For release May 12, 1961

Atlanta 22, Georgia

Vol. 10, No. 18

Provisional Information on Selected Notifiable Diseases in the United States and on Deaths in Selected Cities for Week Ended May 6, 1961

Hepatitis - The sustained high incidence continues. The total of 1,744 cases is slightly less than the 1,831 cases reported one week ago, but does not represent a significant decline from past high levels.

In the second week of nationwide reporting of hepatitis cases by age — under 20 years and 20 years or over — 38 States included this breakdown with their current morbidity telegram. These data are presented in tabular form on Page 8. States with an adult preponderance of cases include New Jersey (81 percent), Upstate New York (60 percent) and New York City (61 percent), Connecticut, Missouri and Oregon (54 percent).

EPIDEMIOLOGICAL REPORT

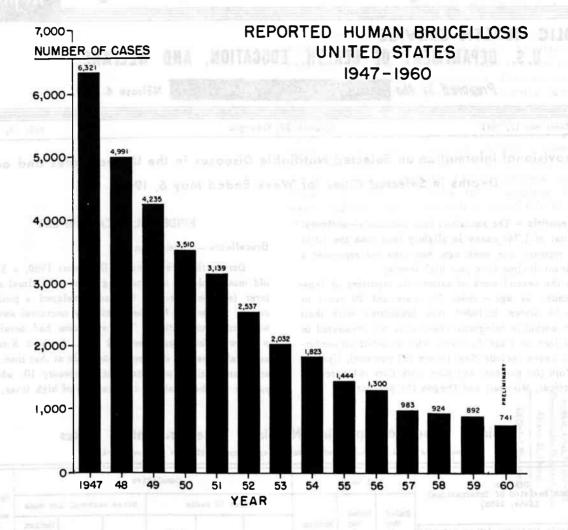

Brucellosis - Pennsylvania

During the first week in December 1960, a 57-year-old man employed at a packing plant as a ritual slaughterer (shochet) became ill and developed a productive cough, followed a few days later by nocturnal sweating, weakness, and fatigue. The symptoms had persisted a week when he sought medical care. A chest X-ray was unrevealing and no diagnosis was made at that time. Weakness and fatigue persisted until February 10, when the patient was hospitalized complaining of high fever, weak-

ness, periods of chilling and sweating, arthralgia, myalgia and severe spine pain. Blood cultures were obtained from which *B. abortus* was isolated. An agglutination test for brucellosis revealed a titer of 1:1,280.

This man slaughters cattle, many of which are brucella positive, by means of a sharp knife which is used to cut the arteries of the neck. Following slaughter, the carcass is opened and the shochet proceeds to palpate with bare arms the pleural and peritoneal cavities which places him in contact with the viscera. Doing this, he frequently nicks and scratches his arms by contact with bone splinters. Occasionally during the slaughtering operation he becomes splashed with blood which enters his eyes and mouth. In spite of the exposure involved, this man, during a life time in this occupation, has never had a known previous attack of this disease nor is it apparently common in others so employed.

(Submitted by Milton Werren, V.M.D., Chief, Veterinary Public Health Section, Philadelphia Department of Health.)

BRUCELLOSIS SURVEILLANCE - 1960

The reported number of human brucellosis cases continued to decline in 1960 (741 cases) as it has for the past 14 years. Preliminary data for 1959 included 721 cases but a total of 892 cases were tabulated when the final reports were received from the States. The 1960 preliminary report of 741 is slightly higher than the 1959 preliminary reports so the final figure for 1960 may actually exceed the total cases in 1959.

The decline in incidence has been dramatic since 1947 when 6,321 cases were reported to the National Office of Vital Statistics (see bar graph). The States having the highest incidence of disease in 1960 were Iowa, Illinois, Kansas, Virginia, California, South Dakota, Texas, and Nebraska. These 8 States reported 75 percent of the cases in the nation. Iowa with 307 cases reported 41 percent of the country's cases. Dr. Stanley L. Hendricks, Iowa State Health Department's Public Health Veterinarian, reported

The chart shows the number of deaths reported for 117 major cities of the United States by week for the current year, a 5-week moving average of these figures plotted at the central week, and an adjusted average for comparison. For each region the adjusted average was computed as follows: From the total deaths reported each week for the years 1956-1960, 3 central figures were selected by eliminating the highest and lowest figure reported for that week. A 5-week moving average of the arithmetic mean of the 3 central figures was then computed with adjustment to allow for population growth in each region. The average value of the regional increases was 2 percent which was incorporated in the adjusted average shown in the chart.

Table 4 shows the number of death certificates re-

ceived during the week indicated for deaths that occurred in selected cities. Figures compiled in this way, by week of receipt, usually approximate closely the number of deaths occurring during the week. However, differences are to be expected because of variations in the interval between death and receipt of the certificate and because of incomplete reporting due to holidays or vacations. If a report is not received from a city in time to be included in the total for the current week, an estimate is used.

The number of deaths in cities of the same size may also differ because of variations in the age, race, and sex composition of the populations and because some cities are hospital centers serving the surrounding areas. Changes from year to year in the number of deaths may be due in part to population increases or decreases.

Table 3. DEATHS IN SELECTED CITIES BY GEOGRAPHIC DIVISIONS (By place of occurrence and week of filing certificate. Excludes fetal deaths. Data exclude figures shown in parentheses in table

⁽⁾ Figures shown in parenthesis are from cities which have been reporting less than five years and hence are not included in Table 3.

that there was a large epidemic among the 1500 employees of a swine slaughtering plant in that State. The epidemic began late in 1959 and extended into the first half of 1960. There were 128 clinical cases which is the largest epidemic to be reported in recent years.

Epidemiological reports submitted to the Communicable Disease Center indicate that most of the human infections in 1960 were due to occupational exposure, and a large proportion were associated with swine. (Prepared by the Veterinary Public Health Section, Communicable Disease Center).
