## ABSTRACT

Filtering facepiece respirators (FFRs) and elastomeric half-mask respirators (EHRs) are commonly used by workers for protection against potentially hazardous particles, including engineered nanoparticles. The purpose of this study was to evaluate the performance of these types of respirators against 10–400 nm particles using human subjects exposed to NaCl aerosols under simulated workplace activities. Simulated workplace protection factors (SWPFs) were measured for eight combinations of respirator models (2 N95 FFRs, 2 P100 FFRs, 2 N95 EHRs, and 2 P100 EHRs) worn by 25 healthy test subjects (13 females and 12 males) with varying face sizes. Before beginning a SWPF test for a given respirator model, each subject had to pass a quantitative fit test. Each SWPF test was performed using a protocol of six exercises for 3 min each: (i) normal breathing, (ii) deep breathing, (iii) moving head side to side, (iv) moving head up and down, (v) bending at the waist, and (vi) a simulated laboratory-vessel cleaning motion. Two scanning mobility particle sizers were used simultaneously to measure the upstream (outside the respirator) and downstream (inside the respirator) test aerosol; SWPF was then calculated as a ratio of the upstream and downstream particle concentrations. In general, geometric mean SWPF (GM-SWPF) was highest for the P100 EHRs, followed by P100 FFRs, N95 EHRs, and N95 FFRs. This trend holds true for nanoparticles (10–100 nm), larger size particles (100–400 nm), and the 'all size' range (10–400 nm). All respirators provided better or similar performance levels for 10–100 nm particles as compared to larger 100–400 nm particles. This study found that class P100 respirators provided higher SWPFs compared to class N95 respirators ( $P < 0.05$ ) for both FFR and EHR types. All respirators provided expected performance (i.e. fifth percentile SWPF > 10) against all particle size ranges tested.

**KEYWORDS:** elastomeric half-mask respirators; filtering facepiece respirators; nanoparticle; N95 respirators; P100 respirators; simulated workplace protection factors

## INTRODUCTION

Aerosolized nanoparticles generated by a variety of natural and industrial processes exhibit unique properties (e.g. chemistry and toxicity) due to their

greater surface area and may be inhaled, ingested, or absorbed through skin (Baroli *et al.*, 2007). Inhalation of nanoparticles is believed to be the primary route of exposure and is of the greatest concern

(Birch *et al.*, 2011; Dahm *et al.*, 2013). Recent studies have reported the adverse effects of known mass concentrations of nanomaterial exposures on pulmonary and systemic functions in several systems (Shvedova *et al.*, 2009; Brooks *et al.*, 2010). Exposure to nanoparticles also has been shown to increase the incidence of pneumoconiosis among workers (Byrne and Baugh, 2008).

Filtering facepiece respirators (FFRs) and elastomeric half-mask respirators (EHRs) are commonly used by workers for protection against potentially hazardous particles, including engineered nanoparticles (Dahm *et al.*, 2011). Respirator performance is dependent on many variables, such as filter penetration, face seal leakage (FSL), and leakage through other respirator components (i.e. exhalation valves). The filter penetration of particles is dependent on particle diameter, particle charge state, filter fiber charge, fiber packing density, and filtration velocity, while FSL is dependent on the fit of the respirator to the face and work activity (Liu *et al.*, 1993; Han *et al.*, 2005; Grinshpun *et al.*, 2009).

Although numerous research studies have measured laboratory filtration performance against particles (Wilkes, 2002; Rengasamy *et al.*, 2009; Vo *et al.*, 2013), only a few of them have used human subjects exposed to particles for evaluating respirator performance. The respirator performance study of Lawrence *et al.* (2006) was focused only on N95 FFRs and EHRs and the respiratory performance level was determined based on the total particle counts using a PortaCount without the N95-Companion accessory. The respirator performance study of Grinshpun *et al.* (2009) was targeted toward testing N95 FFRs and surgical masks. Grinshpun *et al.* found higher levels of inward leakage for particles  $< \sim 200$  nm. Zhuang *et al.* (2013) reported a laboratory FSL evaluation of N95 FFRs against nanoparticles in the laboratory. In that study, Zhuang *et al.* concluded that FSL for negatively charged  $\sim 40$ – $60$  nm nanoparticles is not greater than the FSL for the larger distribution of charged and uncharged 20 to  $> 1000$  nm particles. This finding contradicts that of Grinshpun *et al.* (2009) which found greater leakage for nanoparticles in that size range.

The recommended process for selecting respirators for protection against various workplace hazards can be found in the 2004 NIOSH Respirator

Selection Logic (NIOSH, 2005–100) and elsewhere (BS EN 529, 2005; CSA Standard Z94.4–11). As nanoparticles and engineered nanomaterials in particular have found increasing use in workplaces, questions have been raised about whether the 2004 NIOSH Respirator Selection Logic can also be applied to nanoparticles. NIOSH research (prior to December 2008) to address this question was reviewed by Shaffer and Rengasamy (2009). It was noted that the employer should take particle size into account when making a respirator selection decision. In addition, the Occupational Safety and Health Administration (OSHA) has recommended to use the 100 efficiency level filters (e.g. class P100 respirators) when exposed to potentially harmful levels of engineered nanomaterials (OSHA, FS-3634). However, no test data for class P100 respirators using human subjects exposed to aerosols under simulated workplace activities are available to validate this recommendation. Thus, there is a need for evaluating and comparing the performance of class N95 respirators (containing a most common filter with a 95% filtration efficiency) and class P100 respirators (containing a filter with a 99.97% filtration efficiency) in the two most common respirator types (FFRs and EHRs) using human subjects under simulated workplace activities. There is also a need for evaluating respirator performance as a function of particle size to further assist respiratory protection program managers in the respirator selection process.

The aim of this study was to evaluate the performance of class N95 and class P100 respirators for both FFR and EHR types against 10–400 nm particles using human subjects exposed to NaCl aerosols under simulated workplace activities. This study was conducted to achieve three specific research objectives: (i) measure simulated workplace protection factors (SWPFs) for both FFR and EHR types as a function of particle size; (ii) determine if individual models within each type provide the expected level of performance; and (iii) compare SWPF levels between class N95 and class P100 respirators and between FFR and EHR types. This was the first study to measure respirator performance against nanoparticles under simulated workplace conditions and to determine performance differences between respirators with different filter series (N versus P) and different filter efficiency levels (95 versus 100).

## MATERIALS AND METHODS

### Equipment and supplies

#### Respirator selection and test subjects

Eight NIOSH-approved respirator models (Table 1) were randomly selected from among models previously tested (Vo *et al.*, 2012; Rengasamy *et al.*, 2013) in our laboratory. Each respirator filter had a multi-layer structure with the main layers of these filters composed of electrostatically charged polypropylene fibers; however, each filter had different characteristics, such as the number of layers, thickness, and hydrophilic/hydrophobic fiber materials.

Twenty-five subjects (13 females and 12 males) participated in this study (Fig. 1). The age of the panel members ranged from 19 to 65 years. The NIOSH bivariate panel was used for placement of test subjects in specific face length by face width cells (Zhuang *et al.*, 2007). This study

was approved by the NIOSH Institutional Review Board (IRB) and all subjects gave written consent to participate.

#### Equipment and supplies for the fit test and SWPF test

**Aerosol generator solutions:** Two NaCl solutions in distilled water were used as generator solutions. The solution concentrations for the fit test generator and the SWPF test atomizer were 2 and 0.2%, respectively. These different solution concentrations were chosen to ensure that adequate particle concentrations were generated for the standard fit test as described by Lawrence *et al.* (2006) and the SWPF test as described by Vo and Zhuang (2013).

**Fit test:** A particle generator (Model 8026, TSI, Shoreview, MN) and a PortaCount Plus (Model 8038, TSI) were used for the fit test.

**Table 1. Summary GM-SWPF and fifth percentile values by respirator model**

Respirator type	Class of filter	Respirator model	Respirator features	GM_SWPF <sup>a</sup> ( $\pm$ GSD)	Fifth percentile
FFRs	N95	N95-A	Cup, nonadjustable straps, metal nosepiece, one size	$103 \pm 3.3$	14
		N95-B	Cup, nonadjustable straps, metal nosepiece, one size	$94 \pm 2.0$	30
	P100	P100-A	Cup, adjustable straps, exhalation valve, metal nosepiece, one size	$6586 \pm 2.8$	1207
		P100-B	Cup, adjustable straps, exhalation valve, metal nosepiece, one size	$3200 \pm 5.2$	213
EHRs	N95	N95-A	S, M, L sizes, adjustable straps, exhalation valve	$136 \pm 1.9$	47
		N95-B	S, M, L sizes, adjustable straps, exhalation valve	$257 \pm 1.9$	88
	P100	P100-A	S, M, L sizes, adjustable straps, exhalation valve	$8157 \pm 2.9$	1388
		P100-B	S, M, L sizes, adjustable straps, exhalation valve	$9923 \pm 2.9$	1759

<sup>a</sup>Total number of observations ( $n$ ) of each respirator-model GM-SWPF data point = 75 ( $n = 1$  model  $\times$  3 replicates  $\times$  25 subjects).

**SWPF test:** An aerosol chamber testing system (ACTS) consisting of an aerosol generation set, an exposure chamber system, and a particle detector component was used for the SWPF test (Fig. 2). The aerosol generation set has a six-jet atomizer (Model 9306, TSI), a Kr-85 aerosol neutralizer (Model 3054, TSI), and an ultrafine condensation particle counter (UCPC, model 3776, TSI) to track the particle concentration in the testing chamber. A compressed air supply for the generator was filtered with a high efficiency particulate air (HEPA) filter (Model 2074B, TSI). The chamber testing system consisted of an exposure chamber (Model 222-6, Dynatech, Albuquerque, NM, USA), a humidity/temperature sensor (Model RHXL3SD, Omega Engineering, Stamford, CT, USA), circulation fans, and a 14-cm diameter exhaust port. The exposure chamber height, width, and depth were  $2.5 \times 2.5 \times 1.5$  m, respectively. The chamber contained sufficient space for a human subject,

with a respirator, to perform a SWPF test inside comfortably. The particle detector component consisted of two scanning mobility particle sizers (SMPSs, Model 3080 with Model-3772 CPCs, TSI). Two SMPSs were used simultaneously to measure the upstream (outside the respirator) and downstream (inside the respirator) test aerosol (Fig. 2).

### Fit test and SWPF test procedures

#### *The fit test procedure*

A fit test was conducted under laboratory conditions for each subject and each respiratory protective device prior to the start of a SWPF test. A particle generator (Model 8026, TSI) was used to keep room concentrations between 3000 and 8000 particles  $\text{cm}^{-3}$  for the fit test. When the laboratory particle concentrations reached the designated level, subjects trained by a test operator (the training included demonstrating

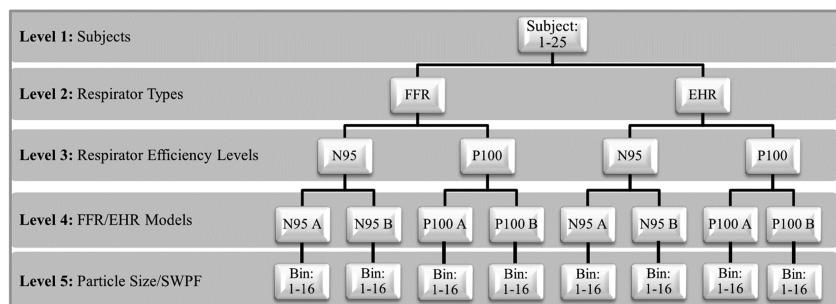

Figure 1 Schematic diagram of experimental study design for simulated workplace protection factors (SWPF) test.

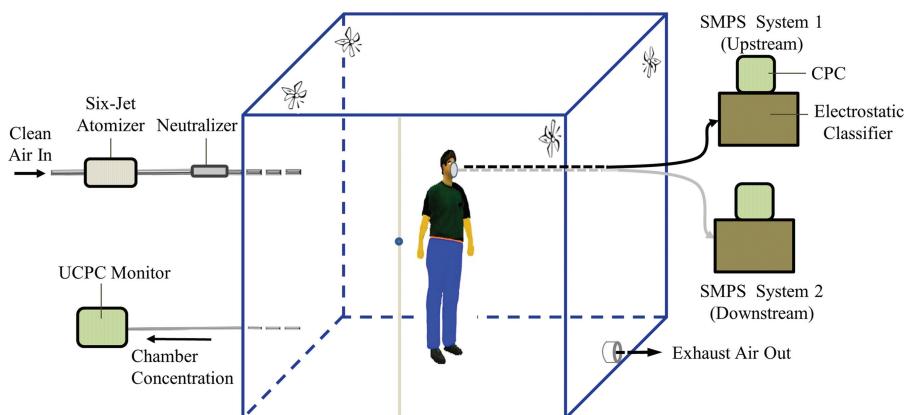

Figure 2 Schematic diagram of an aerosol chamber testing system: including an aerosol generator system with a particle concentration monitor, exposure chamber with an exhaust port, and particle detector systems [scanning mobility particle sizer (SMPS)].

how to don a respirator using the manufacturer's user instructions) donned the FFR or EHR and connected the PortaCount sample line to the respirator. The fit test was initiated after the test operator assured that the respirator was properly donned by the test subject, including performance by the subject of the standard respirator user seal check. Subjects performed the eight exercises described in the OSHA standard fit test (OSHA, 2002). The eight exercises were performed in the following order: (i) normal breathing, (ii) deep breathing, (iii) turning head side to side, (iv) moving head up and down, (v) talking out loud, (vi) reaching for floor and ceiling, (vii) grimacing, and (viii) normal breathing. The fit factor (FF) was determined by the PortaCount Plus based on the ratio of the upstream and downstream concentrations of each exercise. A harmonic mean of the FFs measured for these exercises, except the grimace exercise (the grimace exercise was excluded from the overall FF calculation), was also obtained directly from the PortaCount. If the subject received a FF value of  $\geq 100$ , the fit test was considered a pass. If the subject received a FF value of  $< 100$ , the fit test was considered a failure. If the subject did not pass the fit test during the first trial, to ensure they passed, a test operator was required to help them don the respirator, adjust its head straps, and reshape its metal nosepiece (if equipped). Once a proper fit was achieved, the subject continued to don the respirator with the connector tube sealed using a clamp, and was escorted to the exposure chamber for the SWPF test.

#### *The SWPF test procedure*

A NaCl solution was aerosolized using the single jet mode of the six-jet atomizer at a dispersion of  $30 \text{ l min}^{-1}$ . The output aerosol was dried with 30% dilution air in an atomizer self-contained dilution system, followed by neutralizing with the Kr-85 charging source before entering into the exposure testing chamber (Fig. 2). The aerosol in the exposure chamber was mixed using four internal fans positioned on the top of four inner corners of the chamber (Fig. 2). Throughout the experiment, an UCPC tracked the total particle concentration at  $1.5 \text{ l min}^{-1}$ , and the climate conditions were tracked by a humidity/temperature sensor (Fig. 2). During particle generation and sampling, NaCl aerosol particles were continuously dispersed into the chamber, while the exhaust port was in the open position to remove excess air and maintain

neutral pressure. When the NaCl aerosol concentration in the chamber stabilized at the exposure level of  $\sim 2 \times 10^5 \text{ particles cm}^{-3}$ , the subject pre-donned with the respirator entered into the exposure chamber for the SWPF test.

After connecting the SMPS sample line to the respirator, the clamp on the connector tube was removed by the test operator to allow aerosol flow. The SWPF test was then performed using six exercises for 3 min each: (i) normal breathing, (ii) deep breathing, (iii) moving head side to side, (iv) moving head up and down, (v) bending at the waist, and (vi) a simulated laboratory-vessel cleaning motion. The simulated laboratory-vessel cleaning motion involved the subject moving their arms forward-down and backward-up in a shovel-scooping-like fashion, with a distance of about 30 cm at a rate of approximately one completed motion every 5 s to simulate a common workplace activity observed by Dahm *et al.* (2011). Test data was recorded and each individual exercise SWPF was calculated as a ratio of the upstream and downstream particle concentrations as in (1):

$$\text{SWPF}_i = \frac{C_{\text{out}}}{C_{\text{in}}} \quad (1)$$

where SWPF, simulated workplace protection factor for a given exercise;  $i$ , exercise number;  $C_{\text{out}}$ , upstream particle concentration;  $C_{\text{in}}$ , downstream particle concentration

An overall SWPF for each respirator model obtained from the six individual SWPF exercises was derived from (2):

$$\text{Overall SWPF} = \frac{6}{\frac{1}{\text{SWPF}_1} + \frac{1}{\text{SWPF}_2} + \dots + \frac{1}{\text{SWPF}_5} + \frac{1}{\text{SWPF}_6}} \quad (2)$$

After completing testing with each respirator model, the subject removed the respirator and gave it to the test operator. The subject then donned the next respirator model and repeated the fit test and the SWPF test for all eight respirator models. This procedure was conducted three times for each respirator model for each subject on three different days.

## DATA ANALYSIS

The data analysis was performed using an analysis of variance (ANOVA) model provided by the Statistical Analysis System version 9.3 (SAS Institute Inc., Cary, NC, USA). The ANOVA was also used for analyzing statistical computations, including overall SWPF, geometric mean (GM) SWPFs, and all pairwise SWPF comparisons.  $P < 0.05$  were considered significant. The fifth percentile SWPF was computed from the formula  $GM/GSD^{1.645}$ , where GSD equals the geometric standard deviation (Lenhart and Campbell, 1984).

## RESULTS

Based on the particle size range of interest for this respirator performance study against nanoparticles, the size distribution range of 10–400 nm was measured. Within this size range, 96% of particles were centered between 28 and 350 nm with a mode of 82 nm, a count median diameter (CMD) of 60 nm, and GSD of 2.88 (Fig. 3).

All subjects passed the fit test with all FF values  $\geq 100$  with all N95 and P100 EHR models. All subjects also passed the fit test with two P100 FFR models; however, some subjects failed the fit test during the first trial with two N95 FFR models. Therefore, a test operator helped these test subjects with donning the N95 FFRs and reshaping the metal nosepiece to ensure the subjects passed their fit test with N95 FFRs before performing an SWPF test.

**Table 1** is a summary of the respirator performance statistics (i.e. GM-SWPF, GSD, and fifth percentile) for the eight respirator models across the size range of 10–400 nm. The results show the GM-SWPF values for both N95 FFR models were the lowest level of performance with the GM-SWPF range of 94–103 and the SWPF fifth percentile range of 14–30 (Table 1). The two N95 EHR models had GM-SWPF values in the range of 136–257 and SWPF fifth percentiles in the range of 47–88 (Table 1). The GM-SWPF values of the two P100 FFR models provided the better level of performance with a GM-SWPF range of 3200–6586 and a SWPF fifth percentile range of 213–1207 (Table 1). Both P100 EHR models provided the greatest level of performance with a GM-SWPF range of 8157–9923 and a SWPF fifth percentile range of 1388–1759 (Table 1). In general, all class P100 respirators provided significantly higher SWPF values compared to class N95 respirators (all  $P < 0.05$ ) for both FFR and EHR types (Table 1).

The average SWPF values of different respirator models (models A and B) within each class respirator (N95 or P100) across the particle size range of 10–400 nm are shown in Table 1. The results show that the SWPFs were not statistically different between the N95-A FFRs (GM-SWPF = 103) and the N95-B FFRs (GM-SWPF = 94) with  $P = 0.06$ ; however, the SWPFs were statistically different between the P100-A FFRs (GM-SWPF = 6586) and the P100-B FFRs (GM-SWPF = 3200), the

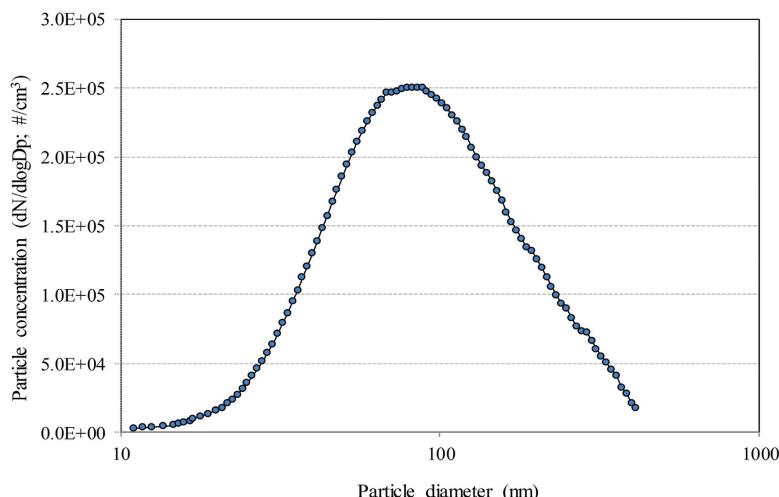

Figure 3 Size distribution of the NaCl aerosols in the exposure chamber measured using the SMPS.

N95-A EHRs ( $GM-SWPF = 136$ ) and the N95-B EHRs ( $GM-SWPF = 257$ ), or the P100-A EHRs ( $GM-SWPF = 8157$ ) and the P100-B EHRs ( $GM-SWPF = 9923$ ) with all  $P < 0.05$  (Table 1).

The respirator performance statistics for the different respirator filter classes (N95 and P100) for both EHR and FFR types as determined by the SWPF testing across the nanoparticle size range (10–100 nm) were determined and compared to the larger size range of 100–400 nm (Table 2). The results show that the GM-SWPFs for nanoparticles were significantly larger than those of larger particles (100–400 nm) (all  $P < 0.05$ ), except N95 EHRs ( $P = 0.06$ ). In general, the GM-SWPFs in both ranges had a similar trend order with the highest for the P100 EHRs, followed by P100 FFRs, N95 EHRs, and N95 FFRs (Table 2). All class P100 respirators in both ranges provided significantly higher SWPF values compared to class N95 respirators (all  $P < 0.05$ ) for both EHR and FFR types (Table 2). The results also show that P100 and N95 EHRs exhibited better performance than P100 and N95 FFRs (all  $P < 0.05$ ), respectively (Table 2).

The average SWPF values as a function of particle diameter for the four combinations of filter classes and respirator types (N95 FFRs, P100 FFRs, N95 EHRs, and P100 EHRs) are shown in Fig. 4. These results show that the average SWPFs were the highest for the P100 EHRs, followed by P100 FFRs, N95 EHRs, and N95 FFRs (Fig. 4). All class P100 respirators provided significantly higher SWPF values compared to class N95 respirators (all  $P < 0.05$ ) for both FFR and EHR types (Fig. 4). For all four combinations of filter classes and respirator types, the average SWPFs decreased with increasing particle diameter.

## DISCUSSION

In general, all eight respirator models provided different values of SWPFs: EHR-P100 model-B > EHR-P100 model-A > FFR-P100 model-A > FFR-P100 model-B > EHR-N95 model-B > EHR N95 model-A > N95 FFR model-B > N95 FFR model-A. A possible explanation for the different values of SWPFs among eight respirator models is that these respirator models had different design features, such as sizes, shapes, and other different characteristics [i.e. a foam face seal (an additional foam piece attached to the surface perimeter of a respirator to create a seal against the wearer's face) versus nonfoam face seal; metal nosepieces versus no metal nosepieces]. The performance levels of all eight models were also compared based on their fifth percentile SWPF values. The results revealed that the fifth percentile SWPFs for all models were different and had a similar trend as the GM SWPF values. All these respirators provided the expected levels of performance (fifth percentile SWPF > 10).

Class P100 respirators provided significantly higher SWPF values compared to class N95 respirators (all  $P < 0.05$ ) for both FFR and EHR types. For the FFR type, the main reasons that the P100 FFRs performed better than N95 FFRs would be: (i) P100 FFRs had a foam face seal against the wearer's face while N95 FFRs did not have a foam face seal and (ii) P100 FFRs contained a 100 efficiency level filter while N95 FFRs contained a 95 efficiency level filter. For the EHR type, although both P100 and N95 EHRs had the half-mask shape, P100 EHRs contained a 100 efficiency level filter while N95 EHRs contained a 95 efficiency level filter. Therefore, respirators with 100 efficiency level filters provided a high

**Table 2. GM-SWPF and fifth percentile values: nanoparticles versus larger particle range**

Respirator type	Class of filter	Size range: 10–100 nm		Size range: 100–400 nm	
		GM_SWPF ( $\pm$ GSD)	Fifth percentile	GM_SWPF ( $\pm$ GSD)	Fifth percentile
FFR	N95	112 $\pm$ 2.5	45	83 $\pm$ 3.0	14
	P100	6595 $\pm$ 4.2	1574	3439 $\pm$ 4.5	292
EHRs	N95	196 $\pm$ 2.7	72	202 $\pm$ 1.9	68
	P100	11 800 $\pm$ 3.1	3777	6780 $\pm$ 2.9	1199

<sup>a</sup>Total number of observations of each respirator series GM-SWPF data point = 150 ( $n = 2$  models in each series  $\times$  3 replicates  $\times$  25 subjects).

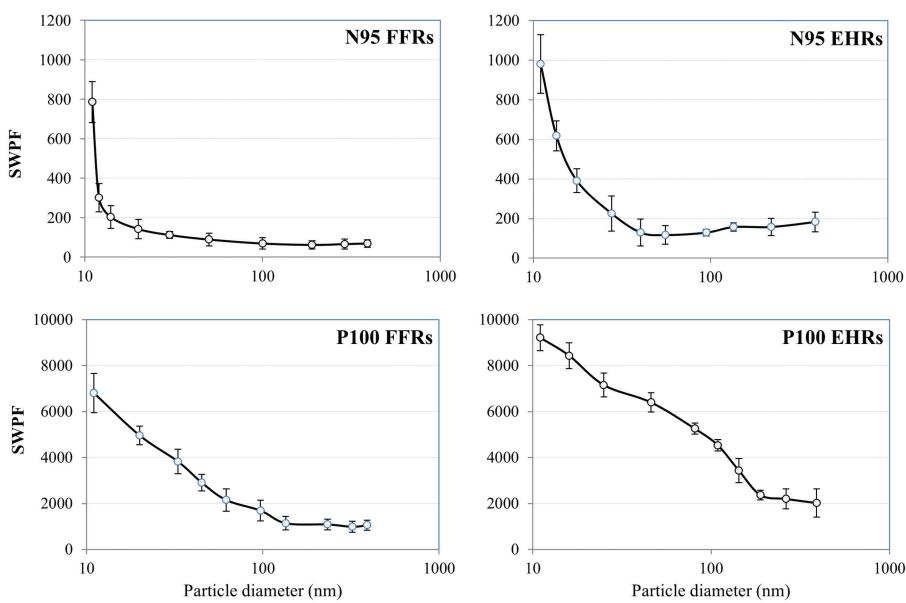

Figure 4 The average SWPF values ( $n = 150$ ; 2 respirator models  $\times$  3 replicates  $\times$  25 subjects) as a function of particle diameter for the four combinations of filter classes and respirator types.

level of efficiency against the 10–400 nm NaCl particles used in the SWPF tests.

For a given filter type (N95 or P100), the results show that EHRs always performed better than FFRs (all  $P < 0.05$ ). Differences in design features, such as sizes (three different sizes for EHRs versus one size for FFRs), shapes (half-mask shape for EHRs versus cup shape for FFRs), and metal nosepieces (no metal nosepiece for EHRs versus metal nosepieces for FFRs) could be the reason EHRs provided a higher performance than the FFRs. It should be noted that all FFRs used in this study had metal nosepieces (Table 1), so the wearer may not have remolded the nosepiece the same way during each donning, causing different SWPF values between tests. For class N95 respirators, the EHRs were equipped with adjustable head straps, whereas the N95 FFRs had only non-adjustable straps (Table 1). Adjustable head straps may allow a better customized seal because they can be tightened to a high degree of accuracy for fitting a wider variety of users and they may allow users to maintain a secure tight and comfortable seal of the respirators. Thus, having adjustable head straps could have contributed to the assessment that the N95 EHRs had a higher performance than the N95 FFRs. For both N95 and P100 classes used in this study,

the FFRs came in one configuration, cup-shaped and one size, while the EHRs came in three different sizes (large, medium, and small sizes) (Table 1). Therefore, EHRs with different sizes provided a better fit against the different face sizes of the human subjects, resulting in greater performance.

When comparing the average SWPF values as a function of particle diameter for the four combinations of filter classes and respirator types (N95 FFRs, P100 FFRs, N95 EHRs, and P100 EHRs), it was found that the average SWPFs decreased with increasing particle diameters for all four combination groups. A possible explanation for it is that NaCl particles are hygroscopic. With the relative humidity (RH) inside the respirator at  $\sim 99\%$ , the particles could have absorbed moisture and either grew or agglomerated, decreasing the particle concentrations of small particles and increasing the particle concentrations of larger particles inside the respirator. It must be noted that some inhaled NaCl particles which were not adsorbed by the body would return to the downstream sample area (inside the respirator) during exhalation; therefore, the inhaled NaCl particles returned from the body during exhalation would also increase the particle concentrations of larger particles inside the respirator. Interestingly, Rengasamy and co-workers reported that the most penetrating particle

size (MPPS) through the class N95 and class P100 respirators was around 30–60 nm when these respirator classes were tested against a monodisperse NaCl (20–400 nm) at 85 l min<sup>-1</sup> (Rengasamy *et al.*, 2009). The MPPS range of 30–60 nm (Rengasamy *et al.*, 2009) does not show in the results of our study. The main reason for the differences is that in our study FSL is the dominant cause of leakage into the class N95 and P100 respirators tested.

This study had several limitations as follows. A limited number of respirator models were tested, where other models that are also used in the workplace may perform better or worse than those selected. Although the SWPF exercise regime used in this study consisted of six exercises, these test exercises were centered around protection achieved in a working situation where respirator wear time was very short and associated with a single repetitive task at a relatively low metabolic rate; therefore, this SWPF exercise regime may not be representative of work activities in actual work environments. Another limitation might be the SWPF test was performed using NaCl aerosols, neutralized aerosols, and the particles were focused in the range of 10–400 nm, which may not be representative of actual workplace particles.

## CONCLUSIONS

This study has shown there is a difference in the level of performance provided by class N95 and class P100 respirators. All class P100 respirators provided significantly higher SWPF values compared to class N95 respirators for both FFR and EHR types. In general, the levels of performance were the highest for the P100 EHRs, followed by P100 FFRs, N95 EHRs, and N95 FFRs. All these respirators provided expected levels of performance (fifth percentile were >10). This trend holds true for nanoparticles (10–100 nm), larger size particles (100–400 nm), and the 'all size' range (10–400 nm). All respirators provided better or similar performance levels for nanoparticles as compared to larger particles in the 100–400 nm size range. Results from this study also revealed that the levels of performance increased with decreasing particle diameters.

The authors thank Dr Mark Hoover (NIOSH/DRDS, Morgantown, WV, USA), Dr Peter A. Jaques (URS Corp., Pittsburgh, PA, USA), Mr Michael Bergman, and Dr Ron Shaffer (NIOSH/NPPTL, Pittsburgh, PA, USA), for their valuable review comments on the manuscript. The authors also want to thank Mr Lee Portnoff (URS Corp., Pittsburgh, PA, USA) for his valuable contributions to the project.
