## Provisional Information on Selected Notifiable Diseases in the United States and on Deaths in Selected Cities for Week Ended July 16, 1960

There was a sharp increase in the number of reported cases of poliomyelitis for the week ended July 16 as compared with the previous week. There was a total of 95 cases of which 69 were paralytic and 21 nonparalytic as compared with the previous week's total of 49 cases of which 39 were paralytic. For the same week in 1959 there were 255 cases, 169 paralytic. For the same week in 1958 there was a total of 123 cases, 52 being paralytic. The cumulative total of paralytic cases for 1960 is 457 as compared with 969 in 1959 and 437 in 1958.

The largest number of cases was reported in Rhode Island. Eighteen of the total of 24 were paralytic, 5 nonparalytic, and 1 unspecified. The cases continue to be concentrated in Providence ( 12 cases) and Pawtucket ( 6 cases). The remainder were scattered. Eleven of the 24 cases were under 5 years of age,

12 were 5 to 9 years, and 1 was 10 years old. A total of 47 paralytic cases have been reported in Rhode Island since January 1 as compared with 2 last year.

California reported 12 paralytic cases with 1 death. Nine of the 12 occurred in Los Angeles County. The number of paralytic cases reported in the State since January 1 is 134 as compared with 100 for the same period last year. While 61 cases with paralysis have been reported in Los Angeles County and 15 in San Diego County there has been no significant local concentration in either of these highly urbanized areas. Information that is available for 97 of the 134 paralytic cases reported in the State shows that 70 percent were under 10 years of age. About 62 percent of the cases under 10 had had no poliomyelitis vaccine and 20 percent had 1 or 2 doses.

[^0]A small concentration of cases was reported in South Carolina where there were 12 cases of which 7 were paralytic. There were 2 deaths. Seven of the 12 cases occurred in Cherokee County and 5 in adjoining Spartanburg County. It was reported that none of the cases reported had been adequately immunized.

Illinols reported 7 cases ( 5 paralytic), Pennsylvania 5 cases ( 3 paralytic), and Alabama 4 paralytic cases. The number reported in Puerto Rico was 19, all paralytic. A total of 306 paralytic cases have been reported since January 1 as compared with 3 last year.

## EPIDEMOI OGICAL REPORTS

## Staphylococcal food poisoning

Dr. I. J. Tarakow, Nassau County, New York Health Department, has supplied a delayed report of an outbreak involving a housewife and 3 teenage children. Onset of illness began 3 to 5 hours after eating lunch which consisted of egg salad sandwiches, well-cooked Polish sausage, ice cream, and coffee. The housewife was admitted to a hospital in shock and with an imperceptible pulse. However, she recovered. The 3 children were less seriously ill but had vomiting, abdominal cramps, and diarrhea. The egg salad was preparedfrom 5-day old unrefrigerated "Easter eggs" and mayonnalse. Specimens of the egg salad and mayonnaise were reported to be "loaded" with coagulase-positive staphylococci. It was believed by the investigator that staphylococcal enterotoxin was preformed in the mayonnaise.

## Gastroenteritis

Dr. D. S. Fleming, Minnesota Department of Health, has supplied information on an outbreak of gastroenteritis in a school. Fifty-five cases were reported among 280 pupils and 18 teachers who ate a noonday school lunch consisting of potato salad, fish sticks, egg salad sandwiches, pineapple, rice, cornbread, cheese, and milk. Symptoms which began 4 to 5 hours after eating consisted of nausea, vomiting, abdominal cramps, and occasional diarrhea. One person had to be hospitalized. No samples of food were available for bacteriologic examination, but it is stated that the potato salad was the suspected source because of 'improper refrigeration of the
cooked potatoes' used in preparation of the salad.
Dr. C. M. Steward, District Health Officer, New York State, and H. C. Paller have reported the occurrence of 7 cases of gastroenteritis following consumption of cream-filled pastries purchased from a bakery. The 7 persons became ill after an incubation period of 2 to 4 hours with vomiting, diarrhea, abdominal cramps, and prostration. Specimens of the pastry were not examined bacteriologically. However, it was learned that there was no refrigeration of this product after baking.

Dr. F. K. Laurentz, Texas Department of Health, has supplied information on an outbreak of gastroenteritis among persons who attended a wedding reception. Twenty-three of 200 persons who attended the reception became ill with abdominal cramps and nausea 2 to 4 hours after eating. The food served consisted of potato salad, rice, beans, chicken with sauce, and punch. The only food commonly eaten by all who became ill was potato salad which had been prepared in different homes. It remained unrefrigerated for approximately 6 to 7 hours before serving. The lack of refrigeration when the temperature was about $98^{\circ} \mathrm{F}$. and the fact that all who were ill ate the salad were considered to indicate that the salad was the vehicle of infection. None was available for bacteriologic examination.

Dr. W. R. Giedt, Washington State Department of Health, has reported a family outbreak of gastroenteritis that followed the eating of canned boneless ham. The ham had been purchased from a commissary about 2 weeks prior to the time it was eaten. The family had eaten some of the ham on one day with other food, in sandwiches the next day, and for lunch on the third day. Three members of the family became ill 2 to 4 hours after the meal on the third day. The symptoms were severe and consisted of nausea, vomiting, abdominal pain, diarrhea, dehydration, and low blood pressure. All were hospitalized. None of the ham was available for bacteriologic examination. It was stated that all cannedhams at the commissary were under refrigeration.

## QUARANTINE MEASURES

Immunization Information for International Travel No changes reported

## Table 2. CASES OF SPECIFIED NOTIFIABLE DISEASES: UNITED STATES, EACH DIVISION AND STATE, AND PUERTO RICO, FOR WEEKS ENDED JULY 18, 1959, AND JULY 16, 1960 - Continued

(By place of occurrence. Numbers under aiseases are category numbers of the Seventh Revision of the International Lists, 1955)

The chart shows the number of deaths reported for 117 major cittes of the United States by week for the current year. a 5 -week moving average of these figures plotted at the central week, and an adjusted average for comparison. The adjusted average is computed as follows: From the total deaths reported each week for the years 1955-59, 3 central figures are selected by eliminating the highest and lowest figures reported for that week. A 5 -week moving average of the arithmetic means of the 3 central figures is then computed. The adjusted average shown in the chart is this moving average increased by 4.0 percent to allow for estimated population growth in the cities and surrounding areas.

The use of the adjusted average is basedon the assumption that the crude death rate and changes in population will remain at the level of recent years. No allowance has been made for increased use of city hospital facilities.

Table 4 shows the number of death certificates recelved during the week indicated for deaths that occurred in selected cities. Figures complled in this way, by week of receipt, usually approximate closely the number of deaths occurring during the week. However, differences are to be expected because of variations in the interval between death and receipt of the certificate and because of incomplete reporting due to holidays or vacations. If a report is not received f. om a city in time to be included in the total for the current week, an estimate is used.

The number of deaths in cities of the same size may also differ because of variations in the age, race, and sex composition of the populations and because some cities are hospital centers serving the surrounding areas. Changes from year to year in the number of deaths may be due in part to population increases or decreases.

Table 3. DEATHS IN BELECTED CITIES BY GEOGRAPHIC DIVISIONS

## SOURCE AND NATURE OF MORBIDITY DATA

These provisional data are based on reports to the Public Health Service from the health departments of each State and Puerto Rico. They give the total number of cases of certain communicable diseases reported during the week usually ended the preceding Saturday. Total figures for the United States and the Pacific Division include data for Alaska for 1959 and 1960; data for Hawaii are included for 1960 only. Cases of anthrax, botulism, and rabies in man are not shown in table 2, but a footnote to table 1 shows the States reporting these diseases. When diseases of rare occurrence are reported by a State (cholera, dengue, plague, louse-borne relapsing fever, smallpox, louse-borne epidemic typhus, and yellow fever) this is noted below table 1.

[^0]:    ${ }^{1}$ Data show no pronounced seasonal change in incidence.

[^1]:    ${ }^{1}$ Includes cases not specified by type, category number 080.3.

[^2]:    ${ }^{2}$ Adjusted average used as base.
    ${ }^{2}$ Includes estimates for missing cities.

[^3]:    ${ }^{1}$ Estimated.
    ${ }^{2}$ Includes estimate for current week.
