

## U.S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE / public health service health services and mental health administration

## EPIDEMIOLOGIC NOTES AND REPORTS GASTROENTERITIS ATTRIBUTED TO IMPORTED FRENCH CHEESE - United States

Between Nov. 12 and 26, 1971, at least 111 persons in 20 separate outbreaks had onset of acute gastroenteritis approximately 24 hours after eating imported Camembert cheese. Typical symptoms included nausea, diarrhea, fever, myalgia, and in some cases, bloody diarrhea and vomiting. Two persons were hospitalized; there were no deaths. The average duration of illness was $24-48$ hours. In addition, 16 persons in six outbreaks experienced a similar illness after eating imported Brie cheese. One of these persons was hospitalized.

Food-specific attack rates strongly implicated Camembert and Brie cheese imported from France by Anco Cheese Imports, Inc., of Elmsford, New York. These products bear the label "LeRoitelet, manufactured by S.A.F.R., 44 R. Louis

Blanc, Paris, France." They are sold in 8 -ounce packages and have the code number 3169 stamped on the bottom.

The importers have voluntarily recalled both products. The recall is being monitored by the Food and Drug Administration. The cheeses have been distributed to consignees in New York, Connecticut, New Jersey, Massachusetts, Michigan, Colorado, Georgia, California, Louisiana, Pennsylvania, Washington, Maryland, and the District of Columbia.

## GASTROENTERITIS - (Continued from front page)

The etiology of this illness has not been confirmed. Several laboratories are analyzing stool specimens obtained from patients as well as multiple samples of the cheeses to determine the causative agent.
(Reported by L. W. Schnurrenberger, M.D., Acting Chief, Robert Beck, Advisor, Bureau of Food and Drug, John Pate,
M.D., Chief, Venereal Diseases, Communicable Disease Control. District of Columbia Department of Public Health; the Food and Drug Administration, Washington, D.C.; the Bacterial Diseases Branch, Epidemiology Program, CDC; and an EIS Officer.)

## TYPHOID FEVER IN AMERICAN TOURISTS TO EUROPE

Between July 9 and Aug. 9, 1971, a group of 81 American students and their counselors from 15 states traveled in Germany, France, and Italy. Between August 9-22, after their return to the United States, eight persons had onset of symptoms suggestive of typhoid fever (Figure 1). Four persons were hospitalized; three had fever with headache, and one had fever with diarrhea. Six of the patients were from Virginia, and two were from Alabama.

Blood and stool specimens were obtained from all eight patients. Four had blood cultures positive for Salmonella typhi, and one of these and one other had positive stool cultures (Table 1). All isolates were of the same phage type, degraded Vi. Although cases 5 and 6 did not have positive cultures, both had symptoms and 0 antibody titers compatible with typhoid. All patients recovered uneventfully.

An epidemiologic investigation was conducted in which 61 other members of the tour were interviewed. None had symptoms suggestive of typhoid fever. Members of the group recalled an event that had occurred sometime between July 24 and August 7 while they were in northern Italy. They had been traveling by train on a very hot day when the train

stopped to take on water from a nearby pond. Some members of the group drank some of this water in spite of warnings from the counselors. Of the 19 persons in the group from Viriginia, 10 drank the water and six of them later became ill with typhoid fever. The other nine Virginians said they had not drunk the water; none of them experienced typhoid. The two patients from Alabama denied drinking this water. The Virginians were generally together in the same small group during the various art tours. The patients from Alabama did not recall being part of that group.
(Reported by H. E. Gillespie, M.D.. Chief of Division of Special Health Services, Virginia State Department of Health; Frederick S. Wolf, M.D., Director, Bureau of Preventable Diseases, Alabama Department of Public Health; the Laboratory Division, CDC; and two EIS Officers.)

## Editorial Note

Typhoid fever is becoming increasingly rare in the United States. However, physicians should consider typhoid fever in the differential diagnosis of febrile patients who have a history of foreign travel from 1 to 4 weeks prior to the onset of fever. An epidemiologic investigation should be conducted of all travelers who accompany such patients.

## INTERNATIONAL NOTES <br> SALMONELLA INFECTION FROM A TORTOISE - United Kingdom

Approximately 300,000 tortoises are imported into the United Kingdom each year. It is estimated that about 85 percent of them are infected with salmonellae. Nevertheless, there have been very few recorded cases of human infection from these reptiles. Most cases have occurred in young children.

Recently, a 10 -year-old girl, whose father owns a pet shop, was admitted to a hospital with a temperature of $105^{\circ} \mathrm{F}$. and pain in the right hip which she had had for 3 days. Sal-
monella overschie was isolated from blood and stool specimens and from pus aspirated from the hip joint. Septicemia with or without localization is a well known complication of salmonella infection. This patient had a prolonged illness and was finally discharged after 14 weeks.

Approximately 2 weeks before she became ill, her pet tortoise had excreted copiously over her hands and arms. Cloacal swabs and droppings from the tortoise were cultured
and found to contain $S$. overschie and $S$. uphill. Specimens from contacts, a rabbit, a dog, two guinea pigs, and a hamster were also cultured, but no salmonellae were found.

Both serotypes isolated from the tortoise are very rare in England. Indeed, $S$. overschie has not been isolated previously in the United Kingdom. S. uphill, a subgenus II Salmonella, was first identified from a tortoise in Taunton in 1951, and most of the isolations in the United Kingdom have been made from tortoises or terrapins. A human case of infection was reported in 1965, and there were two more in 1969. All three patients were young children; two of them had a pet tortoise.

The tortoise implicated in the present case was the last in a batch of about 50 sold by the child's parents, and it was therefore not possible to examine the remainder of the batch. They were bought from a wholesaler who obtains them in large quantities from Mediterranean countries and sells about 10,000 a year. No further cases of infection due to $S$. over-
schie have been reported.
When tortoises were first investigated as a possible source of infection approximately 20 years ago, they were found to harbor salmonella serotypes very rarely found in man. Recently, however, more common human pathogens have been isolated from tortoises. Earlier this year, there was circumstantial evidence from one report that $S$. enteritidis isolated from a patient might have been acquired from a tortoise. There is also a suggestion from the United States that tortoises may be a more important problem than has been recognized so far [MMWR, Vol. 20, No. 11]. In the United Kingdom, infection from tortoises is, as far as is known, very uncommon, but to wash the hands after handling one is a wise precaution.
(From notes based on reports to the Public Health Laboratory Service from Public Health and Hospital Laboratories in the United Kingdom and Republic of Ireland, published in the British Medical Journal Nov. 20, 1971.)

## SURVEILLANCE SUMMARY <br> MEASLES - United States, 1970-71

In the measles epidemiologic year (EY*) 1970-71, 77,682 cases of measles were reported in the United States (Figure 2). This represents a 73.8 percent increase over the total reported for EY 1969-70 and a 225 percent increase over that for EY 1967-68. Many epidemiologic investigations have shown that the overwhelming majority of the cases this year occurred in unvaccinated children.

In the past decade, the case fatality ratio for measles has regularly been 1.0-1.5 per 1,000, and the occurrence of

[^0]measles-associated encephalitis has been approximately 1 per 1,000 ; in 1967, for example, when 62,705 cases of measles were reported, there were 81 measles deaths, 52 of them in children less than 5 years old, and 62 cases of measles-associated encephalitis. Although similar data for EY 1970-71 are not yet available, the great increase in measles in this EY has undoubtedly resulted in deaths and encephalitis cases equal to or greater than those in 1967.
(Reported by the Field Services Branch, Epidemiology Program, and the Immunization Branch. State and Community Services Division, CDC.)
