Current Trends

## Rubella - United States, 1978-1981

A record low number of 3,904 cases of rubella was reported in the United States for 1980. This was $66.9 \%$ less than the 1979 total of 11,795 cases, the previous record low. Between 1978 and 1980, the number of reported rubella cases declined $78.6 \%$. This trend continued throughout the first 35 weeks of 1981 (ending September 5), when 1,717 cases of rubella were reported, a $46.3 \%$ decline from the 3,196 cases reported for the same period in 1980 (Figure 1).

Age-specific data were available for $2,964(76.0 \%)$ of the cases reported for 1980 . The reported age-specific incidence rate of rubella has decreased for all age groups over the past 2 years, with the greatest decline being that for the 15 - to 24 -year-old group (Table 1). This has resulted in a marked change in the age-specific characteristics. In 1978, the highest agespecific incidence rate was for 15- to 19-year olds. From 1978 through 1979, 73.8\% of the reported cases of rubella were among persons $\geqslant 15$ years old. For 1980 , only $46.6 \%$ of the cases were reported among persons $\geqslant 15$ years old, and the highest incidence rate was for the $<5$-year olds.
Reported by Surveillance and Assessment Br, Immunization Div, Center for Prevention Services, CDC.
Editorial Note: Initially, rubella-control programs in the United States emphasized vaccination of preschool and elementary school children; vaccination of older individuals received only secondary emphasis. This strategy caused a dramatic decline in reported rubella and eliminated the characteristic 6- to 9 -year cycle of epidemic rubella (1). There was also a marked change in the age characteristics for reported rubella cases. Whereas rubella was considered a disease of young children before vaccine licensure in 1969, from 1976 through 1979 approximately $70 \%$ of reported rubella cases were among individuals $>15$ years of age and the highest incidence rate was for the 15-to 19-year olds (2).

[^0]
## Rubella - Continued

The 1980 and 1981 surveillance data show a continuation of the rapid decline in reported rubella to record low levels. Much of this recent decrease is probably due to the Childhood Immunization Initiative which began in 1977. The goal of the initiative was to achieve and maintain immunization levels in excess of $90 \%$ for all childhood, vaccine-preventable diseases, including rubella. Because of improvement in and better enforcement of school immunization laws, rubella vaccination is now required in many states. The Measles Elimination Initiative, begun in 1978, has probably further influenced reduction in the incidence of rubella since most of the measles vaccine administered during this program has been given as MMR (measles, mumps, rubella vaccine) or MR (measles, rubella vaccine).

Data on age-specific incidence rates for 1980 show that rates for adolescents and young adults are now similar to those for young children. This shift probably results from the fact that the young children who were targeted for vaccination in 1969 moved into older age groups and from the increased effort over the past 2-3 years to vaccinate adolescents and young adults. Increased efforts to vaccinate adolescents and young adults were prompted by continued reporting of $27-50$ cases of congenital rubella syndrome per year from 1971 through 1979 (1) and by the knowledge that $10 \%-25 \%$ of adolescents and adults were susceptible to rubella (3-5).

The current strategy for rubella control is based on continued routine vaccination of all children $\geqslant 12$ months of age, vaccination of all school children not vaccinated in infancy and vaccination of susceptible adults - particularly females and/or hospital personnel (6). Such a combined strategy, if applied rigorously, may eliminate both rubella and the congenital rubella syndrome in the United States.

## Epidemiologic Notes and Reports

## Raynaud's Phenomenon in a Foundry - Wisconsin

A high prevalence of Raynaud's phenomenon (also called vibration-induced white finger, or VWF) among metal foundry workers exposed to hand vibration when using air hammers and grinding tools was recently found in a National Institute for Occupational Safety and Health (NIOSH) investigation.

In June 1980, the International Molders and Allied Workers Union requested that NIOSH evaluate 74 men employed as chippers and grinders in 2 metal casting cleaning rooms ( 51 in Room A and 23 in Room B) at a foundry in Wisconsin. In August and September 1980, NIOSH investigators conducted medical evaluations and assessed vibration exposure.

Sixty-four employees ( 47 in Room A and 17 in Room B) were interviewed and examined. Fifty-five percent (26/47) of Room A employees and $18 \%$ ( $3 / 17$ ) of Room B employees reported experiencing symptoms of Raynaud's phenomenon since beginning work as chippers. Men who were symptomatic also tended to have decreased sensory abilities in their hands. Of 14 men with 3 or more years of work as chippers in Room A, 2 had not suffered episodes of Raynaud's phenomenon.

Assessment of vibration exposure revealed that the chipping hammer (a tool similar to a small jackhammer used to remove excess metal from castings) had handle accelerations in the range of $15-60 \times g$ (comparable to those of similar tools previously measured by NIOSH [ 1 ]), and the handles of the grinding machines had accelerations in the range of 15-20 $\times g$ (15-50 times the level of similar tools previously measured by NIOSH). Room A employees used the chipping hammer approximately 2-3 hours/day and the grinding machines 4-5 hours/day, while Room B employees used vibrating tools to a lesser extent because the Room B castings required less thorough or precise metal removal. The lower prevalance of Raynaud's symptoms in Room B employees may be due to the lower mean years of exposure of these workers (Room B, 2.3 years; Room A, 4.1 years) and the lesser time per day that they used vibrating tools.
Reported by W Taylor, MD, University of Dundee, Scotland; Physical Agents Effects Br, Div of Biomedical and Behavioral Science, Hazard Evaluations and Technical Assistance Br, Div of Surveillance, Hazaro Evaluation, and Field Studies, NIOSH, CDC.
Editorial Note: European and American studies of foundry workers using chippers and of loggers operating chain saws have shown prevalences of Raynaud's phenomenon ranging from $20 \%$ to $90 \%$ (depending on the duration and intensity of vibration exposure), while $<10 \%$ of male controls not exposed to vibration experienced symptoms of Raynaud's phenomenon. The increased risk of developing Raynaud's phenomenon due to long-term use of vibrating hand tools has received little attention in the United States (2-5).

The initial symptoms of vibration-induced Raynaud's phenomenon consist of an episodic blanching and numbness of a fingertip and are usually initiated by exposure to cold. With continued vibration exposure, VWF may involve more fingers, require less cold stimulus for initia-

## Raynaud's Phenomenon - Continued

tion and, consequently, occur more frequently. Even persons with only moderately advanced VWF avoid outdoor activities (occupational endeavors, fishing, hunting, etc.) in cool or cold weather, because exposure to cold brings on attacks of Raynaud's phenomenon, and they are unable to grasp objects or safely hold tools. Many persons with advanced disease have decreased sensory abilities in the hand and are unable to grasp small objects or perform fine motor and/or hand movements. A small proportion of workers develop ulceration or gangrene of the fingers because of peripheral arterial occlusion. If vibration exposure is stopped before symptoms become severe, episodes of Raynaud's phenomenon usually subside over a period of several years. The pathogenesis of the initial blanching episodes and subsequent sensory and motor impairment is not well understood, particularly whether the primary lesion is neurologic or vascular ( $2,4,5$ ).

While changes in work practice may lessen an individual worker's vibration exposure, ultimate control of vibration-induced Raynaud's phenomenon depends on development of tools which greatly reduce the vibration imparted to the user's hand.

## Surveillance Summary

## Nutrition Surveillance - United States, 1980

The Coordinated Nutrition Surveillance Program of the Centers for Disease Control uses nutrition-related data collected by local health departments as part of routine delivery of child health services. During 1980, data were submitted for more than 250,000 children, ages 6 months- 10 years. These data concerned new patients at more than 1,300 clinics in 22 states.

The data consist primarily of identifying demographic information, height (length), weight, birth weight, and hemoglobin and/or hematocrit determinations. Data on height (length), weight, and age are converted to percentiles for height-for-age and weight-for-height, using the National Center for Health Statistics reference population (1). Levels <5th percentile height-for-age and weight-for-height and $>95$ th percentile weight-for-height are reported as potentially abnormal values. Results based on these cutoff points are shown in Table 2. (Asians 6-10 years old are not represented because data for $<100$ children were reported.)

TABLE 2. Nutrition indices, by age and ethnic group*

| Age group | Number examined | Height-for-age <br> Percentage in the 5th \%tile | Weight-for-height |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Percentage in the 5th \%tile | Percentage in the 95th \%tile |

## Nutrition - Continued

For children 6 months- 5 years old, data from the surveillance population show greater percentages of children in each age/ethnic group whose height-for-age levels are $<5$ th percentile than do data from the reference population. These percentages are highest among Asian children who range from $14.8 \%$ for the $6-11$ month age group to $28.3 \%$ for the 2-5 year group. Low height-for-age values ( $<5$ th percentile) show a peak for 11-23 month olds. There is a slight decrease in the prevalence of these low values for the 2-5 year age group and a more marked decrease for the 6-10 year age group. This pattern is particularly evident in the black population, where the prevalence of low height-for-age levels is $12.2 \%$ for the 11-23 month age group and $3.1 \%$ for $6-10$ year olds. These changes with increasing age may represent secular differences among age cohorts or may be a result of catch-up growth, but this cannot be determined from cross-sectional data alone. A comparison of low height-for-age values for 11-23 month old whites, blacks, and Hispanics in 1978 with values for 3-4 year olds in 1980 suggests that there may indeed be catch-up growth and improvement in overall nutritional status.

Weight-for-height is the anthropometric index related to possibly acute undernutrition. The prevalence of low weight-for-height levels ( $<5$ th percentile) is consistently at or below $5 \%$ for all age/ethnic groups (except Asians 11-23 months old). The data suggest that acute undernutrition is not a major public health problem in these ethnic populations and that the overall growth and development of these groups is similar to that of a representative group of U.S. children. However, overweight children (weight-for-height $>95$ th percentile) constitute more than the $5 \%$ of the population that would be expected from a normal distribution of anthropometric values. Overweight is generally more prevalent among Hispanics and American Indians than among other ethnic groups. There is a slight decrease with age in the tendency for children to be overweight except among American Indians, for whom there is an increase.

In 1980, there was a large influx into the United States of Southeast Asian refugee children, many of whom were treated at clinics submitting nutrition surveillance data. Data on more than 1,700 of these children, ages 6 months-10 years, are presented in Table 3. Comparison of these figures with those in Table 2 shows that the refugee children have greater prevalences of low height-for-age and low weight-for-height levels than do any of the other groups of children. This is consistent with data from developing countries throughout the world. Attempts have been made to separate data on Southeast Asians from those on other Asians, but the high percentage of low height-for-age and low weight-for-height values seen in the total Asian population may result partially from the inclusion of some refugee children.

There is no consensus on which levels of hemoglobin and/or hematocrit should be used to define low values and/or anemia. Most clinics providing data to the nutrition surveillance system have adjusted the levels to reflect normal increases in hemoglobin that occur with age. At present, these values are $10.0 \mathrm{~g} / 100 \mathrm{ml}$ for children $6-23$ months old, $11.0 \mathrm{~g} / 100 \mathrm{ml}$

TABLE 3. Nutrition indices for Southeast Asian refugees by age*

| Age group | Number examined | Height-for-age <br> Percentage in the 5th \%tile | Weight-for-height |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Percentage in the 5th \%tile | Percentage in the 95th \%tile |
| 6-23 months | 329 | 31.6 | 10.0 | 3.0 |
| 2-5 years | 810 | 42.6 | 5.3 | 4.2 |
| $6-10$ years | 579 | 47.3 | 4.3 | 1.6 |

[^4]
## Nutrition - Continued

for $2-5$ year olds, and $12.0 \mathrm{~g} / 100 \mathrm{ml}$ for $6-10$ year olds. The World Health Organization and others have suggested the use of $11.0 \mathrm{~g} / 100 \mathrm{ml}$ for the age range 6 months- 5 years. To provide widely useful information, Table 4 lists, by age and ethnic group, 4 selected cutoff points for hemoglobin prevalences. These data show that the prevalence of low hemoglobin levels is greatest for the 6-23 month group, remains high for 2-5 year olds, and decreases markedly for the 6-10 year group. In all age groups, blacks tend to have greater prevalences of low hemoglobin values than do other ethnic groups, with the exception of 6-23 month old Asians. Here, too, the inclusion of Southeast Asian refugee children may have lowered the hemoglobin values in Asians $\leqslant 2$ years old. Data on the prevalence of hematocrit levels below the 4 selected cutoff points are presented in Table 5. The same pattern of prevalences among age/ethnic groups is evident for both hematocrit and hemoglobin data.

Low hemoglobin and/or hematocrit levels, indicative of probable anemia due to iron deficiency, remain a major problem in these population groups. Because the selection of any specific cutoff level for hematocrit/hemoglobin values identifies a population consisting of both normal and abnormal individuals, the lower the level selected the higher the probability that individuals in that group will be abnormal. The use of a commonly accepted hemoglobin cutoff of $11.0 \mathrm{~g} / 100 \mathrm{ml}$ for the group 6-23 months old, suggests that between $25 \%$ and $33 \%$ of this population are potentially anemic.
Reported by Field Services Br, Nutrition Div, Center for Health Promotion and Education, CDC.

The Morbidity and Mortality Weekly Report, circulation 96,000, is published by the Centers for Disease Control, Atlanta, Georgia. The data in this report are provisional, based on weekly telegraphs to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the succeeding Friday.

The editor welcomes accounts of interesting cases, outbreaks, environmental hazards, or other public health problems of current interest to health officials. Send reports to: Attn: Editor, Morbidity and Mortality Weekly Report, Centers for Disease Control, Atlanta, Georgia 30333.

Send mailing list additions, deletions and address changes to: Attn: Distribution Services, Management Analysis and Services Office, 1-SB-419, Centers for Disease Control, Atlanta, Georgia 30333. When requesting changes be sure to give your former address, including zip code and mailing list code number, or send an old address label.
