26 - 26 Region - 4

#### INDUSTRIAL HYGIENE WALK-THROUGH REPORT

PLANT NAME: American Talc Co.

LOCATION: Alpine, Alabama

PURPOSE: The National Institute for Occupational Safety and Health (NIOSH) in cooperation with the Mining Enforcement and Safety Administration (MESA) has underway a preliminary study of the talc mining and milling industry. As part of this study NIOSH is conducting walk-through surveys to compile necessary data in an effort to characterize talc compositions in the U.S.

NIOSH PERSONNEL: Paul L. Johnson

### PLANT HISTORY AND PROCESS:

The American Talc Company is located in Talladega County, approximately 55 miles southwest of Birmingham, Alabama. The nearest city is Alpine located on Highway 235. Ore for milling is extracted and shipped from the Willow Creek Mine located about 22 miles south of Alder, Montana. Milling operations started in 1953 as a talc dry-grinding process and in 1958 wet-grinding was incorporated to enchance the efficiency of mineral separation and processing. A total of 26 workers are employed during the plant's 3 shifts (16 day, 5 night, 5 morning). All work a 5½ to 6 day week (40 to 50 hours). The major product is talc which is ground for application in the cosmetic and pharmaceutical industries.

### PROCESSING:

Rail shipments from the Willow Creek Mine, Alder, Montana, are unloaded (by front end loader) and fed to a primary crusher. Crushed materials, 3/4 inch and less in size, are conveyed to a bucket elevator which feeds a cylindrical wet scrubber. From the scrubber the ore is dropped into a ball mill for additional grinding (minus 40 mesh size), pumped to slurry thickening tanks, and then conveyed back to the plant for treatment. Treated materials are bleached (hydrogen sulfide), filtered, neutralized (hydrochloric acid and water), dried, and then ground. Fine grinding of product is done by both Raymond vertical and Raymond roller mills. Finished products range from 98% - 200 mesh to 99% - 400 mesh in size. All products are shipped in 50 lb bags by either railcar or by truck. Some of the facilities receiving the finished products are: Cheesebrough Ponds Co., Clint, Connecticut, Colgate Palmolive Co., Jersey City, New Jersey and Jeffersonville, Indiana.

### HEALTH AND SAFETY HAZARDS:

- 1. Potential noise exposure.
- 2. Hazardous working conditions in areas made slippery by combination of water and talc dust particles
- 3. Potential exposures to talc dust.

# PERSONNEL RECORDS:

Personnel records include job descriptions, work histories Social Security numbers, and lost time data. Present records date back to 1965. Only 6 of the plant's 26 total workers have been employed with the plant since the operation began in 1958. All records can be located at the facility.

## RECOMMENDATIONS:

- 1. Noise measurements should be obtained to determine noise exposure during milling operations.
- 2. Hazardous conditions exist in the travelways and escapeways due to the water and talc dust accumulations. These areas should be maintained as outlined in the Metal and Nonmetal Mine Health and Safety Standards, Part 57.11.
- 3. Hard hats, respirators, safety glasses, etc., were not being used at time of survey. Personal protective equipment should be made available and properly used as outlined by Part 57.15 of the Metal and Nonmetal Mine Health and Safety Standards.
- 4. Maintenance programs should be improved. Reapirs are needed on duct systems, control valves, liquid holding tanks, and piping systems.
- 5. All toxic materials should be properly identified (e.g. acid solutions unmarked near makeup boxes).
- 6. It is recommended that a safety program, outlined in the Metal and Nonmetal Health and Safety Standards, Part 57.18-1 through 14, be implemented.

## PRODUCTION PROCESSES:

Stockpiled ore for processing is fed by conveyor to a rotating hammer mill for crushing. The crushed ore, & inch or less in size, is elevated by bucket to ore holding bins. From the holding bins the crushed materials are fed to a cylindrical scrubber (wetting process) and then to a ball mill for grindings of 30 to 40 mesh. Products from this mill are pumped to a Wifflay 30 to 40 mesh gravity screen for grit separation and regrinding. For additional separation the materials are pumped across a James table or wet vibrator. Further processing consists of clarifying units or thickners. To these units polymers are added as filtering agents to aid in settling out the talc. Chlorinators are also added during this process as bactericidal agents. Before final grinding the product is pumped to treaters, where k-brite (hydrogen sulfide), sulfur dioxide, and hydrochloric acid are added as bleaching compounds. Treated materials from these tanks pass through make-up boxes (solidifies product) and then through an acid bath (hydrochloric acid and fresh water) for 45 minutes to lower the pH. The product is then repulped and pumped to storage bins for final milling. Preparation for fnal milling consists of a drum filter (dewaters and cakes materials), an Imp mill (breaks up conglomerates) and a flash dryer. All materials, after being dried, are fed to mills of two types - a Raymond vertical and a Raymond roller (35 inch, 42 rollers). Attached to each mill is a cyclone ventilation system for capturing the reprocessing excess and/or oversized particles. Connected to each mill in addition to the cyclone is a unit for bagging materials (50 lb bags) for shipment.

Finished products for shipment are made by both railcar and by truck. Cheesebrough Ponds Company, Clint, Connecticut and Colgate Palmolive Company, Jersey City, New Jersey and Jeffersonville, Indiana receive a large percentage of the finished products.

| S. Abstract (Limit: 200 words) As part of a preliminary study of the talc mining and milling industry SIC-1499) a walk through survey was made at the American Talc Company to gather data needed of characterize talc (14807966) compositions in the United States. Twenty six workers were mployed during the three shifts at the facility. All worked a 5.5 to 6 day work week. The ajor product was talc which was ground for applications in the cosmetic and pharmaceutical ndustries. Health and safety hazards identified at the site included potential noise xposure, hazardous working conditions in areas made slippery by a combination of water and alc dust particles, and potential exposure to talc dust. Personnel records were available rom 1965. Only six of the current 26 workers have been employed with this same company since to began operating in 1958. It was noted that hard hats, respirators, safety glasses and ther protective equipment was not being used at the time of the survey. The author recommends hat such equipment should be available and its proper use should be explained. Maintenance rograms should be improved and all toxic materials should be properly identified.   |  |   |   |  |   | ر المراجعة |
