## Current Trends

## Goal to Eliminate Measles from the United States

On October 4, 1978, the Secretary of the Department of Health, Education, and Welfare, Joseph A. Califano, Jr., announced that the United States would seek to eliminate indigenous measles from the nation by October 1, 1982. This goal is a possibility because of the decline in incidence of measles in the United States and the major progress that the Nationwide Childhood Immunization Initiative has made in attaining immunization levels of at least $90 \%$ in those under 15 years of age by October 1, 1979.

Thus far this year, 24,179 cases of measles have been reported in the United States, a decline of $55 \%$ compared to the same period of 1977 . From 1950 through 1959 (the decade before vaccine was licensed), $5,487,332$ cases of measles and 4,950 related deaths were reported. In addition to death (occurring in approximately 1 out of 1,000 reported cases) , the complications of measles include otitis media, pneumonia, measles-encephalitis, and subacute sclerosing panencephalitis (a rare and fatal degenerative disease).

The availability of an effective vaccine, the absence of a non-human host, and the absence of a carrier state indicate that elimination of indigenous measles from the United States is a scientifically valid goal.

The 4 major thrusts of the effort to eliminate measles will be:

1. Increased emphasis on identifying and immunizing susceptible adolescents and young adults, who now represent an important segment of the pool of susceptibles;
2. Increased efforts to broaden school immunization requirements to cover children in all grades (rather than just first entrants) and rigorous enforcement of those requirements;
3. Strengthening of surveillance systems with institution of active surveillance systems where they do not now exist. Active surveillance involves aggressive search for cases that would previously have gone unreported; and
4. Improvements in the efficiency and effectiveness of outbreak-control measures.

Achievement of this goal will depend primarily on the efforts of local and state health departments and on the support they receive from organized medicine and all levels of government. Maintaining this goal, once achieved, will require vigilance and an ability to respond promptly to the importations of measles which are bound to occur.
Reported by Immunization Div, Bur of State Services, CDC.

## Epidemiologic Notes and Reports

## Echovirus Type 9 Outbreak - New York

An outbreak of echovirus type 9 infection is occurring on Long Island, New York. Between April 20 and September 23, 1978, 158 viral isolates have been obtained from 106 persons ages 1 day to 30 years (Figures 1 and 2). The outbreak peaked during the summer months and currently appears to be declining.

FIGURE 1. Onset of illness, by week, in ECHO 9 cases,* Long Island, New York, 1978

*date of onset unknown in 2 cases
FIGURE 2. Clinical presentation of ECHO 9 cases with either pharyngitis or aseptic meningitis, by age, Long Island, New York, April 20-September 23, 1978

Echovirus - Continued
Several patients presented with aseptic meningitis, but the vast majority have had upper respiratory tract involvement, primarily pharyngitis (Table 1). Twenty-eight of the 106 persons were hospitalized. Seventeen patients (16\%) presented with meningitis. Of the 89 patients who did not have meningitis, 68 (76\%) had clinical pharyngitis. The 21 ( $24 \%$ ) without meningitis or apparent pharyngitis had fever or sepsis (8), rash (4),diarrhea (4), or other respiratory findings (5). Nearly half of these (10/21) were younger than 1 year.
TABLE 1. Clinical findings among ECHO 9 patients, Nassau County, 1978 and 19701977

| Clinical finding | 1978 <br> $(\mathbf{n}=\mathbf{1 0 6 )}$ | Percent with finding | $\mathbf{1 9 7 0 - 1 9 7 7}$ <br> $(\mathbf{n}=86)$ |
| :--- | :---: | :---: | :---: |
| Fever | 83 | 77 |  |
| Pharyngitis (total) | 67 | 33 |  |
| Pharyngitis with exudate | 20 | 0 |  |
| Nausea/vomiting | 39 | 26 |  |
| Headache | 34 | 32 |  |
| Rash | 24 | 25 |  |
| Nasal congestion | 22 | 22 |  |
| Diarrhea | 16 | 3 |  |
| Otitis media | 16 | 4 |  |
| Cough | 13 | 15 |  |
| Nuchal rigidity | 6 | 22 |  |
| Photophobia | 6 | 4 |  |

Of the 17 patients with aseptic meningitis, $88 \%$ were age 9 or older. Significantly more males ( $15 / 17$ ) than females had aseptic meningitis ( $p<0.05$ ). The clinical presentation was typical of that generally seen with meningitis; rash and/or pharyngitis were also found in several patients. Echovirus type 9 was isolated from all 17 aseptic meningitis cases, $60 \%$ from throat swabs, $60 \%$ from cerebrospinal fluids. Virus was isolated from both sources in only 2 patients.

Ninety-two percent of the patients this year were children under 15 years of age. $A$ comparison of the age distributions of ECHO 9 cases from this outbreak with cases from 1970-1977 on Long Island and with cases from 1967-1970 among 20 nations (1) reveals that patients were generally older in previous outbreaks.
Reported by SW Klein, MD, J McPhee, MS, Nassau County Medical Center, New York; DO Lyman, MD, State Epidemiologist, New York Dept of Health; Viral Diseases Div, Bur of Epidemiology, CDC.
Editorial Note: ECHO 9 is classically associated with infection of the central nervous system (CNS) $(2,3)$; it is primarily seen in older children and adolescents. In this outbreak only $16 \%$ of patients had CNS infection, in comparison with $79 \%$ of patients in the 20 -nation study by the World Health Organization (1).

The Nassau County Medical Center actively encouraged specimen collection for purposes of virus isolation of all febrile pediatric patients and all patients suspected of having an illness of viral etiology. Because of this, several cases of pharyngitis or upper respiratory tract infection were identified as probably due to ECHO 9.

Whereas pharyngitis without evidence of Group A $\beta$-hemolytic Streptococcus is often presumed to be "viral"-without further definition-active surveillance and laboratory evaluation, in this instance, identified ECHO 9 as one such viral agent that can cause pharyngitis in children.

## Legionnaires' Disease - Los Angeles, California

Forty-three confirmed Legionnaires' disease (LD) cases occurred from May 1, 1977. through July 31, 1978, in patients and employees of the Wadsworth Veterans Administration Hospital in Los Angeles, California. Forty-one cases had pneumonia (1,2), and 10 patients died.

The LD patients ranged in age from 39 to 84 years with a median age of 57 . Thirtythree cases were confirmed by $\geqslant 4$-fold rise in the serum indirect fluorescent antibody titer, 6 by direct fluorescent antibody examination of lung tissue, and 4 by both methods. An isolate of the LD bacterium was obtained in July 1978 from the lung tissue of a fatal case.

All of the LD patients had been inside the hospital before onset of LD: 30 had been inpatients at the time of onset, 7 had been discharged within 2 weeks prior to onset, 3 had been seen as outpatients, and 3 cases were hospital employees. For inpatients the median interval from admission to onset of pneumonia was 18 days (range: 6-276 days).

[^1]reparted by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

- APneumonia and influenza

A serologic survey of employees at the hospital and at an office building one-half mile away revealed a significantly higher prevalence of positive titers ( $\geqslant 1: 128$ ) in the hospital employees ( $4.2 \%$ vs. $15.8 \%$ ) ( $p=0.004$ ). The highest prevalence was in groundskeepers; 6 of 12 had positive titers ( $p<0.02$ vs. all hospital employees).

In a study comparing inpatient cases with inpatient controls matched only for day of admission, more of the cases were immunosuppressed ( $p<.01$ ) and cases had longer hospitalizations before developing pneumonia ( $p=.0005$ ). There were no significant differences in sex, age, race, history of smoking, place of residence, location in the hospital, medications (other than immunosuppressives), or use of respiratory therapy.

In 1977 the incidence of nosocomial pneumonia was not increased over the preceding year in the hospital as a whole. However, $50 \%(6 / 12)$ of the renal homograft recipients acquired pneumonias in 1977 (all LD) compared to $14 \%$ (3/22) from any other single etiology for the preceding 3 years ( $\mathrm{p}=0.031$ ). There was no increase in pneumonia among leukemia and lymphoma patients during the same time periods. The renai transplant program has been suspended until the risk of infection can be reduced in the hospital.

In a survey from February through April 1978 of 1,500 consecutive admissions, $13 \%$ of patients had a titer $\geqslant 1: 128$ to the LD bacterium on admission to the hospital and $3.2 \%$ of 900 patients who provided paired serum specimens developed a $\geqslant 4$-fold rise in titer to the LD bacterium in the 6 -week period following their hospitalization. Seventytwo cases of nosocomial pneumonia occurred in these 1,500 patients ( $4.8 \%$ ); 5 of these 72 had LD.

Attempts to recover the LD bacterium from the environment by cultures of air conditioning filters and condensate, exposure of guinea-pigs to the air inside the hospital, and cultures of soil, dust, and bird droppings, were unsuccessful.
Reported by PH Edelstein, MD, SM Finegold, MD, J Halter, RN, BD Kirby, MD, RD Meyer, MD, Wadsworth Veterans Administration Hospital, UCLA School of Medicine, Los Angeles; Infectious Diseases Section, California Dept of Health; Field Services Div, Bacterial Diseases Div, Bur of Epidemiology, CDC.

## Rabies in a Pet Skunk - Arizona

Twenty-three persons in Arizona were exposed recently to a rabid skunk that had been captured in the wild and sold by a pet store.

The rabid animal was one of 50 descented skunks that a Cross Plains, Texas, supplier had sent on July 31 to a wholesale pet dealer in Phoenix, Arizona. By August 2, the dealer had distributed them to 8 pet shops in the Phoenix area and Tucson. All but 4 of these skunks have since been accounted for.

On August 12, one of the skunks was sold to a family from near Show Low, Arizona. The owners returned it to the store on August 13 and were given another because the original animal was vicious and had bitten them. The skunk was resold to a Phoenix resident on August 14, this time at a discount because of its aggressive behavior. It was taken to Yuma and left with another family where, on approximately August 24, the animal had onset of excessive salivation and screaming and began viciously biting at its cage.

Rabies - Continued
The skunk died on August 27 and was submitted to the state health laboratory on September 1, where it was found to be positive for rabies. A total of 23 persons including owners and store employees were exposed to the rabid skunk. One person was bitten more than 35 times by the animal. All are undergoing anti-rabies treatment.

Investigation by the Arizona Department of Health Services indicated that 1 other skunk in the shipment of 50 had been dead on arrival at a pet store and that subsequently 6 more had died in the stores. It was assumed by the pet dealers that all had died from complications of descenting-primarily rectal prolapse.

In tracking down the 50 animals from the shipment, the Arizona Department of Health Services found 2 in the neighboring states of Colorado and New Mexico; both were found to be negative for rabies. A total of 31 well skunks from Arizona (only 6 of which had not been sold) were sacrificed and examined for rabies by the state health laboratory; all were negative both by fluorescent antibody and mouse inoculation tests. The 7 animals that had died in the pet stores had been discarded before examination of the rabies-positive skunk. Four of the purchased skunks had escaped, and 1 had been killed in an accident.

The Texas Department of Health reported that the supplier did not have sufficient facilities to pen, breed, and raise enough skunks to meet the demand, so he was accustomed to trapping and selling young skunks or trapping pregnant females and selling their offspring. He also purchased skunks from local trappers. In 1977 he had distributed over 200 raccoons and approximately 500 skunks to several states including Arizona, Missouri, Michigan, Illinois, and Texas. The Texas Department of Health has notified the states that have received shipments of skunks from this particular distributor. The area of Texas from which these animals were obtained has had epizootic skunk rabies for a number of years.
Reported by T Kelly, DVM, Maricopa County Rabies Animal Control, Phoenix; W Bilderback, DVM, JM Counts, DrPH, P Hotchkiss, DVM, A Kelter, MD, State Epidemiologist, Arizona Dept of Health Services; F Marks, BS; C Webb, MD, State Epidemiologist, D Woodall, BS, Texas Dept of Health; Respiratory and Special Pathogens Br, Viral Diseases Div, Bur of Epidemiology, CDC.
Editorial Note: An increasing number of cases of rabies in wild pets, especially skunks, are being reported to CDC. In 1977 Oklahoma reported that in a 5 -week period 3 pet skunks from different areas of the state were found rabies-positive (1). At least 50 persons were exposed to the infected animals. Montana reported, late in the summer of that year, that a rabid pet skunk had exposed 10 persons (2). In June 1978, 29 other persons were exposed to a rabid pet skunk in Oklahoma (3). And Indiana reported a similar incident, in which 26 persons were exposed, in July of this year. All of these incidents emphasize the need for more stringent control of wildlife that have been captured and kept as pets.

More persons come in contact with animals in captivity than would be the case if they were left in the wild. When rabies develops in captive wild animals, many persons may be exposed and need anti-rabies treatment.

CDC strongly urges that exotic or wild animals not be kept as pets and that states consider legislation against selling or keeping captured wild animals. Few states presently have the necessary laws to control the capture, distribution, and sale of such animals. Long and variable rabies-incubation periods in some wild animals kept as pets have been reported. In addition, rabies has been induced occasionally by modified, live virus vaccines given to wild animals. Finally, none of the vaccines currently available are known to be effective in immunizing wildlife against rabies. Recently the U.S. Animal Health Association promulgated a recommendation against interstate shipment or private ownership of wild animals that may have been collected in rabies-enzootic areas.

## Measles - Maryland

During the first half of 1978, 46 cases of measles were reported in Maryland, the lowest reported incidence since 1974. These cases were distributed in 11 of 24 counties.

Further epidemioiogic data and vaccine histories were available for analysis from all cases. Cases in children under 5 accounted for $22 \%$ of the total, and persons $\geqslant 10$ for $59 \%$. Twenty-three (50\%) of the cases occurred in unvaccinated persons; 22 cases (48\%) occurred in persons who had documented histories of vaccination; vaccine history was unknown in the other person (Table 1). Twelve cases (26\%) occurred in children with religious exemptions to vaccination; 11 of these children were exposed to a patient at a religicus meeting.
TABLE 1. Vaccination status of 46 reported measles cases, January 1, 1978, through June 30, 1978, Maryland

| Vaccination status |  | Number of cases | Percent of total |
| :--- | ---: | :---: | :---: |
| Vaccinated | 22 | 47.8 |  |
| Killed virus only | 1 |  |  |
| Vaccine $<12$ months | 3 |  |  |
| Vaccine $\geqslant 12$ months | 18 |  |  |
| Not vaccinated | 12 |  |  |
| Religious objection | 3 |  |  |
| Less than 15 months old | 6 |  |  |
| At least 15 months old | 1 |  |  |
| Egg allergy | 1 | 1 | 2.2 |
| History of disease |  |  |  |
| Unknown status |  |  |  |

Reported by CH Acree, MDCM, Maryland State Dept of Health \& Mental Hygiene; Immunization Div, Bur of State Services, CDC.

Editorial Note: Twenty-four (52\%) of these 46 cases occurred in children who were old enough for routine measles vaccination or who should have been revaccinated. Many of these inadequately immunized children could have been identified prior to their exposure to measles by careful immunization record-review. The observation that $26 \%$ of the cases occurred in children with religious exemptions to vaccination is of interest. A

[^2]
## Meas/es - Continued

recent survey has demonstrated that fewer than $1 \%$ of Maryland school children have such religious exemptions. During the periods when measles is known to be in the community, effective control of the disease may require that children with religious, medical, or other exemptions to immunization be excluded from school.

## Follow-up on Vibrio cholerae serotype Inaba Infection - Louisiana

Vibrio cholerae serotype Inaba organisms have been isolated from canal water near White Lake, Louisiana, that had been sampled using a Moore swab (1) on October 2-3. Crabs caught in the vicinity on September 22 caused 6 known human infections with the organism (2). V. cholerae serotype Inaba also has been isolated from sewage from the town of Gueydan in Vermilion Parish. However, no cases have been reported from that town, nor have any additional cases been found elsewhere in the state.

The state of Louisiana is continuing surveillance of the commercial processing of crabs and of seafood. The public is also being urged to boil crabs at least 15 minutes before eating.

A reduced volume of unprocessed refrigerated and/or frozen crabs continue to be shipped from Louisiana. State and territorial public health officials have been notified of the investigation in Louisiana and, as part of its monitoring system of crabs, the U.S. Food and Drug Administration (FDA) is culturing appropriate specimens for $V$. cholerae.

No cases of cholera have been reported in states other than Louisiana, and none of the Louisiana cases have been associated with commercially prepared crabs. Close monitoring of specific commercial processing and cooking practices ensures a more uniform standard of quality than in home-prepared crabs.
Reported by HB Bradford, PhD. Director, Bur of Laboratories, CT Caraway, DVM, State Epidemiologist, Louisiana Dept of Health and Human Recources; FDA; Enteric Diseases Br, Epidemiologic Investigations Laboratory Br, Bacterial Diseases Div, Quarantine Div, Field Services Div, Bur of Epidemiology, CDC.
