Epidemiologic Notes and Reports

## Follow-up on Deaths Associated with Liquid Protein Diets

The investigation by the Food and Drug Administration and CDC into the deaths associated with the liquid protein diets is continuing. A total of 58 such deaths have been reported; all occurred in the latter half of 1977 and early 1978.

Sixteen of these deaths, all in white women between the ages of 23 and 51 , fit a distinctive clinical and pathologic pattern that has been previously described $(1,2)$. This pattern is characterized by either sudden death or death due to intractable cardiac arrhythmias in individuals with no previous history of heart disease. Pathologically, the syndrome is associated with degenerative and inflammatory changes in the myocardium. All 16 women used liquid protein products as the primary source of calories for periods of greater than 2 months.

A nationwide telephone survey was performed during March and April of this year to determine how many women between the ages of 25 and 44 were on similar dietary regimens for 1 month or longer in 1977. The survey estimated that no more than 98,000 white women were on the liquid protein diet for a month or more and that no more than 37,000 were on it for 2 months or more in 1977. Usage of the diet did not differ significantly among the racial groups surveyed.

Of the 16 deaths fitting the distinctive pattern, 11 occurred in the United States from July through December of 1977 among women aged 25-44. Relating these 11 deaths to the estimated 37,000 users from the telephone survey gives an adjusted annual mortality rate of 59 deaths per 100,000 white women in this age group on the diet for periods of greater than 2 months in 1977. National mortality data indicate that the annual death rate due to etiologies consistent with the pattern of these deaths is less than 2 per 100,000 women aged $25-44$ in the general population. Thus, it appears that in this age group prolonged use of the liquid protein diet accounts for a significant increase in mortality. Reported by Food and Drug Adminstration, Bur of Health Education, Bacterial Diseases Div, Bur of Epidemiology, CDC.
Editorial Note: The FDA is developing regulations to require mandatory warninglabels on protein products promoted for weight reduction. Additional studies are in progress to clarify further the magnitude of the risk involved for individuals on these diets and to determine the exact mechanism of the deaths that have occurred. There is little reason to doubt that the present data, which show an increased risk for white women aged 25-44 with prolonged use of the diet, would also apply to both sexes and all age and racial groups.

At the present time, insufficient information is available to insure the safety of persons on such regimens. A recent editorial suggested that ". . . the liguid protetifnegimens should be used with extreme caution and only under canofully contralded cotiditions.

## Protein Diets - Continued

conventional medical supervision is not an adequate safeguard"(3). Additionally, prolonged use should be limited to research settings controlled by protocols approved by committees on human experimentation and only with the informed consent of the participants.

## International Notes

## Influenza - South America

Argentina: Influenza $\mathrm{A} / \mathrm{USSR} / 77(\mathrm{H} 1 \mathrm{~N} 1)$-like viruses were isolated in Córdoba during a sharp outbreak of influenza which started on April 7, 1978, at the Air Force Academy. Individuals from 15 to 21 years of age were affected, with an attack rate of $27 \%$. This outbreak began in what is early autumn in Argentina and is the earliest recorded influenza epidemic there since 1965.

In Buenos Aires an outbreak of influenza occurred in a military barracks in mid-April; viruses resembling A/Texas/1/77 were isolated. In May, A/USSR/77(H1N1)-like viruses were isolated during an outbreak of influenza among Air Force recruits.
Brazil: In April and May, H3N2 strains which cross-reacted equally with A/Victoria/3/ 75 and A/Texas/1/77 were isolated in Rio de Janeiro. A/USSR/77(H1N1)-like viruses were isolated in Belem during May from patients whose ages ranged from 9 to 26 years. A/USSR/77-like viruses were also reported in June from São Paulo, where they were isolated only from children and young adults.
Chile: During May, A/USSR/77-like viruses were isolated in Valparaiso from Navy cadets and in Santiago from personnel at an Air Force school and from high school students. Ecuador: Isolation of H3N2 viruses has been reported from residents of Guayaquil. Reported by the National Influenza Centres in Córdoba and Buenos Aires, Argentina; Belem and SĨo Paulo, Brazil; Santiago, Chili; Guayaquil, Ecuador; and the WHO Collaborating Center for Influenza, CDC.

## Current Trends

## Vaccine-Induced Canine Rabies - California

On June 1, 1978, the California Department of Health (CDH) withdrew approval for the use in that state of low-egg-passage, chick-embryo-origin rabies vaccine (LEPCEO), a modified live virus vaccine used only for immunization of dogs. The state withdrew the vaccine because a study completed recently by the CDH had shown that the vaccine can cause rabies in dogs at a rate of approximately 3 cases/million doses of vaccine administered; no other rabies vaccine was so incriminated.

Because no virus markers are known which positively differentiate vaccine virus from street virus, the CDH accepted for the study only those cases that adhered rigidly to a set of epidemiologic, laboratory, and clinical characteristics associated with vaccine-induced disease.

The study also found that, on the average, 1.9 persons were required to take antirabies treatment as a result of exposure to each case of presumed vaccine-induced disease. Although California will no longer allow the use of the LEP-CEO vaccine in that state,

## Canine Rabies - 'ontinued

it will contirse to recognize immunity conierred by that vaccine in dogs vaccinated in other states.
Reported by DG Constantine, EV Bayer, GL Humphrey, California Dept of Health; Respiratory and Special Pathogens Br, Viral Diseases Div, Bur of Epidemiology, CDC.
Editorial Note: A review of reported cases of vaccine-induced rabies in the rest of the United States for the period January 1976 through April 1978 yielded an attack rate of 0.4 cases/million vaccinates with the LEP-CEO vaccine and 0.01 cases/million with other modified live virus rabies vaccines. For the same time period California had reported 3 cases/million LEP-CEO vaccinates and 0 cases/million with other modified live virus vaccines. The much higher overall attack rate in California undoubtedly represents a more intensive surveillance for vaccine-associated disease. Particularly in vaccine-induced rabies, where non-fatal disease is common (5 of 12 cases in California), intensive surveillance is required to identify cases.

All states are now being asked to review retrospectively cases of rabies since 1976, with consideration to the possibility of vaccine-induced disease, and to be alert to this possibility in reviewing the epizootiology of future cases of dog rabies.

## Epidemiologic Notes and Reports

## Follow-up on Outbreak of Dengue - Puerto Rico, 1978

Reports of dengue-like illness continue to occur in Puerto Rico; for the week ending June 28, 1978, a total of 955 cases of suspected dengue were reported (Table 1). Of these, 175 were reported from the Bayamon area, 234 from the remainder of the San Juan metropolitan area, and 546 from the rest of the island. Cases were widespread: 69 of the 78 municipios of Puerto Rico reported dengue-like illness. The total number of reported cases since March 30, 1978, is 5,092.
TABLE 1. Reports of dengue-like illness, Puerto Rico, June 1978

| Weak ending | Bayamon | Rest of San Juan | Rest of island | Total |
| :---: | :---: | :---: | :---: | ---: |
| June 7 | 130 | 229 | 215 | 574 |
| June 14 | 187 | 490 | 462 | $\mathbf{1 . 1 3 9}$ |
| June 21 | 181 | 362 | 671 | 1.214 |
| June 28 | 175 | 234 | 546 | 955 |

When 249 paired serum specimens from cases with onset since April 1 were tested, $82 \%$ were positive for recent dengue infection. Twenty-five of 26 isolates from cases with onset in May were type 1, and one was type 2.

Weekly average catches of adult Aedes aegypti mosquitoes increased during May and early June. In addition to extensive source reduction to control mosquito breeding throughout the island and ground-based insecticide spraying, 3 cycles of repeated ultra-low-volume applications of malathion over the metropolitan San Juan area were completed on June 16.
Reported by $J$ Chiriboga, MD, Environmental Health, Puerto Rico Dept of Health; San Juan Lab-
Oratories, Bur of Laboratories, Vector Biology and Control Div, Bur of Tropical Diseases, and Viral oratories, Bur of Laboratories, Vector B
Diseases Div, Bur of Epidemiology, CDC.
Editorial Note: Although the risk of dengue infection appears small and there have been no confirmed cases recently in travelers returning to the continental United States frem Puerto Rico, CDC has alerted travel agencies, airlines, and shipping companies of the current situation. Travelers should take such precautions as applying insect repellant and wearing protective clothing to avoid mosquito bites.

## Campylobacter Enteritis - Colorado

On June 24, 1978, the first U.S. outbreak of waterborne Campylobacter gastroenter-itis-involving an estimated 2,000 persons in Vermont-was reported (1). An additional small outbreak due to Campylobacter organisms has now been reported in Colorado.

On June 7, 1978, 3 of 5 family members in Colorado ranging in age from 20 to 60 became ill with malaise, myalgias, and nausea. Within the next 24 hours, the illness was marked by severe cramping, lower abdominal pain, and explosive diarrhea which in 1 case became bloody. All had fever (ranging up to 40 C [104 F]), which lasted for 2 days. In 2 of the patients all symptoms remitted within 4 days with symptomatic treatment that included oral and intravenous fluid therapy. The patient with bloody diarrhea continued to have diarrhea and abdominal pain for 6 days. Erythromycin was started, and the patient subsequently improved.

Stool cultures from all 3 patients yielded C. fetus sub. jejuni. No salmonellae, shigellae, or protozoans were found. Stool cultures from the 2 asymptomatic family members were negative.

The family operates a small farm with chickens, swine, sheep, calves, and a cow. Raw milk from the cow was consumed by all 3 patients and one of the other family members. On June 13, raw milk, eggs, and all animals from the farm were cultured for Campylobacter organisms. All were negative with the exception of the stool culture of the cow, which yielded C. fetus sub. jejuni.
(Continued on page 231)

[^2]Campylobacter Enteritis - Continued<br>Reported by MJ Blazer, MD, J Cravens, P Riepe, B Powers, WL Wang, PhD, VA Hospital, Denver; TA Edell, MD, Acting State Epidemiologist, Colorado State Dept of Health; Enteric Diseases Br, Bacterial Disease Div, Bur of Epidemiology, CDC.

Editorial Note: Campy/obacter is the generic name proposed in 1963 (2) for a group of microaerophilic organisms that clearly differed from Vibrio organisms. The type species is $C$. fetus (Vibrio fetus), which had been known as a cause of abortion in cattle and sheep; other members of the new genus have been associated with diseases of domestic animals, including enteritis of calves and pigs.

Although evidence from the outbreak reported here is incomplete, it is compatible with the transmission of Campylobacter organisms by unpasteurized milk. Unpasteurized milk has been previously suggested as a vehicle for such infections $(3,4)$.

A recent review of the clinical and epidemiologic features of persons in Engiand from whose feces Campylobacter organisms were isolated reveals that $94 \%$ had diarrhea ( $15 \%$ with blood, pus, or mucus), $8 \%$ had persisting or recurring diarrhea for 2 weeks or more, and $13 \%$ had severe abdominal pain. Sixty-six percent were individuals 15 years of age or older (5).

## Typhoid Vaccine

## INTRODUCTION

The incidence of typhoid fever has declined steadily in the United States in the last half century, and in recent years fewer than 400 cases have been reported annually. The continuing downward trend is due largely to better sanitation and other control measures; vaccine is not deemed to have played a significant role. An increasing proportion of cases reported in the United States (about $50 \%$ in 1976) were acquired by travelers in other countries.

## TYPHOID AND PARATYPHOID A AND B VACCINES

Although typhoid vaccines* have been used for many decades, only recently has definitive evidence of their effectiveness been observed in well-controlled field investigations. Several different preparations of typhoid vaccine have been shown to protect $70-90 \%$ of recipients, depending in part of the degree of their subsequent exposure.

[^3]
## Typhoid Vaccine - Continued

The effectiveness of paratyphoid $A$ vaccine has never been established, and field trials have shown that usually small amounts of paratyphoid $B$ antigens contained in "TAB" vaccines (vaccines combining typhoid and paratyphoid $A$ and $B$ antigens) are not effective. Knowing this and recognizing that combining paratyphoid $A$ and $B$ antigens with typhoid vaccine increases the risk of vaccine reaction, one should use typhoid vaccine alone.

## VACCINE USAGE

Routine typhoid vaccination is no longer recommended for persons in the United States. Selective immunization is, however, indicated for:

1. Persons with intimate exposure to a documented typhoid carrier, such as would occur with continued household contact.
2. Travelers to areas where there is a recognized risk of exposure to typhoid because of poor food and water sanitation. It should be emphasized, however, that even after typhoid vaccination there should be careful selection of foods and water in these areas.

There is no evidence that typhoid vaccine is of value in the United States in controlling common-source outbreaks. Furthermore, there is no reason to use typhoid vaccine for persons in areas of natural disaster such as floods or for persons attending rural summer camps.

## Primary Immunization

On the basis of the field trials referred to above, the following dosages of typhoid vaccine available in the United States are recommended:

Adults and children 10 years and older: 0.5 ml subcutaneously on 2 occasions, separated by 4 or more weeks.

Children less than 10 years old*: 0.25 ml subcutaneously on 2 occasions, separated by 4 or more weeks.

In instances where there is not sufficient time for 2 doses at the interval specified, it has been common practice to give 3 doses of the same volumes listed above at weekly intervals, although it is recognized that this schedule may be less effective. When vaccine must be administered for travel overseas under constraint of time, a second dose may be administered en route at the more desirable interval.

## Booster Doses

Under conditions of continued or repeated exposure, a booster dose should be given at least every 3 years. Even when more than a 3 -year interval has elapsed since the prior immunization, a single booster injection is sufficient.

The following alternate routes and dosages of booster immunization can be expected to produce comparable antibody responses. Generally less reaction follows vaccination by the intradermal route, except when acetone-killed and dried vaccine is used. (The latter vaccine should not be given intradermally.)

Adults and children 10 years and older: 0.5 ml subcutaneously or 0.1 ml intradermally.

Children 6 months to 10 years: 0.25 ml subcutaneously or 0.1 ml intradermally.

## PRECAUTIONS AND CONTRAINDICATIONS

Typhoid vaccination often results in 1-2 days of discomfort at the site of injection. The local reaction may be accomoanied by fever, malaise, and headache.

#### Abstract

Readers will note that, beginning this issue, the MMWR has increased to 12 pages that are reduced in size to $6-1 / 8$ inches by $8-1 / 2$ inches. This redesign was necessary because of new U.S. Postal Service regulations that substantially increase mail rates for publications over a certain size.
