ing responsible for nosocomial infection. Items used during the patient’s ocular surgery were confirmed to be disposable and nonreused.

Topical drops of corticosteroids commonly applied during cataract surgery for intraocular lens implantation penetrate ocular structures. An alternative hypothesis is that corticosteroids applied during ocular surgery reactivate a latent ocular infection. Our review indicated that 13 of 19 patients with documented T. whipplei uveitis had received topical or systemic corticosteroids before the diagnosis (Table) (7). Worsening of Whipple disease has been reported in patients receiving corticoid therapy for arthralgia (10). We speculate that our patient had an asymptomatic ocular infection before surgery.

This case shows that ocular surgery and use of topical corticosteroids that penetrate ocular structures could reactivate a latent T. whipplei ocular infection. We suggest that patients with postoperative panendophthalmitis be tested for T. whipplei by PCR.

Klebsiella pneumoniae Carbapenemase, Canada

To the Editor: Carbapenem are used to treat life-threatening infections caused by extremely drug-resistant gram-negative pathogens; these drugs represent the last line of defense in the antimicrobial drug armamentarium against serious or invasive infection (1). The rapid global spread of Klebsiella pneumoniae that produces K. pneumoniae carbapenemase (KPC), especially in the northeastern United States (e.g., New York state), is of major concern (2,3). KPC β-lactamases belong to the family of serine carbapenemases and are usually found in K. pneumoniae and Escherichia coli. KPC hydrolyzes β-lactam agents, thereby reducing their action. KPC activity has been reported, albeit less frequently, in other family Enterobacteriaceae (K. oxytoca, Enterobacter spp., Salmonella spp., Citrobacter freundii, and Serratia spp.) as well as in Pseudomonas aeruginosa (1).

The blaKPC genes have been identified on conjugative plasmids and pose an infection control problem because plasmids could theoretically be transmitted from one species to another (4). The few therapeutic options for treating infections caused by organisms containing these β-lactamases are aminoglycosides, glycolcycelines, polymyxins, or combinations (1). A major concern is that routine susceptibility testing methods based on existing breakpoints can falsly identify KPC producers as susceptible to carbapenem. Such results pose the potential risk for increased illness and death, longer hospital stays, and nosocomial spread of infection.

In 2008, the Public Health Laboratory in Toronto received clinical isolates of K. pneumoniae from urine and sputum of 1 patient. The hospital laboratory had forwarded the isolates to the
Public Health Laboratory because they were possible KPC producers. The patient was a 73-year-old man with a history of emphysema and hypertension, seen at a tertiary care hospital in the Toronto area, 80 miles from the New York state border, for a laparoscopic nephrectomy. He had no risk factors for acquisition of KPC producers, e.g., travel to the United States or prior carbapenem exposure.

Susceptibility testing of K. pneumoniae was performed by the agar dilution method, using breakpoints set by the Clinical and Laboratory Standards Institute (5,6). The sputum isolate (7315) was susceptible to meropenem (MIC 4 μg/mL), and the urine isolate (7184) was intermediately susceptible (MIC 8 μg/mL). The K. pneumoniae isolates were screened for extended-spectrum β-lactamas (ESBLs) and AmpC production according to Ontario guidelines (7).

Briefly, to screen for ESBL enzymatic activity, a double-disk diffusion method was used: a clavulanic acid-containing disk was placed adjacent to a disk containing one of several cephalosporins such as ceftazidime and cefotaxime. Enhanced killing of the organism in the area between the drug with and without clavulanate indicates ESBL. Cefoxitin resistance (zone ≤17 mm) indicates AmpC-like β-lactamase activity. In addition, testing for ESBL/AmpC was performed according to Clinical and Laboratory Standards Institute guidelines (6). When the screening result for ESBL or AmpC is positive, the clinical laboratory issues a warning that no β-lactam except carbapenems can effectively treat this infection. The Table summarizes results of initial susceptibility testing and supplementary laboratory testing for KPC.

The initial result was consistent with a possible AmpC/ESBL producer for the sputum and urine isolates (6,7). However, because the patient responded poorly to empiric vancomycin and imipenem therapy and because of the elevated MIC to meropenem for isolate 7184, further laboratory testing was conducted to rule out the possibility of carbapenemase activity.

The modified Hodge test is a phenotypic test proposed to confirm the presence of carbapenemase activity such as KPC in K. pneumoniae and E. coli (8). Universal primers for blaKPC family, Uni-KPC-F (′-ATGTCACTGTATCGCCGTCT-3′) and -R (′-TTACTGCCGTGTGA CGCCC-3′), were used for the entire 882-bp coding sequence. Amplicons were bidirectionally sequenced by using the BigDye Terminators method and a 3130xl Genetic Analyzer (Applied Biosystems, Foster City, CA, USA) and primers Uni-KPC-F and -R. Multiple nucleotide and protein sequence alignments were performed with the ClustalW2 software (www.ebi.ac.uk/Tools/clustalw2/index.html). To aid the clinician, an Etest method was used to measure the MIC of this KPC-producing K. pneumoniae isolate to colistin (0.5 μg/mL) and tigecycline (2.0 μg/mL). However, before this information could be used, the patient had died of respiratory failure, presumably caused by K. pneumoniae. Infection control measures and laboratory screening were undertaken in the hospital to limit transmission to other patients.

This report shows that KPC-producing organisms such as K. pneumoniae may pose a major risk for clinical disease and a challenge for infection control if they were to spread to other hospitals in Canada. Current testing algorithms focus on ESBL- and AmpC-producing gram-negative bacteria, which may not detect KPC-producer strains. We suggest that reference laboratories validate a screening method coupled with confirmatory phenotypic assay for carbapenemase activity for suspected organisms, especially K. pneumoniae and E. coli. Our in-house validation studies confirm that use of the etrapenem disk followed by the modified Hodge test to confirm carbapenemase activity may be effective (D.R. Pillai et al., unpub. data). Public health officials should be aware that this report further expands the international distribution of KPC-producing K. pneumoniae.

The research component of this report was funded by the Ontario Agency for Health Protection and Promotion.

*AMP, ampicillin; FOX, cefoxitin; CIP, ciprofloxacin; GEN, gentamicin; CTRX, ceftriaxone; MEM, meropenem; CAZ, ceftazidime; CAC, ceftazidime-clavulanic acid; CTX, cefotaxime; CTC, cefotaxime-clavulanic acid; ESBL, extended-spectrum β-lactamase; KPC, Klebsiella pneumoniae carbapenemase.
†MIC values for clinical isolates 7184 (urine) and 7315 (sputum) were obtained by using agar macrodilution.
‡Initial screening for ESBL or AmpC β-lactamase activity, performed by Kirby Bauer disk diffusion according to Clinical Laboratory Standards Institute guidelines (6,7), suggested ESBL or AmpC β-lactamase activity.
§Supplementary modified Hodge test; PCR (specific for blaKPC family), and DNA sequencing confirmed the presence of KPC activity due to blaKPC-2.
Cryptosporidium sp. Rabbit Genotype, a Newly Identified Human Pathogen

To the Editor: Most human cases of cryptosporidiosis are caused by Cryptosporidium parvum or C. hominis, but pathogenicity of some unusual Cryptosporidium species/genotypes is uncertain (1). In July 2008, an outbreak caused by Cryptosporidium sp. rabbit genotype was linked to consumption of tap water in Northamptonshire, England (2). On June 23 and 24, Cryptosporidium oocysts were detected by operational monitoring of treated water at a surface water treatment works. A precautionary boil-water notice was implemented on June 25.

Enhanced surveillance for cases was established by the health protection team on June 25 in the affected area. Eight single-well immunofluorescent microscopy slides, on which oocysts were detected by water company sampling of the distribution system, were sent to the UK Cryptosporidium Reference Unit, Swansea, for typing. Slides contained 49–197 oocysts, and the rabbit isolate were homologous with isolates from rabbits in the People’s Republic of China (6) and the Czech Republic (7) (GenBank accession nos.AY120901 and AY273771, respectively) (online Appendix Table, available from www.cdc.gov/EID/content/15/5/829-appT.htm). One sample from 1,391 L of water contained 259 oocysts but was not amplified. Other cryptosporidia were not identified.

Human stool samples from 34 local laboratory-identified cases of cryptosporidiosis in the affected area were sent to the UK Cryptosporidium Reference Unit for typing. To differentiate rabbit genotype from C. hominis (1), enhanced typing by SSU rRNA nested PCR–restriction fragment length polymorphism analysis with Sspl and Vspl (1.5) was used for all isolates submitted to the UK Cryptosporidium Reference Unit during July and August. Samples from 23 cases (22 primary and 1 secondary) with rabbit genotype profiles were identified by visualization of 472-, 267-, and 109-bp bands generated by digestion with Sspl (1). All case-patients lived in the area affected by the water supply incident and had onset dates consistent with exposure by drinking water consumption or by person-to-person spread. All 23 samples were homologous to AY120901 and AY273771 (online Appendix Table). Of the other 11 samples, 6 were not confirmed by IFAT or PCR, 2 were C. hominis, 1 was C. parvum, and 2 were not typeable.
