Urinary Tract Infection Caused by Capnophilic Escherichia coli

To the Editor: Increased atmospheric CO₂ concentrations promote the growth of fastidious microorganisms. However, the possibility that a strain of *Escherichia coli* can be CO₂ dependent is exceptional (1).

An isolate of capnophilic *E. coli* was responsible for a urinary tract infection (UTI) in a 77-year-old woman at the University Hospital of Guadalajara (Spain) in November 2002. Urine was cultured on a cystine-lactose-electrolyte-deficient agar plate and incubated at 37°C in an atmosphere containing 6% CO₂ for 1 day. After 24 hours, the culture yielded gram-negative rods (>10⁶ CFU/mL) in pure culture. The organism was motile, catalase positive, and oxidase negative. The strain could not be identified by using the MicroScan WalkAway-40 system (DadeBerhing, Inc., West Sacramento, CA, USA). A subculture incubated at 37°C for 24 hours in an atmosphere of 6% CO₂ produced smooth colonies 2–3 mm in diameter on sheep blood agar and MacConkey agar plates. The organism fermented lactose, and the indole reaction (BBL DrySlidet, Becton Dickinson Co., Sparks, MD, USA) performed on sheep blood agar was negative. The strain grew well on Schaedler agar plates after anaerobic incubation for 48 hours. The isolate remained capnophilic after 5 subcultures. The strain was identified as *E. coli* by using the Biolog GN2 panel (Biolog, Inc., Hayward, CA, USA) (100%, T = 0.534), after incubation of the panel in an atmosphere containing 6% CO₂ for 1 day. The API 20E system (bioMérieux, Marcy-l’Etoile, France) according to the manufacturer’s instructions without CO₂ incubation also identified *E. coli* (profile 5004512). The identification was confirmed by means of 16S rDNA sequence analysis (1,472 bp obtained by PCR amplification by a previously reported method [2]), which showed 99% similarity with *E. coli* sequence (GenBank accession no. CP000802). The 16S sequence showed similarity with *Shigella* species; however, this identification was not considered because the strain fermented lactose on MacConkey agar and agglutinations with *Shigella* antiserum were negative. The original 16S rDNA sequence was deposited in GenBank (accession no. EU555536).

The antimicrobial drug susceptibility profile was determined by incubating Mueller-Hinton agar plates at 37°C in an atmosphere containing 6% CO₂ by the disk diffusion method, according to National Committee for Clinical Laboratory Standards recommendations (3). The isolate was susceptible to ampicillin, amoxicillin/clavulanic acid, piperacillin, ceftazolin, cefuroxime, cefotaxime, nitrofurantoin, fosfomycin, trimethoprim-sulfamethoxazole, gentamicin, tobramycin, amikacin, norfloxacin, and ciprofloxacin. MICs were obtained for the following antimicrobial agents with the E-test method (AB Biodisk, Solna, Sweden), performed on Mueller-Hinton agar plates incubated in a 6% CO₂ atmosphere: ampicillin (1.5 μg/mL), amoxicillin (3 μg/mL), cefotaxime (0.064 μg/mL), imipenem (0.094 μg/mL), piperacillin (2 μg/mL), and ciprofloxacin (0.008 μg/mL).

*E. coli* is the most common pathogen among patients with uncomplicated UTIs (4). Two cases of UTIs due to carbon dioxide–dependent strains of *E. coli* have been reported (1). The mechanisms for development of CO₂ dependence are unknown (5). CO₂ can play a role in the growth of *E. coli* as a substrate for carboxylation reactions (6). Other members of the family *En-
terobacteriaceae (such as some strains of Klebsiella spp.) and other organisms (such as Staphylococcus aureus), can have similar requirements.

There is not 1 best way of performing urine cultures. Guidelines for the diagnosis of UTI includes the use of sheep blood agar and either MacConkey agar or a similar selective medium for routine urine culture. The plates should be incubated overnight (at least 16 hours) at 37°C in ambient air; alternatively, the blood agar plate can be incubated in elevated (3%–8%) CO₂ (9). For fastidious microorganisms, chocolate agar can be added to the MacConkey agar and the plates incubated in 5% CO₂ for 2 days (9).

The real incidence of these infections is unknown, but the rarity of these strains suggests that the incidence is low. However, the real incidence of UTI caused by capnophilic E. coli may be underestimated because urine cultures are not usually incubated in CO₂. In addition, urine cultures are not performed for many women with uncomplicated cystitis. Other fastidious uropathogens such as Haemophilus influenzae and H. parainfluenzae, also require special media and incubation in an atmosphere of CO₂ (9). The low frequency of these strains suggests that incubation of routine urine cultures in an atmosphere containing CO₂ is not necessary. Incubation in CO₂ should be ordered only if the patient has pyuria and a previous negative urine culture after incubation in ambient air or if the patient is unresponsive to empiric therapy and routine urine culture is negative. Good clinician–laboratory communication is vital. Further studies should be performed to ascertain the real incidence of UTIs caused by capnophilic strains of E. coli.

Because no breakpoints are available for antimicrobial agents against capnophilic strains of E. coli, we used published interpretative criteria or Enterobacteriaceae (3). The strain was susceptible to all antimicrobial agents that we tested. The impact of CO₂ on the susceptibility of capnophilic strains of E. coli is unknown. Susceptibility of some antimicrobial agents such as quinolones can be influenced by the pH change and enhanced growth that occur during CO₂ incubation when testing capnophilic organisms (10).

Duck Migration and Past Influenza A (H5N1) Outbreak Areas

To the Editor: In 2005 and 2006, the highly pathogenic avian influenza (HPAI) virus subtype H5N1 rapidly spread from Asia through Europe, the Middle East, and Africa. Waterbirds are considered the natural reservoir of low pathogenic avian influenza viruses (1), but their potential role in the spread of HPAI (H5N1), along with legal and illegal poultry and wildlife trade (2), is yet to be clarified.

The garganey (Anas querquedula) is the most numerous duck migrating between Eurasia and Africa: ≈2 million gather in the wetlands of Western Africa every northern winter (3). We report on a spatial correlation between the 2007 migration path of a garganey monitored through satellite telemetry and areas that had major HPAI (H5N1) outbreaks from 2005 through 2007.

Seven garganeys were captured, sampled, and fitted with a 12-g satellite transmitter in northern Nigeria (Hadejia-Nguru Wetlands; 12°48′N; 10°44′E) in the period February 7–15, 2007. All cloacal and tracheal swabs tested negative for avian influenza virus by real-time reverse transcription–PCR analysis of the matrix gene. One second-year (>9-month-
