size and yield production of EPS, which was species specific. Microcystis panniformis and Scenedesmus sp. exhibited small EPS, with a higher propension to disaggregate, and consequently lower capabilities to aggregate microplastics. Tetraselmis sp. displayed a higher ability to aggregate both low and high-density microplastics, being partially limited by the size of the microplastics. Gloeocapsa sp. had an outstanding EPS production and presented excellent microplastic aggregation capabilities (adhered onto the surface and also incorporated into the EPS). The results highlight the potential of microalgae to produce EPS and flocculate microplastics, contributing to their vertical transport and consequent deposition. Thus, this work shows the potential of microalgae as biocompatible solutions to water microplastics treatment.

Cunha, C., et al. (2019). "Ecotoxicological and biochemical effects of environmental concentrations of the plastic-bond pollutant dibutyl phthalate on Scenedesmus sp." Aquatic Toxicology **215**: N.PAG-N.PAG.

• Dibutyl phthalate (DBP) is a phthalate derived from plastic pollution that is widely found in aquatic environments. • DBP effect on Scenedesmus sp. growth is dose-dependent, with a more negative effect within the first 48 h of exposure. • Environmental concentrations of DBP decreased the microalgal growth and carbohydrates but did not change the pigment and protein concentration. • DBP environmental concentrations decrease the microalgal growth and carbohydrates but did not change the pigment and protein. Phthalate esters are highly present in aquatic plastic litter, which can interfere with the biological processes in the wildlife. In this work, the commonly found freshwater microalga Scenedesmus sp. was exposed to environmental concentrations (0.02, 1 and 100 μg L−1) and to a higher concentration (500 μg L−1) of dibutyl phthalate (DBP), which is an environmental pollutant. The growth, pH variation,

production of photosynthetic pigments, proteins and carbohydrates were evaluated. The main inhibition effect of DBP on the microalgal growth was observed in the first 48 h of the exposure (EC 50 : 41.88 µg L-1). A reduction in the photosynthetic pigment concentration was observed for the 0.02, 1 and 100 µg L-1 conditions indicating that the DBP downregulated the growth rate and affected the photosynthetic process. A significant increase in protein production was only observed under 500 µg L−1 DBP exposure. The extracellular carbohydrates production slightly decreased with the presence of DBP, with a stronger decrease occurring in the 500 µg L-1 condition. These results highlight the environmental risk evaluation and ecotoxicological effects of DBP on the production of biovaluable compounds by microalgae. The results also emphasize the importance of assessing the consequences of the environmental concentrations exposure as a result of the DBP dose-dependent correlation effects. [ABSTRACT FROM AUTHOR]

Cunliffe, J. (1996). "MUNICIPAL WASTE - TRASH OR TREASURE." Recycling Textile & Plastic Waste: 17-26.
The article discusses the implications of municipal waste found in Great Britain. The country is facing a problem concerning waste disposals, hence rising cost of landfill disposal. The concerned organizations are increasing environmental awareness which focuses on problems associated with land filling such as landfill gas contributing to global warming, water and ground pollution, restoration of the landscape and long term aftercare for the integrity of the site. It is noted that waste management includes reduce, reuse and recycle which contribute to a more sustainable use of natural resources.

Cunningham, E. M. and J. D. Sigwart (2019). "Environmentally Accurate Microplastic Levels and Their Absence from Exposure Studies." Integrative & Comparative Biology **59**(6): 1485-1496.
Microplastics (synthetic polymers; <5 mm) are ubiquitous, in the environment and in the news. The associated effects of microplastics on flora and fauna are currently only established through laboratory-based exposure trials; however, such studies have come under scrutiny for employing excessive concentrations with little environmental relevance. This critical review is intended to summarize key issues and approaches for those who are considering the need for local microplastics research, both in terms of environmental pollution and the impacts on aquatic species. A meta-analysis of results from published experimental (n = 128) and environmental (n = 180) studies allowed us to compare the reported impacts from experiments that expose organisms to microplastics, and the concentrations of environmental microplastics found in the wild. The results of this meta-analysis highlight three issues that should be modified in future work (1) use of extreme dosages, (2) incompatible and incomparable units, and (3) the problem of establishing truly informative experimental controls. We found that 5% of exposure trials examined did not use any control treatment, and 82% use dramatically elevated dosages without reference to environmental concentrations. Early studies in this field may have been motivated to produce unequivocal impacts on organisms, rather than creating a robust, environmentally relevant framework. Some of the reported impacts suggest worrying possibilities, which can now inspire more granular experiments. The existing literature on the extent of plastic pollution also has limited utility for accurately synthesizing broader trends, as has been raised in previous reviews; environmental extraction studies use many different units,

among which only 76% (139/180) could be plausibly converted for comparison. Future research should adopt the units of microparticles/kg (of sediment) or mp/L (of fluid) to improve comparability. Now that the global presence of microplastic pollution is well established, with more than a decade of research, new studies should focus on comparative aspects rather than the presence of microplastics. Robustly designed, controlled, hypothesis-driven experiments based on environmentally relevant concentrations are needed now to understand our future in the new plastic world.

Curren, E. and S. C. Y. Leong (2019). "Profiles of bacterial assemblages from microplastics of tropical coastal environments." Science of the Total Environment **655**: 313-320.

Plastic waste is a global issue of an increasing concern in aquatic ecosystems. Microplastics form a large proportion of plastic pollution in marine environments. Although microplastics are prevalent, their distribution along the coasts of tropical regions is not well studied. Microplastic pieces (1–5 mm) were collected from two distinct regions along the coastlines of Singapore, from the northern coast in the Johor Strait and the southern coast in the Singapore Strait. Microplastics were present in concentrations ranging from 9.20–59.9 particles per kg of dry sand sediment. The majority of microplastics identified were foam particles (55%) and fragments (35%). Microplastics were significantly more abundant on heavily populated beaches compared to pristine beaches. High throughput sequencing was used to profile the communities of bacteria on the surfaces of microplastic particles. The structure of the microbial communities was primarily characterised by Proteobacteria and Bacteroidetes and were distinct across sites. Hydrocarbon-degrading genera such as Erythrobacter were dominant in areas with heavy shipping and pollution. Potential pathogenic genera such as Vibrio and Pseudomonas were also identified. This study highlights the diverse bacterial assemblages present on marine microplastic surfaces and the importance of understanding the bacterial plastisphere. Graphical abstract Unlabelled Image Highlights • Microplastics are prevalent pollutants in tropical coastal ecosystems. • Microplastic abundance influenced by anthropogenic activities • Rich assemblage of microbial communities found on microplastic surfaces • Putatively pathogenic and hydrocarbon degrading bacteria identified • Microplastics act as a vector for the transport of harmful bacteria. [ABSTRACT FROM AUTHOR]

Currie, J. J., et al. (2019). "Nearshore sea surface macro marine debris in Maui County, Hawaii: Distribution, drivers, and polymer composition." Marine Pollution Bulletin **138**: 70-83.

Located within the subtropical convergence zone, the Hawaiian archipelago is subject to high debris loads. This paper represents the first study to determine the spatial and temporal trends of floating macro debris quantities and polymer composition within Maui County waters. Ocean surveys were conducted from 2013 to 2017 and collected 2095 debris items of which 90% were plastic. Attempts to categorize items by source resulted in only 6% likely from land, 12% from ocean-based sources, 50% from either land or ocean, and 32% from unknown sources. Results found a multi-step process for debris accumulation, with temporal trends linked to survey day and year and spatial trends linked to ocean processes. High- and low-density polyethylene and polypropylene accounted for the majority of polymer types. The results of this study

demonstrate minimal debris in Maui originates from land/local sources, and the importance of baseline data to guide further research and mitigation measures. Copyright © 2018

Curtis, B. R. and J. G. McFarland (2006). "Mechanisms of transfusion-related acute lung injury (TRALI): anti-leukocyte antibodies." Critical Care Medicine **34**(5 Suppl): S118-123.

There is abundant evidence that leukocyte antibodies in blood donor products are somehow involved in transfusion-related acute lung injury (TRALI). Human leukocyte antigen (HLA) class I, HLA class II, and neutrophil-specific antibodies in the plasma of both blood donors and recipients have been implicated in the pathogenesis of TRALI. The case for a relationship between leukocyte antibodies and TRALI is more compelling if concordance between the antigen specificity of the leukocyte antibodies in the donor plasma and the corresponding antigen on the cells of the affected recipient is demonstrated. Such antibody-antigen concordance can be investigated by typing the recipient for the cognate leukocyte antigens or by cross-matching the donor plasma against the recipient's leukocytes. Two proposed pathophysiologic mechanisms for TRALI have received the most attention: the antibody hypothesis and the two-event hypothesis. The final common pathway in all of the proposed pathogenic mechanisms of TRALI is increased pulmonary capillary permeability, which results in movement of plasma into the alveolar space causing pulmonary edema. A typical TRALI serologic workup consists of tests for HLA class I and II and neutrophil-specific antibodies. The use of flow cytometry and HLA-coated microbeads is recommended for detection of HLA antibodies in plasma of implicated blood donors and a combination of the granulocyte agglutination test and granulocyte immunofluorescence test for detection of neutrophil-specific antibodies. Genotyping for class I and II HLA and for a limited number of neutrophil antigens may also be helpful in establishing antibody-antigen concordance. [References: 55]

Cushing, K. W., et al. (2017). "Ultrasound Characterization of Microbead and Cell Suspensions by Speed of Sound Measurements of Neutrally Buoyant Samples." Analytical Chemistry **89**(17): 8917-8923.

We present an experimental method including error analysis for the measurement of the density and compressibility of cells and microbeads; these being the two central material properties in ultrasound-based acoustophoretic applications such as particle separation, trapping, and up-concentration. The density of the microparticles is determined by using a neutrally buoyant selection process that involves centrifuging of microparticles suspended in different density solutions, CsCl for microbeads and Percoll for cells. The speed of sound at 3 MHz in the neutrally buoyant suspensions is measured as a function of the microparticle volume fraction, and from this the compressibility of the microparticles is inferred. Finally, from the obtained compressibility and density, the acoustic scattering coefficients and contrast factor of the microparticles are determined, and in a sensitivity analysis, the impact of the measurement errors on the computed acoustic properties is reported. The determination of these parameters and their uncertainties allow for accurate predictions of the acoustophoretic response of the microparticles. The method is validated by determining the density (0.1-1% relative uncertainty) and compressibility (1-3% relative uncertainty) of previously well-characterized polymer microbeads and subsequently applied to determine the density (0.1-1% relative uncertainty), compressibility (1% relative uncertainty), scattering coefficients, and acoustic contrast factors for nonfixed and fixed cells, such as red blood cells, white blood cells, DU-145 prostate cancer cells, MCF-7 breast cancer cells, and LU-HNSCC-25 head and neck squamous carcinoma cells in phosphate buffered saline. The results show agreement with published data obtained by other methods.

Cuthbert, R. N., et al. (2019). "The influence of microplastics on trophic interaction strengths and oviposition preferences of dipterans." Science of the Total Environment **651**(Part 2): 2420-2423.

Microplastic (MP) pollution continues to proliferate in freshwater, marine and terrestrial environments, but with their biotic implications remaining poorly understood. Biotic interactions such as predation can profoundly influence ecosystem structuring, stability and functioning. However, we currently lack quantitative understandings of how trophic interaction strengths and associated behaviours are influenced by MP pollution, and how transference of MPs between trophic levels relates to consumptive traits. We also lack understanding of key life-history effects of MPs, for example, reproductive strategies such as oviposition. The present study examines the predatory ability of non-biting midge larvae, Chaoborus flavicans, towards larvae of Culex pipiens mosquitoes when the latter are exposed to MPs, using a functional response (FR) approach. Transfer of MPs occurred from larval mosquitoes to larval midges via predation. Microplastics transfer was significantly positively related to predation rates. Predation by C. flavicans followed a Type II FR, with average maximum feeding rates of 6.2 mosquito larvae per hour. These and other FR parameters (attack rates and handling times) were not significantly influenced by the presence of MPs. Further, C. pipiens adults did not avoid ovipositing in habitats with high concentrations of MPs. We thus demonstrate that MPs can move readily through freshwater food webs via biotic processes such as predation, and that uptake correlates strongly with consumption rates. Further, as MPs do not deter adult mosquitoes from ovipositing, our experiments reveal high potential for MP exposure and transference through ecosystems.

Cuthbertson, J., et al. (2019). "Current and Emerging Disaster Risks Perceptions in Oceania: Key Stakeholders Recommendations for Disaster Management and Resilience Building." International Journal of Environmental Research & Public Health [Electronic Resource] **16**(3): 05.

Identification and profiling of current and emerging disaster risks is essential to inform effective disaster risk management practice. Without clear evidence, readiness to accept future threats is low, resulting in decreased ability to detect and anticipate these new threats. A consequential decreased strategic planning for mitigation, adaptation or response results in a lowered resilience capacity. This study aimed to investigate threats to the health and well-being of societies associated with disaster impact in Oceania. The study used a mixed methods approach to profile current and emerging disaster risks in selected countries of Oceania, including small and larger islands. Quantitative analysis of the International Disaster Database (EM-DAT) provided historical background on disaster impact in Oceania from 2000 to 2018. The profile of recorded events was analyzed to describe the current burden of disasters in the Oceania region. A total of 30 key informant interviews with practitioners, policy managers or academics in disaster management in the Oceania region provided first-hand insights into their perceptions of current and emerging threats, and identified opportunities to enhance disaster risk management practice and resilience in Oceania. Qualitative methods were used to analyze these key informant interviews. Using thematic analysis, we identified emerging disaster risk evidence from the data and explored new pathways to support decision-making on resilience building and disaster management. We characterized perceptions of the nature and type of contemporary and emerging disaster risk with potential impacts in Oceania. The study findings captured not only traditional and contemporary risks, such as climate change, but also less obvious ones, such as plastic pollution, rising inequality, uncontrolled urbanization, and food and water insecurity, which were perceived as contributors to current and/or future crises, or as crises themselves. The findings provided insights into how to improve disaster management more effectively, mainly through bottom-up approaches and education to increase

risk-ownership and community action, enhanced political will, good governance practices and support of a people-centric approach.

Cuvillier-Hot, V., et al. (2014). "Impact of ecological doses of the most widespread phthalate on a terrestrial species, the ant Lasius niger." Environmental Research **131**: 104-110.

Phthalates are synthetic contaminants released into the environment notably by plastic waste. Semi-volatile, they adsorb to atmospheric particles and get distributed in all ecosystems. Effects of this major anthropogenic pollution in economical species in aquatic habitats have attracted large interest. On the contrary, very few studies have focused on wild terrestrial species. Yet, these lipophilic molecules are easily trapped by insect cuticle; ants and other insects have been shown to permanently bear among their cuticular components a non-negligible proportion of phthalates, meaning that they suffer from chronic exposure to these pollutants. Oral route could also be an additional way of contamination, as phthalates tend to stick to any organic particle. We show here via a food choice experiment that Lasius niger workers can detect, and avoid feeding on, food contaminated with DEHP (DiEthyl Hexyl Phthalate), the most widespread phthalate found in nature. This suggests that the main source of contamination for ants is atmosphere and that doses measured on the cuticle correspond to the chronic exposure levels for these animals. Such an ecologically relevant dose of DEHP was used to contaminate ants in lab and to investigate their physiological impact. Over a chronic exposure (1 dose per week for 5 weeks), the egg-laying rate of queens was significantly reduced lending credence to endocrine disruptive properties of such a pollutant, as also described for aquatic invertebrates. On the contrary, short term exposure (24 h) to a single dose of DEHP does not induce oxidative stress in ant workers as expected, but leads to activation of the immune system. Because of their very large distribution, their presence in virtually all terrestrial ecosystems and their representation at all trophic levels, ants could be useful indicators of contamination by phthalates, especially via monitoring the level of activation of their immune state.

Czarnecka, M., et al. (2013). "Role of CD19^{pos} lymphocytes in human IgE-production in vitro." Experimental Dermatology **22 (3)**: e5.

In vitro, peripheral blood mononuclear cells (PBMC) from patients with extrinsic atopic dermatitis/ atopy syndrome produce IgE. Supposedly, CD19^{pos} plasma cells are the main source. Whereas in mice IgE-producing B cells can be killed by CD8pos T cells, regulation of IgE-producers in humans remains unclear. Heparinised blood of nine adults with exacerbated extrinsic atopic dermatitis / atopy syndrome (IgE > 150 < 15000 kU/l, no immunosuppressive systemic therapy >8 weeks, mean serum IgE-levels 2800 4546 kU/l) were depleted of either C19pos or CD8pos lymphocytes by magnetic beads using two purification cycles following manufacturer's instruction (MS-columns, anti-CD19 or anti-CD8 microbeads, Miltenyi Biotec, Bergisch Gladbach). Cells were incubated in RPMI/10% FCS in 1.8 ml round bottom cryovials for 10 days at 37degreeC. Conditions: (i) all PBMC, (ii) isolated CD19^{pos} cells, (iii) PBMC depleted of CD19^{pos} cells, (iv) PBMC depleted of CD8pos cells, (v) PBMC CD8-depleted and subsequently reconstituted with CD8pos cells. Purification efficacy was monitored by immuno flow cytometry. Cell free supernatants were collected at different time points and stored at -80degreeC until determination of IgE levels using the ImmunoCap100 system (low level range, Phadia, Freiburg). Data were expressed in relation to the maximal IgE-level produced by all PBMC (=100%). A two-tailed student t-test was applied for statistical analysis. IgE-production in vitro was detectable in 6 of 9 of patients. In all cases, isolated CD19^{pos} cells did not show any IgE-production. Unexpectedly, supernatants of PBMC depleted of CD19^{pos} cells contained significant elevated IgE-levels as compared to condition (i) and/or (iii). Thus, under experimental conditions described (i) the source of IgE in vitro from atopic PBMC seem not to be CD19^{pos} plasma cells and (ii) within the CD19^{pos} B memory cell fraction IgE-regulatory activity can be postulated.

Czech, A., et al. (2009). "Increased levels of proinflammatory cytokines are associated with impaired immune activity of natural killer (NK) cells of prediabetic subjects (PS)." Diabetologia **52 (S1)**: S248.

Background and aims: Inflammatory mechanisms are believed to be involved in the pathogenesis of diabetic complications. Diabetic hyperglycemia may suppress the function of peripheral blood NK cells. Recent experimental studies have shown significant differences in immune activity of NK cells of Type 2 diabetic patients in comparison to healthy subjects. The aim of this study was to asses the relation between the plasma concentration of selected proinflammatory cytokines (interleukin 1; IL-1 and interleukin 6; IL-6) and the number and activity of NK cells obtained from PS. Material(s) and Method(s): The study group included 12 newly-diagnosed (according to WHO definition) PS, naive to any hypoglycaemic drugs and 8 normoglycaemic control subjects (CS) matched for sex, BMI and waist circumference. Peripheral blood mononuclear cells (PBMC) were isolated by Ficoll gradient centrifugation. Immunofluorescent phenotyping of NK (CD16⁺) cells in PBMC was performed using specific murine anti-human CD16 PE-conjugated monoclonal antibodies. The K562 human erythroleukemia cell line was used as the standard target for human NK cytotoxicity assay. K562 were labelled with DIO(3,3-dioctadecyloxacarbocyanine perchlorate). Target and effector cells were added to reach effector/target rations: 50:1 ,12:1. Dead target cells were stained with PI (propidium iodide). After 4 hours of incubation data were collected for analysis on the Becton-Dickinson FACScalibur flow cytometer. The data was analyzed using Cell Quest software. Concentrations of IL-1 and IL-6 were determined using fluorescent cytometric microbead assay. Plasma aliquots were incubated with color-coded fluorescent microbeads labeled with antibodies against respective cytokines. The fluorescence intensity was determined using dual-laser detector and cytokines concentrations were read from standard curve. Result(s): PS exhibited higher insulin resistance reflected by HOMA-IR (3.21+/-2.32) compared to control group (1.96+/-1.18, p=0.03). Plasma concentrations of investigated cytokines were significantly higher in the PS compared to CS (IL-1: 1.36+/-1.27 vs 0.35+/-0.31 pg/ml, p=0.01; IL-6: 4.09+/-3.30 vs 2.12+/-1.13 pg/ml, p=0.03). Correlations between cytokines and HOMA-IR were weak and non-significant (all p>0.05). The PS in comparison to healthy subjects had an increased number (12,45+/-5,8% vs 9,63+/-4,7%) but decreased activity (4,4+/-2,0% vs 9,2+/-3,7%) of NK cells (p=0.01). Correlations between cytokines and both the number and activity of NK cells were statistically significant (p<0.05). Conclusion(s): In the prediabetic state the increased number and decreased activity of peripheral NK cells are associated with high excretion of proin-flammatory cytokines (IL-1, IL-6). This supports the hypothesis that inflammation is involved in the pathogenesis of early impairment of NK cell killing function. Inflammation markers are likely to be useful in the screening of metabolically vulnerable individuals.

da Costa Araujo, A. P., et al. (2020). "How much are microplastics harmful to the health of amphibians? A study with pristine polyethylene microplastics and Physalaemus cuvieri." Journal of Hazardous Materials **382**: 121066.

Microplastics (MPs) are critical emerging pollutants found in the environment worldwide; however, its toxicity in aquatic in amphibians, is poorly known. Thus, the aim of the present study is to assess the toxicological potential of polyethylene microplastics (PE MPs) in Physalaemus cuvieri tadpoles. According to the results, tadpoles' exposure to MP PE at concentration 60mg/L for 7 days led to mutagenic effects, which were evidenced by the increased number of abnormalities observed in nuclear erythrocytes. The small size of erythrocytes and their nuclei area, perimeter, width, length, and radius, as well as the lower nucleus/cytoplasm ratio observed in tadpoles exposed to PE MPs confirmed its cytotoxicity. External morphological changes observed in the animal models included reduced ratio between total length and mouth-cloaca distance, caudal length, ocular area, mouth area, among others. PE MPs increased the number of melanophores in the skin and pigmentation rate in the assessed areas. Finally, PE MPs were found in gills, gastrointestinal tract, liver, muscle tissues of the tail and in the blood, a fact that confirmed MP accumulation by tadpoles. Therefore, the present study pioneering evidenced how MPs can affect the health of amphibians.

Da Costa, J. P., et al. (2018). "Degradation of polyethylene microplastics in seawater: Insights into the environmental degradation of polymers." Journal of Environmental Science and Health - Part A Toxic/Hazardous Substances and Environmental Engineering **53**(9): 866-875.

Microplastic contamination of aquatic environments has become an increasingly alarming problem. These, defined as particles <5 mm, are mostly formed due to the cracking and embrittlement of larger plastic particles. Recent reports show that the increasing presence of microplastics in the environment could have significant deleterious consequences over the health of marine organisms, but also across the food chain. Herein, we have studied the effects of artificial seawater on polyethylene (PE)-based beads by exposing them up to eight weeks to saltwater in stirred batch reactors in the dark and examined the structural and morphological changes these endured. Electron microscopy observations showed that artificial seawater induces severe microcracking of the pellets' surfaces. Additionally, Fourier transform infrared spectroscopy (FTIR) analyses evidenced the formation of oxidized groups whenever these particles were exposed to water and an increase in organic matter content of the waters in which the pellets were kept was evidenced by Raman spectroscopy. There were also noticeable consequences in the thermal stability of the polyethylene pellets, as determined by thermogravimetric studies (TGA). Furthermore, the parallel exposure of polyethylene pellets to UV radiation yielded less pronounced effects, thus underscoring its lower preponderance in the degradation of this material. These results highlight the importance of determining the mechanisms of degradation of microplastics in marine settings and what the implications may be for the environment. Overall, the herein presented results show that a relatively short period of time of accelerated exposure can yield quantifiable chemical and physical impacts on the structural and morphological characteristics of PE pellets. da Costa, J. P., et al. (2016). "(Nano)plastics in the environment - Sources, fates and effects." Science of the Total Environment **566-567**: 15-26.

There has been a considerable increase on research of the ecological consequences of microplastics released into the environment, but only a handful of works have focused on the nano-sized particles of polymer-based materials. Though their presence has been difficult to adequately ascertain, due to the inherent technical difficulties for isolating and quantifying them, there is an overall consensus that these are not only present in the environment - either directly released or as the result of weathering of larger fragments - but that they also pose a significant threat to the environment and human health, as well. The reduced size of these particulates (<1 mum) makes them susceptible of ingestion by organisms that are at the base of the food-chain. Moreover, the characteristic high surface area-to-volume ratio of nanoparticles may add to their potential hazardous effects, as other contaminants, such as persistent organic

pollutants, could be adsorbed and undergo bioaccumulation and bioamplification phenomena. In this review, we describe the most relevant sources of nanoplastics and offer some insights into their fate once released into the environment. Furthermore, we overviewthemost prominent effects of these small particulates, while identifying the key challenges scientists currently face in the research of nanoplastics in the environment. Lastly, we give a brief summary of the economic impacts of the pollution caused by plastic litter - a potential key source of nanoplastics - in the oceans, the most common destination of these contaminants. da Luz, J. M., et al. (2014). "Abiotic and biotic degradation of oxo-biodegradable plastic bags by Pleurotus ostreatus." PLoS ONE [Electronic Resource] **9**(11): e107438.

In this study, we evaluated the growth of Pleurotus ostreatus PLO6 using oxo-biodegradable plastics as a carbon and energy source. Oxo-biodegradable polymers contain pro-oxidants that accelerate their physical and biological degradation. These polymers were developed to decrease the accumulation of plastic waste in landfills. To study the degradation of the plastic polymers, oxo-biodegradable plastic bags were exposed to sunlight for up to 120 days, and fragments of these bags were used as substrates for P. ostreatus. We observed that physical treatment alone was not sufficient to initiate degradation. Instead, mechanical modifications and reduced titanium oxide (TiO2) concentrations caused by sunlight exposure triggered microbial degradation. The low specificity of lignocellulolytic enzymes and presence of endomycotic nitrogen-fixing microorganisms were also contributing factors in this process.

da Luz, J. M., et al. (2013). "Degradation of oxo-biodegradable plastic by Pleurotus ostreatus." PLoS ONE [Electronic Resource] **8**(8): e69386.

Growing concerns regarding the impact of the accumulation of plastic waste over several decades on the environmental have led to the development of biodegradable plastic. These plastics can be degraded by microorganisms and absorbed by the environment and are therefore gaining public support as a possible alternative to petroleum-derived plastics. Among the developed biodegradable plastics, oxo-biodegradable polymers have been used to produce plastic bags. Exposure of this waste plastic to ultraviolet light (UV) or heat can lead to breakage of the polymer chains in the plastic, and the resulting compounds are easily degraded by microorganisms. However, few studies have characterized the microbial degradation of oxo-biodegradable plastics. In this study, we tested the capability of Pleurotus ostreatus to degrade oxo-biodegradable (D2W) plastic without prior physical treatment, such as exposure to UV or thermal heating. After 45 d of incubation in substrate-containing plastic bags, the oxo-biodegradable plastic, which is commonly used in supermarkets, developed cracks and small holes in the plastic surface as a result of the formation of hydroxyl groups and carbon-oxygen bonds. These alterations may be due to laccase activity. Furthermore, we observed the degradation of the dye found in these bags as well as mushroom formation. Thus, P. ostreatus degrades oxo-biodegradable plastics and produces mushrooms using this plastic as substrate.

D'Agostino, C., et al. (2017). "Swelling-induced structural changes and microparticle uptake of gelatin gels probed by NMR and CLSM." Soft Matter **13**(16): 2952-2961.

Gelatin gels are increasingly involved in many industrial applications due to several advantages including cost efficiency and biocompatibility. Generally, their production requires the use of aqueous solvents, which cause significant swelling, due to the ability of solvent molecules to penetrate through the gel microstructure and increase its volume. Since swelling mechanisms and their effect on the gel structure are not fully understood, further investigations are required. In this work, we combine macroscopic measurements of the swelling ratio (SR) with Nuclear Magnetic Resonance (NMR) and Confocal Laser Scanning Microscopy (CLSM) to investigate changes in the gelatin structure as a function of both polymer concentration and swelling time. SR values increase as a function of time until a maximum is reached and then show a slight drop for all the gelatin concentrations after 24 h swelling time, probably due to a network relaxation process. NMR allows determination of mass transport and molecular dynamics of water inside the gelatin pores, while CLSM is used to visualize the penetration of tracers (polystyrene microbeads) with a diameter much larger than the gel pores. Structural parameters, such as average pore size and tortuosity, are estimated. In particular, the pore size decreases for higher polymer concentration and increases during swelling, until reaching a maximum, and then dropping at longer times. The penetration of tracers provides evidence of the heterogeneity of the gel structure and shows that single microcarriers can be loaded in gelatin gels upon swelling.

Dahdouh, N., et al. (2020). "Removal of Methylene Blue and Basic Yellow 28 Dyes from Aqueous Solutions Using Sulphonated Waste Poly Methyl Methacrylate." Journal of Polymers & the Environment **28**(1): 271-283.

This work focuses on two different environmental problems: the recovery of plastic wastes PMMA (W PMMA) and their application in the removal of textile dyes Methylene Blue (MB) and Basic Yellow 28 (BY28) in aqueous solutions. The selected waste plastic was upgraded to produce an adsorbent suitable for dyes removal. For that, the material was grinded cryogenically up to a particle size of less than 100 µm and treated with sulfuric acid. The sulphonated waste PMMA (SW PMMA) was characterized by FTIR, scanning electronic microscopy (SEM) and chemical composition analysis (C, H, N, O and S content). The formation of sulphonic groups in the material after sulphonation reaction has been successfully demonstrated by FTIR, and can be observed mainly in the region 3087 cm−1 to 3657 cm−1, where an intense band bound to the stretching of the SO3H appeared; another absorption band appeared in the region from 1138 to 1271 cm−1 that corresponds to the symmetric stretching of the SO2 group. The effects of solution pH, initial dyes concentration, adsorbent dose and temperature were studied in batch experiments. The obtained data showed that SW PMMA adsorbent exhibit significant adsorption capacities of 97.09 mg g−1 and 222.22 mg g−1 for MB and BY28, respectively. The complete removal of MB and BY28 on the SW PMMA was achieved in less than 45 min. The Langmuir, Freundlich and Temkin models were applied and it was found that the equilibrium data could be satisfactory fitted to Langmuir adsorption isotherm. The kinetic study showed that the pseudo second order kinetic model correlates the experimental data. Furthermore, the thermodynamic parameters were determined for both dyes. As a result, the negative values of Gibbs free energy ΔG° indicated the spontaneity of the adsorption of MB and BY28 by SW PMMA. The negative values of ΔH° revealed the exothermic nature of the process and the negative values of ΔS° suggest the stability of MB and BY28 on the surface of SW PMMA. [ABSTRACT FROM AUTHOR]

Dahl, C. P., et al. (2009). "Increased levels of cytokines, vasoactive peptides, and growth factors in alveolar macrophages in heart failure." European Heart Journal **1)**: 15.

Purpose: Pathophysiologic interactions between the heart and the lungs in heart failure (HF) are well recognised. Increased circulating levels of vasoactive peptides and cytokines known to be synthesised in the heart in HF may directly affect the lungs and potentially also vice versa. The purpose of the present study was to investigate whether expression of different factors known to be increased in the myocardium and/or the circulation in HF is also increased in alveolar macrophages in HF. Method(s): Twenty-two non-smoking HF patients (NYHA functional class II-IV) and 16 healthy controls were included in the study. Lung function and diffusion capacity were investigated by spirometry and DLCO, respectively. Induced sputum was performed after inhalation of hypertonic saline, and alveolar macrophages were isolated from the sputum by use of magnetic microbeads. Gene expression was examined in alveolar macrophages and in peripheral blood by real-time RT-PCR. Result(s): Lung function and diffusion capacity were reduced in HF patients compared to controls with significantly lower FVC (88+/-4 vs. 112+/-3% of predicted value), FEV1 (84+/-4 vs. 104+/-3% of predicted value), and DLCO (69+/-4 vs. 101+/-3% of predicted value) (P<0.05 for all). Real-time RT-PCR demonstrated increased mRNA levels of several important cytokines, chemokines, vasoactive peptides, and growth factors in alveolar macrophages from HF patients compared to controls (P<0.05): endothelin-1 (1.8-fold), adrenomedullin (10-fold), TNFalpha (2.3- fold), IL-1beta (3.9-fold), IL-6 (12-fold), MCP-1 (2.2-fold), IL-8 (4.2-fold), activin A (10.5-fold), and CTGF (3.2-fold). MIP-1alpha mRNA levels were not altered in HF. A similar increase in mRNA levels was not found in peripheral blood, indicating that the increase in gene expression is taking place in the lungs and is not a result of induction in monocytes in the circulation before entering the pulmonary compartment. mRNA levels of adrenomedullin, IL-6, MCP-1, IL-8, and CTGF in alveolar macrophages from HF patients displayed a negative correlation to left ventricular ejection fraction (P<0.05). Conclusion(s): Several important cytokines, chemokines, vasoactive peptides, and growth factors are induced in alveolar macrophages in human HF. Further studies should clarify whether this induction affects pulmonary remodelling and whether the increased synthesis of these factors is reflected by increased release to the circulation and thus potentially may affect the failing myocardium.
