

March 30, 2004 Public Meeting Summary with Public Comments / Questions & Answers

Historical Document

This page is archived for historical purposes and is no longer being maintained or updated.

(Slides are reproduced from presentation; speaker comments follow.)

(Statements are not direct quotes, they are paraphrased.)

(Public comments and questions made during the meeting are preceded by the word "Public." Response to the questions/comments are preceded by the responder's name when available.)

Release of DRAFT Interim Report

Time 5:00-7:00 p.m.

Location Cities of Gold Hotel
Pojoaque, New Mexico

Speaker Tom Widner, Project Director ([Project Summary](#))

Summary Tom Widner summarized the project goals and accomplishments, introduced the DRAFT Interim Report explaining how the report is organized and summarizing some of the information contained in the report, and discussed work that remains to be done. The CDC, while addressing public comments, provided an update on the outlook for continuation of the project.

The meeting concluded with [public comments and questions](#).

Note: To review background information on the project, please see the [February 23, 1999](#) meeting summary and slides.

Slides & Notes [Tom Widner \(Project Summary\)](#)
[Public Comments / Questions and Answers](#)

Los Alamos Historical Document Retrieval and Assessment Project		
	Phil Green C. M. Wood	In attendance this evening...
	Cheryl Allen Peter Rasco	
	Joe Shonka	
	Tom Widner Susan Flack Dennis Paustenbach	

Slides 1 and 2 of 49

Tom Widner thanked those attending the meeting for coming and introduced project participants attending the meeting including Phil Green, Project Officer from the Radiation Studies Branch of the Centers for Disease Control and Prevention (CDC) and C.M. Wood, also from CDC's Radiation Studies Branch. Another CDC member attending was Judy James.

1994: CDC staff began conducting exploratory investigations at Los Alamos National Laboratory (LANL)

- Records suggested that off-site releases have occurred
- Large repositories of records exist at LANL
- Most of these records classified
- Ability to review records and number of records needing review largely unknown

Slide 3 of 49

The project was initiated in response to a letter from a New Mexico official and after exploratory visits by CDC that suggested that Los Alamos National Laboratory contains large repositories of records with many records of potential interest.

1998: ChemRisk was selected to begin Los Alamos Historical Document Retrieval & Assessment (LAHDRA) Project

- The original term of contract was 3 years
- The contract term was extended an additional 5 years in 2001
- The ceiling of the contract is \$4.4 million
- The financial ceiling of the contract cannot be raised substantially

Slide 4 of 49

ChemRisk was selected to perform the project work. Originally the contract was for three years and then it was extended for an additional five years. The contract extension did not include additional funding. While there have been changes in ownership of the prime contractor, the study team has remained intact throughout the project.

Goals of the LAHDRA Project

- Retrieve historical documents and evaluate their usefulness for off-site dose assessment
- Declassify (if necessary) relevant documents and release them to the public
- Enter relevant documents into a database
- Develop a prioritized list of contaminant releases from the LANL site

Slide 5 of 49

Four goals were set for the project that dealt with off-site releases or health effects. Relevant documents were to be entered into a database to allow searches and make them more accessible.

Five Phases of Dose Reconstruction

- ① Retrieval and assessment of data
- ② Source term and transport pathway analysis
- ③ Screening-level dose assessment
- ④ Development of Methods for Assessing Environmental Doses
- ⑤ Calculation of Environmental Exposures, Doses, and Risks

Slide 6 of 49

CDC conducts projects like this in five phases; however, CDC does not guarantee all phases will be conducted at a site. This project was established to complete the first phase, retrieval and assessment of data.

The original plan for document review

- Planned to review collections in series-
 - LANL Central Records Center
 - LANL Archives
 - Technical Report Library
 - Technical Areas
 - "Work for Others"
 - Records at Other Sites
- Because of access restrictions, we began working at multiple venues.

Slide 7 of 49

The original plan for the document review was to conduct the information gathering in a sequential fashion, where one repository would be searched before beginning work in another repository. After about 1 to 1½ years into the project, LANL started placing restrictions on the number of people allowed in a repository at one time. The limits included classification reviewers and document analysts, so the project started reviewing the documents in multiple repositories simultaneously.

Products of the LAHDRA Project

- Database of relevant information
- A collection of relevant documents
- Report with a summary of historical operations, identification of releases, and prioritization of releases
- A chronology of incidents and off-normal events

Slide 8 of 49

Products produced during the project include a database; a document collection; and a report summarizing operations, releases, and a prioritization of releases. The draft interim report takes the first step towards prioritization of releases. The interim report will include a chronology of incidents and off-normal events.

What we have accomplished

- We have reviewed documents from quite a few document collections
- We have completed review of several collections
- We have not begun review of some others

Slide 9 of 49

To date we have reviewed documents from a number of repositories, we have completed several, and we have almost completed several others. However, we have not even started reviewing one of the most important collections, the LANL Archives. It is the next priority. In addition, many records are located in the individual technical areas. We have visited some of them, but there are more to review.

Status of the LAHDRA Project

- CDC instructed the project team to bring information gathering to a close under the existing contract.
- Based on an Interim Report, information in the database, progress on access issues, CDC will decide whether to continue.
- Currently available online
<http://www.shonka.com/ReConstructionZone/>
- Comments will be accepted for 60 days

Slide 10 of 49

CDC asked us to bring work to a close under the existing contract. Based on the interim report and documents in the database, CDC will determine how to proceed. Please send your comments regarding the draft report so that they can be considered in preparation of the final version.

Contents of the Draft Interim Report

- Introduction to the LAHDRA project
- Overview of Operations at LANL
- Products of the LAHDRA project
- Methods used to gather information
- Summaries of document review progress
- Challenges of document review at LANL
- Preliminary prioritization of releases
- Appendices

Slide 11 of 49

Contents of the draft interim report are summarized here. The Introduction presents the goals of the project, which were touched upon a few minutes ago. The report takes the first steps toward prioritizing releases.

Overview of Historical Operations

- A general overview of LANL operations is near the front of the draft report.
- More details are presented in appendices-
 - Plutonium processing
 - Uranium, fission products, radium, polonium, barium/lanthanum
 - Reactor operations
 - Tritium processing
 - Beryllium processing
 - High explosives
 - Accelerator operations
 - The LANL Health Division
 - Environmental monitoring

Slide 12 of 49

We have taken a different approach with the interim report than with earlier drafts. A summary of operations and an overview of our preliminary assessments are presented up front, and supporting details are provided in the appendices.

Methods of Information Gathering

- Systematic document review
 - As opposed to *directed* searching
 - Systematic review best builds public credibility
- Interviews of current and former workers, area residents
 - By the project team
 - Peter Malmgren's "Los Alamos Revisited"

Slide 13 of 49

There are two types of search strategies. Let's say you are gathering documents from a file cabinet that you need to do your taxes. It is not well organized, but you want to gather everything needed to fill out your forms. In a systematic search, you would move from front to back and search all of the documents in each drawer. In a directed search, you would go directly to folders with labels relevant to your taxes, such as receipts and payroll records, or folders that are likely to contain relevant data based on your experience using your files. Directed searching can be more efficient, but systematic searching gives you higher confidence that nothing was missed. In studies like

LAHDRA, systematic searching is effective in building public credibility. We conducted systematic searches in the LAHDRA project. We also interviewed current and former workers and worked with Peter Malmgren, who conducted an oral history project that included interviews of almost 150 people who worked at or lived near Los Alamos. We appreciate his involvement. Interviews help fill in gaps and direct us to other areas of interest.

Recent Interviewees

Carl Buckland-	<i>H-1 radiation monitoring</i>
Bill Van Buskirk-	<i>beryllium operations</i>
Clarence Courtright-	<i>high explosives</i>
Jerry Dummer-	<i>radiation safety</i>
Harry Ettinger-	<i>chemicals/industrial hygiene</i>
Roger Goldie-	<i>high explosives</i>
Jim Lawrence-	<i>radiation safety/dosimetry</i>
Jim McInroy -	<i>autopsy data</i>
Bill Moss-	<i>industrial hygiene, Pu in soil</i>
John Nyhan-	<i>plutonium air releases</i>
Bill Romero-	<i>H-1 radiation monitoring</i>

Slide 14 of 49

This slide identifies some of the people we interviewed. Some of them are here tonight. These people reviewed our process and gave feedback. They were helpful with preliminary assessments and provided assurances that our approach was not off base.

14 document analysts participated

Slide 15 of 49

The project included 14 document analysts. Nadine Tafoya and Toby Herzlich were involved early on, assisting with public involvement. The document analysts pick out documents relevant to off-site releases. The group includes scientists and engineers that hold master and doctoral degrees and have a lot of experience in dose reconstruction.

The LAHDRA Document Summary Form

Los Alamos Document Summary Form		Document Requested: <input type="checkbox"/> Complete <input type="checkbox"/> Partial <input type="checkbox"/> None	
DOCUMENT TITLE: <i>Facts about Los Alamos Scientific Laboratory of the University of California</i>

Document Abstract: Original <input type="checkbox"/> <i>Provides summaries of research and development programs at LASL, including weapons development and testing, Rover, plasma thermocouple, Project Sherwood, reactors, critical assemblies, theoretical physics and mathematics, Vala Program, accelerators, explosives research, health research, chemistry & metallurgy research, and cryogenics. Includes a chronology of LASL "firsts" from 1943 to 1964. Includes some historical facts about LASL and the Los Alamos community.</i>			

Slide 16 of 49

When the document analysts find a relevant document, they fill out a document summary form by hand. The top of the form is used to identify essential bibliographic information, the type of document, and where the document is located. The term document is loosely used. It could mean a large group of records or one sheet of paper.

The LAHDRA Document Summary Form

Document Abstract: Original <input type="checkbox"/> <i>Provides summaries of research and development programs at LASL, including weapons development and testing, Rover, plasma thermocouple, Project Sherwood, reactors, critical assemblies, theoretical physics and mathematics, Vala Program, accelerators, explosives research, health research, chemistry & metallurgy research, and cryogenics. Slide 18 of 49

This shows how the database version of the form appears. Each document is given a repository number, which is used to track it within the system.

The Project Information Database

- A Microsoft Access® database holds the information from DSFs
- Each document or group of documents is assigned a repository number
- Contains 4,066 bibliographic records

Slide 19 of 49

Microsoft Access was used as the database. Each document is assigned a repository number.

The LAHDRA Document Collection

Slide 20 of 49

Documents are contained in file cabinets in the Atlanta office. Another set located in California will be handed over to CDC. A third set is located in the Zimmerman Library on the University of New Mexico campus in Albuquerque. It is the official public reading room as established by DOE. In the photograph, Jody Simmons is organizing document copies that have been scanned and cataloged.

The Document Collection

- 45% of documents in the database are Category 1, 44% are Category 2, and 11% are Category 3
- 56% came from the Central Records Center, 25% from the Report Collection, 10% from the Research Library
- 75% are documents, 10% boxes, 8% microform, 5% notebooks
- Documents evenly spread 1940s to 1990s.

Slide 21 of 49

These are statistics of the documents that have been assembled by the LAHDRA team. Category 1 records are those documents that would be useful to a competent scientist involved in reconstruction of off-site releases or health effects. Category 2 document help to confirm releases or health effects, but do not provide the most basic information used for evaluating off-site releases. Category 3 documents are relevant to releases or health effects from other DOE sites.

Document Imaging

- Scanning was initiated for preservation and presentation of documents.
- 2,486 image files are available as PDFs.
- Each contains from 1 to over 2000 pages.
- Database records are linked to the associated image files.
- Searches can be performed on the database fields or the full text of the scanned documents.

Slide 22 of 49

We proposed to CDC that documents be scanned to facilitate storage, distribution, and use. Documents were saved as PDFs, which are easily read by Adobe Acrobat Reader. The image files vary from 1 to 2000 pages. The process to locate a document begins with searching the database. Links are used to pull up an image of the scanned document. Full-text searches of all documents are possible, and are quite powerful tools. For example, by entering "nickel carbonyl" all scanned documents are searched and the program lists and provides images of pages where the term appears. Image files are currently contained on two DVDs or about 11 CDs. Zimmerman Library will soon be set up with a database. We also plan to provide similar workstations at the Santa Fe Community College, Northern New Mexico Community College, and Mesa Public Library in Los Alamos. It is a real time saver and increases access to the information released as part of the project.

Document Review at the LANL Central Records Center

- The Records Center was the first repository targeted for review.
- The Center fills a 15,000 sq ft building.
- The Center has provided retrievable storage for records from LANL groups and divisions.
- The Center holds boxes of records, plus microform and notebooks.
- About 200 boxes of documents and 2,000 rolls of microfilm remain to be reviewed.

Slide 23 of 49

Key document centers at LANL were identified for review. They include warehouses of records containing boxes and file cabinets of records, microfilm and notebooks. We spent a long time in the Records Center and have about 200 boxes and 2000 rolls of microfilm remaining. We were told that LANL resources were not sufficient to support us with escorts and classification reviewers for completion of review of paper documents at the Records Center under the existing contract while processing of the backlog of documents for classification review was underway.

Document Review at the LANL Reports Collection

- Classified and unclassified technical reports on paper and microfiche.
- Classified "LA" and LA-MS" reports issued before 1963 were 100% reviewed.
- Classified LA and LA-MS reports issued after 1962 were withheld from review.
- Classified reports by other entities were reviewed up to "L", the remainder withheld.

Slide 24 of 49

This slide summarizes the type of records we reviewed. LA and LA-MS reports are basic technical reports written by LANL scientists, researchers and engineers. We reviewed 100% of the classified "LA" reports produced before 1963. We were denied access to the same type of reports produced after 1962. Classified reports issued by entities other than LANL were reviewed up to those starting with "L" while the remaining were withheld.

Document Review at the LANL Reports Collection

- Unclassified reports by other entities were reviewed up to "P."
- All of the unclassified "LA" reports formerly publicly available on the Internet were reviewed by the LAHDRA team.
- Less than 1% of the unclassified reports on microfiche have been reviewed.

Slide 25 of 49

Because of contractual reasons, work in the LANL Reports Collection had to be brought to a halt. Access was not denied. Formerly, many unclassified LANL reports were available on the Internet, but were pulled from the Internet after the September 11th attacks. Only 1 percent of the microfiche was reviewed because it was not given a high priority. If the project goes forward, some of these documents may warrant review.

Document Review at the ES&H Records Center

- This repository receives records from ES&H Groups.
- They are catalogued and consolidated and forwarded to the Central Records Center.
- Many of the records are from the 1990s.
- A total of 1,187 boxes were reviewed.
- Of these, 227 were deemed to contain material relevant to the project.

Slide 26 of 49

Records are typically housed in the ES&H; Records Center, cataloged, and consolidated before they are sent to the Records Center. By our standards, many of these documents are of a lesser interest because they are mostly newer records.

Document Review at other LANL Locations

- Weapons Engineering and Manufacturing and Weapons Physics Division records in VTR and safes
- LANSCE records
- Lab Counsel Litigation Support Database

Slide 27 of 49

Other locations include the Weapons Engineering and Manufacturing and Weapons Physics Division records contained in vault-type rooms and safes, which number in the hundreds. We spent several months reviewing LANSCE records. The Litigation Support Database is of high interest because it contains some information supporting litigation involving exposures. The project team reviewed a hardcopy listing of documents contained in the database. The team was making some progress with the database listing when the availability of LANL resources became an issue. Review of actual documents had to be put on hold.

Challenges to the Project

- The Cerro Grande fire
- The missing hard drive incident and espionage investigations
- September 11th 2001 terrorist attacks
- Significantly increased restrictions on access to documents

Slide 28 of 49

Because of the "roller coaster ride" of security concerns, LANL has increased security awareness and a high security state now exists at the lab. These incidents have challenged the project team and really slowed things down.

Issues pertaining to document review

- Escorted access with two person limit
- Prescreening by document "owners"
- Categories of deniable information
- Reviews by title alone
- Process to appeal when records withheld
- Access to reports issued by other entities
- Classification reviewer availability

Slide 29 of 49

This slide summarizes the issues and challenges to progress, which are also discussed in the report. At first we were granted unescorted access after several safety briefings. Over the years, more and more rules regarding access were put in place, and now we have to be escorted at all times. Half way through the project, LANL decided that all documents needed to be prescreened by the document "owners". An appeal process was put in place to address cases where it is possible that we were denied access to relevant material. We were asked to review some documents by their titles alone. This is problematic, however, as titles are often not indicative of the actual content of a given document.

Public: Do the restrictions seem reasonable and justifiable?

Tom Widner: I think a response was necessary. LANL was not trying to obstruct the project but trying to protect records. We don't question the restrictions because we do not want to have any improper release of classified records.

The classification review process required multiple reviewers. Once these reviews were completed, then the records were sent to us. In the beginning of the project, the classification reviewers did not have authority to downgrade or declassify documents, which created a sizeable back log. For example, many documents we reviewed in 1999 are now just being released. Over the last few months, we are seeing an increase in support. Previously, the project was seen as an unfunded mandate. Over the last few months, changes have occurred. During the last 4 to 5 months, the lab created a project to support our project. It will apparently be an effective system if the LAHDRA project continues. We have some encouraging signs regarding support.

Preliminary Steps Towards Prioritization of Releases

- Rigorous screening is beyond the scope of this information gathering stage.
- Tasked with prioritizing historical releases that we have documented, we have performed first steps to ascertain which releases were likely most important.
- These assessments were based on releases reported by LANL, with some adjustments, and environmental and biological monitoring that was performed.

Slide 30 of 49

This phase of the project is an information gathering process. Rigorous dose reconstruction is not in the scope of the project, but we have conducted some preliminary analyses. Our emphasis has been to fill in some gaps and make some adjustment to data.

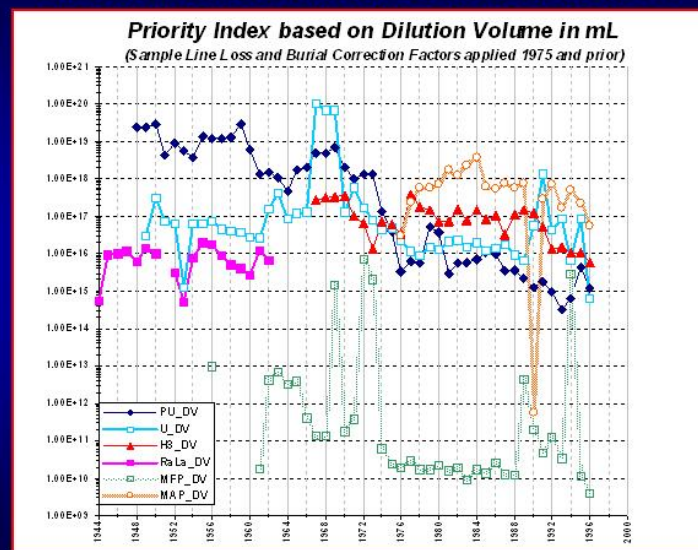

Prioritization of Airborne Releases

- Priority Index values were calculated by computing the air volume required to dilute the annual activity released to the worst-case non-occupational Maximum Permissible Concentration (MPC) per federal regulations.
- An Off-Site Releases database was created to tabulate effluent information and to link it to existing LANL documents assembled by the LAHDRA team.

Slide 31 of 49

Prioritization of airborne releases was performed by determining what volume of air was required to dilute the release to bring it to an acceptable level in public areas. We created a separate database to pull together the information needed for this assessment.

Prioritization of Airborne Releases

Slide 32 of 49

This chart represents our priority indices for airborne radionuclide releases. A high line indicates that more air is required to dilute the release.

Prioritization of Liquid-borne Releases

- Priority Index values were calculated by computing the volume of liquid required to dilute the annual activity released to the worst-case non-occupational MPCs.
- Based on releases asserted by LANL, Priority Indices were calculated for total plutonium, Pu-238, Pu-239, Sr-89, Sr-90, tritium, gross alpha, and gross beta radioactivity.

Slide 33 of 49

In a similar analysis, we examined liquid-borne releases.

Slide 34 of 49

Plutonium releases were of the most importance during early years. Airborne plutonium exposure pathways appear to have been more complete than those for liquid-borne releases, because of the arid environment.

Prioritization of Toxic Chemicals

- LANL has used many non-radioactive metals, inorganic chemicals, and organic chemicals including solvents. We will refer to these materials as “chemicals”.
- Prior to the 1970s, uses and releases of chemicals were poorly documented compared to radionuclides.
- Best data sources to date include a modern chemical inventory, older usage data, and various LANL site documents.

Slide 35 of 49

Relatively poor records were about toxic chemicals prior to the 1970s. Information is scattered through various reports.

Prioritization of Toxic Chemicals

- A modern chemical database shows that each of 37 chemicals were onsite at 250 or more locations and represented the largest onsite quantities.
- These 37 chemicals were ranked in order of decreasing on-site quantities and 13 with USEPA toxicity values were ranked in order of generic toxicity, “1” more toxic than “13”.
- Other tabulations that were prepared based on historical records include:
 - a compilation of quantities of chemicals used or

Prioritization of Toxic Chemicals

- Other tabulations that were prepared based on historical records include:
 - quantities of chemicals used or released historically from LANL
 - reported quantities of high explosives used from 1944 through 1945
 - an effluent summary for group GMX-7 that includes several explosives dispersed at TA-40 July–September 1971
 - estimates of toxic materials dispersed by GMX Division shots for April and May 1971

Slides 36 and 37 of 49

The report includes a table that ranks chemical quantities. A first step in prioritizing chemical releases is to determine the types of chemicals used and in what quantities. Prioritizations were based on inventory records and other tabulations. There are very few places where the information is condensed. We gathered this information from multiple locations.

Prioritization of Toxic Chemicals

- PRGs for soil were used to rank chemicals usually present as particulates, and PRGs for air were used to rank volatile chemicals. Soil and air PRGs were used for explosives.
- A final table presents a ranking based on both annual usage and toxicity parameter.
- This ranking suggests that releases of explosives and volatile organic chemicals were most likely to lead to off-site effects.

Slide 38 of 49

PRGs were used to rank chemicals for off-site populations. The final chemical prioritization table in the report, which ranks LANL chemicals based on toxicity parameter and annual usage, is likely the most useful table for prioritizing chemical releases.

Before health hazards associated with beryllium became known, beryllium was machined in the 1940s until about 1948 without engineering controls. Beryllium might be another material that warrants further investigation.

A Question Area Regarding H-3 Releases

- Airborne effluent data for tritium (H-3) found range for 1967-1996, while H-3 was used at LANL as early as 1946.
- The LAHDRA team has found incident reports that document earlier H-3 release data, including almost 65,000 Ci in 1965.
- Continued assembly of data from scattered documents could help fill in the gap in data regarding past H-3 releases.

Slide 39 of 49

We know from records that tritium was used as far back as 1946. To determine levels of tritium releases, we are pulling scattered incident reports. Assembly of this type of reports is important to fill in gaps before 1967.

A Key Question Regarding Pu Releases

- LANL started up in 1943, but no records found show that LASL actually measured airborne Pu releases until 1951, when releases appear to have been substantially lower than in the 1940s.
- Stack monitoring was of low quality (by modern-day standards) until mid-1950s.
- In these early years, LASL was the lead site for production of U.S. nuclear weapon components.

Slide 40 of 49

LANL started handling plutonium in 1943, but records do not show any monitoring of airborne releases until 1951. LANL was the lead site for production of nuclear weapons components until the Hanford Plutonium Finishing Plant and the Rocky Flats geared up. Stack monitoring began in 1951, but even then it was relatively low-quality monitoring as compared to modern-day standards. We are not making judgments, just evaluating the quality of data.

An Environmental Record of Airborne Plutonium Releases

- Pu in soil has been measured by LANL scientists since the 1970s.
- Lacking effluent data for 1943 to 1951, the LAHDRA team evaluated the use of measurements of Pu in soil around LANL as indicators of past releases.
- The RSAC program was run with LANL meteorological data to calculate Pu-239 deposition at various distances and directions from 1 Ci released over 50 y.

Slide 41 of 49

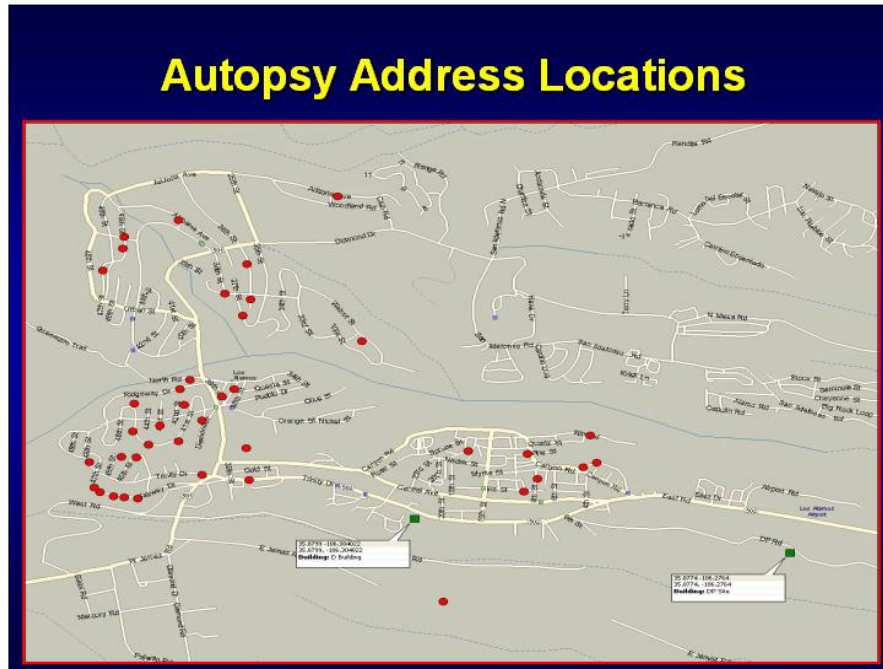

Because of lack of data, we have done some preliminary prioritization assessments by gathering data from about 700 soil samples that the lab shared with us in an electronic form. Soil can be a good indicator because plutonium doesn't travel rapidly once deposited on soil. We used the Radiological Safety Analysis Computer code (RSAC). That program was developed at the Idaho National Engineering and Environmental Laboratory (INEEL). For LANL, we took the best soil samples (those close to the lab that had the least uncertainty) and local meteorological data and calculated what releases would have to have been to match what is in the soil. Results are uncertain, but indicated that airborne releases from LANL could have been much higher than officially reported. We do not have final answers regarding potential health effects around Los Alamos, but the analysis indicates that soil analyses warrant a closer look.

Plutonium in Human Body Tissues

- The human tissue analysis program was a 35-yr LANL study of Pu levels in workers and the general US population.
- The LAHDRA team performed an analysis of human tissue sample data using data from a 1979 Health Physics paper.
- Los Alamos public records were searched for information on included residents.
- The ratio of Pu in the lung vs. that in the vertebrae was calculated for each person.

Slide 42 of 49

Autopsy results from the human tissue analysis program show that non-worker residents of Los Alamos have elevated levels of plutonium in their bodies compared to what you would expect from global fallout. Beginning with the individual autopsy cases, we examined public records to match cemetery records with autopsy cases. We used such information as cemetery records, the Los Alamos Monitor and old telephone directories to determine where a person lived in Los Alamos up to their time of death. We also used GPS to get coordinates of where people lived in relation to D building and DP site. We may be able to use this information to place bounds on the magnitude of past plutonium releases.

Slide 43 of 49

Each red dot on this chart is a location where a non-worker participant in the human tissue analysis program lived. Other areas are not yet pinpointed on the map because there are not homes there anymore. If you have a history and time sequence of where people lived and what was in their bodies, this can be a useful tool.

Liver tissues from Los Alamos area residents were compared to data on liver tissues from Denver cases. The overlay plots show nearly identical levels, without much difference between residents of Denver and Los Alamos. Denver and Los Alamos can't be distinguished from one another in this plot, even though data show that fallout levels in Denver from weapons testing were significantly higher than around Los Alamos. You would expect liver tissue of Denver residents to have higher levels of plutonium than Los Alamos, but Los Alamos is just as high, leaving open the possibility of local contribution from plutonium processing.

Vertebrae samples show higher levels in Los Alamos than Colorado. Different organs of the body have different half lives.

Public: How do you reconcile everybody exposed to above-ground tests?

Joe Shonka: We used autopsy data. All sources show different levels across the country. The levels vary mostly by latitude. Studies in Denver examined cases from fallout alone. Denver is so large, and releases from Rocky Flats don't seem to have been a factor for the residents selected.

Plutonium in Human Body Tissues

- 97 cases were from Los Alamos/White Rock
- 24 were identified from cemetery records and notices in the Los Alamos Monitor.
- The history of residence locations for autopsy cases allows one to establish range & bearing from the release points over time.
- These data could be used to reduce the uncertainty in retrospective dose assessment and possibly permit use of the autopsy data for bounding LANL releases.

Slide 46 of 49

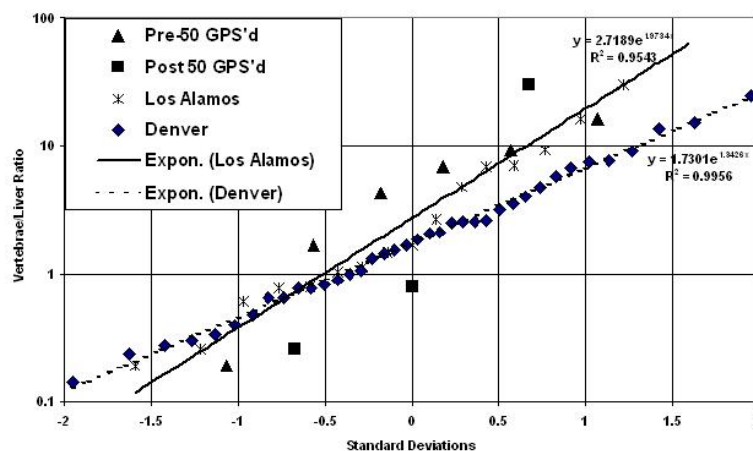

Time history and bearing of distance from release points may allow one to put bounds on how high or low levels could have been.

Dennis Paustenbach: Didn't the people of Los Alamos move around a lot?

Joe Shonka: People moved every two or three years as they moved up in the "pecking order." My daughter looked up addresses back to 1948. People moved because they were living in government housing, which was defined by the size of their family and paycheck. I know people who moved once a year. Government housing went out in 1967.

Tom Widner: Housing was of limited supply on the mesa and was one key criterion for determining the number of people the lab could hire for quite some time.

Vertebrae-to-Liver Ratio

Plutonium in Human Body Tissues

- The calculation demonstrates that excess plutonium is present in non-worker residents of Los Alamos over what would be expected from global fallout from nuclear weapons testing.
- The plutonium in Los Alamos residents appears to be due to exposures to plutonium that were earlier (longer ago) than atmospheric weapons testing exposures in the Denver population.

Slides 47 and 48 of 49

Considering the half-times of the various organs, the analyses indicate that people around Los Alamos were exposed to plutonium in earlier years than the people of Denver.

Summary

- The process of collection of relevant information at Los Alamos has not been completed. Significant collections remain.
- While we have no answers at this time about potential health risks from Los Alamos releases, we have identified several classes of releases that we believe warrant closer examination.
- Please send comments on the Draft Interim Report to Tom Widner at the address given on the second page of the report.

Slide 49 of 49

We have started a systematic review, but it is not complete. The review of some collections has not even been started. We do not have answers, but we have identified some key areas that we believe warrant a closer look. It would be good if some form of document search can continue.

Public Comments / Questions and Answers

Public: Does it look to you that the release of radio nuclides comes from many small releases or a few large releases?

Tom Widner: Plutonium releases were largely routine releases spread over time; tritium releases were more

episodic. There really is a mixture of the two. Soil sampling does not help ascertain the detailed timing of releases.
Joe Shonka: Episodic releases are in some cases very well documented for the time frame and quantity. Specific experiments are well documented. Tritium was typically released in relatively large releases in accidents.

Public: Tritium containers in Area 4 continually leak, which is being denied. Are these contractors at the lab?

Tom Widner: Yes, in most cases.

Public: What is the benchmark for all the reports?

Tom Widner: The owners are the University of California. An appeal process was set up and when we used it there was quite a period where we did not receive a response. Now there is a process in place that will allow the CDC to come in and review documents. CDC will have to push the issue. We are just now ready to test the process.

Public: Can you give us a sense on how long it will take the CDC to make a go, no-go decision?

Phil Green: Once we receive the bid package, we are hoping for release of funds to be in 30 days. A leader from the contracting office indicates funds to be released by the end of the fiscal year.

Public: How long will it take to complete the phases?

Phil Green: We can't release that information. The contractors need to provide that information in their proposals.

Public: The time to complete the review could then vary with the proposals received?

Phil Green: The level of effort, time to gear up, maximum numbers of people working, staffing restrictions will all have play. It also depends on the support received from LANL. As Tom said, we are making good progress in getting documents out of the backlog to be included in the final report in June.

Public: The lead up to public meeting seems to stimulate action.

Phil Green: Improvement was facilitated with ongoing negotiations. Guidance documents evolve as we work through the process. I am cautiously optimistic.

Public: Do you know why there appears to be an equal amount of records per year even with the lab growing?

Tom Widner: A larger fraction of older records are relevant to the project.

Helen Dorado-Gray, Sen. Bingaman's Staff: I represent Senator Bingham. I sent a letter supporting continuation of this work. It is important for workers to know what they were exposed to and at what levels. Bingaman has requested funding to assist in this project.

C.M. Wood: When the project started, support for the project was an unfunded mandate and the costs came out of LANL's overhead. Now they have a line-item to support the project and have the money now to support what we are doing. The lab allocated \$1.2 million this year for their processing of records in the backlog for classification review. Our contractors were also denied access to some records. As government officials, however, CDC will be allowed to review records that our contractors can not. By the next meeting, I should have seen lots of documents previously denied access.

Public: We are impressed with how you overcame pitfalls and landmines, and I thank you.

Tom Widner: We appreciate your involvement.

Roger Snodgrass, Los Alamos Monitor: Can you give a sense of what has changed since the last meeting and how much you have accomplished?

Tom Widner: We are still in the one-half to two-thirds range of completing the review. We had to slow down and

give CDC time to determine how to finish the work with the available funds.

Joe Shonka: We got some significant things done. We scanned in documents and ran OCR on the documents. We assembled a priority list and were able to get the backlog of records out quickly. We have put a lot of effort into the draft report, interviews and critiques of our work.

Roger Snodgrass, Los Alamos Monitor: How did you determine that more plutonium was released than the lab reports?

Tom Widner: We used soil data comparisons based on more careful selection of samples, resulting in the 37 best samples.

Joe Shonka: The issue is not closed. We need to formalize calculations. Emissions from D Building were unfiltered, and it appears from the slope of the line that a lot of the releases apparently came from D Building. The assessment also ignores weathering of the soil.

Public: What is being done to indicate uncertainties?

Tom Widner: That is hard to do this early on, but will be a key consideration as work continues.

Public: Don't just say numbers are higher than reported. You need to indicate the significance of numbers.

Tom Widner: We accept your point. These are preliminary assessments. We can not draw conclusions regarding health effects. It would be premature and not appropriate at this point.

Public: Can you apprise us of how tight the lab is in respect to a terrorist attack? If there is an attack in near future, it could really spread contamination around the area. Have you been apprised?

Tom Widner: No, that is really out of the scope of our work.

Phil Green: Our subject is historical releases.

Tom Widner: We are not focused on current efforts and releases.

Dennis Paustenbach: If this project was taken to an endpoint, is it likely that this site will be as well understood as Rocky Flats?

Tom Widner: Each site is different. Each has data gaps. We have quite a bit of work to do before we can say.

Dennis Paustenbach: At the half-way point of data gathering, is data as robust as compared to other sites?

Tom Widner: Yes. LANL has largely maintained a research atmosphere. Some activities are more documented; others less.

Dennis Paustenbach: Based on other experience, what is the time and cost required to complete the document review?

Tom Widner: That depends on how CDC decides to go forward. Some steps could be collapsed or a directed document review could be considered. I don't know what CDC is going to ask for.

Dennis Paustenbach: How many years will it take to complete a dose reconstruction?

C.M. Wood: We can't talk about that. The RFQ is in procurement. CDC has similar experience at Hanford and the Savannah River Site. These are production sites and easier to calculate. Another research facility is INEEL. It might be instructive to explain what CDC is doing there. Dose reconstruction is a series of iterations at which you come to a decision point. At this point, where a certain amount of funds needs to be added to the contract, you determine if you have enough information to do a dose reconstruction. If the answer is no, you need to gather more information.

Public: What makes a dose reconstruction worthwhile? It was reported that there is an epidemic of cancer among employees in LANL.

C.M. Wood: Radiogenic cancer is very specific. At Hanford, large doses of iodine followed with a Hanford thyroid epidemiology study, which may be an indicator for a dose study. That's one reason. The Snake River Group is not interested in dose reconstruction. They are concerned with current issues.

Helen Dorado-Gray, Sen. Bingaman's Staff: One reason why is it important to do dose reconstruction is to support programs developed to compensate people that suffer resulting disease or ailments. If we don't do dose reconstruction, people can't settle with the government. This is the government's way of saying we have had some bad practices but are willing to compensate.

Tom Widner: A dose reconstruction often provides the public with the first independently generated picture of a site's operations and potential impacts.

Joe Shonka: A dose reconstruction is important because people become distrustful of site-specific assertions of what was released. Independent scientists go in and study an area. They prepare their assessments on releases and potential effects. They can provide some closure on what was released and did it hurt us.

Tom Widner: We are not here to say if lab did no wrong or that they did all evil. We are here to find data, and the data lead us in one direction or another. Some assessments we have conducted showed that releases were lower than expected; others showed that releases were higher than what most folks anticipated. This is the first comprehensive review and compilation of records at LANL. We had to truncate our efforts at this point, but we have added quite a bit.

Public: Is the 60-day comment period from today?

Tom Widner: Yes. The biggest room in the world is the room for improvement, and we look forward to receiving your comments and suggestions.

Public: Could you clarify the compensation act? Individual workers do not pay dividends for workers. There is an overall increase of knowledge in the community. How do you determine if it is appropriate to continue?

Susan Flack: A few workers have been able to use information released through this project. There are a couple of examples where workers could tell the information was about them based on the time frame although the names had been removed. They had the luxury of going through records the lab doesn't have time to go through.

Tom Widner: We are not focused on the workers; that is NIOSH's domain. However, we inform NIOSH about information we find that we think would be useful to them.

Peter Malmgren: I am aware of the struggles, of people feeling abandoned. The people involved in the compensation claim process are frustrated. The lack of attention to these people is shameful.

Tom Widner: Thanks for coming.
