Morbidity and Mortality

Weekly Report

PUBLIC HEALTH SERVICE

U. S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE

Prepared by the NATIONAL OFFICE OF VITAL STATISTICS WORTH 3-4744

September 16, 1960

Washington 25, D. C.

Vol. 8, No. 53

ANNUAL SUPPLEMENT

Reported Incidence of Notifiable Diseases in the United States, 1959

This supplement contains final figures on the reported incidence of notifiable diseases for 1959 which have been compiled from summaries supplied by the States and Territories.

The annual totals of the notifiable diseases for the 10-year period 1950 to 1959 are shown in table 1. Table 2 shows the numbers of deaths for each of the diseases shown in table 1 for the years 1950 to 1958 inclusive. Mortality data for 1959 are not available at this time. Other tables show the number of cases by months (mainly by month of report), the number of cases by age groups for selected diseases, and the distribution of cases by States and outlying areas. The figures for Alaska for 1959 are included in United States totals.

Poliomyelitis

Reported incidence of poliomyelitis in 1959 was 46 percent higher than in 1958 but the number of paralytic cases was 70 percent greater than for the previous year. The number of nonparalytic cases increased only 5 percent. Final figures for 1959 were considerably different from the provisional totals at the end of the year as shown in the following table:

	Provisional	Final
Total-----	8,567	8,425
Paralytic -----	5,709	6,289
Nonparalytic -----	2,165	2,045
Unspecified -----	693	91

These figures indicate that much effort was spent in the States in the establishment of the final diagnosis. The larger number of paralytic cases in final figures compared with provisional figures has been noted in previous years.

The larger proportion (75 percent) of paralytic cases in 1959 compared to 64 percent in 1958 is probably due to the fact that there is an increasing reluctance to report nonparalytic poliomyelitis without confirmatory laboratory examinations.

In 1958, 27 States reported more paralytic cases than in 1957, and in 1959, 39 States reported a higher incidence than in 1958. Several of the States that reported fewer paralytic cases in 1959 had experienced sharp localized outbreaks in the previous year.

In spite of the considerable increase in paralytic poliomyelitis in 1959, its occurrence was predominantly a series of localized outbreaks mainly in the lower socioeconomic sections of urban areas. The size of the localized outbreaks varied from a few to a hundred cases. The largest occurred in

Kansas City, Missouri; Des Moines, Iowa; and Little Rock, Arkansas.

The age distribution of reported cases of paralytic poliomyelitis as shown in table 4 did not vary much from that of 1957 and 1958. The proportion of cases under 5 years of age in 1959 was less than that for 1957 and 1958, and there was a larger percentage in the 5 to 9 group than in the previous 2 years. The proportion of cases 20 years of age and over remained about the same.

Plague

Four cases of plague in 1959 may be regarded as an unusually large number for the United States. Two cases in California occurred in a part of the State where the infection among wild rodents can be considered enzootic. One case in New Mexico apparently developed following contact with wild rabbits. The fourth case, in Maryland, was a laboratory-acquired infection.

Hepatitis

The reported incidence of hepatitis was 44.7 percent higher in 1959 than in the previous year. The increase was apparent for all geographic divisions of the country and in about three-fourths of the States. Most States that did not report an increase had totals that were not far below those for 1958. This disease appears to be occurring in cycles, the last peak of which was in 1954. The low point of the cycle was reached in 1957, followed by an increase of reported cases in 1958 and again in 1959. During the years 1952 to 1958, inclusive, the number of deaths from infectious hepatitis, which is exclusive of those certified as due to homologous serum hepatitis, has been between 800 and 900 per year. In 1954, the number of deaths registered was 821 and in 1957 it was 897. There is no explanation for the fact that numbers of cases, which include homologous serum hepatitis, show a cyclic type of occurrence while deaths from infectious hepatitis have remained relatively constant from year to year. The number of deaths for all age groups under 45 years were essentially the same as in 1954, when there appeared to be a peak in incidence, and as in 1957 when the number of cases was relatively low. However, there were more deaths over the age of 44 years in 1957 (low incidence) than in 1954 (high incidence).

The large number of cases reported and the number of deaths mark this acute infectious disease as a major public health problem. No effective method of control has been devised mainly because the etiologic agent cannot be isolated by any presently used laboratory procedures.

Morbidity and Mortality Weekly Report

Diphtheria

For the first time in 15 years there was a break in the downward trend of reported incidence of diphtheria. The number of cases reported in 1959 was slightly in excess of that for 1958. However, the number remained below 1,000. About 78 percent of the cases were reported in the South Atlantic and South Central States. For individual States, there was an increase in numbers of cases reported in each of the Middle Atlantic States and in Nebraska, Mississippi, and Texas. There was no change in numbers of cases under 5 years of age, but there was an increase in both the 5 to 9 and 10 to 14 age groups. This may be an indication of waning immunity in schoolchildren following primary immunization in early childhood.

Concentrations of cases occurred in 5 areas located in 4 States, 3 in the South. In each of the areas the predominant feature was the poor immunity status of most cases.

Rabies

There were 6 cases of human rabies reported in 1959. Two were bitten by rabid dogs, two by bats, and the source of the remaining two was unknown, although dogs were considered to be the probable source. Rabies in animals continued to decline, the number of cases being about half that of earlier years. In 1944, there were more than 9,000 cases of rabies in dogs, and in 1959 about 1,100 according to the Agriculture Research Service of the Department of Agriculture. During this same period, there was a 6-fold increase in rabies in wild animals, mainly foxes and skunks. According to the Department of Agriculture rabies was confirmed by laboratory tests in 85 bats in 1959.

Arthropod-borne encephalitis

The arthropod-borne component is the most important of the groups making up the category of acute infectious encephalitis. Only three States reported an unusual number of cases in 1959. Eastern equine encephalitis cases were reported in two States: 33 cases with 21 deaths in New Jersey, one case in Maryland. The cases reported in California were predominantly St. Louis encephalitis. The specific type of infection for other States is not known.

Malaria

The incidence of malaria continued to decline in 1959 with 71 cases reported compared to 85 in 1958. A Communicable Disease Center Surveillance Report on 67 of the reported cases shows that 54 could be considered as confirmed or presumptive cases. The history of the cases investigated indicated that 26 of the 54 were having their first attack. Vivax infections were the most common type of infection. Six cases were considered to have been indigenous to the United States, four being naturally acquired infections, and two by blood transfusions.

Typhoid fever and other Salmonella infections

Incidence of typhoid fever continued to decline in 1959, about 200 fewer cases being reported than in 1958. All parts of

the country contributed to the decline. Five definite outbreaks of the disease were reported in 1959, 3 of which were water-borne. One involved a public water supply of a town and two were concerned with water from wells. The source of one outbreak was traced to a carrier who assisted in preparation of food served at a wedding reception.

A large proportion of the cases of typhoid fever reported in the past 2 years have occurred in children under 15 years of age, 46.5 percent in 1958 and 45.8 in 1959. About one-fourth of the cases have been persons 35 years of age and over.

There was a small increase in number of other *Salmonella* infections reported in 1959. The variation in numbers from State to State suggests that utilization of laboratory facilities varied widely and is an important factor in these differences in numbers of cases reported rather than actual variations in incidence.

Botulism

The increase in number of cases of botulism in 1959 compared to 1958 is due to an outbreak of 6 cases each in Alaska and Idaho. In the former, the victims had eaten home-prepared whale meat and in the latter, home-canned beets.

Brucellosis

The 3.5 percent decrease in reported cases of brucellosis is a continuation of the decline that has been in progress during the previous decade. This decline in human cases has been coincident with progress in the program for eradication of the disease in cattle which has been developed by the U.S. Department of Agriculture in cooperation with State agencies. In 23 years ended in 1957, incidence of bovine brucellosis was reduced from about 10 to 1.8 percent. However, another source of infection for human beings is still present, namely swine, for which no comparable eradication program has been developed. In some areas, all human cases have been traced to contact with swine.

Venereal diseases

In 1959, State health departments reported 14.6 percent more cases of early syphilis than in 1958 and 5.0 percent more cases of other forms of syphilis. Furthermore, the Venereal Disease Branch of the Communicable Disease Center reports that primary and secondary syphilis increased 36.4 percent in 1959. The increase in primary and secondary syphilis accounts for most of the increase in early syphilis shown in table 1.

Tuberculosis

In 1959 there were 75,484 newly reported tuberculosis cases in the United States, nearly 10 percent less than in 1958 and about 25 percent less than 5 years ago. As in the past, slightly over three-quarters of the new cases reported were classified as active and probably active. These are the cases that require the closest attention of those concerned with the control of tuberculosis. Detailed information on the active and probably active cases is reported to the Tuberculosis Program of the Public Health Service which publishes these data.

Miscellaneous diseases

Reported incidence of amebiasis in 1959 was 20 percent below that for 1958. A decrease in number of cases was evident in all geographic divisions. Reported cases of Shigella infections increased by more than a thousand cases. The few outbreaks reported during the year do not account for this increase.

The increase in number of reported cases of leptospirosis was due to an epidemic in Iowa, where a large number of individuals were exposed to infection while swimming in streams. Infected cattle in the area were the probable source of infection. Forty-nine of the 83 cases reported in the United States in 1959 occurred in Iowa.

Incidence of endemic typhus and Rocky Mountain spotted fever continued to decline to relatively low levels. There was a further decrease in number of cases of tularemia and psittacosis. The number of cases of trichinosis increased.

Reported incidence of measles in 1959 was much less than in 1958. The number of cases of scarlet fever and streptococcal sore throat increased about 26 percent over 1958. Reported incidence of these infections has been increasing steadily over the past 10 years. During this same period the number of deaths reported annually has declined steadily. The number of cases of whooping cough rose from 28,295 in 1957 to 32,148 in 1958, and to 40,005 in 1959. However, for this disease also deaths declined.
