OFR 28-83. Development of Improved Seatbelt Systems for Surface Mining Equipment, by L. E. Carlson and A. G. Hoffman. Oct. 30, 1981. 127 pp. 4 figs. Tasks required in the development of improved seatbelt systems included a literature and information search, development and test of a prototype seatbelt system, production of field test systems, field tests, and evaluation of the field test results. The systems were a retractable sheath design with both automatic and manual locking features. Results indicate mining equipment operator acceptance of seatbelts were enhanced by the design features of the improved systems. Research done under contract H0202005 by the Mobility System and Equipment Co. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171991; paper copy price code A07.

OFR 29(1)-83. High Angle Conveyor Study. Volume I, by E. A. Mevissen, A. C. Siminerio, and J. A. Dos Santos. December 1981. 294 pp. 93 figs. With the ever-increasing consumption of mineral commodities, the vital question is not whether sufficient mineral quantities will be available, but rather can the known existing low-grade resources be mined economically. Conventional conveyor systems are being used in some open pit mines to decrease haulage costs. This report presents cost analyses that were performed on hypothetical copper, taconite, and phosphate mines. Available high-angle conveying equipment is identified, and the haulage and crushing costs associated with a conventional truck and shovel mining operation and a high-angle conveyor operation are examined. Information was gathered from a series of high-angle conveying equipment and open pit mining operations in the United States. Volume I includes a detailed review of the state of the art in high-angle conveying concepts, the hypothetical mine development, and the cost analyses. Research done under contract J0295002 by the Dravo Corp. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy facilities in Pittsburgh, PA, and Morgantown, WV; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-175042; paper copy price code A13.

OFR 29(2)-83. High Angle Conveyor Study. Volume II, by E. A. Mevissen, A. C. Siminerio, and J. A. Dos Santos. December 1981. 279 pp. 2 figs. This report presents the cost analyses on hypothetical copper, taconite, and phosphate mines. Information was gathered from a series of high-angle conveying equipment and open pit mining operations in the United States. Volume II includes the appendices. Research done under contract J0295002 by the Dravo Corp. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy facilities in Pittsburgh, PA, and Morgantown, WV; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-175059; paper copy price code A13.

OFR 30-83. Phone Line Signal Propagation in Coal Mines, by Terry S. Cory. August 1981. 178 pp. 114 figs. This report describes the results of a measurement program to determine the broad spectral characteristics of both differential and common mode noise on phone lines in three coal mines and signal attenuation spectral characteristics on the same broad basis over phone line strings with taps and/or branches. The frequency range used was a baseband of 1,000 kHz for resolution bandwidth ranging from 100 Hz near baseband to 30 kHz near 1 MHz. The signal attenuation measurements were performed on all three "legs" of taps where possible and applicable. Results were obtained comparing shielded and unshielded phone lines in one mine. The results include an improved electromagnetic noise chart for coal mines showing variations with types of mines, topology, and

location of noise sources. Fundamental high-frequency limit on untreated phone lines in coal mines is identified. Research done under contract J0308095. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171637; paper copy price code A09.

OFR 31(1)-83. Floodplain Disposal of Mill Tailings. Volume I—Text, by K. E. Robinson, B. E. McKee, and M. M. Eivemark. October 1981. 67 pp. 15 figs. Volume I of this two-volume report provides an initial indication that mill tailings produced in the Coeur d'Alene mining district of Idaho can be placed on floodplain areas in a technically acceptable manner without artificial liners and without seriously contaminating the surrounding area. Tests have shown that landfills on these unused areas can result in returning the areas to productive use. Among the environmental considerations in using tailings for landfill construction are acid and other contaminations produced by tailings and wind erosion of exposed tailings surfaces. The results indicate that adverse impacts are not as severe as previously thought and that mitigative measures are feasible. Based on the preliminary data, and in accord with Federal and State waste management regulations, a conceptual design was developed for 23 potential landfill sites in the district that could reclaim 750 acres of floodplain. A cost analysis of landfill construction with mill tailings indicates that the method would be an economically viable means for increasing the valley-wide tailings storage capacity, provided construction with slurried tailings is feasible. Research done under contract J0188146 by Robinson Dames & Moore and Greater Shoshone County Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-170779; paper copy price code A04.

OFR 31(2)-83. Floodplain Disposal of Mill Tailings. Volume II—Appendices A-F, by K. E. Robinson, B. E. McKee, and M. M. Eivemark. October 1981. 242 pp. 152 figs. This study provides an initial indication that mill tailings produced in the Coeur d'Alene mining district of Idaho can be placed on floodplain areas in a technically acceptable manner without artificial liners and without seriously contaminating the surrounding area. Volume II of this two-volume report contains appendices A through F. The report includes (1) the results of a study that evaluates the feasibility of disposing of mill tailings by landfill construction, (2) a description of a field and laboratory testing program that assesses the effectiveness of a soil liner as a means of seepage control, (3) a summary of a thesis on the analysis of acid production potential and the results of geotechnical testing of mill tailings, (4) a description of potential landfill sites and their development to meet the present needs of the mining industry and the future requirements of the community, (5) a description of the legislation impacting on tailings disposal, and (6) a discussion of the environmental and socioeconomic factors that should be considered. Research done under contract J0188146 by Robinson Dames & Moore and Greater Shoshone County Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-170787; paper copy price code A12.

OFR 32(1)-83. Safety Analysis of the Blind Shaft Borer. Volume 1. Summary Report, by C. A. Geffen-Fowler. July 1981. 77 pp. 7 figs. This report presents the results of an examination of the safety of the blind shaft borer (BSB) shaft sinking system and an alternative modified BSB design concept in comparison with conventional shaft sinking technology. Detailed study of the two systems was performed to identify and recommend design changes for optimum safety conditions. A comparison of the BSB system with conventional shaft sinking was made on the basis of relative risk levels, which includes both the frequency and the potential consequence of accidents. A safety evaluation of the component operations of the two BSB systems was performed using a failure modes and effects analysis methodology. The results of this analysis show generally that both BSB systems are safer than conventional shaft sinking. The potential risk of conventional shaft sinking operations could be reduced by over 30% with the use of the original BSB system, and by about 10% with the modified BSB system. Design change recommendations to further improve the safety of these systems include a better fire suppression system, improved worker haulage systems, and more compact hydraulics. An operational safety manual was also developed for the modified BSB system. Research done under contract J0295050 by Battelle, Pacific Northwest Laboratories. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-174284; paper copy price code A05.

OFR 32(2)-83. Safety Analysis of the Blind Shaft Borer. Volume 2. Supplementary Reports A-E, by C. A. Geffen-Fowler. July 1981. 443 pp. 24 figs. This report presents the results of an examination of the safety of the blind shaft borer (BSB) shaft sinking system and an alternative modified BSB design concept in comparison with conventional shaft sinking technology. Detailed study of the two systems was performed to identify and recommend design changes for optimum safety conditions. Volume 2 comprises supplementary reports A

through E. Research done under contract J0295050 by Battelle, Pacific Northwest Laboratories. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–174292; paper copy price code A19.

OFR 32(3)–83. Safety Analysis of the Blind Shaft Borer. Volume 3. Supplementary Reports F-J, by C. A. Geffen-Fowler. July 1981. 434 pp. 10 figs. This report presents the results of an examination of the safety of the blind shaft borer (BSB) shaft sinking system and an alternative modified BSB design concept in comparison with conventional shaft sinking technology. Detailed study of the two systems was performed to identify and recommend design changes for optimum safety conditions. Volume 3 comprises supplementary reports F through J. Research done under contract J0295050 by Battelle, Pacific Northwest Laboratories. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, Co, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-174300; paper copy price code A19.

OFR 32(4)–83. Safety Analysis of the Blind Shaft Borer. Volume 4. Safety Manual, by C. A. Geffen-Fowler. July 1981. 105 pp. 5 figs. This report presents the results of an examination of the safety of the blind shaft borer (BSB) shaft sinking system and an alternative modified BSB design concept in comparison with conventional shaft sinking technology. Detailed study of the two systems was performed to identify and recommend design changes for optimum safety conditions. Volume 4 contains the safety manual. Research done under contract J0295050 by Battelle, Pacific Northwest Laboratories. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-174318; paper copy price code A06.

OFR 33–83. Fluid Cavitation as a Rock Crushing and Rock Fragmentation Tool, by David A. Summers and Marian M. Mazurkiewicz. December 1982. 94 pp. 36 figs. The use of high-pressure fluid cavitation is investigated as a means of breaking an ore into its constituent grains. This cavitational rock disaggregation (CRD) is found to be possible and effective in breaking down galena ore, both in sandstone and dolomite host material. The technique did not work as well in comminuting and cleaning oil shale because the cavitation drove the oil into emulsion with the water. The presence of dominant bedding in the rock also caused preferential breakage to these lines rather than to the individual grain boundaries. This problem was also encountered in tests on igneous ore where weakness planes of the overall ore proved weaker than the boundaries of the individual grains. The prevailing expression of cavitation erosion dependence on pressure was not found to be absolutely valid. In contrast, CRD was found to be much more sensitive to jet flow diameter, and when this was recognized, it was found possible to erode with compressive strength of up to 350 MPa with operating jet pressures of 40 MPa. Research done under grant G1115291 by University of Missouri—Rolla. Available for reference at the Bureau of Mines facilities in Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Spokane, WA, and Office of the Assistant Director—Mining Research, U.S. Bureau of Mines, Washington, DC. Copies of this report will not be available for purchase.

OFR 34–83. Determination of the Washability and Flotation Characteristics of Missouri Coal Seams, by M. Hayri Erten. Sept. 30, 1982. 158 pp. 44 figs. The objectives of this research were (1) to draw the washability curves of Missouri coal seams to determine their washability characteristics, (2) to investigate the possibility of ash and sulfur removal by gravity methods, and (3) to determine the flotation behavior of the seams. During a 2-year period 47 channel and 29 drill-hole samples were received and tested. The samples showed that Missouri coal seams contain high ash and sulfur in the as-received condition. The ash contents of 76 samples tested ranged from 8.30 to 39 percent, whereas the sulfur contents ranged from 0.95 to 14.55 percent. However, the washability tests conducted on —1.00- to —0.25-in channel samples and —0.25-in core samples indicated that 1.40 and 1.50 specific gravity separations, clean coals containing fairly low ash and a total sulfur percentage ranging between 1.02 and 4.69 can be obtained. Research done under grant G1115293 by the University of Missouri—Rolla. Available for reference at Bureau of Mines facilities in Rolla, MO, and Pittsburgh, PA; Office of Assistant Director—Mining, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 35–83. Pilot Study for the Development of Precision Electronic Blasting Delay Detonators Utilizing Self-Contained Integrated Timing Circuits, by Paul Worsey. Nov. 29, 1982. 67 pp. 7 figs. Apart from being inaccurate, electric blasting caps (detonators) are known to be inherently dangerous with respect to potential accidental initiation. This may be caused by different electric and electromagnetic phenomena such as static electricity, overhead powerlines, ground currents, radio waves, stray currents, and electric storms. However, apart from the risk of accidental initiation, commercial detonators are susceptible to misfire from grounding, short circuit, etc., due to the presence of moisture. Because of the latter two problems, certain manufacturers have begun to change production from electrically initiated detonators to encapsulated explosive tube initiated detonators. Although this new form of nonelectrical detonator has none of the quoted potential

risks of accidental initiation or misfire, it contains the same type of chemical delay element that is the major cause of inaccuracy in electric delay series blasting caps. The purpose of this work is to combine the old and new technologies and develop a new integrated electronic delay blasting cap that utilizes an electronic microchip as a delay element. Research done under grant G1114028 by the University of Missouri—Rolla. Available for reference at Bureau of Mines facilities in Avondale, MD, and Pittsburgh, PA; Office of Assistant Director—Mining, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 36–83. Improvement of the Performance of Copper Electrowinning in Fluidized Bed Cells, by J. W. Evans, M. Dubrovsky, and D. Ziegler. Sept. 30, 1982. 11 pp. 7 figs. Research was done on anodes for use with fluidized bed cathodes for electrowinning copper. Suitable anodes must have low power consumption (less than 3 kilowatt hours per kilogram of copper) while operating at high current densities (several thousand amperes per square meter). The anodes must also be free of operating problems and suitable for scale-up. The research resulted in a cell with energy consumption rates less than in conventional cells up to a current density about 10 times greater than in a conventional cell. The anode was tested on both a small, 50-ampere cell and on a larger, 1,000-ampere scale. Auxiliary experiments were carried out on the fluidized bed electrowinning of copper from dilute solutions, from dilute solutions containing cobalt and nickel, and from dilute chloride solutions. Research done under grants G1115061, G1105060, and G1195006 by the University of California at Berkeley. Available for reference at Bureau of Mines facilities in Avondale, MD, Rolla, MO, Reno, NV, and Salt Lake City, UT; at the National Library of Natural Resources, U.S. Department of the Interior, Washington, DC; and Office of the Assistant Director—Mineral and Materials Research, U.S. Bureau of Mines, Washington, DC. Copies of this report will not be available for purchase.

OFR 37–83. Autoclaved Lime-Aluminosilicate Materials for Alumina Extraction and Construction, by Charles A. Sorrell. Sept. 30, 1982. 25 pp. The initial purpose of this project was to investigate reactions between lime and aluminosilicate materials to (1) obtain compounds more susceptible to acid leaching for removal of alumina, titania, or other commercially valuable components, and (2) to develop a cementitious bond strong enough to warrant use of waste materials or inexpensive rock materials for construction materials. It was found that the first objective need not be pursued because it was unnecessary to react many materials prior to acid leaching and that the second objective was not worth pursuing because nothing was found to equal presently available sandlime bricks in terms of strength, durability, or cost. Research done under grant G1115292 by the University of Missouri—Rolla. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, and Salt Lake City, UT; Office of Assistant Director—Minerals and Materials Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 38–83. Characterization of Ohio Limestone To Determine Potential Use in Control of Coal Emissions, by Roger J. Bain. December 1982. 43 pp. 4 figs. Over 200 carbonate rock samples were collected from 33 quarries in Ohio. Quarries were studied and described in detail in order to characterize the nature of the quarry operation, the type of stone being produced, variability in carbonate materials, and the ability to produce a lithologically consistent product. The 200 samples were analyzed by petrographic thin section analysis, scanning electron microscopy, neutron activation, cathode luminescence, X-ray diffraction, sulfur reactivity, chemical analysis, porosimetry, and pore casts. Variations in rock were tested to determine which lithologic features affected reactivity. It was determined that crystallinity, crystal size, porosity, and chemical composition are the major controlling factors. The best sorbent will possess euhedral crystals in the 0.05- to 0.2-mm size range, intercrystalline porosity, and a high calcium content. Dolomites, in general, possess the best texture and several units in Ohio are suitable for use as sorbents. Research done under grants G5105080, G1105080, G1115392, and G5195033 by the University of Akron. Available for reference at the Bureau of Mines Salt Lake City (UT) Research Center; Office of Assistant Director—Minerals and Materials Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 39–83. Nursery Techniques for Production of Tree Seedlings Infected With Specific Mycorrhizal Fungi for Surface Mine Reclamation, by James W. Hendrix. Dec. 30, 1982. 45 pp. 2 figs. A survey of endomycorrhizal fungi occurring on orphan coal mine lands in western and eastern Kentucky revealed a great diversity of species present. Thus, a large number of fungi are available for isolation and evaluation for enhancing revegetation of mined lands. Endomycorrhizal fungi isolated from orphan mines stimulated growth of sweetgum seedlings on mine soil at low fertilization but inhibited growth at high fertilization; this growth inhibition at high fertilizaton did not occur with plants growing on peat-perlite. Banding of endomycorrhizal inoculum was not advantageous, compared with incorporation of inoculum throughout the growth medium, for production of mycorrhizal sweetgum seedlings. Newly reclaimed mine spoils were nearly nonmycorrhizal, compared with land reclaimed 4 or 8 years earlier. A procedure for isolation of single-spore cultures of endomycorrhizal fungi was developed; this is necessary for ecotypic variability. A practical procedure using container-grown *Pisolithus tinctorius*-infected shortleaf pine seedlings for production of large numbers of bareroot pine seedlings infected with *P. tinctorius* for mined land reclamation was demonstrated. Research done under grants G1105004, G1115003, and G1115212 by the University of Kentucky. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Salt Lake City, UT, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 40-83. Wireless Communications for Trackless Haulage Vehicles, by Terry S. Cory. July 1979. 164 pp. 51 figs. This report describes a complete system design methodology for medium frequency

(MF) wireless radio systems for use in coal mines. The emphasis is on ac mines where no trolley wire exists and for which conventional trolley phone communications cannot be used. The report constitutes an MF system design handbook and includes a compendium of all previous MF technology elements as well as a reference index with abstracts of all pertinent literature. Research done under contract J0395072. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171744; paper copy price code A08.

OFR 41-83. Laboratory Evaluation of Janelid Method of Dead Heading Ventilation, by A. Erickson and K. Heller. August 1981. 56 pp. 17 figs. The effectiveness of a loader-mounted fan on diesel vehicles combined with natural convection for ventilation of a dead heading ventilation system was investigated. The results were obtained using CO_2 as a tracer gas in a ¼-scale model heading. Buoyant forces were scaled to establish similarity with full scale. For a loader moving in a typical load-haul-dump cycle, the loader-mounted fan reduced the tracer gas concentration by 26 percent compared with a reduction of 32 percent for a jet fan of four times the flow capacity. Research done under contact J0395016 by Foster-Miller Associates, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy in Pittsburgh, PA, and Morgantown, WV; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171959; paper copy price code A04.

OFR 42-83. In Situ Shear Strength of Rock in Open Pit Benches (Development of Equipment and Field Procedures), by M. K. McCarter and L. R. Partington. August 1982. 173 pp. 54 figs. This project involves the construction and field testing of a large borehole jack designed to operate within a conventional 12 ¼-inch rotary blasthole common to open pit mining. The system is capable of exerting approximately 800,000 pounds on curved platen measuring about 4 by 24 inches. Field tests indicate that the system will operate in a mining environment, and preliminary results suggest the possibility of using the force-displacement data generated by the jack to rank the competency of material within a mine bench. Research done under grant G1195048 by the University of Utah. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171736; paper copy price code A08.

OFR 43-83. Reclamation of Mined Peatlands, by R. S. Farnham. March 1982. 20 pp. 3 figs. Peat is partially decomposed plant material that has accumulated in a saturated environment. Peatlands are located in depressional areas, large sloping lake plains, or any area in which the topography, climate, and hydrology produce an oxygen-deficient environment limited to microbial decomposition. The mining of this material for horticultural peat and energy production has taken place for the past several decades in several European countries and information gathered from past reclamation research on these lands is cited in this report. This project addresses the problems associated with the agricultural reclamation of these mined lands. Peatland drainage, fertility, and field preparation as well as crop selection for these areas is discussed. Laboratory, greenhouse, and field evaluations of representative Minnesota peats are included in the report. Data derived from these investigations suggests that the low natural fertility and short growing season of peatland areas are the major limitations to reclamation. Relatively large amounts of potassium and phosphorus fertilizers and some micronutrient additions are required on peatlands to obtain proper plant growth. It was found that the cole crops (broccoli, cauliflower, cabbage) and short season agronomic crops are suitable on Minnesota peatlands. Research done under contract J0205044 by the University of Minnesota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-172007; paper copy price code A02.

OFR 44-83. Propose and Evaluate Methods of Controlling Mercury Vapor Emissions in a Processing Mill Furnace Room, by Paul T. Bartlett and Terry L. Muldoon. July 1982. 115 pp. 29 figs. The objective of this program was to develop cost-effective methods of controlling mercury vapor in a processing mill furnace room with particular emphasis on the McDermitt mercury mill in Nevada. Process, environmental, and operating data were collected at McDermitt and a preliminary evaluation of control systems was performed. Efforts were focused on the furnace, which is the primary mercury emission source, and furnace positive pressure or "blowback," which is the cause of the greatest furnace emissions. Cost-effective conceptual design alternatives were prepared that addressed the identified emissions problems, particularly furnace blowback. Two designs were selected and detailed design drawings and cost estimates were prepared. The first design agglomerates the filter cake upstream of a belt conveyor, which replaces the existing screw conveyor. The second design dries the filter cake to 5 percent moisture before conveyance on the belt conveyor. Both designs are expected to reduce mercury vapor concentrations by more than 500 $\mu g/m^3$ in the furnace building and approximately 160 $\mu g/m^3$ in the concentrator building during furnace operations. Research done under contract J0318024 by Foster-Miller Associates, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of

the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171751; paper copy price code A06.

OFR 45-83. Evaluating the Impact of Prospective Changes in Materials Use: An Input-Output Approach, by Wassily Leontief, Michael Bever, James C. M. Koo, and Ira Sohn. December 1982. 83 pp. The purpose of this study was to investigate the economic impact of prospective changes in materials use in the U.S. motor vehicle, household furniture and appliances, beverage packaging, and highway and street construction industries under alternative scenarios. The impact of increased imports of automobiles and a changing recycling rate of nickel was also examined. Under assumed economic growth rates and structural changes in the U.S. economy, projections of output and consumption levels of selected industries and level of nonfuel minerals to 2000 were computed. Chapter I of the report addresses the applicability of input-output techniques followed by a detailed description of the structure of the model in Chapter II. Chapter III discusses the economic growth assumptions of the United States to 2000 as well as data and assumptions used in designing each of the eight scenarios included in the study. Results, analyses, and conclusions of each scenario are presented. Research done under contract J0188147 by the Institute of Economic Analysis, New York University. Available for reference at Bureau of Mines facilities in Juneau, AK, Denver, CO, Pittsburgh, PA, and Spokane, WA; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-170845; paper copy price code A05.

OFR 46-83. Improved Fire Protection System for AN-FO Haulers and Loaders, by Bruce Christensen, Steven Hunter, and Lyle McDonald. June 30, 1980. 215 pp. 59 figs. The objectives of this investigation are to (1) conduct a fire hazards analysis of all AN-FO haulers and loaders and (2) to develop and demonstrate an automatic fire sensing and suppression system for this class of surface mining machinery. The research included (1) data acquisition through visits to nine mine sites, two AN-FO hauling contractors, two equipment manufacturers, and a literature search. (2) Analysis of accumulated data providing specific design inputs for an AN-FO hauler representing the greatest overall fire hazard, operating conditions, previous fire experiences and performance, cost, and maintenance factors affecting potential purchases of automatic fire control systems for AN-FO haulers and loaders. (3) Development of a recommended design concept for a low-cost and reliable fire protection system. A specific system design was developed based on the data analysis and system specifications were determined. Factory testing of the fire protection system components included a full-scale fire test of the system on an AN-FO vehicle mock-up. Installation of the prototype system on an AN-FO vehicle at a surface coal mine and a demonstration of performance by fire tests were performed. Research done under contract H0282015 by The Ansul Co. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-170704; paper copy price code A10.

OFR 47(1)-83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in North Dakota. 1. Executive Summary, by Mohan K. Wali.. June 1982. 35 pp. This report, the first in a series of 13, provides a summary of 11 major topics on which individual reports have been prepared. The topics include (1) nature of coal mine spoils, topsoils, and unmined soils; (2) influence of macro- and microclimate on biomass; (3) plant production on spoils and topsoils; (4) prediction of aboveground biomass from plant cover; (5) mineral composition of plants; (6) controlled environment studies on plant growth response; (7) microbial communities; (8) water chemistry and organism diversity of catchbasins; (9) vegetation and soil development on abandoned sites; (10) vegetation and soil development on topsoiled sites; and (11) viability and diversity of seed banks. Based on these investigations, general conclusions and some recommendations are presented. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171322; paper copy price code A03.

OFR 47(2)-83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in North Dakota. 2. Physical and Chemical Properties of Overburden and Topsoils as Affected by Time and Amendments, by Nirander M. Safaya, Richard H. Bares, Nunna Malakondaiah, and Stuart A. Nicholson. June 1982. 180 pp. 88 figs. Field experiments were conducted at six coal mine sites in Oliver and Mercer Counties, ND, to determine the subsequent effects of a single application of selected amendments on spoil and topsoils over the 5-year period, 1974-78. Considerable variations in the physical and chemical properties were found in mine spoils from site to site. The texture of spoils ranged from sandy clay loams to loamy sands. The pH of the sites ranged from 6.5 to 8.2. In many cases, the pH values of mine spoils were not significantly different from the topsoils. The electrical conductivity did not exceed 6 mmhos cm^{-1} at the test sites even though in other studies much higher values were recorded in the vicinity. The spoils can be classed as moderately saline to nonsaline. The sodium adsorption ratios (SAR) ranged from less than 1 to 32, with the lowest SAR values in the topsoiled sites. Some of the spoils were highly calcareous. The spoils that were the least calcareous showed the calcium carbonate equivalent three times higher than that of the topsoil. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171330; paper copy price code A09.

OFR 47(3)–83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in North Dakota. 3. Soil and Vegetation Development of Abandoned Mines, by Mohan K. Wali and Richard H. Pemble. June 1982. 99 pp. Soil and vegetation development were studied on abandoned mine sites in Ward County, ND. The sites studied were 1, 7, 17, 30, and 45 years old since abandonment; unmined sites were also studied to provide measures of comparison. Species diversity was the highest at unmined sites and lowest at the 1-year-old site; sites 7, 17, 30, and 45 years old had 37, 52, 43, and 68 species, respectively. Stand ordination revealed that site ages were the most important in influencing species diversity and composition. Stand-environmental complex ordinations encompassing 53 variables showed topographic variables to be the most important followed by site ages. Species distributional diagrams are provided to show habitat preferences that may be helpful in formulating species prescriptions for revegetation. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–171348; paper copy price code A05.

OFR 47(4)–83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in North Dakota. 4. Soil and Vegetation Development on Topsoiled Areas, by Louis R. Iverson and Mohan K. Wali. June 1982. 68 pp. 12 figs. Four North Dakota reclaimed mined sites 1 to 4 years old were studied for patterns of species colonization, biochemical interaction among species, competitive phenomena, and management applications. *Kochia scoparia*, a colonizer, was the dominant species for the first 2 years, but was completely eliminated by the fourth year; the planted *Agropyron* grasses concomitantly increased during the 4-year period. Chemical analysis of the soils over the same period showed decreases in several soluble elements due to leaching and a slight buildup of nitrogen and organic matter. Competition experiments between *Kochia* and *Agropyron* revealed that *Kochia* initially acted as a "nurse" crop for *Agropyron* establishment, but later in the first season began to shade excessively, reducing *Agropyron* tillering. Studies on the plant population biology of *Kochia* showed that it conformed well to several established laws governing yield versus density relationships. Field and growth chamber experiments revealed that decaying *Kochia* leaves and roots were toxic to *Kochia* growth and were partially responsible for the rapid demise of the species. Chemical analysis of the soils and plant tissues indicated nutritional imbalances may be responsible for the autotoxicity. Another bioassay experiment implicated allelochemics to be important in several other colonizing species. Mowing the first year colonizing species just prior to seed set proved to be effective in reducing weed populations and improving planted *Agropyron* populations in the second year. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–171355; paper copy price code A04.

OFR 47(5)–83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in North Dakota. 5. Plant Production on Spoils and Topsoils as Affected by Time and Amendments, by Richard H. Bares. June 1982. 67 pp. 14 figs. Field study sites were established on recontoured mined areas during the early 1970's in which several amendments were tested for their ability to improve spoil-topsoil conditions and, hence, increase plant production. A number of grass and legume species combinations were studied. The general effects of one-time, single-rate application of leonardite and/or slack coal to spoils and topsoils was the reduction of grass dry matter yields and the promotion of legume establishment and yield. Production of weedy species was remarkably lower on topsoil treated with leonardite than that without leonardite. The general effect of commercial fertilizer applied one time prior to seeding was to increase plant production during the first 2 to 3 years after which the effect disappeared; the effect was much more pronounced on spoils. Weedy species accounted for most of the biomass production during the first growing season. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–171363; paper copy price code A04.

OFR 47(6)–83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in North Dakota. 6. Relationship Between Cover and Aboveground Biomass, by Diana K. Schimmelpfennig. June 1982. 52 pp. 5 figs. A study was done to evaluate the predictability of aboveground biomass production on revegetated mined sites and adjacent native prairies using plant cover estimates made with the point frame method. The predictability of biomass production by cover estimates bears on the need for measurements of both plant cover and aboveground biomass in assessing revegetation success. A positive, statistically significant correlation was demonstrated between plant cover (estimated by the point frame method) and aboveground biomass (estimated by the harvest method) regardless of community type (mined or native), species composition, diversity, or level of biomass production. However, the latter did have their effects on the relationship and must be accounted for in any predictive equations; that is, the predictive equations must be considered site specific. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–171371; paper copy price code A04.

OFR 47(7)–83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in

North Dakota. 7. Mineral Analysis of Plants Grown on Spoils and Topsoils, by Nunna Malakondaiah. June 1982. 46 pp. Plant samples collected from mined and test sites in surface coal mined areas of North Dakota were analyzed for nutrient concentrations. The vegetation from the mined areas generally showed lower concentrations of Na, P, and Cu and failed to meet the nutritional requirements for beef cattle as defined by the National Research Council. Some plants showed generally higher concentrations than others, and lower concentrations of P were reported in most of the plants on some unmined sites. Amending the spoil with slack at one test site decreased the concentrations of Zn, Cu, and P in wheatgrasses grown on spoil from 0- to 2-, 5- to 10-, and 20- to 25-foot depths, respectively. Leonardite amendment at one test site decreased P concentration in grasses compared with control, whereas fertilizer increased the same. The concentrations of Ca, Mg, Na, Fe, Cu, and N in grasses were significantly higher on topsoil than at slack-amended spoil at one test site. The data presented in this report act only as an indication of between-treatment and between-species differences in tissue composition of plants harvested in midsummer season. Since none of the nutrients analyzed were found toxic, the cattle can safely feed on the mined land vegetation. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171389; paper copy price code A03.

OFR 47(8)-83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in North Dakota. 8. Soil Algae, by Thomas L. Starks and L. Elliot Shubert. June 1982. 75 pp. 11 figs. Surface soil and topsoil samples from experimental test sites in western North Dakota were aseptically collected during August 1975 and from May through September during 1976-77. Selected samples were cultured in a defined inorganic medium and after 6 weeks the algae were identified. Chlorophyll *a* content of the soil and spoil was used as a measure of the algal abundance. Soil physical-chemical properties, species variety, and abundance were statistically analyzed. All test sites revealed distinct soil algal communities and demonstrated a successional trend as evidenced by significant increases in species variety and biomass over time. Some soil factors (Ca, Cu, and P) affected species variety and abundance at more than one site. Others were important at specific sites (Si and Al at one site; Mn, Na, and Zn at another site; and B, Cd, and Mg at another site). Topsoiled areas had higher species varieties and abundances when compared with control areas, as did plots treated with amendments such as leonardite and fertilizer. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171397; paper copy price code A04.

OFR 47(9)-83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in North Dakota. 9. Viability and Diversity of the Seed Bank, by Louis R. Iverson and Laura Brophy. June 1982. 43 pp. 7 figs. Analysis of seed numbers present in topsoils indicated that seeds of the most prevalent colonizers were not present in the topsoil in a grazed area, an ungrazed area, and two stockpiles upon respreading but rather reappeared by immigration from the surrounding areas. The grazed site had a seed density of over 7,700 seeds per m^2 and the ungrazed site had 3,900 seeds per m^2; the stockpiled topsoils had very low seed densities (225 and 520 seeds per m^2). Seed densities and diversity decreased with depth on both the grazed and ungrazed sites; this was especially true on the grazed site where 94% of the seeds were found in the surface 7.5 cm. Several species were present in the seed bank that were also found on the 3- and 4-year-old mined sites in the aboveground vegetation survey. Seeds from these species may germinate after several years of dormancy, thereby starting populations on mined sites and enhancing plant diversity. Seed bank analysis was also undertaken on mined sites ranging from 2 to 6 years old and on an unmined site. Mined site seed densities ranged from 1,630 to 3,980 seeds per m^2; the 4-year-old site had the greatest density and the unmined site and stockpiled topsoil sample had lower seed densities. A significant positive correlation between total viable seed content and soil-water saturation percentage indicated that soil texture may influence seed viability-dormancy; there was poor correlation between the aboveground flora and the belowground seed composition. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171405; paper copy price code A03.

OFR 47(10)-83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in North Dakota. 10. Elements of Macro- and Microclimate, by Richard H. Bares. June 1982. 61 pp. 13 figs. The general or macroclimate of the study site in western North Dakota is characterized by rapid and sometimes extreme daily and day-to-day temperature fluctuations, rainfall patterns that are erratic in spatial and temporal distribution and intensity, generally low relative humidity, plentiful sunshine, nearly continuous air movement, and a relatively short frost-free period. Of particular relevance to plant growth and productivity is the mosaic of microclimates that are affected by landform; exposure; slope angle, length, and aspect; and soil color, texture, and surface and vegetation cover. The most critical plant growth-governing factor is available water. It is determined principally by water input (precipitation) and water loss (evapotranspiration), which is increased by high temperatures, wind, and poor surface and vegetation cover. While spring and fall precipitation is generally gentle and soil-soaking, summer rains frequently come in the form of intensive, soil-washing, localized convective thunderstorms of short duration. Due to the convective nature of these storms, summer rainfall is particularly affected by regional topography; southwest slopes and crests often receive more rainfall since the storms usually

move in a northeasterly direction. The water loss due to runoff and consequent soil erosion are major problems resulting from such "cloudbursts." Previous fall precipitation in September and October, when added to the current seasonal precipitation from March through August, was found to be significantly correlated with plant production. Generally clear skies over the region facilitate receipt of abundant sunshine at the earth's surface. While good for early season soil warming and plant photosynthesis, this abundant sunshine coupled with long days and nearly continuous wind is responsible for evapotranspiration exceeding precipitation by an average of 6 inches between June and September. On a local scale, the water deficit is most severe on the southern exposures, which receive the most direct solar radiation and therefore are warmer than other exposures. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171413; paper copy price code A04.

OFR 47(11)-83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in North Dakota. 11. Effect of Amendments on Soil-Plant-Nutrient Relations Under Controlled Conditions, by Nunna Malakondaiah and Nirander M. Safaya. June 1982. 64 pp. 2 figs. Several growth chamber and laboratory experiments were conducted to study the germination behavior of plant species on mine spoils and plant growth responses to nutrients on spoils and topsoils. Experiments were conducted to study the germination potential of some native and introduced species under various conditions. The seeds of green needlegrass, side oats grama, thickspike wheatgrass, crested wheatgrass, birdsfoot trefoil, and emerald crownvetch were less tolerant, whereas those of alkali sacaton, durar hard fescue, slender wheatgrass, yellow sweetclover, and alfalfa were most tolerant to the sodic mine spoil conditions. Addition of leonardite improved the germination potential of some of the poor germinators. Slender wheatgrass and yellow sweetclover were used as test plants to study the fertility status and productivity potential of stockpiled topsoils and spoils collected. The topsoils were neither saline nor sodic but low in N and P; the spoils were neutral to alkaline. Application of N and P together to the topsoils increased the yield of wheatgrass and sweetclover by 88% to 70% of their respective maximum yields, whereas near maximum yields were obtained for both species by the same treatments to the spoils. The average yields on topsoils were higher than the yields on spoils. The concentrations of major nutrients were higher in plants grown on topsoil, whereas the opposite was true with concentrations of Mn, Zn, and Cu. Growth chamber experiments were conducted to study the growth responses of alfalfa, oats, and slender wheatgrass by the application of Mn and Zn to a sodic coal mine spoil tht was previously used for pot culture experiments. Significant growth responses to Mn and Zn were observed in alfalfa but not in oats or slender wheatgrass. Fertilizing the spoil with Mn along with NPK increased the yield of alfalfa to 85% and with Mn plus Zn to 99%. Growth responses and plant composition results of this study confirm that the application of major nutrients to spoils can accentuate Zn and Mn deficiencies in some plants. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171421; paper copy price code A04.

OFR 47(12)-83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in North Dakota. 12. Screening Plants for Phosphorus Requirements, by Nirander M. Safaya and Nunna Malakondaiah. June 1982. 49 pp. 2 figs. Several plant species were screened using continuous-flow and spoil culture methods for their P uptake efficiency. In flow cultures, P was maintained at 0.25, 2.5, and 25 μmoles; while in spoil cultures P was added at 0, 25, and 75 μg/g spoil to a P-deficient spoil. Alfalfa, birdsfoot trefoil, and emerald crownvetch showed P deficiency symptoms, while burning bush and Russian thistle showed no such deficiency symptoms; their dry matter yields in the 0.25-μm P treatment was 24% and 36%, respectively, of their maximum yields obtained with 25 μM P. The root dry weight ratio in the legumes increased from an average 0.22 to 0.43 with the increase in solution P, while in the weeds the increase was 0.14 to 0.30. The low susceptibility of Russian thistle to P deficiency was also demonstrated in the spoil culture experiment. Higher P concentrations were observed in weeds than in legumes or grasses. In general, increases in P supply increased P concentrations and decreased Zn concentrations. The influence of P fertilization on the tissue concentrations of Mn and Zn was similar in both flow culture and spoil culture methods. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171439; paper copy price code A03.

OFR 47(13)-83. Ecological Studies on the Revegetation Process of Surface Coal Mined Areas in North Dakota. 13. Statistical Analysis, by Richard H. Bares. June 1982. 18 pp. This paper describes the purpose and application of 17 statistical and mathematical procedures used in this 13-volume report. The objective of the report is to help readers to better understand the purpose and utility of statistical techniques applied to data from the various subprojects reported in this series. Research done under contract J0295015 by the University of North Dakota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-171447; paper copy price code A02.

OFR 48-83. System To Prevent Clogging of Gas Sampling Tubes, by Kyle W. Charlton and Lloyd

D. Bowman. Dec. 18, 1981. 91 pp. 39 figs. The Bureau of Mines utilizes special testing methods for the analysis of underground mine atmospheres for use during or after mine disasters and fires. These methods depend upon drawing sample gas to the surface through multiple tube bundles with the subsequent analysis of grab samples or the automatic analysis by often remotely located instruments on a continuous, 24-hour basis. During cold weather, low ambient temperature causes condensation and freezing of condensable vapors in the sample, which can result in delayed response times or complete blockage of the sample line. This report covers research and resulting development conducted by the Bureau to produce a reliable method to selectively remove condensable vapors and particulate in the sample gas stream under worst-case field conditions. The effort resulted in two prototype systems that have greater field utility than originally anticipated. Research done under contract H0308042 by Charlton Technology Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy facilities in Pittsburgh, PA, and Morgantown, WV; Mine Safety and Health Administration facilities in Aliquippa and Pittsburgh, PA, and Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-178806; paper copy price code A05.

OFR 49–83. State-of-the-Art Environmental Assessment of Onshore Disposal of Manganese Nodule Rejects, by F. A. Kennedy, E. O. Porter, J. L. Deis, F. C. Brown, and R. E. Versaw. July 30, 1982. 238 pp. 43 figs. As part of a cooperative research program with the National Oceanic Atmospheric Administration, the Environmental Protection Agency, and the U.S. Fish and Wildlife Service, the Bureau of Mines contracted for an environmental assessment on onshore waste disposal that is expected to occur with the development of commercial deep seabed mining. The assessment was conducted in order that testing and refinement of nodule waste disposal techniques can be completed prior to 1988, when commercial seabed mining can begin under U.S. legislation. Three classes of process and four classes of waste disposal techniques were identified, and five sites were selected as representative of first-generation nodule operations. Each site-process-disposal technique combination was compared against potential effects to determine important characteristics of the rejects and the sites. Regulatory requirements were also considered at each site to identify important issues and their effect on the permitting process. The principal conclusions are (1) uncertainties in the regulatory regimes for hydrometallurgical process tailings, primarily regarding classification as hazardous wastes; (2) slags from nodule processing that are expected to be inert and relatively easy to dispose of at all sites; and (3) additional physical and chemical information on properties of rejects from all processes that will be necessary to predict environmental effects. Research done under contract J0100085 by Rogers, Golder & Halpern, EIC Laboratories, and Golder Associates. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-175380; paper copy price code A12.

OFR 50–83. Demonstration of Noise Control Techniques for the Crushing and Screening of Nonmetallic Minerals, by Robert J. Pokora and Terry L. Muldoon. December 1981. 187 pp. 64 figs. The objectives of this program were to identify the prevalent sources of crushing and screening noise in portable and stationary plants, design retrofit noise control treatments for those sources, and field test control treatments under actual operating conditions. A survey was made to assess the variety of noise sources, to determine the worker exposure to those sources, and to identify possible constraints that should be considered in designing and installing retrofit controls. Retrofit noise control treatments designed included a primary crusher operator control booth; screen decks made of resilient cloth; screen feedbox impact pads; and rubber feed plates and chute lines, and noise attenuating curtains for a secondary crusher. A new primary crusher control booth was installed at one plant and the noise levels were reduced from 97 dBA to 78 dBA. Screen noise at two secondary crushing plants was reduced by 3 dBA, and crusher noise at one of these plants was reduced by 5 dBA. Noise levels at normal outside operator and cleanup locations were not significantly reduced in the second plant because of rapid wear of installed materials, but at the other plant the retrofit noise control materials displayed excellent wear characteristics. Research done under contract J0100038 by Foster-Miller, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-173039; paper copy price code A09.

OFR 51–83. Telephone Communication System for a Deep-Vein Metal Mine, by Terry S. Cory. March 1982. 108 pp. 17 figs. This report describes the results of a program to design, procure, install, and evaluate a multichannel underground telephone system of modern design in the Sunshine Silver Mine near Wallace, ID. The report contains a cost benefit analysis for such a system using estimates of operational data for the Sunshine Mine. The results show a centrally switched telephone system of conventional design with ruggedized phone enclosures and special environmentally sealed dial pads to be the most economical. Research done under contract J0100093. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-173021; paper copy price code A06.

OFR 52–83. Microseismic Applications for Mining—A Practical Guide, by Wilson Blake. July 12, 1982. 208 pp. 82 figs. Microseismic activity and properties of microseismic events are treated so that these parameters can be taken into account when develop-

ing monitoring equipment. Microseismic equipment is discussed to provide familiarization with the components of monitoring systems. Factors to be considered and procedures for developing a microseismic monitoring system are presented. Both physical and electrical considerations for the installation of a monitoring system are discussed in detail. The operation of a microseismic system including data analysis procedures is presented. Field examples to illustrate use of microseismic data in evaluating ground control problems in a number of case histories are also included. Research done under contract J0215002. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy facilities in Denver, CO, and Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director —Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-180877; paper copy price code A10.

OFR 53–83. Investigation of Extinguishing Agents for Coal Dust Explosion, by Marcel Vanpee and Reginald W. Tyler. November 1982. 83 pp. 35 figs. Eight extinguishing powders were tested in five types of diffusion flames. The effect of flame temperature on the inhibition efficiency was investigated by varying the oxygen index of the flame-supporting atmosphere. In addition, a spectrographic investigation of powder-flame dissociation products was carried out on the methane-air-ABC ($NH_4H_2PO_4$) flame. Dissociation products for this flame included PO, PH, NH, and Na. It was concluded that the main factor to be considered in the efficiency of the powder is the flame temperature. Purple K ($KHCO_3$) was typically inefficient in low-temperature flames and very efficient in high-temperature flames. On the other hand, ABC ($NH_4H_2PO_4$) was found to lose its efficiency at high temperatures but to be quite efficient in the low-temperature flames. The effect of temperature is offered as an explanation of the poor efficiency of $KHCO_3$ against coal dust explosions in contrast to the high efficiency of the phosphate salts against coal dust explosions. Research done under contract J0395097 by the University of Massachusetts. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-180885; paper copy price code A05.

OFR 54(1)–83. Constitutive Relations of Coal and Coal Measure Rocks. Volume I. Interrelationship of Mechanical, Index and Geologic Properties of Coal Measure Rocks, by T. G. Barbour, R. H. Atkinson, and Hon-Yim Ko. March 1980. 111 pp. 9 figs. Cores of coal measure rocks from five mines across the United States were tested for mechanical, index, and mineralogic properties. About 600 samples were tested to determine 15 mechanical property parameters, 7 index parameters, and 30 geologic parameters. The results were analyzed for their statistical distributions, and bivariate and multivariate, linear and nonlinear correlations were attempted for these groups. Significant correlations were found for some of the parameters. On the basis of these statistics, predictive models are postulated for the mechanical properties on the basis of index and geologic parameters. Research done under grant G0155056 by the University of Colorado. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-178244; paper copy price code A06.

OFR 54(2)–83. Constitutive Relations of Coal and Coal Measure Rocks. Volume II. A Study of the Orthotropy of Coal and Other Rock Materials, by D. J. Hawk and Hon-Yim Ko. March 1980. 129 pp. 13 figs. The mechanical properties of coal are often represented by the orthotropic material model, which consists of nine elastic constants. The material symmetries involved are found in coal primarily because of the natural process by which the coal was formed. In this report, the material properties of five U.S. coals, as obtained from cubical testing, are examined using the assumption of the orthotropic material model as a basis for comparison. An analysis is performed on each set of coal material data in order to examine its conformability to other, less complex material models—the transversely isotropic model consisting of five elastic constants and the isotropic model consisting of two elastic constants. In addition, the material properties of the two U.S. shales are analyzed, based on the assumption that they comply with the transversely isotropic model. An analysis similar to that performed on the coal material is applied to the shale to determine the conformity of its material properties to the isotropic model. Research done under grant G0155056 by the University of Colorado. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-178251; paper copy price code A07.

OFR 54(3)–83. Constitutive Relations of Coal and Coal Measure Rocks. Volume III. Drying Shrinkage and Creep Behavior of Coal, by R. J. Tocher and Hon-Yim Ko. March 1980. 114 pp. 35 figs. Uniaxial testing was performed on coal specimens to determine the time-dependent response. The testing was carried out on coal from six mine sites throughout the Western United States and Pennsylvania. Testing configurations were varied to allow analysis of moisture dependency, stress level, and specimen orientation. Several theories were presented for the behavior of coal due to moisture diffusion. Experimental results showed the correlation between the theories and the actual material response. Coal

deformation was found to be highly dependent on the moisture level of the testing environment. Moisture migration causes drying and shrinkage which lead to progressive degradation of the material. The coal tested experienced a rebound if saturated after a period of drying. This type of time-dependent behavior overshadows a noticeable creep behavior. Analysis of one series of creep test results was performed. A relationship was developed on the basis of a simplified rheological model to describe the coal response to uniaxial stress. Previous empirical formulations in the form of power laws were compared and their deficiencies pointed out. Research done under grant G0155056 by the University of Colorado. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-178269; paper copy price code A06.

OFR 55–83. Automated Blast Hole Logging and Design, by D. E. Scheck, L. H. Mitchell, and G. W. Mack. December 1982. 126 pp. 29 figs. A blast hole drill was instrumented and equipped with a digital recorder to monitor quantitative drilling parameters such as down pressure and rotational speed of the bit. This information was captured on nonvolatile memory and transmitted to a mainframe computer for analysis. The variation in the energy required to turn the bit was found to be correlated with the geological structure of the overburden. This information was used to design explosive loads with hole size, pattern, and powder factor held constant. The decked shots designed from the drilling parameters produced better fragmentation than the mine's standard undecked design. The monitor system on board the blast hole drill was modified to perform the data analysis, identify the hard to fragment zones, and print the recommended blast designs. The final task was to design and build a hardened version of the system. This equipment is now used routinely and is available for further research and testing. Research done under grants G1105006 and G1115006 by Ohio University. Available for reference at the Office of the Assistant Director—Mining Research, Bureau of Mines, Washington, DC; Bureau of Mines, Pittsburgh, PA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 56–83. An Investigation of the Effects of Explosive Primer Location on Rock Fragmentation and Ground Vibrations, by Norman S. Smith. 1982. 10 pp. 5 figs. The degree of fragmentation and the magnitude of ground vibration from rock blasting are affected by numerous factors. Previous investigations have studied many of these factors; however, the influence of the blasthole primer location in a bench blast on the resulting degree of fragmentation or peak particle velocity of ground vibrations has not been investigated. This investigation used a series of three-hole, reduced-scale bench blasts in a dolomite rock mass to examine and compare effects of collar and bottom priming, the two most commonly used primer locations, on fragmentation and near-field ground vibrations. It was found that collar priming produced trends of a lower degree of fragmentation and of greater peak particle velocities than did bottom priming. There was no significant variance in toe formation or overbreak due to primer location. Research done under grant G1114028 by the University of Missouri—Rolla. Available for reference at the Office of the Assistant Director—Mining Research, Bureau of Mines, Washington, DC; Bureau of Mines facilities in Avondale, MD, and Pittsburgh, PA; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 57–83. Evaluation of Effectiveness of Fly Ash in Fixing Metals Within and Controlling Leachate Contamination From Tailings Ponds, by John L. Sonderegger and Joseph J. Donovan. December 1982. 42 pp. 15 figs. Western, calcium-rich fly ash was used as a tailings amendment in laboratory studies with pyrite, galena, and tailings from a complex sulfide deposit. The base buffering capacity of the fly ash reduced dissolved heavy metal content up to three orders of magnitude. When used in this manner, with a 10 wt-pct fly ash amendment per unit weight of pyrite in the tailings, at least a three order of magnitude reduction in quantity of heavy metals leached through the tailings and into local ground and surface water systems can be expected. Research done under grants G1105005 and G1115005 by the Montana College of Mineral Science and Technology. Available for reference at the Office of the Assistant Director—Mining Research and the Office of Minerals and Materials Research, Bureau of Mines, Washington, DC; Bureau of Mines facilities in Avondale, MD, and Salt Lake City, UT; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 58(1)–83. Development of Selective Submicrometer Particulate Fire Detectors for Underground Metal Mines. Volume I, by G. F. Skala and F. W. VanLuik, Jr. December 1979. 129 pp. 43 figs. The development of two prototype instruments for the discrete detection of submicrometer particles in metal and nonmetal mines is described. The detectors are designed to utilize properties of submicrometer particles to distinguish between those produced by fires from mine ambient particles primarily resulting from diesel engine exhaust. One detector is based on the electrical tagging of the diesel exhaust particles with subsequent detection of uncharged fire particles utilizing an ion chamber as the primary sensor preceded by an electrostatic precipitator. The other detector is based on the ability to pyrolyze fire-produced particles, but not diesel exhaust-produced particles, into a high concentration of smaller particles. This concentration was compared with the concentration of unpyrolyzed fire particles and caused an alarm on a preset value. The primary sensors used were two matched cloud chamber devices. Each detector demonstrated good ability to discriminate between fire and ambient diesel-produced particles. The report contains a literature survey, experimental charging and pyrolysis data, detector design descriptions, and test results. Research done under contract H0387025 by Environment/One Corp. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spo-

kane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-178947; paper copy price code A07.

OFR 58(2)-83. Development of Selective Submicrometer Particulate Fire Detectors for Underground Metal Mines—In-Mine Evaluation. Volume II, by G. F. Skala. January 1982. 36 pp. 10 figs. Testing of two prototype instruments for the discrete detection of submicrometer particles in metal and nonmetal underground mines is described. The detectors are designed to utilize properties of submicrometer particles to distinguish between those produced by fires from mine ambient particles primarily resulting from diesel engine exhaust. One detector is based on the ability to pyrolyze fire-produced particles, but not diesel exhaust particles. An alarm is produced when the ratio of pyrolyzed to unpyrolyzed particles exceeds a present value. The other detector utilizes a continuous-flow ion chamber preceded by a denuder to remove charged particles. Discrimination against diesel-produced submicrometer particles results because the diesel particles are naturally more highly charged than fire-produced particles. In-mine testing was conducted over a period of several months. Both detectors exhibited an ability to discriminate against diesel exhaust. However, problems with the recording equipment, and with the detectors themselves due to large ambient dust particles, prevented enough data from being obtained to choose between the two methods. Research done under contract H0387025 by Environment/One Corp. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-178954; paper copy price code A03.

OFR 59-83. Reconnaissance of Tin and Tungsten in Heavy Mineral Panned Concentrates Along the Trans-Alaska Pipeline Corridor, North of Livengood, Interior Alaska, by James C. Barker. 1983. 24 pp. 3 figs. In 1978 through 1980, the Bureau of Mines collected a series of 514 panned concentrates from selected granitic regions along a section of the Trans-Alaska pipeline corridor, bounded on the south by Livengood and on the north by the Koyukuk River. The methods of sample collection and analytical procedures are described. Sample analyses for tin, as well as for tungsten and eight other common pathfinder elements, are presented. The data indicate both tin and tungsten anomalies in the vicinity of the northern Ray Mountains to the Sithylemenkat Lake area, near the Fort Hamlin Hills, and west of Caribou Mountain. Only tungsten anomalies occur on upper Bonanza Creek. Research done by the Alaska Field Operations Center. Available for reference at Bureau of Mines facilities in Anchorage, Fairbanks, and Juneau, AK; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 60-83. Improved Ground Control Safety in the Stone, Sand and Gravel Industries, by Tuncel M. Yegulalp and S. H. Boshkov. June 10, 1981. 299 pp. 8 figs. The objective of this study was to categorize mining operations in the stone and sand and gravel industries into areas of similar ground control functions and define initial factors affecting operational safety in each area by utilizing publicly available data, telephone interviews, and onsite observations. The findings and recommendations presented in this report are based on information collected during the two phases of the project. The report also contains, in part, the collective qualitative opinion of the operators with respect to Government rules and regulations on ground control safety and the implementation of these rules and regulations by Government inspectors. Research done under contract J0100027 by H. H. Aerospace Design Co., Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-183111; paper copy price code A13.

OFR 61-83. Design, Construction & Development of In Situ Mining Wells, by David L. Shuck and James N. Brooke. November 1982. 135 pp. 35 figs. This report describes the current methods of design, construction, and development of wells for in situ leaching of uranium. The discussion includes the alternatives for well design drilling equipment and fluids, grout formulation and emplacement, well integrity testing and repair, and well development and stimulation. Current practice in these areas was determined through interviews and discussions with eight operators of commercial-scale in situ facilities. Based on this information and previous experience, recommendations are made regarding well design, construction, and development for in situ leaching. Research done under contract J0218018 by High Life Helicopters, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-183418; paper copy price code A07.

OFR 62-83. Utilization of Nickel Refining By-Products on Agricultural Lands, by V. V. Volk, E. H. Gardner, P. J. Sheets, and R. J. Gulack. Mar. 1, 1982. 89 pp. 6 figs. Laboratory, greenhouse, and field experiments were conducted to determine the effects of a tailings material and a magnesium ammonium phosphate (MgAP), produced from a Ni refining operation, on plant growth and soil properties. The tailings contain high levels of soluble salts (9.7 mmhos/cm), NH_4-N (0.1%), total Ni (2,470 μg/g), Cr (3,825 μg/g), and Co (313 μg/g), and low levels of Ca (1.3 meq/100 g) and extractable P (1.0 μg/g). Tall fescue (*Festuca arundinaceae S.*) was grown on soils amended with tailings and plant yield and elemental composition was determined. The MgAP was compared with $MgNH_4PO_4$ (MgKAP) and traditional fertilizer as sources of N and P for tall fescue and white clover. Tall fescue established slowly on soils amended with the

highest rate of tailings while other plants grew well. Concentrations of Mn, Ni, Cr, and Co in tall fescue grown on the treated soils were within normal ranges. The tailings should be leached further to reduce the $(NH_4)_2SO_4$ content to allow better stand establishment at high tailing application rates. All fertilizer materials provided similar levels of N and P, as evidenced by plant yield and elemental content. Research done under contract J0295058 by the Oregon Agricultural Experiment Station. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mining Safety and Health Administration, Arlington, VA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–183129; paper copy price code A05.

OFR 63–83. Mesabi Range Water and Iron Ore Industry, by Anching Line. October 1981. 269 pp. 17 figs. The purpose of this study was to provide an evaluation of the current state-of-the-art information concerning the availability, need, use, and degradation of the water systems associated with Mesabi Range iron ore mining. The study was carried out in three phases: (1) characterization of the Minnesota iron ore industry and associated water systems on a regional basis, (2) detailed individual case analysis of present and future iron ore developments and the associated watershed systems, and (3) impacts of potential copper-nickel development on the watershed requirements of the iron ore industry. The conclusions are presented in a summary preceding the three phases of the report. Research done under contract J0208023 by the Uintex Corp. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 64–83. Alumina Miniplant Operations—Removal of Iron From Aluminum Nitrate Pregnant Liquor by Solvent Extraction, by Roy T. Sorensen. 1982. 19 pp. 5 figs. The Bureau of Mines investigated the recovery of aluminum by nitric acid leaching of calcined kaolinitic clay. Most iron impurities were leached from the calcined kaolin during the extraction of aluminum and must be removed before or during the crystallization of aluminum nitrate nonahydrate in order that the subsequent thermal decomposition step will yield an alumina product of acceptable iron analysis. Solvent extraction miniplant studies using di(2-ethylhexyl) phosphoric acid in kerosine diluent have demonstrated that iron content in aluminum nitrate pregnant liquors can be decreased to levels of less than 0.0007 pct (7 ppm), expressed as Fe_2O_3. A number of the miniplant tests were interrupted or terminated because of an increase in the viscosity of the solvent extraction circuit flowstreams. Under these conditions circuit control was difficult, high alumina loss occurred, and iron impurities increased in the recycled solvent. An addition of less than 0.5 mol of nitric acid per liter increased the free acid content of the pregnant liquor and eliminated the viscosity problem in solvent extraction. Bench-scale research was not confirmed because most miniplant testing was not at best operating parameters. Research done by the Boulder City Engineering Laboratory. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Avondale, MD, Twin Cities, MN, Rolla, MO, Boulder City and Reno, NV, Albany, OR, Pittsburgh, PA, and Salt Lake City, UT; Office of Assistant Director—Minerals and Materials Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 65(1)–83. Reduction of Land Recontouring Costs. Volume I—Texas Lignite Field, by J. W. Howland and Lee Wray Russell. September 1981. 39 pp. 8 figs. To determine their effectiveness in different climate and soil conditions, a demonstration of dozer blades specifically designed for recontouring mine spoil was conducted at an east Texas surface coal mine. The specialized equipment included a 48-ft angle blade, a modified 24-ft "U" blade, a 13-ft-deep "U" blade, and a 24-ft grading bar. Both the 48- and 24-ft "U" blades were mounted in a two-tractor, single-operator configuration. To meet flotation problems common in this mining region, a 22-ft lightweight blade was developed and demonstrated for use on a 400- to 430-hp tractor. The demonstration involved 1,185 acres and showed a 50% reduction in reclamation costs and a 47% reduction in fuel requirements over conventional equipment. Research done under contract H0282035 by Russell & Sons Construction Co., Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS. PB 83–191569; paper copy price code A03.

OFR 65(2)–83. Reduction of Land Recontouring Costs. Volume II—Bituminous Coal Field, Northeast Arizona, by J. W. Howland and Lee Wray Russell. June 1982. 48 pp. 9 figs. A demonstration of dozer blades was conducted at a northeast Arizona surface coal mine to determine their effectiveness in different climate and soil conditions. The specialized tools were a 48-ft angle blade on a side-by-side tractor, a 24-ft grading bar, a modified 24-ft "U" blade on a side-by-side tractor, and a 13-ft-deep "U" blade. Interest in the increased dirt-filling capacity of a previously built 22-ft blade resulted in the design of a new center-flow blade of good versatility able to maintain increased flow in otherwise difficult-to-move spoil. The demonstration involved 263 acres and showed a reduction of 50% in reclamation costs and 20% in fuel requirements over conventional equipment. Research done under contract H0282035 by Russell & Sons Construction Co., Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–191577; paper copy price code A03.

OFR 66–83. Frictional Ignition Suppression by the Use of Cutter-Drum Mounted Sprays, by R. O. Ag-

bede, K. L. Whitehead, R. L. Mundell, and R. D. Saltsman. January 1982. 135 pp. 46 figs. The objective of this investigation was to conduct tests with a full-scale longwall shearer drum in a simulated mine environment to determine the effectiveness of drum-mounted water sprays in controlling frictional ignitions. The tests were conducted with a drum equipped with a single bit that cuts a sandstone block enclosed in a chamber filled with a combustible methane-air mixture. Without the sprays operating, no ignition occurred when only the carbide tip was impacting the stone. The likelihood of ignition increased with degree of bit wear and exposed steel contact area. Backflushing sprays, properly applied, were effective in controlling ignitions, but pickflushing and bit-cooling sprays were ineffective. Decreasing drum speed did not reduce the likelihood of ignitions until a bit peripheral speed of 200 fpm, 14 rpm for a 54-in drum, was reached. Research done under contract J0395040 by Bituminous Coal Research, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-191593; paper copy price code A07.

OFR 67–83. Coal Dust Combustion in a Stirred Reactor: Evaluation of Combustion and Extinction Mechanics in Coal Dust Explosion Flames, by R. H. Essenhigh. October 1981. 78 pp. 20 figs. The relative effects of seven additives (N_2, He, CO_2, fly ash, $KHCO_3$, NaCl, and $NH_4H_2PO_4$) on extinction limits of coal dust flames have been studied in a 200-cm^3 jet-stirred reactor. Conditions in the reactor are known to be comparable to those at the head of a coal dust explosion flame. $KHCO_3$, NaCl, and $NH_4H_2PO_4$ are commercial fire retardants and are presumed to be chemically active, but test results support the presumption only for NaCl and $NH_4H_2PO_4$. Curves of weight-of-additive to suppress the flame and temperature at extinction were obtained as a function of stoichiometry. For all but the NaCl and $NH_4H_2PO_4$, 20% to 30% additive in the mixture of coal plus air plus additive is required for extinction of maximum combustibility. With NaCl and $NH_4H_2PO_4$, the figures were 13% and 4%, respectively. The extinction mechanism is presumed to be chain termination of volatiles combustion. Extinction temperatures were found to be substantially independent of kind of additive, with essentially constant values in the fuel-rich region, and declining as fuel concentration decreased. Research done under contract J0199018 by the Ohio State University. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-191585; paper copy price code A04.

OFR 68–83. Preliminary Predictive Model of Subsidence Process Over Room and Pillar Workings. Phase I: Definition of Factors, by S. K. Mathur and M. R. Mikkilineni. April 1982. 113 pp. 38 figs. The report identifies all the possible activities, variables, and factors that contribute to the surface subsidence process over room-and-pillar workings. These factors are responsible for mine instability and collapse that ultimately transforms into surface subsidence. Such a failure mechanism is initiated by the failure of the mine floor bed and/or the failure of the pillars or the failure of the roof after second mining, which eventually brings down the roof. The individual responses of the pillar, floor, and roof rocks to the mining-induced stresses and the complex interaction between these components cannot be attributable to any single factor. Also, no attempt has been made to quantify the significance of each of these factors and relate to the ground subsidence due to the lack of field data. The discussion here is centered primarily on the first mining, although second mining is mentioned very briefly. Research done under contract J0100073 by MRM Engineers. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-191759; paper copy price code A06.

OFR 69–83. Geophysical Hazard Detection From the Working Face, by Sidney A. Suhler, Thomas E. Owen, Bob M. Duff, and Ron J. Spiegel. Jan. 15, 1981. 234 pp. 80 figs. The objective of this project was to define and demonstrate the feasibility of remotely sensing abandoned mine workings from underground. Geophysical probing techniques based upon electrical, seismic, and electromagnetic methods were evaluated; the seismic method was determined to be the most favorable. Guided seismic wave propagation in coal seams offered the potential of detecting inundation hazards 200 ft or more ahead of mining. Controlled waveform seismic source transducers and specialized receiving transducers were developed with emphasis on concept demonstration and experimental guided wave propagation studies. Two major field tests were undertaken in Kentucky and Virginia. Guided wave propagation phenomena were observed in 54- and 70-in coal seams. Normal mode Love waves and Rayleigh-type guided waves were generated by the controlled-source transducers and by hammer blows on a steel anvil attached to the coal. Numerical evaluations of theoretical velocity dispersion characteristics of both Love and Rayleigh-type waves were confirmed in the experimental test results. Analyses of the test results and recommendations for additional future research efforts are presented in detail. Research done under contract H0272027 by the Southwest Research Institute. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-191742; paper copy price code A12.

OFR 70–83. Video Image Sensor Systems Applied to Pit Slope Displacement Monitoring, by Robert J.

Dompe, James L. Eirls, Rodney D. Smith, William G. McKinley, and Gordon B. Hall. December 1982. 274 pp. 92 figs. The objective of this program was to develop a cost-effective microprocessor-based electronic image sensor for monitoring pit slope displacement to detect and/or predict impending slope failure in surface mines. A background study and data analysis yielded a performance specification for candidate video slope monitoring systems. A design concept was developed based on using a pair of solid-state video cameras located on precision pointing assemblies. The digital images from the cameras are compared and, using electronic triangulation, slope topology is calculated. The current and past locations of operator-selected features are compared to determine pit slope displacement. A proof-of-concept test was performed using a laboratory model of a pit slope. Based on the successful results of that test, it is recommended that an in-mine evaluation be performed using a full-scale prototype video slope monitoring system. Research done under contract J0295040 by Tracor MBA and Science Applications. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-191734; paper copy price code A13.

OFR 71–83. Zinc Retorting Without Pollution, by George W. Healy. Nov. 30, 1982. 53 pp. 16 figs. The direct retorting of zinc sulfide concentrates in the presence of lime and carbon was examined on a laboratory scale in an apparatus that permitted the volatilized zinc to be condensed and weighed while the reaction gases were analyzed periodically with a gas chromatograph. The zinc vapor was calibrated on prepared gas mixtures of CO and COS and of CO_2 and SO_2 in nitrogen. Neither of these sulfur gases were detected. Increasing the proportion of lime and carbon enhanced zinc recovery, as did higher temperature; going from 90% to 110% of theoretical reagents and from 1,100° to 1,200° C increased recovery of zinc from 75% to 93%. The reaction rate for direct retorting was compared with that for reduction of oxide with carbon using theoretical amounts of reagents. It was found that above 600° C, where carbon gases were first detected, reaction proceeded almost twice as fast for oxide plus carbon as for sulfide plus lime and carbon. Since CaS might react with the atmosphere to give off sulfur gases, it was attempted to stabilize it by oxidizing to $CaSO_4$. Because a residue of ZnS remained in the material from incomplete retorting, SO_2 was evolved while the CaS oxidized. Oxidation was 20% complete at 800° C, rising to 90% at 1,200° C. It was concluded that while the retorting step is nonpolluting, if stabilization of CaS is included in the process, the pollution is a problem. Research done under contract J0295069 by the University of Utah. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-191726; paper copy price code A04.

OFR 72–83. Monitoring of Gases From Explosives Detonated in an Underground Mine, by Meliton M. Garcia, Edward P. Jucevic, and W. Cary Kittrell. June 30, 1982. 81 pp. 18 figs. The concentration of six different gases produced by the detonation of four explosives was measured in a dry underground metal mine during actual mining operations. The four explosives included one semigelatin dynamite, one gelatin dynamite, and two water gel explosives. A standard drill pattern was used to detonate the explosives as a full-face round in the drift. The gases released by the explosion were trapped in the drift. The concentration of the gases in the test chamber were measured by direct readout instruments. The average volume of each gas per pound of explosives detonated in the following ranges, in cubic feet per pound: NO, 0.04 to 0.14; NO_2, 0.03 to 0.10; CO, 0.08 to 0.45; SO_2, 0.001 to 0.006; NH_3, 0.003 to 0.027; and CO_2, 1.82 to 7.02. Research done under contract H0395098 by the University of Arizona. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Rolla, MO, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-191718; paper copy price code A05.

OFR 73–83. Earth Resistivity Investigations in Reclaimed Surface Lignite Mine Spoils, by A. E. Kehew and G. H. Groenewold. November 1982. 98 pp. 65 figs. Earth resistivity surveys using the Wenner electrode configuration were made in unmined areas and reclaimed spoils at three surface lignite mines in western North Dakota. Automatic interpretation of the curves was accomplished with the method of Zohdy and Bisdorf. Overburden materials become more homogeneous with respect to resistivity during the mining and reclamation process. The spoils curves show localized heterogeneities probably related to discontinuous moisture content variations in the spoils. Consistent resistivity differences in spoils occur between mines with overburdens of different mineralogic compositions. Ground water chemical compositions in terms of total dissolved solids (TDS) is inversely correlated with apparent resistivity at the 80-ft spacing from a survey centered at a piezometer screened near the base of the spoils. Better inverse correlation is probably prevented by high variability in TDS within the spoils ground water. A useful predictive relationship may be the plot of mean apparent resistivity at the 80-ft spacing for an entire mine against mean TDS for all wells in spoils at that mine. Research done under contract J0275010 by the North Dakota Geological Survey. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 74–83. Downhole Rock Borehole Shear Tester, by R. L. Handy, Bruce Roorda, and Steve Futrell. May 30, 1982. 22 pp. 10 figs. The goal of this research was to adapt the rock borehole shear test for use in deep, small-diameter boreholes. Operating somewhat on the principle of a rock bolt, the borehole shear test measures both the expansion pressure

and pulling force to give discrete measures of rock shearing strength as a function of the applied normal pressure. A new instrument was designed and built to fit into a 2-3/8-in-diam hole. Complications attributed to constraints of the small hole, the added requirements of an in-hole anchor to push against, and a rotating shear plate cleaner for repeated tests downhole made the design unreliable. One reason for the complexity could be the length, which is over 10 feet. The instrument also employs concentric cylinders and one hydraulic cylinder bored into the piston of another, or it would be even longer. Since advanced drilling technology has greatly reduced costs of drilling 5- or 6-in-diam holes, the downhole tester should be redesigned and simplified for use in a larger diameter drill hole. Research done under grant G0284002 by the Iowa State University, Ames. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 75–83. A Study of Stability Problems and Hazard Evaluation of the Kansas Portion of the Tri-State Mining Area, by J. R. McCauley, L. L. Brady, and F. W. Wilson. January 1983. 193 pp. 46 figs. The Kansas portion of the tristate (southwestern Missouri, southeastern Kansas, and northeastern Oklahoma) lead and zinc district was studied in order to compile maps and report on the location and extent of past mining activities and the resulting hazardous surface effects of mining. Information was acquired from old mine maps, reports, personal interviews, aerial photo interpretation, and fieldwork. Three maps have been prepared that show (1) extent of underground workings and mine shafts, (2) hazardous mine openings including open mine shafts and mine collapses and (3) waste piles and tailings ponds. In addition, tabulations are included for all mine hazards as well as large waste piles and hazardous tailings ponds. Research done under contract J0100131 by the Kansas Geological Survey. Available for reference at Bureau of Mines facilities in Denver, CO, Rolla, MO, and Pittsburgh, PA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 76–83. A Study of Stability Problems and Hazard Evaluation of the Oklahoma Portion of the Tri-State Mining Area, by Kenneth V. Luza. February 1983. 147 pp. 20 figs. Approximately 2,240 acres are underlain by underground lead and zinc mines in northeastern Oklahoma and approximately 2,900 acres are overlain by mine and mill waste materials. The principal objectives of this investigation are to (1) compile on a series of maps the location and extent of past mining activities and the resulting surface effects, (2) identify hazardous areas with potential for future damage to persons or property, and (3) consider methods for providing public protection from existing and potentially hazardous conditions. Research done under contract J0100133 by the Oklahoma Geological Survey. Available for reference at Bureau of Mines facilities in Denver, CO, Rolla, MO, and Pittsburgh, PA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 77–83. Fire Hazard Evaluations of Mine Materials in a Small-Scale Combustibility Apparatus, by A. Tewarson. June 1982. 79 pp. 8 figs. Fourteen commonly used mine materials were evaluated for combustibility in a small-scale apparatus. The data obtained and predictions of these data from large-scale fires were successfully validated for conveyor belting, brattice cloth, and treated and untreated wood. All the wood treatments except Fireguard were found to be effective for reducing the fire hazard. Five parameters proposed for rating mine materials are (1) ignition and flame spread, (2) generation of combustible vapors, (3) generation of heat, (4) generation of toxic and corrosive products, and (5) light obscuration by smoke particulates. Research done under contract J0395125 by Factory Mutual Research Corp. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-196204; paper copy price code A05.

OFR 78–83. Study of Automated Continuous Explosive Excavation Systems, by E. Concha and J. A Bartol. January 1982. 95 pp. 27 figs. The concept of an automated continuous explosive excavation system (ACEE) for the underground mining applications of development drifting and room-and-pillar mining has been evaluated in comparison with conventional drill, blast, and muck operations. The role and possible extent of application of this method was examined in a defined mine environment. Step-by-step procedures were developed to quantify the evaluation process where this appeared feasible. One conclusion was that a system approach to ACEE design is not only feasible but attainable within the state of the art. Several preliminary design concepts were formulated and examined in order to determine what further research or development might be needed to realize them. Research done under contract J0100082 by Applied Engineering Resources, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-196212; paper copy price code A05.

OFR 79–83. Remote Monitoring of a Coal Waste Impoundment in West Virginia, by Gordon E. Green and David A. Roberts. February 1982. 175 pp. 70 figs. This report addresses remote monitoring of coal waste impoundments for stability. Existing automated geotechnical monitoring systems are described and reviewed along with details of instruments suitable for such systems. An impoundment in West Virginia, which was in the construction stage, was instrumented and monitored between July 1979 and May 1981. Sensors that measure sur-

face and subsurface parameters including settlement, horizontal deflection, surface tilt, pore water pressure, seepage, pond level, and meteorological parameters were installed. Data from 37 sensors were collected by on-site logger and transmitted by telephone to a central processing station in Seattle for recording and interpretation. Difficulties were encountered with telephone and powerline outages and malfunction of electronic units. Detailed descriptions of the design and performance of the system are provided along with evaluation and comparison with other systems. Recommendations for improving and expanding the capabilities of the monitoring system are given. Research done under contract H0282041 by Shannon & Wilson, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-196584; paper copy price code A08.

OFR 80–83. Geological Sampling and Magnetic Surveys of a Tungsten Occurrence, Bonanza Creek Area, Hodzana Highlands, Alaska, by Karen H. Clautice. Mar. 29, 1983. 80 pp. 23 figs. The tungsten occurrence at the margin of the Kanuti batholith in the Bonanza Creek area was investigated by the Bureau of Mines for the Bureau of Land Management as part of an inventory of mineral deposits within and bordering the trans-Alaska oil pipeline corridor. Fieldwork was conducted over a period of 6 weeks during the summer of 1979. Analyses and sample location maps were compiled from stream sediment, panned concentrate, soil, and rock samples. Analytical methods included atomic absorption, X-ray fluorescence, emission spectrography, and neutron activation. Tungsten and molybdenum, occurring in the minerals scheelite and molybdenite, were found in trace amounts throughout the 30-mi² project area. The highest grade tungsten mineralization was found in a pyrrhotite-rich chalcopyrite-bearing tactite adjacent to a biotite quartz monzonite contact. The tactite occurs in pods up to 10 ft wide. Scheelite was most commonly found in a relatively sulfide-free calc-silicate schist that was of lower grade than the tactite. Traces of molybdenite occur in quartz veins, pegmatite, and aplite dikes. No well-developed quartz stockworks were observed. Magnetic surveys show calc-silicate country rock to be more magnetically susceptible than granitic rocks. One magnetic anomaly of 1,700 gammas within calc-silicate schist coincided with a group of anomalous soil samples high in W, Mo, Pb, Cu, and Zn. Research done by the Alaska Field Operations Center. Available for reference at Bureau of Mines facilities in Anchorage, Fairbanks, and Juneau, AK; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 81–83. Hydrologic and Erosional Characteristics of Regraded Surface Coal Mined Land in Colorado, by W. D. Striffler and R. Allan Rhodes. Dec. 31, 1981. 119 pp. 15 figs. Land disturbed by surface mining in Colorado and other Western States has increased substantially over the past several years and is likely to increase even more in the future. This study was initiated to provide basic information on hydrologic and erosional characteristics of regraded coal spoils in Colorado as an aid for planning future reclamation activities. Of 21 surface mines licensed in Colorado, 11 were sampled during the summers of 1980-81. Mines not sampled included those that had not progressed to the point that reclamation had begun and mines where operators denied permission to sample. All coal regions were sampled except the San Juan Coalfield. Physical and hydrologic characteristics of regraded coal spoils in Colorado were determined using standard field and laboratory procedures. Field sampling included characterization of sites (slope, vegetation density, proportion of surface rock, bare soil, etc.) and infiltration measurements using a 1-m² drop former raining on a 1/2-m² rectangular plot frame. Core samples were analyzed for saturated hydraulic conductivity, bulk density, organic matter, moisture retention, and texture. The erosion potential of each site was determined using the Universal Soil Loss Equation. Results of the sampling indicate that infiltration rates vary widely both within and between sites. Research done under grants G5105062 and G5195010 by the Colorado State University. Available for reference at Bureau of Mines facilities in Denver, CO, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 82–83. Hydrogeologic Aspects of Flyash Disposal Sites in Missouri, by Allen W. Hatheway. Mar. 28, 1983. 54 pp. 36 figs. Coal-fired utility generation stations in Missouri and the near environs of Kansas and Illinois have a production capacity of more than 12,546 megawatts of electricity. Annual consumption of coal for these plants is believed to be in excess of 23 million metric tons; most of which is midwestern and of a relatively high sulfur content. The stations produce unique forms of waste that are classified as "special" wastes by the Environmental Protection Agency. Their mineralogical character is probably the most important aspect of the fly ashes, bottom ashes and slags, and flue-gas desulfurization wastes. Most of the wastes are produced in the extreme heat of the powerplant furnaces or in the stream of hot stack gases. Most of the concern for accessory pollutants comes from elements that are carried as surface coatings on these generally fine particles. The main objective of the current research is to provide a single source assessment of the hydrologic status of utility waste disposal sites in the Missouri coal-fired electric generation region. Research done under grant G1114028 by the University of Missouri—Rolla. Available for reference at Bureau of Mines facilities in Avondale, MD, Twin Cities, MN, and Rolla, MO; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 83–83. Radionuclide and Heavy Metal Distribution in Recent Sediments of Major Streams in the Grants Mineral Belt, N.M., by Carl J. Popp, John W. Hawley, and David W. Love. March 1983. 214 pp. 102 figs. The major objective of this research was to determine the extent to which active uranium mining and milling operations in the Grants mineral belt of west-central New Mexico contribute excess trace metals and radionuclides to Rio Puerco and Rio San Jose sediments. Subsidiary objectives include the determination of the modes of sediment move-

ments in the Rio Puerco-Rio San Jose drainage systems and determination of the age of deposits along and adjacent to the modern drainage channels. Procedures used to make these determinations include (1) geomorphic evaluation of the fluvial transport and depositional system and evaluation of loci of sediment deposition along the drainages, (2) historical documentation of loci of deposition to aid in determining the age of sediments, (3) field sampling and sediment characterization, (4) laboratory characterization of grain size and mineralogy of sediment samples, (5) laboratory determination of trace metals and radionuclide concentrations in sediments, and (6) laboratory determination of ages of sediments using radioactive cesium-137 and lead-210. Research done under grants G1115352 and G5105041 by the New Mexico Institute of Mining and Technology. Available for reference at Bureau of Mines facilities in Avondale, MD, and Reno, NV; Office of Assistant Director—Minerals and Materials Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 84–83. Extraction of Radionuclides From Low-Grade Ores and Mill Tailings, by Arpad E. Torma. Mar. 31, 1983. 85 pp. 19 figs. The present study demonstrates the possibility of development of efficient leaching processes for the extraction of uranium from a low-grade ore and for the removal of long half-life radionuclides, especially radium-226, from the leach residues in order to produce environmentally safe and radiochemically innocuous tailings. The report provides kinetic information, not previously available, for low-grade uranium ore leaching by sulfuric and hydrochloric acids and by sodium carbonate and bicarbonate leachants. Based upon a statistical experimental design, a generalized mathematical form was developed for the initial rate of uranium extraction as a function of the leaching parameters using a linear regression computation technique. A specific ion exchanger for the removal of radium-226 from leach solutions and actual neutralized tailings effluents was developed. This solid ion exchanger can be obtained through a simple treatment of commercially available organic resins. Research done under grants G1115353, G5105078, and G5195031 by the New Mexico Institute of Mining and Technology. Available for reference at Bureau of Mines facilities in Avondale, MD, Twin Cities, MN, Reno, NV, and Salt Lake City, UT; Office of Assistant Director—Mineral and Materials Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 85–83. Design Procedures for Coal Mine Tunnels, by Z. T. Bieniawski. Mar. 31, 1983. 49 pp. 14 figs. Although coal mine tunnels such as the main haulageways or roadways are the lifelines of coal mines, little attention has been paid to them in the United States in terms of preconstruction planning and design. This report summarizes the results of a 3-year research project aimed at improving the design procedures for coal mine tunnels. A new design approach was developed for this purpose and roof-support design charts were prepared for mine tunnels and their intersections. Analytical studies, "base friction" model experiments, and in situ rock stress measurements were performed during this research. Research done under grants G1115425, G5105083, and G5195042. Available for reference at Bureau of Mines facilities in Denver, CO, and Pittsburgh, PA; Office of Assistant Director—Mining, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-197624; paper copy price code A03.

OFR 86–83. Characterization and Processing of Coal Fired Copper Reverberatory Flue Dusts, by Srinivasan Raghavan and Aniedi Ette. January 1983. 56 pp. 23 figs. A detailed study of the physical and chemical characteristics of a flue dust sample from a coal-fired copper reverberatory furnace was carried out. The studies revealed that the majority of the copper in the flue dust is strongly associated with iron in the form of a cuprous ferrite, $CuFeO_2$ (delafossite). The flue dust has an extremely fine size distribution with 70% of the particles below 37 μm in size. The recovery of copper from the flue dust was investigated using an ammoniacal carbonate solution. The results indicate that a reductive roast prior to leaching is necessary to obtain high extractions. In order to better understand the leaching characteristics of the flue dust, attempts were made to synthesize and study the leaching of the main copper-bearing constituent, $CuFeO_2$. The dissolution of the $CuFeO_2$ was found to depend on the extent of reduction, particle size, and stirring speed. A film diffusion model was proposed to describe the kinetics of leaching of $CuFeO_2$. Research done under grants G5105012 and G5115042 by the University of Arizona. Available for reference at Bureau of Mines facilities in Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, and Salt Lake City, UT; Office of Assistant Director—Minerals and Materials Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-197707; paper copy price code A04.

OFR 87–83. Beneficiation of Low Grade Appalachian Iron Ores To Recover Enriched Iron Concentrates, by H. S. Hanna and I. J. Anazia. Dec. 20, 1982. 126 pp. 49 figs. The feasibility of applying fine grinding and fine particle processing technology, as practiced in the Lake Superior region, to the low-grade, high-phosphorus red iron ores of the southeastern Appalachian region to recover iron ore products of a quality suitable for smelting competitively with imported materials is discussed. The application of new or improved processing technology or approaches embracing extremely fine grinding to achieve maximum liberation of the iron oxides and gangue constituents also is discussed. The research involved two principal lines. One emphasized the development of fundamental data relating to the fine grinding, sizing, and liberation characteristics of the ores to gain a better understanding of the most effective beneficiation approaches for separating the iron oxide and gangue minerals. The second focused on determining the merits of various beneficiation methods or combined techniques that would yield maximum recoveries of plus 60% iron products. Among the techniques applied were flotation, selective flocculation, reductive roasting and magnetic separation, magnetic flocculation, and hydrocyclone concentration. Research done under grants G1105056, G5105056, and G5195002 by the University of Alabama. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, and Twin Cities, MN; Office of Assistant Director—Minerals and Materials Research, Bu-

reau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 88–83. Workshop—Cyanide From Mineral Processing, ed. by Jerry L. Huiatt, James E. Kerrigan, Ferron A. Olson, and Gary L. Potter. February 1983. 112 pp. 8 figs. A workshop on cyanide use in the minerals industry, sponsored by the Bureau of Mines, the National Science Foundation, the minerals industry, and supporting industries, was held on February 2–3, 1982, at the Bureau's Salt Lake City (Utah) Research Center. The workshop focused on use of cyanide as it relates to the gold and silver mining industry and the froth flotation processes employed by mineral mining companies. The intent was to discuss state-of-the-art technology and provide information pertinent to cyanide use in the minerals industry. No attempt was made to advocate regulatory limits or set policy governing the use of cyanide. The principal topics of discussion included (1) chemistry and use of cyanides, (2) control and treatment of cyanide mining wastes, (3) toxicity of mining wastes, (4) fate of cyanide in the environment, and (5) the analytical chemistry of cyanide. The problems associated with cyanide use in the mining industry and areas where technical information is insufficient were identified. The types of research required to understand and resolve potential adverse environmental problems were also identified. The problems and research needs are mentioned in a special summary to this document. Research done under contract J0113087 by the University of Utah. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Office of Assistant Director—Mining Research and Office of Assistant Director—Minerals and Materials Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 89–83. Fly Ash Pelletization, by Douglas W. Fuerstenau and Vikram P. Mehrotra. June 1982. 76 pp. 27 figs. The use of pulverized coal for power generation results in the production of vast amounts of fly ash in the United States. This research is concerned with the role of the physicochemical characteristics of fly ash in governing its pelletization and the strength of the product pellets in relation to their potential use as lightweight aggregate. The potential impact of the research is extremely great in that a severe environmental problem may be alleviated by converting a huge mineral waste into a resource. Although results on batch and locked-cycle pelletization tests have indicated that it is possible to produce pellets of adequate strength from fly ash, appropriate and precise control of operation conditions is vital. Particle packing characteristics and the pozzolanic nature of ash have been identified as the important factors controlling the pelletization moisture and pellet growth. Pellet strength properties were found to be related to the amount of active silica and lime in the ash, the curing conditions, and the final products of hydration reactions. A thorough understanding of the control of continuous pelletization circuits must be developed if products of uniform quality are to be produced. Research done under grant G5105059 by the University of California. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Avondale, MD, and Albany, OR; Office of Assistant Director—Mineral and Materials Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–201889; paper copy price code A05.

OFR 90–83. Investigation of Microbially Induced Permeability Loss During In-Situ Leaching, by Corale L. Brierley and James A. Brierley. Apr. 16, 1982. 71 pp. 10 figs. Accumulations of microorganisms in the in situ leaching environment are believed responsible for plugging of the ore body and thus decreasing uranium extraction. To assess the contribution of microbial growth to this problem, packed columns of ore and core specimens were leached in the laboratory. Samples collected at four in situ uranium mining operations revealed pseudomonads, Xanthomonads, *Bacillus* sp. and *Micrococcus* sp. These microorganisms, inoculated into simulated leaching conditions, decreased permeability in two uranium ores by one order of magnitude in 20 days. Hydrogen peroxide alleviated microbial plugging in the laboratory. Periodic injection of hydrogen peroxide through the production well into the ore body may reduce microbial plugging problems in the field. Research done under contract S0211032 by the New Mexico Institute of Mining and Technology. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–205534; paper copy price code A04.

OFR 91–83. Development of Improved Scrubbers for Coal Mine Applications, by D. Grigal, G. Ufken, J. Sandstedt, M. Blom, and D. Johnson. July 1982. 124 pp. 63 figs. The objective of this four-task program was to develop smaller, less expensive scrubbers while maintaining or improving scrubber efficiency and reliability. The development included (1) building a scrubber test facility suitable for testing contract-developed and future scrubber systems, (2) develop and test four fibrous-bed panels and two water droplet eliminators to reduce scrubber size and clogging, (3) fabricate and test two fibrous bed panels for use with the Bureau of Mines rotating, flooded-bed scrubber system, and (4) develop and test water-powered scrubber and recycle water systems for use at low water pressures. Tests revealed that the standard water droplet eliminator and the 20 double-layer fibrous-bed panels were the best choices for scrubber improvement. Based on clogging and pressure drop tests, it was recommended using 16 double layers of knitted wire mesh in the rotating scrubber. Research done under contract H0199055 by the Donaldson Co., Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–205385; paper copy price code A06.

OFR 92–83. Preparation and Evaluation of Self-Regenerative Carbon Monoxide Detection Gels, by John G. Palmer, Michelle Cecil, Gerhard N. Schrauzer, and Kurt E. Shuler. September 1982. 51 pp. 7 figs. Continued development of an especially impregnated silica gel capable of reversible chemical detection of carbon monoxide was reported. The effects of changes in mine-related ambient conditions on the detection catalyst's response were explored. Temperature, humidity, and several interfering gases were found to affect the detection catalyst. The interferents include hydrogen sulfide, nitrogen dioxide, acetylene (and methylacetylene), and ammonia. High humidity decreased the detection catalyst's sensitivity to carbon monoxide for some formulations. Increasing temperature generally decreased the reaction time of the detection catalyst with carbon monoxide. A limited physical, chemical, and mechanistic characterization of the detection catalyst and the materials used to prepare it has been carried out. Metal component ratio studies, spectral, analytical, pH, and rate measurements were done. Research done under contract J0188159 by the University of California—San Diego. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-205179; paper copy price code A04.

OFR 93–83. Cable Fault Locator Research, by C. A. Cole, S. K. Honey, J. P. Petro, and A. C. Phillips. July 1982. 128 pp. 45 figs. This work consists of research in cable fault location and the construction of four field test units based on the research. Swept-frequency sounding of mine cables with radio frequency (RF) signals has been the technique most thoroughly investigated. The swept-frequency technique is supplemented with a form of moving target indication to provide a method for locating the position of a technician along a cable and relative to a suspected fault. Separate, more limited investigations involved high-voltage time domain reflectometry and acoustical probing of mine cables. Particular areas of research included microprocessor-based control of the swept-frequency system, a microprocessor-based fast Fourier transform for spectral analysis, RF synthesizers, transmit-receive switches, RF receivers, cable dispersion-compensation techniques, low-voltage multielement display systems, and techniques for injecting or recovering RF energy through cable walls in support of clamp-on fault locators. Research done under contract H0166082 by SRI International. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-205393; paper copy price code A07.

OFR 94–83. A Hydrogen Engine Induction Technique for Backfire-Free Operation, by Ned Baker and Frank Lynch. May 30, 1982. 46 pp. 24 figs. Details are given of a fuel-induction system for a hydrogen-fueled engine. The induction system was designed to preclude backfire otherwise common in hydrogen-fueled engines. System features and test data are presented and discussed in the context of the requirements peculiar to use in an underground mine environment. The fuel-induction system, when tested in conjunction with a modified Caterpillar 3304 engine, provided backfire-free engine operation and satisfactory engine performance. Research done under contract H0202034 by EIMCO Mining Machinery International. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-205443; paper copy price code A03.

OFR 95–83. Personal Dust Monitor—Light Scattering, by Pedro Lilienfeld and Roger Stern. November 1982. 40 pp. 13 figs. The objective of this program was the development, design, and fabrication of six personal-sized, completely self-contained dust monitors capable of real time as well as time-averaged monitoring of the concentration of respirable particles in coal mines in the range of 0.1 to 100 mg/m^3. The operation of these monitors is based on light scattering and passive air sampling. The design stressed overall miniaturization, ruggedness, simplicity, and versatility. These instruments incorporate a single-chip CMOS microprocessor to perform all signal processing, data display and storage, and timing functions. The overall dimensions of these devices are approximately 10 by 10 by 5 cm. Research done under contract H0308132 by GCA Corp. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-205435; paper copy price code A03.

OFR 96–83. A Study of Explosion-Proof Enclosures, by P. A. Cox, O. H. Burnside, E. D. Esparza, F. D. Lin, and R. E. White. December 1982. 426 pp. 204 figs. The purpose of the initial research performed under this contract was to determine the margins of safety in explosion-proof (XP) enclosures that were designed and certified according to Schedule 2G. Results from this work provide baseline data on the current schedule, from which a new schedule can be formulated to give equal or greater levels of safety. Results and discoveries in the initial work led to an expansion of the contract to cover, additionally, weld quality in enclosure fabrication, reliability of enclosures with windows and lenses, and performance tests for enclosure qualification. Finite element calculations and hydrostatic tests revealed wide variations in the margins of safety in the enclosures studied; however, only one enclosure had a safety factor of less than one. Results from a weld quality survey led to the recommendation of AWS Welding Standard D14.4 for the fabrication of XP enclosures. Based on other work, accelerated aging tests were recommended for qualifying plastics and adhesives that are used in some enclosures, and a structural performance test was developed to test enclosure strength for a minimum static pressure of 150 psig. Research done

under contract H0377052 by the Southwest Research Institute. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-205450; paper copy price code A19.

OFR 97-83. Study of Stability Problems and Hazard Evaluation in the Missouri Portion of the Tri-State Mining Area, by Michael C. McFarland and James C. Brown, Jr. Apr. 30, 1983. 141 pp. 39 figs. A 2-year investigation disclosed 469 hazardous sites resulting from past zinc-lead mining in the vicinity of Joplin, MO. Aerial-photo analysis, fieldwork, library research, and personal interviews were conducted to locate and describe the abandoned mining areas and their associated hazards. Open shafts, subsidence pits, and other mine-related dangers exist in areas easily accessible to the public. Accidents involving humans and livestock have been reported. Some recent damage to buildings and roads can be attributed to the collapse of underground mine workings. A few landowners have employed successful methods of safeguarding dangerous sites. In addition, some surface reclamation has been effected by gradual removal and use of mine and mill waste-rock, with subsequent leveling and reuse of the land. Other than backfilling shafts, nothing has been done to stabilize undermined areas. A continuing problem is indicated. Under present laws, most government reclamation funds are designated for coal-mined lands. A comprehensive program of hazard control and monitoring for the entire study area is warranted. Research done under contract J0100132 by the Missouri Department of Natural Resources, Division of Geology and Land Survey. Available for reference at Bureau of Mines facilities in Denver, CO, Rolla, MO, and Pittsburgh, PA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 98-83. Evaluation of Charged Water Sprays for Dust Control, by J. McCoy, J. Melcher, J. Valentine, D. Monaghan, T. Muldoon, and J. Kelly. January 1983. 151 pp. 38 figs. Charged sprays and fog were evaluated for reducing respirable dust concentrations. Charged spray technology was reviewed for effectiveness, equipment, and theoretical considerations. A mathematical model was developed for predicting dust reduction effects. Laboratory tests were made showing charged spray is considerably more effective at reducing dust on a unit water basis than hydraulic spray. Positive and negative sprays are equally effective. Combined polarity sprays are considerably less effective than either polarity alone. Little difference in effectiveness by dust type was observed. The charged cloud can present a spark hazard in explosive atmospheres; therefore, this technique must not be used in gassy mines. Predictions were made for field test conditions but confirmation was impossible because of particles resulting from dissolved solids in the spray water. Dissolved or suspended solids in atomizing sprays can result in an increase of the respirable dust burden. Charged sprays are an available dust control technique best suited to applications where water usage must be limited and long contact time between spray and dust is possible. Research done under contract H0212012 by Foster-Miller, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-210476; paper copy price code A08.

OFR 99-83. An Observational Study of Classroom Health and Safety Training in Coal Mining, by R. Michael Digman and John T. Grasso. April 1982. 65 pp. 3 figs. This study was concerned with the quality and effectiveness of existing classroom coal mine health and safety training programs. The study involved field data collection through pre- and posttesting of trainees, audiotaping class sessions, and administering short feedback forms with trainers and trainees at 14 sites in West Virginia, Maryland, Kentucky, and Pennsylvania. Results indicate that goals, methods, materials, and outcomes of existing training programs vary widely among trainers and sites. The report provides less by way of solution to problems than it highlights the breadth of issues that relate to the question of training effectiveness and quality. The report concludes that additional work by industry, labor, government, and academia is necessary to improve health and safety programs. Recommended steps are (1) to develop performance standards and measurable criteria in each of the types of mandated training, (2) to develop better training of trainers, (3) to develop expanded training support services, and (4) to undertake further research and development in health and safety training in the mining industry. Research done under contract J0188069 by the West Virginia University. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-210518; paper copy price code A04.

OFR 100(1)-83. Evaluation of Proximity Warning Devices. (Phase III, Volume 1), by J. H. Nixon, J. E. Hipp, T. C. Green, G. H. Munsch, and J. P. Cater. Dec. 31, 1982. 91 pp. 46 figs. A three-phase program evaluated commercial proximity warning devices, developed and designed a microprocessor-based electrostatic field measurement instrument, and utilized the instrument to investigate the electrostatic fields about powerlines. Phase I consisted of test evaluations of these commercially available proximity devices. Phase II resulted in the design and development of a microprocessor-based distributed sensor ac electrometer that measures the electrostatic field at 17 discrete locations along a crane boom. Under the phase III program, electrostatic fields around a crane boom were measured by the instrument at 17 high-voltage powerlines of various voltages and geometries. The data were processed and plotted versus boom distance from the powerlines. Analysis of the data indicate that the distances at which a single sensor alarm will activate vary by a factor of 3 to 1, due primarily to

variations in boom orientation. The results also indicate that in the case of multiple powerlines, a single electrostatic field sensor cannot reliably be used to determine the distance from a powerline. Research done under contract J0188082 by Southwest Research Institute. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, and Pittsburgh, PA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-210260; paper copy price code A05.

OFR 100(2)-83. Evaluation of Proximity Warning Devices. (Phase III, Volume 2), by J. H. Nixon, J. E. Hipp, T. C. Green, G. H. Munsch, and J. P. Cater. Dec. 31, 1982. 311 pp. 277 figs. Phase I of this three-phase program consisted of test evaluations of commercially available proximity warning devices. Phase II resulted in the design and development of a microprocessor-based distributed sensor ac electrometer that measures the electrostatic field at locations along a crane boom. In volume 1 of phase III the electrostatic fields around a crane boom were measured by the instrument at high-voltage powerlines of various voltages and geometries. Volume 2 of phase III contains the appendixes. Research done under contract J0188082 by Southwest Research Institute. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, and Pittsburgh, PA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-210278; paper copy price code A14.

OFR 101-83. Catalysis of Chlorination Reactions, by Y. K. Rao. May 5, 1982. 24 pp. 11 figs. The objective of this research was to determine the feasibility of catalyzing the chlorination of alumina using inexpensive catalytic substances. The chlorination kinetics of alumina in the presence of carbon were investigated for different forms of carbon and two different alumina particle sizes. The influence of catalysts such as ternary, NaF, and cryolite were studied for different carbon materials. The following observations were noted: (1) sodium fluoride appears to be the most stable catalyst, (2) ternary catalyst is quite powerful initially but its catalytic activity diminishes gradually possibly because of progressive deactivation, and (3) cryolite is an intermediate catalyst that may be more desirable than NaF in industrial applications. Research done under grant G1105054 by the University of Washington. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Avondale, MD, Twin Cities, MN, and Salt Lake City, UT; Office of Assistant Director—Mineral and Materials Research, Bureau of Mines, Washington, DC.; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 102-83. Computer Simulation of Mining Subsidence Using the Zone Area Method, by M. Karmis and C. Haycocks. March 1983. 95 pp. 43 figs. The objective of this research was to develop a computer model of subsidence prediction based on the zone area method. This technique was chosen because of its potential to investigate a mining plan of any shape, thus facilitating subsidence prediction over longwall as well as room-and-pillar coal mining systems. A comprehensive subsidence data bank was established that included published as well as unpublished information on subsidence measurements. Based on these studies, some fundamental characteristics of longwall subsidence were established, and this information was utilized to develop an empirical prediction method. The established relationships were also used for the formulation and subsequent testing of the modeling procedures. The results and comparisons of the study demonstrated that the zone area method has considerable potential for accurate, rational, and flexible subsidence predictions. Research done under grants G1105051 and G1115512 by the Virginia Polytechnic Institute and State University. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 103-83. Probabilistic Modeling of Soil Loss From Surface Mined Areas, by K. B. Rojiani, K. A. Tarbell, V. O. Shanholtz, and F. E. Woeste. Apr. 28, 1983. 77 pp. 24 figs. The goal of this study was to provide a rational basis for selecting a sediment control system for surface mine regions that would minimize the chance of exceeding effluent standards set by regulatory agencies for total sediment yield. A probabilistic model to predict storm sediment yield and sediment yield over the lifetime of the mining operation was developed. This model can be used to predict sediment yield for a given period of occurrence that can subsequently be used as a basis for the design of sediment control structures. Probability distributions of sediment yield were determined by coupling probabilistic models of rainfall amount, duration, and time between storms with a deterministic event-based model of the sediment yield process. A modified universal soil loss equation formed the basis for the deterministic sediment yield model. Runoff volume and peak flow were computed using the Soil Conservation Service runoff curve number method. Using probabilistic analysis procedures and a simulation approach sediment yield probability, distributions were determined for individual storm events and for the lifetime of the mining operation. Research done under grant G1115514 by the Virginia Polytechnic Institute and State University. Available for reference at Bureau of Mines facilities in Denver, CO, Avondale, MD, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 104-83. A Low-Cost Landsat Digital Technology Training Package, by John A. Harrington, Jr. May 1983. 49 pp. 17 figs. The purpose of this report is to document a computer-assisted instruction package developed to facilitate instruction of computer-based, interactive, image processing of remote sensor data. The computer software was designed for a low-cost Apple II+ microcomputer and four-channel Landsat digital data. Utilization of this educational package should extend the availability of college-level instruction concerning multispectral digital image analysis in remote sensing,

especially since this technology is now coming into research and commercial application in the mining and mineral industries. Research done under grant G1195039 by the University of Oklahoma. Available for reference at the Bureau of Mines facility in Avondale, MD, and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 105–83. The Competitive Position of the United States Copper Industry: 1980–2000, by Patricia T. Foley and Joel P. Clark. Oct. 29, 1982. 306 pp. 9 figs. An engineering-economic model was used to determine the effects that U.S. State tax actions can have on U.S. copper mines operating in a world market. The copper model used in this report is based on site- and input-specific data for 65 copper operations in the United States and site-specific data for 348 copper operations in the rest of the world. These data are used to develop world shortrun and longrun supply functions that are equated with an econometric estimate of world demand and solved for price and production under various tax scenarios. The shortrun analysis included currently producing mines; deposits for which the development decision has been made and for which the financing has been arranged are included in the longrun analysis. Research done under grants G5105029 and G5115253 by the Massachusetts Institute of Technology. Available for reference at Bureau of Mines facilities in Avondale, MD, and Salt Lake City, UT; Office of Assistant Director—Minerals Data Analysis, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 106(1)–83. The Effects of Increasing Energy Costs on the Future Relation Between Open Pit and Underground Mining. Volume I: Chapters 1–10, by Dan S. Nilsson. December 1982. 253 pp. 67 figs. The objective of this study was to evaluate the energy consumption in some open pit and underground mines and to show the optimal proportion between open pit and underground mining for different types of commodities. The results show (1) the future relation between open pit and underground mining of different types of deposits, (2) the future competitiveness between large-scale mining of low-grade ore and small-scale mining of high-grade ore, (3) actual power consumption figures for different mining activities, and (4) guidelines for a more energy-efficient mining industry. The study provides a base for forecasting mine production of different commodities and for decisions about how to spend research money and organize education in the field of mining engineering. Volume I contains chapters 1 through 10. Research done under grant G5105032 by Michigan Technological University. Available for reference at Bureau of Mines facilities in Denver, CO, and Avondale, MD; Office of Assistant Director—Minerals Data Analysis and Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-216515, paper copy price code A12.

OFR 106(2)–83. The Effects of Increasing Energy Costs on the Future Relation Between Open Pit and Underground Mining. Volume II: Chapters 11–17, by Dan S. Nilsson. December 1982. 216 pp. 43 figs. The objective of this study was to evaluate the energy consumption in some open pit and underground mines and to show the optimal proportion between open pit and underground mining for different types of commodities. The results show (1) the future relation between open pit and underground mining of different types of deposits, (2) the future competitiveness between large-scale mining of low-grade ore and small-scale mining of high-grade ore, (3) actual power consumption figures for different mining activities, and (4) guidelines for a more energy-efficient mining industry. The study provides a base for forecasting mine production of different commodities and for decisions about how to spend research money and organize education in the field of mining engineering. Volume II contains chapters 11 through 17. Research done under grant G5105032 by Michigan Technological University. Available for reference at Bureau of Mines facilities in Denver, CO, and Avondale, MD; Office of Assistant Director—Minerals Data Analysis and Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-216523; paper copy price code A10.

OFR 107–83. Control of Blackwater in Coal Preparation Plant Recycle and Discharge, by P. A. Rey, R. Hogg, and F. F. Aplan. Apr. 29, 1983. 38 pp. 6 figs. Water recycle is an important part of the coal preparation process. This study was directed toward (1) a survey of current practice and an evaluation of both the solid and liquid components of blackwater, (2) an experimental study of blackwater flocculation, and (3) a fundamental analysis of the flocculation process. The solids contained in the blackwater discharge to the fine refuse thickener of a coal preparation plant were found to contain, on average, 56% coal and 44% mineral matter. The mineral matter was largely illitic clay, while the water phase contained relatively large amounts of SO_4 and Ca^{++}. Detailed studies were made of both natural and synthetic flocculants and the influence of polymer type and pH on the settling rate, turbidity of the supernatant liquid, and sludge volume of the settled solids. More fundamental studies were made that clearly indicate the need for controlled mixing of polymer into the suspension to be flocculated and the need to evaluate more closely the structure of the flocs formed during the process. Research done under grants G1115424, G5105082, and G5195041 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Denver, CO, and Pittsburgh, PA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-216481; paper copy price code A03.

OFR 108–83. Flotation Properties and Selective Flotation of the Slightly Soluble Minerals, by F. F. Aplan and M. Castillo. March 1983. 27 pp. 7 figs. Separation of the slightly soluble minerals, $K_{sp} \approx 10^{-10}$, is one of the more difficult tasks confronting flotation engineers. This study focused on means of separating such prominent members of this class as scheelite, fluorite, and calcite from one another. Some experimental work was also done on magnesite, dolomite, and apatite. Four techniques were evaluated for separation of the minerals: (1) control of potential determining ions, (2) use of stereo-

specific collectors, (3) use of flotation rate differences, and (4) use of selective activating and depressing compounds. Each of these techniques was found to be a possible method of achieving selectivity between scheelite, fluorite, and calcite. The use of stereospecific fatty acid or sulfonate collector appears to be a particularly promising method of achieving selectivity between minerals of the slightly soluble class. Research done under contract J0199162 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Office of Assistant Director—Minerals and Materials Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–218412; paper copy price code A03.

OFR 109–83. Incorporation of Fire Extinguishing Agents in High Expansion Foam, by S. S. Gross. July 1982. 34 pp. 9 figs. A program was conducted to determine whether sufficient quantities of the flame retardant, ammonium phosphate, could be incorporated in a water-based foam solution to prevent or delay reignition (burnback) without significant degradation of foam properties. Up to 20% of monoammonium and diammonium phosphate was added to a high-expansion foam solution. This mixture was applied to burning wood and coal samples. The effect of the mixture on burnback was laboratory tested by placing the wood or coal sample in front of a radiant panel. It was found that diammonium phosphate levels of 20 wt-pct prevented reignition without degrading foam properties. A field test was then conducted using a 20% diammonium phosphate mixture and a control with no phosphate on a wood crib fire. The experimental foam did extinguish the crib fire faster than the control as evidenced by the smoke from the crib; however, neither crib reignited. Research done under contract H0308064 by MSA Research Corp. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–218859; paper copy price code A03.

OFR 110–83. Personal Equipment for Low Seam Coal Miners: VIII. Improved Traction Rubber Boot Soles, by Mark S. Sanders and Jacqueline V. Downing. October 1982. 26 pp. 3 figs. Based on laboratory and preliminary field tests of off-the-shelf steel-toed rubber boots, a molded sole design was developed to provide increased traction over conventional calendared sole miners' boots. The pattern provided sharp edges perpendicular to both lateral and fore-aft slip vectors. The sole was designed to reduce mud caking. An instep lace-up capability was added to better secure the foot inside the boot. A 5-month field evaluation compared the prototype boots to the boots the participants usually wear. Although objective slip and fall data showed no significant advantage for the prototype, subjective evaluations made by the participants indicated increased traction for the prototype boots. Approximately 75 percent preferred the prototype to their own boots. Approximately one-third used the lace-up capability. It was concluded that molded soles provide better traction than calendared soles for the underground mining environment. Research done under contract J0387213 by the Canyon Research Group, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-218594; paper copy price code A03.

OFR 111–83. Development of a Prototype Retrofit Noise Control Treatment for Jumbo Drills, by Nicholas R. Dixon and Matthew N. Rubin. July 1982. 106 pp. 70 figs. The noise and vibration levels of four jumbo drills were characterized and a survey of percussive rock drill usage is reported. A Gardner-Denver DH 123 drill was chosen as a demonstration drill, and extensive noise diagnostic studies were performed. Noise control treatments were designed, developed, and evaluated in a reverberant drill test facility. The treatments consisted of an integral enclosure-muffler for the drifter, vibration isolation of the drifter from the enclosure and feed, and a drill steel sheath. A 19-dbA reduction in overall sound power level was achieved with no loss in drilling rate. The prototype retrofit treatments were field tested in an aboveground mine and in a production section of an underground zinc mine. Long-term durability and operator acceptance of the enclosure-muffler treatment were excellent. Preliminary evaluation of the drill steel sheath was encouraging, although additional testing is required. Research done under contract H0387006 by Bolt Beranek and Newman Inc. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-218800; paper copy price code A06.

OFR 112–83. Dust Control on Active Tailings Ponds, by Russel R. Bohn and Jeffrey D. Johnson. February 1983. 124 pp. 42 figs. The objectives of this study were to (1) determine the state of the art for the control effectiveness of various chemical dust suppressants, (2) field test the effectiveness of the dust suppressants, and (3) develop technical guidelines for selecting and implementing cost-effective tailings pond dust control programs. Chemical stabilizers evaluated under field conditions were Coherex, calcium lignosulfonate, Nalco 656 and 655, and magnesium chloride. Testing in the field utilized a portable field in situ wind tunnel. The wind tunnel was placed on the tailings surface, and simulated wind speeds up to 80 mph were used to determine wind erosion threshold velocities. Emission rate testing was performed with the wind tunnel through the use of a real-time cascade impactor. A control cost-effectiveness evaluation was performed to determine how efficient the chemical stabilizers were on a dollars expended per acre basis. Research done under contract J0218024 by Environmental Services & Technology. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT,

and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-216382; paper copy price code A06.

OFR 113-83. Improving Check Curtains, Line Curtains and Extensible Face Ventilation Systems, by T. Muldoon, P. Bartlett, and W. Schroeder. November 1982. 112 pp. 56 figs. A fieldworthy 10-ft extensible brattice to maintain a 10-ft setback was found in use in two mines on continuous miner faces. The technique was evaluated in the laboratory for leakage and methane control at the face. Significant results include the following: (1) Air leakage through a gap in the extensible curtain depends upon the ratio of the cross-sectional areas between entry and return as well as gap area, (2) gap shape has no significant effect on methane concentrations at the face—increasing gap area diminishes ventilation effectiveness, and (3) substantial reductions of CH_4 concentrations at the face were accomplished by brattice extensions with gaps up to 5 ft^2 in area. An inby hook, inserted in the roof automatically to make possible the deployment of a longer brattice extension in the context of a remotely controlled miner, was tested in various roof types. Insertion of this design succeeded only in coal. Research done under contract J0100075 by Foster-Miller, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interor, Washngton, DC. Order ONLY from NTIS: PB 83-216242; paper copy price code A10.

OFR 114-83. Development of a Slurry Filling System for Modified In Situ Oil Shale Mining, by E. A. Ziemba, G. H. Watson, P. H. Bissery, D. L. Namy, P. Pfister, and R. L. Griffis. March 1982. 190 pp. 74 figs. The modified in situ process is one of the methods being considered for extracting oil from oil shale. One of the questions to be answered for this approach is the environmental consequence of underground retort abandonment. This report outlines a study that addresses the question in terms of a grouting solution. The report covers the development of a spent shale-ash-based grout that will fulfill the environmental requirements in terms of strength, stability, and impermeability. In addition, the grout will allow the reinjection of up to 50 percent of material mined and surface retorted as part of the process. Research done under contract J0295046 by Rio Blanco Oil Shale Co. and Soletanche & Rodio, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Office of Assistant Director—Mining, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-216374; paper copy price code A09.

OFR 115(1)-83. Development of an Improved Man Transit Vehicle. Volume 1. Prototype Demonstration Vehicle, by Bruce Pinkston and William F. Hahn. January 1981. 81 pp. 17 figs. This report presents a description of a prototype demonstration vehicle that was constructed to assess the feasibility of a set of equipment-related guidelines. State-of-the-art improvements were embodied in such areas as collision survivability, occupant comfort, and multiple-mode operation. The electric battery-powered vehicle carries a 12-person section crew at speeds up to 12 mph. The description of the demonstration vehicle is presented in volume 1. Research done under contract J0366003 by Booz, Allen & Hamilton Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-218156; paper copy price code A05.

OFR 115(2)-83. Development of an Improved Man Transit Vehicle. Volume 2. Safety Guidelines, by Bruce Pinkston and William F. Hahn. January 1981. 124 pp. This report presents a description of a prototype demonstration vehicle that was constructed to assess the feasibility of a set of equipment-related guidelines. State-of-the-art improvements are embodied in such areas as collision survivability, occupant comfort, and multiple-mode operation. The electric battery-powered vehicle carries a 12-person section crew at speeds up to 12 mph. Safety guidelines are presented in volume 2. Research done under contract J0366003 by Booz, Allen & Hamilton Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-218164; paper copy price code A06.

OFR 116-83. Management and Supervisory Training: Review and Annotated Bibliography, by Joseph A. Olmstead and Devah R. Galloway. June 1980. 83 pp. Literature concerned with management and supervisory training was reviewed and analyzed from the perspective of relative effectiveness of various training methods for improving knowledge and awareness, changing attitudes, improving problem-solving skills, improving interpersonal skills, and improving on-the-job performance. Conclusions were drawn relative to each method and the current state of the field of management and leadership training. A 168-item annotated bibliography is presented. Research done under contract J0188053 by the Human Resources Research Organization. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: AD-A102589; paper copy price code A05.

OFR 117–83. Portable Dynamic Brake Testing Apparatus for Mobile Underground Mine Equipment, by Martin Smirlock and Mark Tanquary. December 1981. 166 pp. 40 figs. A novel instrumentation system was developed that enables simple, quick, and accurate measurement of vehicular dynamics within low-speed ranges. The system, consisting of a microwave transceiver and microprocessor data acquisition and reduction system, measures the deceleration dynamics of low-speed mining and construction equipment. It makes the basic measurement; calculates key parameters such as average deceleration, initial velocity, stopping distance, and brake system delay time; and produces autoscaled graphs of velocity, acceleration, and displacement versus time. Research done under contract H0308033 by Foster-Miller Associates, Inc. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-218511; paper copy price code A08.

OFR 118–83. Automated Cableless Face Haulage Vehicle, by T. M. Heinrich. Aug. 27, 1979. 108 pp. 34 figs. An automated haulage system is described that utilizes existing battery-powered face haulage vehicles modified such that they follow a guidepath defined by an electrically excited wire fixed to the mine roof. Rerouting of the haulage paths is accomplished by simply reconnecting the guidewires. The development of the system was carried out through a design phase, and the impact on safety, productivity, and cost effectiveness was studied. Research done under contract H0155103 by Westinghouse Electric Corp. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-220988; paper copy price code A06.

OFR 119–83. Driver Alertness Monitoring System for Large Haulage Vehicles, by Slade F. Hulbert, Robert J. Dompe, and James L. Eirls. November 1982. 120 pp. 11 figs. A driving simulator for large haulage vehicles (100+ tons capacity) was designed and assembled to conduct experiments leading to the definition of prototype driver alertness monitoring and driver warning systems for installation on-board operating vehicles for in-mine tests and evaluation. The truck-mounted system would monitor driver performance and physical condition-behavior to determine onset of unalertness that could lead to an accident. The report describes the large truck simulator, tests using the simulator on driver subjects, and the specifications for on-board driver alertness monitoring and driver warning system for in-mine testing. Research done under contract H0282006 by Tracor MBA. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-220640; paper copy price code A06.

OFR 120–83. Mine Hoist Operator Training and Information Processing Workload, by Richard Rosenblatt, Paul Loustaunau, and Devah Galloway. August 1982. 97 pp. 2 figs. This report describes a training program for mine hoist operators and a human factors study on the possibility of an information processing overload in mine hoist operators. The first effort addresses formalizing and accelerating the process of hoist operator training. This was achieved through the collection of task data, development of training objectives, specifications of controlled training exercises, and development of requisite training materials. Validation results are presented. The second effort, addressing hoist operator overload, investigated the potential overload of the hoist operator's abilities to process information and control the hoist. Data were gathered in the field during periods when the probability of operator overload was greatest. The data were analyzed and the conclusions drawn therefrom are presented. Research done under contract H0387003 by the Human Resources Research Organization. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-220434; paper copy price code A05.

OFR 121–83. Alumina Extraction From Anthracite Culm With Energy Recovery, by Robert P. Apa, Earl S. Grimmett, F. Ralph Keller, and John N. McFee. Sept. 21, 1982. 86 pp. 14 figs. The objective of this program was to develop a process to recover alumina and energy from northeastern Pennsylvania anthracite culm. The program located culm banks of sufficient size and quality to support a commercial plant. The method of using a fluidized bed to process the ore for alumina and energy recovery was demonstrated to be technically feasible. The fluidized bed can tolerate large fluctuations in both carbon and ash contents without affecting alumina recoverability. Based on the tests, a conceptual design was prepared and is included in this report. Based upon 1982 values for alumina and electricity, a facility of this magnitude has a marginal economic return. Increases in either the market value of alumina or the sale price of electricity may provide economic justification for the construction of such a facility in the near future. Research done under contract J0215022 by Energy Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Avondale, MD, Twin Cities, MN, Reno, NV, Rolla, MO, Albany, OR, and Salt Lake City, UT; U.S. Department of Energy, Pittsburgh, PA; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-220897; paper copy price code A05.

OFR 122–83. Novel Cab Design Concepts To Improve Large Haulage Vehicle Safety, by Glenn E. Adkins, John L. Dahle, and Lawrence Owens. November 1982. 152 pp. 47 figs. The objective of this work

is to improve the safety potential associated with off-highway haulage truck operations. The report describes the development and evaluation of seven novel cab location concepts for large off-highway haulage trucks. A preliminary design of a completely novel truck configuration is also described. An analysis of 1978–79 haulage truck accidents as well as the fundamental parameters of haulage truck design, operation, and selection are presented. Research done under contract J0295013 by Woodward Associates, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA; Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-221085; paper copy price code A08.

OFR 123–83. Design of an Extended Bumper for Mine Haulage Trucks, by John L. Dahle, Lawrence Owens, and Glenn E. Adkins. May 15, 1981. 88 pp. 40 figs. This report presents extended bumper designs for 170-ton rear-dump haulage trucks used in the mining industry. The extended bumper designs are to provide operator protection in the event of rear-end collisions between two trucks. The bumper designs are a result of studying critical truck characteristics important in rear-end collisions and haulage truck accident data, as well as the dynamics of a collision. In addition, existing extended bumper designs were analyzed and evaluated. Research done under contract J0215003 by Woodward Associates, Inc. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-221515; paper copy price code A05.

OFR 124–83. Fatalities in Small Underground Coal Mines, by National Academy of Sciences. May 1983. 20 pp. 2 figs. The National Academy of Sciences, in a prior report "Toward Safer Underground Coal Mines," identified a strong correlation between mine size and fatality rate. That work showed that the fatality rate in mines with fewer than 50 employees was nearly three times that of large mines (those who employ over 250 employees). The current report determines why small mines have a higher fatality rate. The high rate is contributed to several factors that include (1) the intermittent mode of small mine operation, (2) insufficient financial resources, and (3) inadequacies in the training of workers and managers. It was also determined that 85 pct of all small mines are concentrated in Virginia, West Virginia, and Kentucky. It is recommended that the governments of these three States should provide assistance to small mine operators in the form of advice on safety. Research done under contract J0100145. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 125(1)–83. Technological Innovation in the Copper Industry. Volume I. Methodology, by Alfred Weiss, Nicholas Themelis, and Nellie Guernsey. March 1983. 58 pp. 7 figs. The objective of this report was to develop and apply a methodology to quantitatively assess the probability and potential benefits of technological innovation over the next 25 years to solve copper industry problems in the United States. Volume I describes the methodology procedures used to survey the opinions of experts, analyze the findings, and prepare the report. Research done under contract J0100063 by Mineral Systems Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-227066; paper copy price code A04.

OFR 125(2)–83. Technological Innovation in the Copper Industry. Volume II. Technology Forecast, by Alfred Weiss, Nicholas Themelis, and Nellie Guernsey. March 1983. 137 pp. 29 figs. The objective of this report was to develop and apply a methodology to quantitatively assess the probability and potential benefits of technological innovation over the next 25 years to solve copper industry problems in the United States. Volume II presents the consensus technology forecast of the experts surveyed in the study. Research done under contract J0100063 by Mineral Systems Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-227074; paper copy price code A07.

OFR 125(3)–83. Technological Innovation in the Copper Industry. Volume III. Cost/Benefit Analysis, by Alfred Weiss, Nicholas Themelis, and Nellie Guernsey. March 1983. 91 pp. The objective of this report was to develop and apply a methodology to quantitatively assess the probability and potential benefits of technological innovation over the next 25 years to solve copper industry problems in the United States. Volume III provides estimates of the net present value cost effectiveness of each technology assessed under both optimistic and pessimistic scenarios. Research done under contract J0100063 by Mineral Systems Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-227082; paper copy price code A05.

OFR 126–83. Propagation of EM Signals in Underground Metal/Non-Metal Mines, by Terry S. Cory and Richard J. Mahany. Aug. 20, 1981. 266 pp. 142 figs. This report describes the results of a measurement and analysis program to characterize wireless radio transmission in metal-nonmetal mines over a wide frequency range from 0.2 to 1,000 MHz and over a variety of mine environments. Six

mines were chosen based on the relative economic significance of their product to the U.S. economy. Mine types include oil shale, uranium, potash, lead-zinc, copper, and silver. Particular mines were chosen to embody the most important mining techniques of the group. The results show that transmission at medium frequencies are optimum for wireless mine communications, agree with extensive testing previously performed in coal mines, and that minewide wireless systems are feasible with a minimum requirement for new dedicated wiring. Research done under contract J0308012 by Terry S. Cory. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-234666; paper copy price code A12.

OFR 127–83. Evaluation and Acceptance Criteria for Innovations in Explosionproof Electrical Enclosures, by R. J. Gunderman. March 1982. 141 pp. 25 figs. A conventional trailing cable connection box on a continuous mining machine was modified by the addition of two innovative devices: A pressure vent to preclude buildup of high pressure caused by an explosion inside the enclosure and a grommet-type cable entry to simplify and speedup cable entering procedures. The devices were evaluated for 8½ months in a working section of an underground coal mine. Laboratory tests before and after the in-mine exposure show no measurable change in the devices. Following the favorable in-mine evaluation, technical performance criteria were defined to serve as the basis of approval for the use of the devices. Additional tests to measure comparable gripping of the cable by asbestos rope, substitution rope materials, and by the urethane grommet-type entry were included. Also, literature covering the last 80 years was searched. Comments are provided as to how the devices comply with 30 CFR Part 18. Research done under contract H0357107 by Jeffrey Mining Machinery Div., Dresser Industries, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-233379; paper copy price code A07.

OFR 128–83. Investigation of the Mechanics of Mine Acid Formation in Underground Coal Mine Drainage, by Fraser M. Walsh. July 1982. 69 pp. 3 figs. The objective of this program was to determine by laboratory experiments the kinetics and mechanics of the reactions that produce acid in coal mine drainage. The program was divided into three phases: In phase I, five coal mines, representative of Appalachian coal mines, were chosen for sampling and an experimental design was identified suited to accomplish the program objectives. In phase II, the five mines were sampled and test protocols applied. The results showed most pyrite weathering to be based on oxidation in the presence of water. Iron bacteria, especially *Thiobacillus ferrooxidans*, catalyzed the rate of pyrite weathering by a factor of three. An increase in initial iron concentration in a system that modeled the mine environment acted to inhibit bacterial catalysis of weathering. In phase III, five tailings piles were sampled and the material obtained was used to evaluate this method of bacterial catalysis inhibition. The evaluation verified method effectiveness; inhibition over 80% of the release of weathering was observed. Research done under contract J0387215 by ECO, Div. of KOR, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-233387; paper copy price code A04.

OFR 129–83. Assessment of a 40-Kilowatt Stirling Engine for Underground Mining Applications, by James E. Cairelli, Gary G. Kelm, and Jack G. Slaby. June 1982. 75 pp. 54 figs. The National Aeronautics and Space Administration (NASA) Lewis Research Center performed an assessment of alternative power sources for the Bureau of Mines. As part of this assessment, NASA tested a 40-kW Stirling research engine to evaluate its performance and emission characteristics when operated with helium working gas and diesel fuel. This report describes the engine, the test facility, and the test procedures. Performance and emission data for the engine operating with helium working gas and diesel fuel are reported and compared with data obtained with hydrogen working gas and unleaded gasoline fuel. Helium-diesel test results are compared with the characteristics of current diesel engines and other Stirling engines. External surface temperature data are also presented. Emission and temperature results are compared with Federal requirements for diesel underground mine engines. The durability potential of Stirling engines is discussed on the basis of the experience gained during the engine tests. Research done under contract J0100026 by NASA Lewis Research Center. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: N82-30714; paper copy price code A04.

OFR 130–83. Effects of Engineering Parameters on the Control of Respirable Dust, by R. L. Rankin, S. J. Rodgers, and E. V. Polite. November 1982. 49 pp. 4 figs. Field studies were conducted on eight continuous miner sections and two longwall sections operating in five different coal seams. Data and information on dust concentrations and engineering dust controls were acquired for normal operations. Dust concentrations at the mine operator and longwall face locations were evaluated using gravimetric samplers and instantaneous dust monitors. Engineering dust controls that were evaluated included airflow rates and/or velocities, waterflow rates and/or pressures, brattice distances, and face cutting times or rates. An analysis of the data acquired during the field studies was performed using multiple regression methods. Several relationships describing the influence of dust control parameters upon dust levels of mining equipment operators are

presented. The effects of engineering dust controls upon miner operator dust concentration may be expected to be different from mine to mine and sometimes from section to section. A consistent relationship between the dust concentration variations and dust control variations was not observed. Research done under contract J0387226 by MSA Research Corp. Div., Mine Safety Appliances Co. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-232207; paper copy price code A04.

OFR 131–83. Safety and Health in Underground Mine Waste Disposal, by J. P. Schmid, M. R. Schmidt, G. J. Colaizzi, and R. H. Whaite. December 1982. 221 pp. 23 figs. Results of a comprehensive investigation of the impact of underground mine waste disposal on the health and safety of miners are presented. Information was gathered through an extensive search of U.S. and foreign literature and personal communication with professionals in private industry and government. All conceivable health and safety hazards directly or indirectly related to underground mine waste disposal are analyzed, categorized, and ranked on an industry-wide basis. Positive health and safety effects are analyzed and ranked in a similar way. Both potential and known hazards and positive impacts are included. Recommendations on abatement techniques for the various hazards are presented. Case histories of a fill-related accident in a metal mine and a health hazard associated with coal waste backfilling are included and causes and possible abatement procedures are discussed. The role of management in the promotion of health and safety in backfilling operations is discussed. Research done under contract H0218021 by Goodson & Associates, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-232140; paper copy price code A10.

OFR 132–83. Direct Smelting of Lead Sulfide, by Y. K. Rao. June 1983. 94 pp. 53 figs. The extraction of lead from lead sulfide by a direct-smelting process that is free of sulfur oxide emissions was investigated. The process involved reducing lead sulfide with carbon in the presence of limestone. Under the conditions employed, limestone dissociates readily into lime and carbon dioxide. The limestone is the active desulfurizing agent that fixes the sulfur in the charge by forming CaS residue. The investigation focused on the measurement of reduction kinetics in the temperature range of 768° to 1,026° C. The reduction of PbS in the presence of lime using CO-CO_2-N_2 gas reductant was also studied. The kinetics of both the catalyzed and uncatalyzed reduction processes were investigated. The catalyst used is an equimolar ternary eutectic $(K,Na,Li)_2CO_3$ that has a relatively low melting point of 397° C. Research done under contract J0205011 by the University of Washington. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities. MN. Rolla. MO. Reno. NV. Albanv. OR. Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 133–83. Development of Environmentally Attractive Leachants. Volume I, A Minitest for In Situ Uranium Leaching, by Robert S. Schechter, Larry W. Lake, and Muhammad I. Kabir. Jan. 31, 1983. 314 pp. 80 figs. This report describes a minitest consisting of a central injection production well surrounded by at least two observation wells designed to detect the arrival of injected fluid, leached minerals, and nonideal flow. The goals of the test are to determine the susceptability of the host formation for uranium leaching, to establish important kinetic parameters so that the results of the minitest can be used to correctly scale the process, and to identify those factors that may render site restoration difficult. The report considers nonidealities such as reservoir permeability heterogeneities, nonuniform mineral distribution, and minerals other than uranium that may react with the leach solution. To circumvent these difficulties, methods of interpretation were proposed and tested by analysis of realistic data generated by a computer simulator. Clear-cut methods of interpretation were not found in the more complex cases, but in every case the design of an optimum test was considered and recommendations made. Research done under contract H0282016 by the University of Texas at Austin. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-234497; paper copy price code A14.

OFR 134–83. Mine Waste Location by Satellite Imagery, by Michael A. Anuta and Om P. Bahethi. December 1982. 100 pp. 19 figs. This report describes the potential for utilization of satellite observations for remote sensing of mine waste disposal areas. Four study sites consisting of metal and nonmetal mining areas in different climatic and physiographic regions of the contiguous United States were used in the investigation. The mine waste disposal sites consisted of mining of phosphates in Florida, copper in Arizona, silver in Idaho, and coal in West Virginia. Landsat satellite multispectral scanner observations were used together with aerial photographs, ground surveys, U.S. Geological Survey maps, and other ancillary information. Landsat digital data were categorized using automated supervised classification algorithms and an image analysis system. Detailed descriptions of automated classification techniques employed and the accuracy attained are provided together with the results of manual interpretations. The inventory of areas disturbed for phosphate mining and a change detection investigation for Polk County, FL, were also undertaken during the study. Research done under contract J0208030 by Science Systems and Applications, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin

Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-238519; paper copy price code A05.

OFR 135-83. Critical Parameters for Tailings Embankments, by Gregory B. Baecher, W. Allen Marr, J. S. Lin, and John A. Consla. January 1983. 282 pp. 186 figs. Geotechnical data on copper, uranium, and phosphate tailings from 41 mines were collected and analyzed to empirically establish the variability in strength properties for tailing embankments. These data were analyzed both from geotechnical and statistical perspectives to infer typical strength parameters for slope stability analysis. The results indicate large variability of strength properties both within and among tailings embankments. However, this variability in most cases appears statistically regular and tends toward normal distributions when spatial trends are removed. The implication is that probabilistic techniques can be used to assess the importance of strength property variability for embankment stability and that the assumption of common distributional forms for input to such modeling is appropriate. Research done under contract J0215028 by Baecher, Marr and Associates. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-238394; paper copy price code A13.

OFR 136-83. Technique for Determining Efficiency of Sorbents in Diffusion-Type Samplers, by E. D. Palmes. March 1983. 28 pp. 2 figs. Phase I of this study demonstrated the feasibility of measuring the efficiency and capacity of sorbents in tube samplers for contaminant gases. This was accomplished by measuring concentration at various points along the length of the diffusion path during sampling by removing small aliquots with gas-tight syringes and injecting them into a gas chromatograph. With hexane as the gas and activated charcoal as the sorbent, the procedure was successful. Phase II involved application of the principle to gases of importance in diesel exhaust using a variety of sorbents. High concentrations of the test gas clearly demonstrated the differences in both efficiency and capacity of the sorbent for each of several gases. The chief drawbacks of the system were that efforts to determine more toxic gases at realistic occupational exposure levels or to determine formaldehyde at any level using the flame ionization detector were unsuccessful. It was concluded that, although the method is feasible, oresensitive methods of measuring concentrations of gas in the tube must be developed to make the procedure applicable to regions of chief industrial hygiene interest. Research done under contract J0308072 by the New York University Medical Center. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-236190; paper copy price code A03.

OFR 137-83. A Simulation Model for Predicting the Performance of Vibrating Screens, by Kevin Hennings and Doug Grant. December 1982. 120 pp. 44 figs. Screening efficiency models developed to date rely almost exclusively on empirical formulas based upon large amounts of acquired operating data. A screening model was developed using a combination of empirical coefficients and explicit mathematical expressions that quantify screening phenomena. A series of screening tests was run to supply data for purposes of correlation and empirical coefficient evaluation. The model was implemented as a digital computer program. The validity of the modeling procedure was established by laboratory testing. The results were used to compile an applications handbook that can be used to predict screening performance instead of using the computer program. Research done under contract J0395138 by Allis-Chalmers Corp. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-238386; paper copy price code A06.

OFR 138-83. Removal of Pyrite From Coal by Heap Leaching, by L. M. Cathles and K. J. Breen. June 1983. 287 pp. 34 figs. The feasibility of leaching pyrite from coal heaps is analyzed by adapting a model of the heap-leaching process developed in the copper industry. Parameters in the model are first determined through literature review and direct measurement. The model is then used to predict how coal fragments will leach in reaction kettles containing ferric sulfate solution, in columns through which air is circulated, and in actual heaps. Model parameters are verified and refined by kettle and column experiments. The model is then used to determine the optimum heap size and operating procedures. Eight-foot heaps of ¼-inch coal fragments leach best. The average rate of application of flush solutions should be less than 0.01 gal/ft^2-hr. It should be possible to leach more than 90% of the finely disseminated pyrite from the coal in 9 months, providing the flush solutions are recirculated. Removal of pyrite from coal utilizing such a process is economically attractive. A heap-leaching operation capable of depyritizing 1 million tons of coal per year has a positive net present value at discount rates up to 16% (base case) to 33% (best case). Research done under grants G1115427, G5105007, and G5115007 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Denver, CO, Avondale, MD, Pittsburgh, PA, and Salt Lake City, UT; Office of Assistant Director—Mining Research, and Office of Assistant Director—Mineral Data Analysis, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-238758; paper copy price code A13.

OFR 139-83. Leaching of Bornite With Oxygen and Ferric Chloride as Oxidants, by Ferron A. Olson.

June 11, 1982. 183 pp. 98 figs. Natural bornite (Cu_5FeS_4) leached in ferric chloride or in sulfuric or hydrochloric acid solutions with oxygen showed several differences. In ferric chloride 80% of the copper was leached in two stages. The first was controlled by liquid ferric ion diffusion and chemical surface reaction and required 1 minute for a 30% copper removal. The second was controlled by formation of a surface sulfur layer and then diffusion through the sulfur. With oxygen in sulfuric acid, reaction was slow and only the first stage was studied. Copper removal had an induction period. The bornite structure disappeared at 12% copper removal (also found with ferric chloride) and covellite formed on the surface with a species inside the particles with an X-ray structure similar to $CuFeS_2$ but with Cu_5FeS_4 composition and ferric chloride. Copper removal was controlled by iron dissolution. Surface iron vacancies filled with Cu^+ to give CuS while interior copper dissolution produced Cu_5FeS_4. Preliminary results with oxygen and hydrochloric acid showed 80% copper removal and sulfur as end products. Research done under grant G0284001 by the University of Utah. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, and Albany, OR; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-234997; paper copy price code A09.

OFR 140(1)-83. Development and Fabrication of a Continuous Miner Training System. Volume 1, by C. W. Morris, E. H. Conklin, and F. J. Bick. August 1982. 64 pp. 6 figs. This report describes the major technical activities that were accomplished to produce a comprehensive continuous miner training system (CMTS) for coal industry utilization. The primary product of this program was a continuous miner part-task trainer. It is composed of an interactive computer graphics system combined with the operating controls of a continuous mining machine mounted in a simulated cab. The cab contains an audio system for reproducing continuous miner operational sounds. The trainer is supplemented with a complete set of cognitive materials that provide instruction in the operation, safety, and health of continuous miner operations. A complete summary of the field test and evaluation of the CMTS is provided along with recommendations for further training program refinements, expansions, and utilization. Research done under contract H0377025 by McDonnell Douglas Electronics Co. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 140(2)-83. Development and Fabrication of a Continuous Miner Training System. Volume 2, by C. W. Morris and E. Conklin. August 1982. 79 pp. 18 figs. The continuous miner training system provides classroom materials, training aids, and a continuous miner simulator to provide a short, intensive instruction and skills development program for training or retraining continuous miner operators. The project included refinement of training objectives, revision of training aids, improvements to the simulator, and evaluation of the entire system. This report describes the revised materials and the validation of the training system. Research done under contract H0377025 by McDonnell Douglas Electronics Co. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 141-83. Particle Dispersion in Fine Mineral Flotation, by Maurice C. Fuerstenau. July 1982. 58 pp. 29 figs. Studies on the composition of aluminum hydroxy silicate polymer were undertaken using gel filtration chromatography. Preliminary analysis indicates that 14 to 17 silicon atoms to 1 aluminum atom are contained in the polymer. Optimal pH for formation is between 5.5 and 6.5. Electrokinetic and microflotation studies on pure minerals were undertaken to establish mechanisms of aluminum hydroxy silicate adsorption and to determine the effect that this dispersant exhibits on flotation response. The polymer chemisorbs on chrysocolla, chalcopyrite, and chalcocite but does not interfere with flotation even with relatively large additions. Dispersion of finely divided particles with aluminum hydroxy silicate sol results in improved recovery in copper flotation systems. Copper recovery is increased by 4.9 pct from an oxide ore and 2.1 pct from a sulfide ore in the presence of low additions of aluminum hydroxy silicate sol. Research done under contract J0295077 by the South Dakota School of Mines and Technology. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Avondale, MD, Rolla, MO, Reno, NV, Albany, OR, and Salt Lake City, UT; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-238360; paper copy price code A04.

OFR 142-83. The Impact of Surface Lignite Mining on Surface- and Ground-Water Quality in Texas, by C. C. Mathewson, K. W. Brown, L. E. Deuel, and D. G. Kersey. August 1982. 84 pp. 28 figs. The impact of surface mining of Texas lignites on surface and ground water systems was investigated. Surface water and/or hydrogeologic analysis were conducted at two active and three proposed mines in the Texas lignite belt. Field and laboratory studies measured the infiltration characteristics of surface mined land, determined the quality of surface water runoff, and analyzed the hydrogeologic impacts of surface mining on ground water quality and quantity in resaturated mine spoil. Adverse impacts of surface mining were found to be minimal in deltaic and coastal lagoon lignite deposits, which have shale-rich overburden; disturbances to the hydrologic balance were negligible. Mining of fluvial lignites associated with thick aquifer sands may result in degraded ground water quality and quantity, but long-term impacts are projected to be minimal. Runoff from mined land is similar to that from unmined native soils; both have high suspended loads. Research done under contract J0295016 by Texas A&M University. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-238378; paper copy price code A05.

OFR 143-83. Demonstrating the Noise Control of a Coal Preparation Plant. Volume II: Long Term Treatment Evaluation, by Matthew N. Rubin. June 1982.

91 pp. 56 figs. The purpose of this work was to obtain operational data on retrofit noise control treatments suitable for use in coal preparation plants. These data were obtained by evaluating the performance of four categories of noise control treatments (resilient screen decks, resilient impact pads, chute liners, and curtains) that were installed in a commercial coal preparation plant. The selection, installation, and initial evaluation of the treatments were presented in volume I of the report. Volume II, the present work, summarizes the results of the long-term evaluation of the original treatments, as well as some additional tests that were conducted on elastomer-clad (resilient) screen decks. The project demonstrated the feasibility of a number of retrofit noise control treatments, some of which also proved to be quite durable over the long term. Research done under contract H0155155 by Bolt Beranek and Newman Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-237354; paper copy price code A05.

OFR 144–83. Scaling in Geothermal Systems: Investigations of Geothermal Brines of the Salton Sea Area, by H. L. Barnes, J. D. Rimstidt, D. O. Hayba, and J. B. Murowchick. December 1978. 223 pp. 55 figs. The objective of this research was to develop an understanding of the fundamental processes involved in the formation of geothermal scales. One step toward this understanding involves compiling available data on brine composition and temperatures. Also, chemical and mineralogical analyses of scales that have precipitated from these brines under known and controlled conditions are necessary. To obtain especially documented samples, field tests were developed and performed to simulate the scale-forming processes. Laboratory studies of the thermodynamic and kinetic characteristics of silica-water reactions were carried out. Silica was emphasized because it is the most common, pervasive, and bothersome scale component. The resulting insights into the physical chemistry of the scale-forming processes are presented here together with some of their implications for scale prevention. Research done under grant G0155140 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Avondale, MD, and Reno, NV; Office of Assistant Director—Minerals and Materials Research, Bureau of Mines, Washington, DC; and National Library of Natural Resources, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 145–83. Point Defects in Hydrometallurgical Processes, by G. Simkovich and K. Osseo-Asare. June 1983. 16 pp. 9 figs. This project investigated the effect of point defects on hydrometallurgical processes of mineral dissolution. Samples of NiO, ZnO, α Fe_2O_3, and CuO that were doped with lower and higher valent dopant cations showed significant changes in dissolution rate when compared with that of the pure compound. Doping and stoichiometry control in ZnS, however, have a lesser effect when compared with the specific interaction from copper ions. Research done under grants G1115426, G5105084 and G5195040 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Avondale, MD, Rolla, MO, Reno, NV, and Salt Lake City, UT; Office of Assistant Director—Minerals and Materials Research, Bureau of Mines, Washington, DC; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 146–83. Applications of Image Processing to the Comminution of Fine-Grained Complex Sulfide Ores, by J. R. Craig, R. M. Haralick, and R. H. Yoon. June 1983. 244 pp. 59 figs. This investigation was directed toward a detailed study of the comminution of complex sulfide ores from the Eastern United States. The first part deals with laboratory batch grinding experiments in which several different ore samples are characterized in terms of rate of breakage and breakage distribution functions. Using these parameters, the batch grinding experiments are simulated by the ESTIMILL program. In the second part, both pulverized and uncrushed ore samples are examined using an optical microscope, with the images processed by a computer. A software package named the General Image Processing System (GIPSY) was adapted and expanded to process the optical images and to characterize the ore samples and mill products. Finally, the image analysis data are compiled to determine the degree of liberation of the various minerals present in the complex sulfide ores. Research done under grants G1105052 and G1115513 by the Virginia Polytechnic Institute and State University. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Avondale, MD, Rolla, MO, Reno, NV, Albany, OR, and Salt Lake City, UT; Office of Assistant Director—Minerals and Materials Research, Bureau of Mines, Washington, DC; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 147–83. Development of Chromium-Free Grades of Constructional Alloy Steels, by Carl J. Keith and V. K. Sharma. May 15, 1983. 60 pp. 26 figs. The objective of this research was to develop a new series of cost-effective chromium-free steels. The new steels are intended to be capable of adoption by a broad range of industry as a substitute for the chromium-containing 8600 and 4100 standard grades of heat-treated constructional alloy steels. Based upon several socioeconomic scenarios and their projected impacts on alloying element cost and availability in 1985, a computerized metallurgical design system was used to design two substitute steels for each of the standard grades. Both steels, a manganese-molybdenum substitute and a manganese-nickel-molybdenum substitute, are expected to provide heat-treat response and mechanical properties equivalent to the 8600 and 4100 steels. Small, experimental heats of the chromium-free replacement steels were prepared and their hardenability response and mechanical properties were evaluated and compared with the base-line 8620 steel. Research done under contract J0113104 by the International Harvester Co. Available for reference at Bureau of Mines facilities in Avondale, MD, Rolla, MO, Albany, OR, and Pittsburgh, PA; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-243873; paper copy price code A04.

OFR 148–83. Evaluation of Novel Coal Cutting Concepts for Reduced Dust Generation, by Robert W. Decker. July 1981. 147 pp. 38 figs. This report presents a survey of published novel cutting (mining) concepts along with a brief discussion of each.

A preliminary evaluation follows that identifies promising concepts, emphasizing reduced dust generation and economic production potentials. The promising concepts are then studied more deeply and evaluated in more detail with recommendations given for further development action. Research done under contract J0199065 by Ingersoll-Rand Research, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-243717; paper copy price code A07.

OFR 149–83. Copper Sulfide Flotation in an Air-Sparged Hydrocyclone, by David J. Kinneberg and Jan D. Miller. May 1983. 85 pp. 25 figs. The concentration of a low-grade porphyry ore by froth flotation in a 4.7-cm-diam air-sparged hydrocyclone was investigated. The effects of important design and operating variables on the separation efficiency were examined. The variables included slurry feed rate, airflow rate, pulp density, cell length, wall porosity, and kerosine additions. Several modifications to the basic design of the air-sparged hydrocyclone were also studied. A comparison of performance of the air-sparged hydrocyclone with conventional flotation for this particular ore showed that remarkably short retention times were required to achieve satisfactory separations. Moreover, preliminary data indicated that the recovery of molybdenum and gold with the air-sparged hydrocyclone was comparable with that obtained in a conventional cell. It was concluded that the air-sparged hydrocyclone has the potential to significantly alter conventional copper rougher or scavenger circuits, although additional research will be required before this potential can be realized. Research done under grants G1105049 and G1115492 by the University of Utah. Available for reference at Bureau of Mines facilities in Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, and Salt Lake City, UT; Office of Assistant Director—Minerals and Materials Research, Bureau of Mines, Washington, DC; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-253526; paper copy price code A05.

OFR 150–83. Ground Control in Multi-Level Room and Pillar Mines, by William G. Pariseau. June 1983. 122 pp. 36 figs. This research is concerned with ground control in multiseam mining and relates mainly to the analysis of stress about multiseam room-and-pillar mines. The two variables of most concern are distance between seams and alignment of the pillars between seams. The first efforts of the investigation apply to the development phase of mining when the extraction is typically less than 50%. The second efforts are concentrated on retreat mining and barrier-pillar safety when the extraction is typically greater than 50%. The procedures in both cases are readily applicable to more than two seams. Although two-seam mines are the most frequent type of multiseam operations, because of the potential for three-seam operations in the Western United States, a number of three-seam development analyses are also presented. Research done under grants 1105048 and G1115491 by the University of Utah. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-252965; paper copy price code A06.

OFR 151(1)–83. Development of a Procedure for Land Use Potential Evaluation for Surface-Mined Land. Final Report, by Raja V. Ramani and Richard J. Sweigard. Jan. 31, 1983. 116 pp. 18 figs. Productive and beneficial use of reclaimed surface-mined land is a concern of industry, Government, and the general public. An investigation was conducted on current mined-land practices to aid in the development of a procedure to evaluate postmining land use potential that considers both industry and public approaches. A detailed review of the impact of regulations, factors that determine land use, and current site planning methods employed by the mining industry is included. The investigation included three in-depth case studies of surface mines in the Eastern, Central, and Western United States. A site planning process was developed and applied to the studies to evaluate the economic, environmental, and social impacts of postmining land use alternatives. In addition, guidelines were proposed to enhance the cooperation between local land use planners and surface-mine planners, as well as to improve comprehensive planning with regard to mineral resources at the local and regional levels. Research done under grants G1115428, G5105085, and G5195043 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Denver, CO, Avondale, MD, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-253401; paper copy price code A06.

OFR 151(2)–83. Development of a Procedure for Land Use Potential Evaluation for Surface-Mined Land. Appendix I: Eastern U.S. Surface Mine Case Study, by Raja V. Ramani and Richard J. Sweigard. Jan. 31, 1983. 89 pp. 30 figs. The potential usefulness of reclaimed surface-mined land has received much attention in recent times. This is partially because of the establishment of Federal environmental reclamation standards, but concern for achieving better land uses has also been shown by interested members of the mining industry. In an effort to develop a procedure for evaluating postmining land use potentials, specific mines in various regions of the United States were studied to determine the extent of current mined-land planning and to discover characteristics that are regional in nature. As part of this investigation, a 430-acre surface mine in Clearfield County, PA, was studied. Established site planning principles were applied to the study site including formation of a data base, development of alternate land use plans, and evaluation of the economic, environmental, and social impacts of the land use alternatives. Key factors affecting site realization were identified along with positive suggestions for applying land use planning processes to mined-land planning. Research done

under grants G1115428, G5105085, and G5195043 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Denver, CO, Avondale, MD, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-264325; paper copy price code A05.

OFR 151(3)-83. Development of a Procedure for Land Use Potential Evaluation for Surface-Mined Land. Appendix II: Central U.S. Surface Mine Case Study, by Raja V. Ramani and Richard J. Sweigard. Jan. 31, 1983. 137 pp. 38 figs. In an effort to develop a procedure for evaluating postmining land use potentials, specific mines in various regions of the United States were studied to determine the extent of current mined-land planning and to discover characteristics that are regional in nature. As part of this investigation, the Chinook Mine-West Field, located in western Indiana, was studied. The Chinook Mine is presently operated by AMAX Coal Co. and has been in continuous operation since 1928 under various ownerships. The status of current reclamation and land use planning was reviewed. In addition, site planning principles were applied to the active mine area that include the formation of a data base and development of postmining land use plan alternatives. Key factors affecting site potential realization for Midwestern area mines were identified along with suggestions for applying land use planning processes to mined-land planning. Research done under grants G1115428, G5105085, and G5195043 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Denver, CO, Avondale, MD, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-264333; paper copy price code A07.

OFR 151(4)-83. Development of a Procedure for Land Use Potential Evaluation for Surface-Mined Land. Appendix III: Western U.S. Surface Mine Case Study, by Raja V. Ramani and Richard J. Sweigard. Jan. 31, 1983. 108 pp. 31 figs. In an effort to develop a procedure for evaluating postmining land use potentials, specific mines in various regions of the United States were studied to determine the extent of current mined-land planning and to discover characteristics that are regional in nature. As part of this investigation, the Indian Head Mine, which is located in Mercer County, ND, was studied. The Indian Head Mine is presently operated by American Coal Corp., Western Div., and has been in operation since 1917 under various ownerships. The status of current reclamation and postmining land use planning was reviewed. In addition, the relationship between mine planning and public planning in an area impacted by energy development was investigated. Finally, key factors affecting site potential realization for Western surface mines were identified. Research done under grants G1115428, G5105085, and G5195043 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Denver, CO, Avondale, MD, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-264341; paper copy price code A06.

OFR 152(1)-83. Noise Attenuating Properties of Earmuffs Worn by Miners. Volume 1: Comparison of Earmuff Attenuation as Measured by Psychophysical and Physical Methods, by Kenneth C. Stewart and Ernest J. Burgi. January 1980. 46 pp. 22 figs. This contract was directed toward a study of the attenuating properties of earmuffs as worn by miners. Two attenuation measurement procedures were utilized. Human subjects were tested in a diffuse sound field according to threshold shift procedures recommended by the American National Standards Institute and a physical measurement procedure was accomplished in the same diffuse field on the same subjects with microphones placed simultaneously on the inside and outside of the muffs. All measurements were obtained on 1/3 octave of random noise. The results indicated that physical and psychophysical attenuation measurements are in essential agreement at frequencies from 125 Hz to 2 kHz. Above 2 kHz the psychophysical measurement demonstrates larger amounts of attenuation than the physical measurement. The difference in attenuation ranged from approximately 7.0 to 9.0 dB at frequencies of 4 kHz and above. A possible explanation for the differences in attenuation is presented. Research done under contract J0188018 by the University of Pittsburgh. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-257063; paper copy price code A03.

OFR 152(2)-83. Noise Attenuating Properties of Earmuffs Worn by Miners. Volume 2: Development of a Laboratory Procedure for the Physical Measurement of Earmuff Attenuation, by Kenneth C. Stewart and Ernest J. Burgi. June 1980. 37 pp. 17 figs. The purpose of this study was to develop and evaluate, in the laboratory, instrumentation and procedures that might allow for the use of physical measurements of earmuff attenuation that would yield results equivalent to those obtained from psychophysical measures of attenuation. The ultimate goal was to evaluate techniques that might subsequently prove feasible for physical measurement of earmuff attenuation in the field. Instruments currently in use were modified to have a response similar to differences observed in earmuff attenuation as observed in volume 1 of this report. Mining noise spectra were selected and presented to a single subject seated in a diffuse noise field wearing one of the muffs evaluated in the earlier study and fitted with two physical sound measurement systems. A linear system measured the outside noise level and a linear system plus correction filter measured the inside noise level. The measurement indicated that under the procedures presented in this report, a laboratory method for measuring earmuff attenuation is feasible and yields results comparable with an extensive psychophysical procedure. Research done under contract J0188018 by the University of

Pittsburgh. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-257071; paper copy price code A03.

OFR 153-83. System Study of Mine Rescue Through Electromagnetic Means, by Robert L. Lagace, James M. Dobbie, Gordon Raisbeck, Richard H. Spencer, Mark A. Degatano, Francis J. Lambiase, and N. Albert Moussa. October 1982. 181 pp. 1 fig. This report describes the results of a system study of factors influencing mine rescue attempts based on the use of electromagnetic VF (voice frequency) rescue transmitters by trapped miners and helicopter-borne search receivers by mine rescue personnel. The report covers four areas: (1) mine emergency and disaster considerations that concentrate on characterizing the events and key parameters of mine fires and explosions related to trapped miner location and rescue activities, (2) hardware considerations that concentrate on characterizing the relevant properties of VF rescue transmitters and search receivers; oxygen-type self-rescuers; and helicopter performance, signal detectability, and sensor sweepwidths, (3) a search theory probabilistic model that develops a method to identify the most important regions to be searched and to allocate helicopter-based search efforts to maximize the number of miners detected in time to be rescued, and (4) sensitivity analyses and application of the search model on representative mine emergency and disaster scenarios to assess the impact and effectiveness of helicopter-based searches. Conclusions and recommendations are presented, together with a set of search planning guidelines. Research done under contract J0113043 by Arthur D. Little, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-253393; paper copy price code A09.

OFR 154-83. Validation and Extension of Visibility Requirements Analysis for Underground Mining Equipment, by Mark S. Sanders and Gregory S. Krohn. January 1983. 65 pp. 25 figs. Six underground coal mine shuttle cars were used to assess visibility using visual attention locations (VAL) and an improved human eye reference measurement instrument (HERMI Mark II). Each machine was assessed in the inby and outby directions of travel without a canopy and with a canopy in its highest and lowest positions, enabling the illumination level at each VAL to be determined. The results showed that operator eye position was the most important variable determining visibility. When this variable is controlled, the addition of a canopy has no effect on visibility. Further, with the eye position controlled, there is no difference between high and low seam machines. The assessments showed blind spots on the opposite side of the car from the operator and ahead of the machine. The report includes suggestions to reduce the blind spots and a procedures manual for using HERMI Mark II and the system of VAL to assess visibility from underground mining equipment. Research done under contract J0318072 by the Canyon Research Group, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-252957; paper copy price code A04.

OFR 155-83. Evaluation of the Black River Mine Telecommunication System, by Dana T. Updyke and Howard C. Turnage. February 1983. 104 pp. 7 figs. An evaluation was made of one of several improved underground communication systems sponsored by the U.S. Bureau of Mines. The system was installed in a typical metal-nonmetal, room-and-pillar mine and utilized ultrahigh frequency repeaters connected to a unique distributed antenna and passive reflector system that provided minewide communications. A microprocessor-controlled data collection system was assembled and installed for the evaluation. Data consisting principally of times and durations of messages and identities of the originating transceivers were collected over a 6-month period. Analyses of these data show that the principal benefits are reduction in time required for unscheduled maintenance and repair, enhancement of safety, and better coordination of production activities. A cost benefit analysis shows a net benefit over cost, although it is also concluded that the capacity of the system is greater than can be justified by current activity in the mine. Research done under contract J0318074 by the Atlantic Research Corp. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-257097; paper copy price code A06.

OFR 156-83. Diesel Engines in Underground Mining: A Bibliography With Abstracts, compiled by Robert W. Waytulonis and Wanda J. West. April 1983. 443 pp. 1 fig. This publication contains 1,000 citations of technical and semitechnical literature treating diesel-powered equipment usage underground both generally and specifically. The citations were gathered by Bureau of Mines personnel during 1978-83. The citations concern diesel engines as powerplants for underground mining use; their design, emission characteristics and control, maintenance, and usage; and health and safety aspects. All of the citations have been abstracted and arranged in a subject classification system with extensive cross-referencing. Work done by the Bureau of Mines Twin Cities Research Center. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO,

Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-258608; paper copy price code A19.

OFR 157–83. Use of Surfactants To Improve Oil Recovery, by W. Fred Ramirez. June 1983. 93 pp. 25 figs. The theory of optimal control of distributed parameter systems is presented for determining the best possible injection policies for enhanced oil recovery processes. The optimization criterion is to maximize the amount of oil recovered while minimizing injection costs. Necessary conditions for optimality are obtained through application of the calculus of variations and Pontryagin's Weak Minimum Principle. A gradient method is proposed for the computation of optimal injection policies. Research done under grant G1115081 by the University of Colorado. Available for reference at Bureau of Mines, Avondale, MD; U.S. Department of Energy, Bartlesville, OK; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 158–83. Develop Data for Review of Metal and Nonmetal Mine Methane Hazard Classification, by Alastair M. Lumsden and Richard Talbot. January 1983. 519 pp. 15 figs. A study was initiated to examine the ways in which a number of foreign countries classify and regulate metal and nonmetal mines that experience problems caused by naturally occurring flammable gases. Twenty countries were selected for study and useful information was obtained from 16. Nine countries were visited to hold meetings with representatives of government mine regulatory agencies and mine operators and to visit mines encountering methane, carbon dioxide, nitrogen, etc. Seven gassy metal and nonmetal mines in the United States were visited to provide a basis for comparison, and hence the evaluation of both U.S. and foreign gassy mine regulations. In addition to obtaining copies of the mining laws and regulatons of a number of foreign countries, nine foreign and seven U.S. gassy mines were documented in as much detail as possible. Research done under contract J0100060 by Golder Associates, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-258624; paper copy price code A22.

OFR 159–83. Heat-Pulse Anemometer for Measuring Air Velocities in the Range 0.4 to 7 Ft/Sec. Part I: Development. Part II: Microprocessor-Based Instrument, by G. T. Skinner, M. G. Dunn, and R. J. Hiemenz. May 1982. 110 pp. 39 figs. This report describes the development of a portable low-speed heat-pulse anemometer for underground mine airflow measurements. Part I describes the development of the instrument. Various physical and electrical parameters such as wire diameter, spacing of the probe wires, operating temperature of the pulsed wire, signal processing and system control, ambient thermal properties, and flow alignment were varied in a successful effort to find a method of operating a heat-pulse anemometer over the range of air velocities from 24 to 390 ft/min. Part II describes the implementation of these findings in a personal, self-contained microprocessor-based instrument measuring 6 by 7 by 2½ in, with a sectioned 2-ft wand. Mechanical, aerodynamic, and electronic design details are given, and the software is documented. Research done under contract H0377029 by Calspan Corp. Advanced Technology Center. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-256917; paper copy price code A06.

OFR 160–83. Coal Fines Recovery and Utilization, by Juh W. Chen, Albert C. Kent, and Charles B. Muchmore. May 1983. 134 pp. 33 figs. A process to recover energy from waste coal fines, developed through laboratory, bench, and pilot plant experiments, was investigated. The process consisted of mechanical cleaning followed by high-temperature oil agglomeration and pelletization. The process can produce a quality product under an economically and environmentally acceptable condition. Waste coal fines with ash less than 35% and high-heat value (HHV) greater than 6,000 British thermal units per pound (Btu/lb) were upgraded to a product with less than 15% ash and HHV greater than 11,500 Btu/lb. A computer model was developed to optimize the processing costs and to perform economic evaluation of specific sites. Ultimately, the model can be utilized to establish a priority listing for a region in assisting the determination of reclamation strategy. Research done under grants G1105064, G1115172, and G1195016 by Southern Illinois University. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, and Pittsburgh, PA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 161–83. A Study of Superconducting Separators for Weakly-Magnetic Ores, by M. K. Abdelsalam, R. W. Boom, and R. R. Hughes. June 1, 1983. 200 pp. 100 figs. A high field helical flow slurry separator was constructed to concentrate weakly magnetic ores with a magnetic moment about the value of hematite. The process is to flow the slurry helically around a current-carrying conductor in a cylindrical annulus. The magnetic field gradient forces magnetic particles inwards while nonmagnetic particles are deflected outwards by centrifugal force. Separation occurs at the exit end of the channel by a divider that separates inboard from outboard slurry. The separator performance was studied both theoretically and ex-

perimentally. A universal theoretical model was developed based on turbulent diffusion in cyclones. The model is in good agreement with experimental data. Research done under grant G0177066 by the University of Wisconsin—Madison. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, and Salt Lake City, UT; Office of Assistant Director—Minerals and Materials Research Bureau of Mines, Washington, DC; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 162(1)–83. Mining in Low Coal. Volume I: Biomechanics and Work Physiology, by M. M. Ayoub, N. J. Bethea, M. Bobo, C. L. Burford, D. K. Caddel, K. Intaranont, S. Morrissey, and J. L. Selan. November 1981. 175 pp. 69 figs. The objectives of this research were (1) to evaluate the job demands associated with low coal mining; (2) to survey the anthropometry, strength, and aerobic capacity of low coal miners to determine if they differ from the U.S. population; and (3) to recommend, on the basis of available information, optimal job and work station design for low coal mining. The male and female anthropometry, except for weight and circumferential dimensions, was quite similar to the comparison populations. Back strength for male and female miners was significantly lower than the industrial worker population. This can be one of the contributing factors of low back problems in mining. Shoveling, timbering, and helpers tasks were physiologically demanding activities. However, because of the frequent stoppage of work, adequate rest was usually available. If work stoppage is corrected, then better work and rest schedules are essential. Research done under contract H0387022 by Texas Tech University. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–258160; paper copy price code A08.

OFR 162(2)–83. Mining in Low Coal. Volume II: Anthropometry, by M. M. Ayoub, N. J. Bethea, M. Bobo, C. L. Burford, D. K. Caddel, K. Intaranont, S. Morrissey, and J. L. Selan. Jan. 15, 1982. 123 pp. 54 figs. This report covers the anthropometric study of low coal miners. The male and female anthropometry, except for weight and circumferential dimensions, was quite similar to the comparison populations. The miners tended to be heavier and have greater circumferences. The measurements made in this study were used to develop 5th, 50th, and 95th percentile, quarter- and half-scale, male and female mannequins. The mannequins can be used in workplace and equipment design and redesign. Research done under contract H0387022 by Texas Tech University. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–258178; paper copy price code A06.

OFR 162(3)–83. Mining in Low Coal. Volume III: Clothing Design Study, by D. K. Caddel, J. L. Selan, J. L. Smith, and M. M. Ayoub. Jan. 15, 1982. 75 pp. 48 figs. Several problems exist with the present design of coveralls used by low coal miners. The back of the coveralls often tears when roof bolts or rough areas in the roof are hit. Movement in the shoulder area is restricted. Female low coal miners find it difficult to purchase coveralls that fit properly and must remove both their hard hat and safety belt to urinate and defecate. The objective of this research was to design coveralls that would alleviate these problems. The following features were incorporated into the coveralls: padding in the back, an action pleat in the shoulders, an inseam zipper to more easily allow miners to perform their bodily functions, and reflective tape to increase visibility of the miner. A heavy denim fabric was used to increase warmth and durability. The coveralls were assessed for comfort, safety, worker productivity, and fabric suitability using both an infield assessment by miners and simulation studies. The experimental coveralls proved superior to standard coveralls along all four parameters. Work clothing sizes for female miners were developed. Research done under contract H0387022 by Texas Tech University. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–258186; paper copy price code A05.

OFR 163–83. Proceedings of the Sixth WVU Conference on Coal Mine Electrotechnology, ed. by Wils L. Cooley. July 1982. 428 pp. 170 figs. This report is a compilation of papers presented at the 6th West Virginia University Conference on Coal Mine Electrotechnology in Morgantown, WV, on July 28–30, 1982. The papers cover areas of power systems, communications, safety systems, automation and control, safety devices and instrumentation, and monitoring systems. Report prepared under contract J0123017 by West Virginia University. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–255984; paper copy price code A19.

OFR 164–83. Evaluation of Bulkheads for Radon Control, by Clifford H. Summers, Donald B. Lindsay, Richard S. Lindstrom, and Kenneth L. Alder. July 1982. 88 pp. 19 figs. The objective of this task was to investigate the availability and suitability of some novel materials and methods of

construction for air-restraining bulkheads for use in confining radon-rich air in unused sections of underground uranium mines. Two preferred systems of bulkhead construction were proposed, based on a search of commercially available materials, and were successfully tested in an operating commercial mine in LaSal, UT. Both systems were found to be generally satisfactory under the conditions of the 5-month-long test. As an auxiliary aid to prevent leakage of radon-polluted air from the bulkhead area, a servocontrolled exhaust system was designed to maintain a favorable atmospheric-pressure gradient relative to the rest of the mine. A radon-scavenging system, based on adsorption on activated charcoal, was also designed and successfully tested for use in connection with the pressure-balancing exhaust unit. Research done under contract H0212003 by Arthur D. Little, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-256503; paper copy price code A05.

OFR 165-83. Development of a Nondestructive Test Device for Friction Rock Supports, by R. Lusignea, J. Felleman, and K. Kirby. February 1983. 135 pp. 58 figs. A device was developed for nondestructive testing of the holding power of split-tube friction rock supports. The device operates by measuring the amount of decrease in internal volume when the support is forced into the drilled hole. The pullout force, or slip load, is a function of the decrease in volume. The device gives readouts of the average internal diameter and predicted pullout force for the support. Laboratory and field tests showed excellent repeatability and good correlation between predicted and actual pullout force. The device is hand-operated, lightweight, and can be used on any friction support. Research done under contract H0202030 by Foster-Miller, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-257519; paper copy price code A07.

OFR 166-83. Assessment of Alternative Power Sources for Mobile Mining Machinery, by James E. Cairelli, William A. Tomazic, David G. Evans, and John L. Klann. December 1981. 109 pp. 60 figs. The National Aeronautics and Space Administration Lewis Research Center, under an agreement with the Bureau of Mines, performed an assessment of alternative power sources for mining applications, primarily mobile underground equipment. Each alternative power source was assessed in terms of (1) ability to achieve the duty cycle, (2) ability to meet Government regulations, (3) production readiness, (4) market availability, and (5) packaging capability, which were established as a first step in the assessment. An initial screening reduced possible alternative power sources, that were evaluated in more detail, to (1) improved diesel, (2) Stirling, (3) gas turbine, (4) Rankine, (5) advanced electric, (6) mechanical energy storage, and (7) use of hydrogen evolved from metal hydrides. The alternative power sources were divided into two categories, heat engines and energy storage systems, because heat engines are basically limited by emissions and energy storage systems are limited by energy storage density. Each alternative power source is described briefly, including its current development status, specific problem areas, and possible future improvements. Each is then evaluated against the requirements initially established. Research and development efforts for each alternative power source are discussed and evaluated in terms of potential. Research done under contract J0100026. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: N83-14691; paper copy price code A06.

OFR 167-83. Field Demonstration of Deep-Penetrating Geophysical Techniques, by S. A. Suhler and T. E. Owen. January 1983. 68 pp. 27 figs. Field tests were conducted to demonstrate the performance of an advanced development model borehole directional radar probe in coal measure rocks. Preliminary test site evaluations at five candidate coal mines were performed to determine the electromagnetic propagation parameters of the coal seams and to inspect available geologic mine hazards such as paleochannel sand cutouts, faults, and weak roof conditions as potential radar test targets. The York Canyon Mine near Raton, NM, was selected as the demonstration site. Surface-operated tests in vertical boreholes as well as in-mine tests in horizontal boreholes were conducted using the radar probe, resulting in the detection of a near-vertical seam displacing fault. Other electromagnetic tests using separate source and receiving probes in vertical boreholes as well as in through-transmission tests in underground coal pillars provided useful data on the electromagnetic parameters of the coal and large-scale geologic structures. One series of transmission tests was successful in coupling across the fault-displaced coal seam. All of the tests utilized pulsed electromagnetic signals in the 30- to 300-frequency range. Research done under contract H0212018 by the Southwest Research Institute. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; U.S. Department of Energy, Pittsburgh, PA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-256222; paper copy price code A04.

OFR 168-83. Recommended Acceptance Criteria for Potting Materials Used in Explosion Proof Enclosures in Coal Mines, by W. R. Herrera, R. E. White,

L. M. Adams, and H. S. Silvus. March 1982. 100 pp. 17 figs. Research was conducted to develop methodology for evaluating candidate potting materials intended for use in explosion-proof enclosures. The primary purpose was to develop acceptance guidelines based on arc decomposition products. Acceptance criteria can be based on (1) inherent thermochemophysical, mechanical, and electrical properties; (2) arc decomposition products (nature of volatile products produced; e.g., flammability, explosivity, synergistic effects on existing environment in the enclosure, and toxicity; and quantity produced as a function of arc power and duration); and (3) acceleration aging tests to evaluate breakdown under electrical stress. Research done under contract J0100041 by the Southwest Research Institute. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-254722; paper copy price code A05.

OFR 169-83. Low Glare Luminaire for Thin Seam Mining, by John R. Parker and William F. Hahn. October 1982. 102 pp. 42 figs. Work places of an underground coal mine are required (30 CFR 1719) to be illuminated while self-propelled equipment is used. Permissible machine-mounted systems have been developed and applied satisfactorily to many mining operations. However, some low- and thin-seam equipment has been difficult to illuminate because reliable, direct current (dc) systems and compact, low output, low-glare luminaires were not available. This program resulted in the design and prototype construction of compact, low-glare luminaires and alternate current (ac) power systems, particularly suited to resolving illumination problems on low- and thin-seam mining equipment. Design objectives were based on enhancing the prospects for thin-seam illumination solutions through definition of a product that could challenge markets enjoyed by higher glare luminaires and through reduction of technical risks associated with any new product development as well as the MSHA certification process. Research done under contract J0188077 by Booz, Allen & Hamilton, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-257246; paper copy price code A06.

OFR 170-83. Cost-Effectiveness of Increasing Airflow at Any Location in Underground Coal Mines (Volume I), by Sandip K. Mukherjee, Anthony W. Laurito, M. O. Rahim, and Madan M. Singh. February 1983. 113 pp. 16 figs. This report presents the results of the economic analyses of several applicable alternatives to increase airflow in four underground coal mines. Pressure and quantity surveys were conducted underground, and measurements were made at the main mine fans. The existing ventilation networks were modeled using a modified ventilation simulator, and the applicable alternatives were simulated. Performance data obtained from the simulation runs were utilized to conduct the cost-effectiveness analyses. The costs for each of the alternatives included capital, operating, and maintenance. These costs were expressed as annual ventilation costs per active section in terms of dollars per cubic foot per minute, taking into account the economic life associated with each of the alternatives. The benefits were expressed as increased airflow quantity in the critical sections. A section of the report also deals with comparison of simulator-predicted air quantity values against air quantity values measured underground. Research done under contract J0100066 by Engineers International, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-257105; paper copy price code A06.

OFR 171-83. Noise Reduction of Chain Conveyors. Volume II, by A. Galaitsis, R. Madden, and D. Andersen. February 1983. 63 pp. 26 figs. This report briefly reviews the aboveground tests performed on a Jeffrey 120M conveyor that were documented in volume I of this study, and describes the performance of treatments implemented on underground equipment. The noise level at the operator's position in the aboveground test facility was reduced from 101.5 to 91 dBA using treatments with satisfactory aboveground durability. Extensive underground evaluation was performed only on the constrained layer damping, which has reduced the conveyor noise by 2 to 6 dBA, depending upon the operating conditions, and was shown to be sufficiently durable. Other promising candidates for exploratory evaluation include resilient layers for the top and bottom decks and smoother discontinuities between adjacent conveyor sections. Research done under contract H0155113 by Bolt Beranek and Newman Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-262634; paper copy price code A04.

OFR 172-83. Theoretical Study, Design and Analysis of an Improved Shuttle Car Cable Reel, by P. W. Meisel and G. J. Hundman. August 1983. 70 pp. 42 figs. A hydraulic-powered reel system to minimize peak tension transients in shuttle car trailing cables was theoretically designed and analyzed using

a computer. A single, spring-loaded takeup sheave stores or gives up cable to maintain tension within specified limits. Controls were incorporated to shut down the vehicle before all cable is removed from the reel and to deenergize the cable in the event of a reel-cable jam. Full-scale hardware configuration drawings sufficient for manufacture of a test system were completed. Research done under contract J0318086 by Jeffrey Mining Machinery Div., Dresser Industries, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-262352; paper copy price code A04.

OFR 173-83. Instruments and Techniques for Dynamic Particle Size Measurement of Coal Dust, by Virgil A. Marple and Kenneth L. Rubow. January 1981. 242 pp. 122 figs. The purpose of this study was to conduct research in several areas of instrumentation used to determine the quantity of respirable dust in a mining atmosphere. The study was divided into eight tasks including (1) the feasibility of using a dichotomous impactor in conjunction with two photometers for a machine-mounted dust monitor, (2) development of a laser diode optical particle counter, (3) development of an instrument evaluation chamber, (4) instrument evaluations and calibrations, (5) development of a new personal respirable dust sampler, (6) development of a uniform deposit cascade impactor, (7) inertial impactor calibrations and theoretical investigations, and (8) descriptions of field studies. Research done under contract H0177026 by the University of Minnesota. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-262360; paper copy price code A15.

OFR 174-83. Safety Evaluation of Conveyor Belt Cleaning Systems, by William Kleysteuber. Jan. 14, 1983. 118 pp. 88 figs. The focus of this study was to determine the effectiveness of practical conveyor belt cleaning devices in removing the material that carries back past the normal discharge point from the return strand belt so that it can not fall off. The material that falls off becomes part of the spillage that requires manual cleanup and increases miner exposure to hazards. The belt-cleaning problem was found to be much more complex than simply the removal of this material. The material becomes spillage by an interaction of the belt with the return roller that is governed by the characteristics of the carry-back material and is dependent upon moisture content and particle size distribution. The results of laboratory tests show that practically any type of blade held in intimate contact with the belting will reduce the amount of material carried back. Effective cleaning, however, requires high pressure on a blade material compatible with the carried back material in that it is not cut and grooved by the particles. Selection of cleaning methods is largely controlled by site-specific conditions at the installations and the end use of the product. This report defines engineering criteria that will increase the effectiveness of belt cleaning devices and methods and suggests a method to predict the costs of cleaning. Research done under contract J0215015 by Wyle Laboratories. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-262592; paper copy price code A06.

OFR 175-83. Fire Hazard Criteria for Noise Control Products in Underground Coal Mines, by Mark R. Pettitt, R. E. Giuntini, and William R. Wessels. May 1983. 211 pp. 61 figs. The development of fire hazard criteria for noise control products in underground coal mines are presented. Qualifying requisites of the criteria include maintaining miners' safety, allowing for maximum use of noise control products, and economic feasibility. The burning process is analyzed for its relationship to fire hazard criteria developed by the National Aeronautics and Space Administration and the Federal Aviation Administration, and the mine environment is analyzed in conjunction with the end-use applications of noise control products. Also, the interim fire hazard specification developed by the Mine Safety and Health Administration is appraised as it applies to end-use applications of noise control products. From these analyses and a literature survey, fire hazard criteria are developed that include an initial screening procedure that evaluates the level of flammability testing required. Research done under contract J0395100 by Wyle Laboratories. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83-262584; paper copy price code A10.

OFR 176-83. Design and Demonstration for Area Walkway Lighting on Electric-Powered, Mobile, Surface Mining Equipment, by Martin H. Wahl. Nov. 1, 1982. 119 pp. 46 figs. The January 13, 1977, Federal Register (v. 42, No. 9, sec. 77.027, par. d) proposed new regulations specifically applicable to aboveground operations directly related to illumination of areas in, on, and around draglines, shovels, and wheel excavators. This report details the design, installation, and demonstration of lighting systems of large draglines and shovels for areas 20 ft in all directions from the main frame, exterior walkways on board the mining machines, and the area beneath the boom 20 ft from the main frame to the farthest point the equipment is capable of excavat-

ing or discharging materials. Research done under contract H0387024 by the Mine Safety Appliances Co. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 83–262600; paper copy price code A06.

OFR 177(1)–83. Electrical-Shock Prevention. Volume I—Protection of Maintenance Personnel, by L. A. Morley, T. Novak, and F. C. Trutt. Dec. 8, 1982. 127 pp. 61 figs. The objective of this four-volume report was to investigate the application, economic, and safety considerations of electrical-shock prevention techniques applied to surface and underground mines This report is primarily concerned with the protection of maintenance personnel. The scope of the work is specified, electrical shock is defined, and needed ground-fault relay characteristics to prevent ventricular fibrillation are established. This is followed by an analysis of ac systems, a comparison of these systems with respect to body currents, the advantages and disadvantages of the various ground-fault protection techniques, and an analysis of dc systems for off-track vehicles. Summaries and synopses of each of the three remaining volumes are included. Research done under contract J0113009 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Assistant Director—Mining Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–102946; paper copy price code A07.

OFR 177(2)–83. Electrical-Shock Prevention. Volume II—Ground-Fault Interrupting Devices, by L. A. Morley, F. C. Trutt, and D. J. Rufft. Dec. 8, 1982. 110 pp. 60 figs. This report is primarily concerned with the application of sensitive ground-fault interrupters (GFI's) to ac utilization circuits in U.S. mines. The main concepts examined are shock prevention and methods to reduce nuisance tripping. The research involved a literature search, input from previous Bureau of Mines contracts, and contacts with electrical manufacturers and mining personnel. Several devices that showed promise were tested and the results indicate the existence of GFI's that may be modified to perform adequately on U.S. mining systems. A set of guidelines covering design, construction specifications, and performance tests is included. Research done under contract J0113009 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Assistant Director—Mining Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–102953; paper copy price code A06.

OFR 177(3)–83. Electrical-Shock Prevention. Volume III—Fault Protection for Motion-Drive Equipment, by L. A. Morley, F. C. Trutt, and G. M. Buchan. Dec. 8, 1982. 65 pp. 17 figs. This report examines the indication versus interruption procedures used on motion-drive power equipment with emphasis on surface excavators. A review of the electromechanical ac-dc conversion used with the control system is presented. Protection for the drive-system components are discussed. Fault sources and calculations for both the ac supply source and dc power loop are introduced to assist in discussing indication and interruption procedures. The dynamic process of the machine is examined and the effects of fault current and position of the machine to allow for an orderly shutdown is determined. Possible indication and interruption procedures are given for the four-quadrant duty cycle of excavators. The report is concluded by introducing other mining operations that utilize similar motion-drive systems and static (solid-state) drives and recommends further research in these areas, as well as a more detailed examination of the dynamic fault analysis for excavators. Research done under contract J0113009 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Assistant Director—Mining Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–102961; paper copy price code A04.

OFR 177(4)–83. Electrical-Shock Prevention. Volume IV—Overhead-Line Contact Fatalities, by L. A. Morley, F. C. Trutt, and G. T. Homce. Dec. 8, 1982. 116 pp. 35 figs. This report examines the problem of indirect contact of overhead high-voltage powerlines by mining personnel. This refers to the contact of energized lines by workers through an intermediate conductor such as a metallic tool or a piece of high-reaching mobile equipment. The shock hazard by such contact has been a major cause of electrical fatalities associated with mining operations. The report is divided into three areas. The first gives a general background of overhead lines, basic characteristics, and associated hazards and describes presently used techniques and devices that attempt to alleviate the contact problem. The second area presents a detailed analysis of 39 overhead-line contact accidents in mining since 1970. The third section used the information in the first two areas to formulate recommendations to prevent these accidents and subsequent electrocutions at mining installations. Research done under contract J0113009 by the Pennsylvania State University. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Assistant Director — Mining Research, Bureau of Mines, and the Natural Resources Library,

U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-102979; paper copy price code A06.

OFR 178-83. Compressed Oxygen One-Hour Self-Rescuer, by Michael A. Borrello. January 1983. 49 pp. 18 figs. A 60-min-duration, compressed-oxygen self-rescuer for emergency escape from coal mines was developed. The design, a closed-circuit pendulum-type rebreather, contains special techniques in packaging, cooling, gas flow, and human engineering factors. Test results on the performance of the apparatus are presented and recommendations are made for further improvement of the design. Research done under contract J0100074 by U.S.D. Corp., Survivair Div. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-105337; paper copy price code A03.

OFR 179-83. Analysis of Electrical Accident Prevention Countermeasures, by W. L. Cooley, W. Collins, Z. Elrazar, R. Kumar, R. McConnell, and M. Jerabek. Dec. 31, 1982. 359 pp. 84 figs. This report provides a detailed analysis of 23 electrical accident countermeasures contemplated for use in the metal-nonmetal mining industry. The costs and potential benefits of implementing groups of countermeasures are estimated, and methods are outlined by which countermeasures can be selected in an effective manner. The analysis is based largely on an extensive electrical accident event tree that is developed in detail. For those countermeasures that are not currently technically feasible, several prototype devices were developed to help speed development. Research done under contract J0113064 by the West Virginia University. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Assistant Director—Mining Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-102987; paper copy price code A16.

OFR 180-83. Modeling of Solution Mining Systems for Deep Mineral Resources Recovery, by Milton E. Wadsworth and H. Y. Sohn. May 1983. 110 pp. 32 figs. Laboratory studies were carried out to identify and quantify the important processes operative in solution mining of minerals. Specifically, the kinetics of leaching copper from chalcopyrite-bearing ore particles were determined under various oxygen partial pressures and temperatures. The effect of particle size on the rate of leaching was also investigated. Computer simulation models to predict the copper recovery from an underground rubblized ore body were developed. One model describes the process in which oxygen-saturated leach solution is used with no bubbles in the bed. The other model is applicable when leach solution containing oxygen bubbles is used for leaching. Research done under grants G1105088, G1115494, and G1195047 by the University of Utah. Available for reference at Bureau of Mines facilities in Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, and Salt Lake City, UT; Office of Assistant Director—Mineral and Materials Research and Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-103837; paper copy price code A06.

OFR 181-83. Simplex Gasification Demonstration in the Wellman-Galusha Gasifier, by the Mining and Industrial Fuel Gas Group, the U.S. Bureau of Mines, and Dynecology, Inc. June 30, 1982. 110 pp. 40 figs. The objectives of this project were to produce at least 200 tons of simplex briquets and to evaluate their performance as a fixed-bed, dry-bottom gasifier feedstock. To accomplish this, 240 tons of caking coal and shredded municipal refuse were compacted into simplex briquets and gasified in a Wellman-Galusha producer at the Bureau of Mines in Minneapolis, MN. It was concluded that the briquets have good potential as a gasifier feedstock and that the briquets do not swell or cake even though they contain 67 wt pct of a highly caking eastern bituminous coal. Research done under contract J0205070. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Avondale, MD, Twin Cities, MN, Reno, NV, Albany, OR, and Salt Lake City, UT; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-103324; paper copy price code A06.

OFR 182-83. Leaching of Uranium and Fluorine From Quenched Slag, by C. M. Wai and K. A. Prisbrey. Jan. 15, 1982. 28 pp. 17 figs. Waste slag from the Phosphoria Phosphate Formation in Utah, Idaho, and Montana contains one of the Nation's largest reserves of uranium. Large quantities of phosphate slag was premised in pretreatments and fluorite from before solidifying. By appropriate pretreatment, it was anticipated to stimulate selective leaching of valuable constituents at low acid consumption. In this project, the mechanisms of leaching were identified by analysis of leaching kinetics. The change in mechanisms associated with slag pretreatments were identified and quantified in terms of mass transfer, solid-state diffusion, and chemical reaction rates. A kinetic leaching model was used to predict treatments that were potentially economical. Although this research did not show that the economics of dilute acid leaching are favorable, it does point toward some innovations. Research done under grant G5105020 by the University of Idaho. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Avondale, MD, Reno, NV, Albany, OR, and Salt Lake City, UT; and Office of Assistant Director—Mineral and Materials Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 183-83. Combined Stability-Deformation Analysis for Rock Slopes in Open Pit and Strip Mines, by John Kafritsas, Herbert H. Einstein, and Gregory B. Baecher. September 1983. 115 pp. 23 figs. This report presents a computer analysis that couples the deformation of a rock mass and the flow of water in its joints. Two-dimensional prob-

lems involving a rock mass transversed by relatively closely spaced joint sets that divide it into distinct blocks can be treated. Deformations are modeled using the rigid block method, which assumes that the rock mass is composed of rigid rocks with the deformable contact points. The analysis proceeds in time steps, evaluating at a series of successive instants the forces acting on each block. The forces are used to find the acceleration of each block, which is then integrated to find the displacement increment of each block during the time step under consideration. There are considerably different force-deformation laws, time-dependent behavior, or expansive properties of joint fillers. Flow is modeled by recognizing its discontinuous features as occurring in a system of interconnected conduits formed by the joints. Both laminar and nonlaminar flow can be modeled, as can problems involving free-surface flow. Full account is taken of the coupling between flow and deformation. Water forces are continuously updated to account for changing joint and apertures caused by block displacements, and vice versa, and block displacements between time steps take into account the changing water-pressure field. Research done under grants G1105027 and G1115251 by the Massachusetts Institute of Technology. Available for reference at Bureau of Mines facilities in Denver, CO, Avondale, MD, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 184–83. Solids Flow in a Recirculating Fluidized Bed, by Takafumi Matsuzaki and John F. Elliott. June 1983. 115 pp. 59 figs. The objective of this study was to evaluate the general nature of solids flow in a 30-cm-ID recirculating fluidized bed using silica sand. A bubbling or turbulent bed with a density of $\frac{1}{2}\rho_b$ was observed in the lower part of the reaction and a pneumatic transport phase with a density of $\frac{1}{100}\rho_b$ was observed in the upper part. The solids feed rate was regulated by a nonmechanical valve called an "L-valve." The maximum solids feed rate through the L-valve is limited by the head of solids in the downcomer. The saturated solids carryover rate was found to be proportional to the fourth power of the gas velocity. Recommendations for further studies and modifications to the system are presented. Research done under grant G1115252 by the Massachusetts Institute of Technology. Available for reference at Bureau of Mines facilities in Avondale, MD, and Albany, OR; Office of Assistant Director—Mineral and Materials Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 185–83. Iowa Coal Project Demonstration Mine, Oskaloosa, Iowa, by Iowa State University. May 1981. 35 pp. 5 figs. This 37-acre tract was leased by Iowa State University in 1975 and is located 8½ miles southwest of Oskaloosa. Reclamation was completed in November 1977, after 108,000 tons of coal was mined at the site. The present research deals with the post-restoration management of reconstructed soil and the environmental quality of reclaimed land. Research done under grant G1105024. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, Washington, DC; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 186(1)–83. Development of a Continuous Shaft Lining System, Volume I, by Robert Torbin, Tom Brunsing, Douglas Ounanian, Ray Henderson, Jonathan Kelly, and George Kirby. May 1983. 224 pp. 72 figs. The objective of this three-volume report was to develop a system to reduce the costs, safety hazards, and time currently required in lining mine shafts with concrete. The continuous shaft lining (CSL) system will line machine-bored shafts downward from the shaft collar on a continuous basis using an inverted, pressurized slipforming technique. Volume I describes the basic CSL concept, the design and operation of a prototype unit, and estimates of cost. Research done under contract J0333915 by Foster-Miller, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS; PB 84-113216; paper copy price code A10.

OFR 186(2)–83. Development of a Continuous Shaft Lining System. Volume II, by Robert Torbin, Tom Brunsing, Douglas Ounanian, Ray Henderson, Jonathan Kelly, and George Kirby. May 1983. 120 pp. 42 figs. The objective of this three-volume report was to develop a system to reduce the costs, safety hazards, and time currently required in lining mine shafts with concrete. The continuous shaft lining system will line machine-bored shafts downward from the shaft collar on a continuous basis using an inverted, pressurized slipforming technique. Volume II summarizes the results of the laboratory- and full-scale tests conducted during the program. Research done under contract J0333915 by Foster-Miller, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-113224; paper copy price code A06.

OFR 186(3)–83. Development of a Continuous Shaft Lining System. Volume III, by Robert Torbin, Tom Brunsing, Douglas Ounanian, Ray Henderson, Jonathan Kelly, and George Kirby. May 1983. 510 pp. 79 figs. The objective of this three-volume report was to develop a system to reduce the costs, safety hazards, and time currently required in lining mine shafts with concrete. The continuous shaft lining system will line machine-bored shafts downward from the shaft collar on a continuous basis using an inverted, pressurized slipforming technique. Volume III, the appendix, contains related information on the laboratory tests and test facilities. Research done under contract J0333915 by Foster-Miller, Inc. Available for reference at Bureau of Mines facili-

ties in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-113232; paper copy price code A22.

OFR 187-83. The Impact of Longwall Mining on the Hydrologic Balance; Premining Data Collection, by Ginger S. Evans, Tsegaye Hailu, Helen M. Weagraff, James W. Warner, and G. Steve Lowry. May 31, 1983. 141 pp. 34 figs. This report documents a preliminary hydrologic investigation of an area where longwall mining methods are to be used. The scope of work includes determination of physical and chemical characteristics of major soil types in the area; determination of physical and chemical properties of surface water bodies; collection of geologic characteristics, including stratigraphy, structure, and detailed aquifer descriptions; a 10-year collection of meteorological data and installation of a weather station; and a detailed ground water investigation that includes completion of observation wells, aquifer testing, water quality sampling, and analysis using a 3-D computer model. The Trescott model developed by the U.S. Geological Survey was used to simulate steady-state aquifer conditions. Input data from eight multiple-completion monitor wells were used to model an area of approximately 10 square miles. Two confined layers, coal and overburden, were simulated. Model results showed good agreement with known piezometric data, desaturated areas, and flow from springs. Research done under contract J0218025 by J. F. Sato and Associates, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-113174; paper copy price code A07.

OFR 188-83. Survey of Blasting Effects on Ground Water Supplies in Appalachia. Part II, by Philip R. Berger, D. T. Froedge, James A. Gould, and Lorraine F. Kreps. August 1982. 114 pp. 25 figs. This report covers an 18-month study of the performance of a 300-ft-deep test water well located at the Ayrshire Mine of the AMAX Coal Co. near Evansville, IN. Well performance, as characterized by 10-hr drawdown tests, was monitored as the strip mining operation approached the well site from distances of 2,000 to 15 ft (overburden removal). Blast-induced ground motion was measured at the surface next to the test well, and peak particle velocities in excess of 4 in/s were obtained. No evidence of changes in water quantity or quality could be directly attributed to the blasts. However, some lowering of the static water level in the observation well, and a simultaneous increase in the adjusted specific capacity of the test well, suggest that overburden removal caused lateral stress relief with consequent opening of vertical fractures. Research done under contract J0285029 by Philip R. Berger and Associates, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-113182; paper copy price code A06.

OFR 189-83. Stable Isotope Variations in Coals and Associated Mineral Matter, by Thomas F. Anderson. August 1983. 79 pp. 18 figs. Measurements of stable isotopic variations (sulfur, carbon, and oxygen), supplemented by chemical, mineralogical, and petrographic analyses, were used to investigate the processes responsible for the incorporation of sulfur in coal and the development of permineralized peat zones (coal balls). Sulfur isotopic results indicate that there are two principal sources in Pennsylvania coals from the Illinois Basin: (1) primary sulfur assimilated by plants (low-sulfur coal), and (2) secondary sulfur produced by reactions involving H_2S that was produced by the anaerobic reduction of sulfate in seawater that permeated the peat during postdepositional marine transgressions (the dominant source of sulfur in high-sulfur coals). Sulfur isotopic compositions of low-sulfur coals in several Tertiary basins of Wyoming are consistent with a plant sulfur source. However, the inverse correlation between content and isotopic composition of sulfur observed in coals from the Powder River Basin suggest some secondary additions to these low-sulfur coals. Several Quaternary freshwater peats that were submerged by sea level rises during deglaciation have sulfur contents and isotopic compositions similar to high-sulfur coals. Carbon and oxygen isotopic compositions of calcareous coal balls from North America and Europe suggest that the carbonate was derived from variable proportions of oxidized plant matter and inorganic carbonate, and the carbonate minerals were precipitated from fresh-to-brackish waters. Local geochemical and hydrological conditions were apparently more important than regional depositional environments in controlling the source of carbonate and the development of coal balls. Research done under grant G1115171 by the Southern Illinois University at Carbondale. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 190-83. Iowa Coal Project Demonstration Mine, Oskaloosa, Iowa. Annual Progress Report—1982, by Stan Henning, R. B. Hall, G. A. Miller, M. L. Thompson, C. R. Klein, R. C. Schultz, and H. M. Van Es. May 1983. 50 pp. 12 figs. This 37-acre tract was leased by Iowa State University in 1975 and is located 8½ miles southwest of Oskaloosa. After 108,000 tons of coal were mined at the site, reclamation was completed in November 1977. The present research deals with the postrestoration management of reconstructed soil and the environmental quality of reclaimed land. Research done under grants G1105024 and G1115191 by the Iowa State University. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Office of Assistant Director—Mining Research, Bureau of Mines, and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 191–83. Mining Resources and Potential Problems Associated With Mining of Cenozoic Rocks of the Williston and Powder River Basins, Northern Great Plains, by Richard D. LeFever and Edward C. Murphy. September 1983. 174 pp. 73 figs. The objective of this study was the compilation and assessment of existing data on mining resources and potential problems associated with mining of Cenozoic rocks in the Williston and Powder River Basins in the Northern Great Plains. The report presents an interpretation of the three-dimensional stratigraphic framework and depositional setting of the Cenozic sedimentary section, and the construction of a data base accessible to scientists and other users. The bibliography consists of about 800 references on sedimentology, stratigraphy, coal and uranium reserves, coal chemistry, ground water and rock geochemistry, and rock mineralogy. The references are cross-indexed by subject matter and geographic location. The computer data base contains data from 8,508 locations and has about 12,500 entries in the various individual data sets. Research done under grants G1105042 and G1115381 by the University of North Dakota. Available for reference at the Bureau of Mines Avondale (MD) Research Center; Office of Assistant Director—Mineral Data Analysis and Office of Technical Information, Bureau of Mines, and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 192–83. Characterization of Subsidence Over Longwall Mining Panels—Eastern Coal Province, by Peter J. Conroy and Julianne H. Gyarmaty. May 1983. 120 pp. 53 figs. The objective of this study was to describe the physical response of overlying strata to longwall mining of panels and observe changes in surface and ground water flows caused by subsidence from underground mining. The study was performed at Quarto Mining Co.'s No. 4 mine in the eastern coal province. The work included monitoring both surface and underground instrumentation and characterizes surface subsidence and strain, determines the potential effects of subsidence on cultural features including structures and water supplies, and develops criteria to assist in predicting subsidence for mines with similar mining and geologic conditions. Research done under contract J0133920 by Dames & Moore. Available for reference at the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 193–83. Testing and Demonstration of Roof Bolter Instrumentation for Detecting Hazardous Roof, by Richard Lusignea and John Felleman. April 1983. 165 pp. 34 figs. A single-boom roof bolting machine was outfitted with measurement and recording systems to detect changes in machine parameters while drilling. The purpose of the instrumented bolter was to detect changes in roof conditions from the machine parameters of penetration rate, thrust, rotation rate, torque, reflected light from rock cuttings, and vibration of the roof during drilling. The system was demonstrated underground in coal mine conditions and showed correlation between rock type and drilling parameters. Research done under contract H0202008 by Foster-Miller, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 194–83. Dry Dust Collector, by Gary R. Gillingham and Jon P. Sandstedt. March 1982. 121 pp. 57 figs. The objective of this investigation was to design, fabricate, and demonstrate a small, safe, simple, and rugged dry dust collector suitable for face (including machine mounting), belt transfer, and other mining applications. The report traces the development of the dry dust collector from the original design concept and component testing performed during phase I to the fabrication, laboratory testing, and field evaluation of two mine-worthy dry dust collector prototypes during phase II. Successful field evaluations took place at a belt transfer point in a trona mine and a bagging station at a silica sand plant. Future modifications suggested by the field evaluations as well as production cost estimates are included in the report. Research done under contract H0395039 by Donaldson Co., Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; and Office of Assistant Director—Mining Research, Bureau of Mines, and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-127356; paper copy price code A06.

OFR 195(1)–83. Evaluation of Safety Assessment Methods for the Mining Industry. Volume I, by P. M. Daling and C. A. Geffen. May 1983. 123 pp. 19 figs. The objectives of this study were to examine a representative cross section of formal safety analysis techniques developed for the nuclear and aerospace industries, to recommend those methods that would be suitable for application to the mining industry, and to include those methods in a user's manual. Volume I of this two-volume report presents the results of the examination of available safety assessment methods. The major safety concerns and needs of mine operators were identified through telephone contacts and a visit to a minesite. Safety assessment methods recommended for use by the mining industry were also investigated for potential adaptability to a user-interactive computer system. Several methods were determined to be immediately transferrable to the mining industry and are described in Volume II. Research done under contract J0225005 by Battelle, Pacific Northwest Laboratories. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Assistant Director—Mining Research, Bureau of Mines, and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-126440; paper copy price code A06.

OFR 195(2)–83. Evaluation of Safety Assessment Methods for the Mining Industry. Volume II. User's Manual of Safety Assessment Methods for Mine Safety Officials, by P. M. Daling and C. A. Geffen. May 1983. 96 pp. 15 figs. The objectives of this study were to examine a representative cross section of formal safety analysis techniques developed for the nuclear and aerospace industries, to recommend those methods that would be suitable for application to the mining industry, and to include those methods in a user's manual. The user's manual, this report, describes several methods that were determined to be immediately transferrable to the mining industry. The manual gives detailed instructions on appropriate application and utilization of the methods. Research done under contract J0225005 by Battelle, Pacific Northwest Laboratories. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Assistant Director—Mining Research, Bureau of Mines, and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–126457; paper copy price code A05.

OFR 196–83. Shearer Mounted Dust Collector. Laboratory Testing, by J. Kelly, T. Muldoon, and W. Schroeder. October 1982. 168 pp. 69 figs. Effective control of respirable dust is one of the most serious problems associated with longwall mining in the United States. This report describes the development and laboratory testing of dust collectors for use on double-drum shearers. The systems tested included a high-capacity flooded-bed scrubber and water-powered extraction cowls, extraction drums, and spot scrubbers. The systems were tested using tracer gas in a full-scale model of a longwall shearer face. A detailed description of the test facility, test methods, and system test results is provided. Research done under contract J0387222 by Foster-Miller, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–126614; paper copy price code A09.

OFR 197–83. In-Situ Shear Strength Tester for Coal, by Richard L. Handy, Lawrence E. Engle, and John M. Pitt. May 10, 1976. 125 pp. 42 figs. The objective of this research was to develop a lightweight, portable device for rapid in situ measurement of rock shearing strength and to compare the results with those obtained by other test methods. The rock borehole shear test (RBST) operates by expansion of two opposed steel plates against rock in the periphery of a 76-mm (13-in) diameter borehole, followed by axial movement of the plates. Small teeth on the contact plates cause shearing to occur with the rock itself. Several tests were conducted at different applied expansion pressures to generate a failure envelope of shearing strength versus applied normal stress. The envelope is plotted while the test is being conducted; a complete envelope may be generated by four tests in about 45 min. The slope of the envelope is the angle of internal friction, and the extrapolated shearing strength at zero normal stress is the cohesion. Analogous data are obtained for the residual shear strength, or strength along the induced fractures. The device also indicates whether dilatancy, or rock volume expansion, occurs during shearing. Comparative RBST versus triaxial and other tests indicate close agreement of friction angles but somewhat lower cohesions caused by disturbance by the shear plate teeth. Research done under grant G0144021 by Iowa State University. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–126481; paper copy price code A06.

OFR 198–83. Foreign Literature on Environmental and Personal Factors Affecting the Safety and Productivity of Miners: A Topical Listing and Annotated Bibliography of Recent Research, by Robert H. Peters. Jan. 4, 1983. 91 pp. 4 figs. This report is a review of foreign literature concerning human factors issues in the mining industry and updates Bureau of Mines OFR 27–72. About 500 references were located using computerized literature research systems. The references were sorted by topic into six major categories including accident and safety, individual miner, health and medicine, technical and engineering, environment, and ergonomics. Some of the major issues include effects of environmental stress on health and productivity, accident prevention, protective clothing and equipment, miner-machine relationship, training programs, and psychological principles applied to mine problems. Summaries are included for publications that describe the results of empirical investigations of factors affecting miner safety or productivity. It is concluded that foreign countries are improving the safety and productivity of mining operations through (1) improvements in technologies associated with mining processes; (2) improvements in equipment design; (3) improved understanding of miner physiological, anatomical, and psychological limitations; and (4) implementation of more sophisticated technical devices to monitor and control the underground environment. Research done by the Bureau of Mines Industrial Safety and Training Systems. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–127687; paper copy price code A05.

OFR 199–83. Determination of Velocity Measurement Correction Factors and Guidelines, by J. L. Kohler and L. M. English. June 1983. 216 pp. 97 figs. The objective of this study was to establish a set

of guidelines to select locations for and applying correction factors to vane anemometer, smoke, and tracer gas velocity measurements. A literature search and analysis was performed, in-mine experiments were conducted, and a quantitative analysis of the data was used to develop correction factor tables and site selection guidelines. The report also presents guidelines to select velocity measurement locations and discusses how to improve cross-section measurements. Research done under contract J0308027 by Ketron, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-127851; paper copy price code A10.

OFR 200-83. Floodplain Landfill With Mill Tailings, by K. E. Robinson and H. M. Eivemark. July 1983. 206 pp. 99 figs. This study develops a valley-wide mill tailings disposal plan to utilize 20 potential landfill sites on floodplain areas in the Coeur d'Alene mining district in Idaho, and presents measures to reclaim the sites for subsequent productive use. Field and laboratory testing on one test section and two abandoned impoundments support the use of hydraulically deposited tailings for landfill construction. Hydrological testing showed that controlled discharge from tailings impoundments results in contaminant levels in the discharge below regulated standards. Additional testing indicated that compacted soil liners and pond management provide adequate contaminant abatement where acid-generating tailings are encountered. Mechanical compaction, including surcharge loading, upgrades foundation support capacity so that construction on the surface of tailings deposits is feasible. Details concerning potential landfill sites were refined. At recent production rates, the 20 sites would result in 680 acres of reclaimed land while providing a minimum of 40 years of tailings storage capacity. Research done under contract J0113047 by Greater Shoshone County Inc. and Robinson Dames & Moore. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-125707; paper copy price code A10.

OFR 201-83. Evaluation of Longwall Dust Sources, by Jonathan Ludlow and Eric Marshall. April 1983. 260 pp. 72 figs. To define the relative contributions of various sources of respirable airborne dust on longwall faces, continuous dust level data were recorded on five longwalls for an average of five shifts each. Analyses of these data with records of face activity showed that it was possible to determine the overall contribution of each major element. Average levels were determined for roof support generated dust, conveyor and intake dust, and for dust levels during various shearer activities. When average levels were compared between mines, a significant degree of consistency was noted. To differentiate the various dust sources associated with the shearer, fly cuts ranging from 6 to 30 in were closely monitored as were dust levels at operator positions over the various segments of the longwall cycle. These data indicate that the clearance ring of the shearer drum is a disproportionately heavy contributor to shearer dust make. A statistical analysis of the effect of shearer haulage speed on dust make revealed that high haulage speeds are associated with low specific dust make. Research done under contract H0202016 by Foster-Miller, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Assistant Director—Mining Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-127018; paper copy price code A12.

OFR 202-83. Geological and Geochemical Controls on the Chemical Evolution of Subsurface Water in Undisturbed and Surface-Mined Landscapes in Western North Dakota, by G. H. Groenewold, R. D. Koob, G. J. McCarthy, B. W. Rehm, and W. M. Peterson. May 1983. 292 pp. 39 figs. Studies of several surface coal mining sites in western North Dakota resulted in the development of a hydrogeochemical model that accounts for the observed chemical characteristics of subsurface water in undisturbed settings. The near-surface several meters of the landscape is constantly subjected to alternate wetting-drying, a key mechanism in hydrogeochemical evolution. The purposes of this study were to refine the model, with particular emphasis on the sulfur cycle, and to determine the applicability of the model to post-mining landscapes (spoils). Field activities included detailed ground water instrumentation of undisturbed and spoils areas at two sites. Refinement of the model included detailed analyses of the texture, bulk and clay mineralogy, sulfide abundance, and sulfur concentrations in overburden core samples. Laboratory experiments were designed to determine the source and mechanisms of sulfate salt production from overburden samples. It was concluded that the hydrogeochemical model is equally applicable to undisturbed and spoils landscapes and that the major species of concern in this region are sodium and sulfate. It was also concluded that the major source of sulfate is sulfides in the overburden and that the solubility of sulfate in ground water in these settings is largely controlled by the sodium-calcium ratio. Research done under contract J0275010 by the North Dakota Geological Survey. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-126952; paper copy price code A13.

OFR 203-83. Coupled-Transport Membranes for Metal Separations—Phase V, by W. C. Babcock, M. B. Chidlaw, D. J. Kelly, and E. D. LaChapelle. August 1983. 52 pp. 24 figs. This report covers phase V of a continuing program to apply a new

liquid membrane process called coupled transport to the recovery of metals from hydrometallurgical leach solutions. During this phase, a membrane system of moderate scale was constructed and field-tested at the Exxon Highlands Mine and Mill Co. site near Douglas, WY. The test unit contained four hollow-fiber membrane modules, each with 100 ft^2 of membrane area. In the field tests, about 1,000 gallons per day of leach solution was processed. The unit was operated on the leach solution for about 50 days. Leach solution entering the unit contained 100 ppm uranium. This concentration was reduced to about 5 ppm by coupled-transport treatment, and the uranium was concentrated to about 2 wt % as a uranyl carbonate product. Under these conditions, a transmembrane uranium flux of about 2.5 lb/ft^2 per year was obtained. An economic analysis showed that the cost of recovering uranium from this leach solution via coupled transport is about $1.20 per pound. At higher concentrations the cost is reduced; for example, at 1,000 ppm the cost of uranium recovery is about $0.30 per pound. Research done under contract J0205061 by Bend Research, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and Office of Assistant Director—Minerals and Materials Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-127034; paper copy price code A04.

OFR 204–83. Continuous Respirable Dust Monitoring System (CRDMS), by Pedro Lilienfeld, Roger Stern, and Gary Tiani. May 1983. 101 pp. 28 figs. The objective of this program was the development, design, fabrication, and laboratory testing of a mine-worthy continuous respirable dust monitoring system (CRDMS). The operation of the sensor unit of the system is based on the light scattering intensity of the respirable fraction of the airborne dust. The CRDMS is compatible with the typical environmental rigors that characterize coal mines, and, in particular, the shock, vibration, impact, moisture, and dust conditions prevailing at active mining machines. The sampled area must be within the breathing zone of the mining machine operator whose dust exposure is to be monitored. Instantaneous, as well as shift-averaged dust concentrations, are displayed and recorded for later retrieval. Alarm indications and other diagnostic information are provided. Research done under contract H0100110 by GCA Corp. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Assistant Director—Mining Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-126473; paper copy price code A06.

OFR 205–83. Environmental Assessment of Stream Pollution by Mine Drainage as a Function of Geologic Type and Reclamation Success, by H. S. Boyne, J. B. Ingwersen, J. V. Ward, Lawrence J. Gray, James Harvey, and S. L. Ponce. March 1982. 69 pp. 34 figs. The purpose of this study was to examine effects of acid mine drainage (AMD) originating from volcanic, igneous, and sedimentary watersheds in the Colorado mineral belt on stream chemistry and macroinvertebrates. Specific objectives were to (1) quantify water quality derived from mine drainage in relationship to macroinvertebrate community structure, (2) assess the natural downstream recovery rates of stream water quality and aquatic biota, and (3) compare inorganic water quality and macroinvertebrate community structure as related to the degree of reclamation success for mines located in volcanic, igneous, and sedimentary rock types. Criteria for the selection of study watersheds were a well-defined point source of AMD, presence of suitable control site, and accessibility. The selected watersheds were Kerber Creek near Villa Grove in the San Luis Valley, Peru Creek near Dillon in central Colorado, and Coal Creek near Crested Butte. The report presents results of monthly sampling conducted from July-September 1980 through May-July 1981. Kerber and Peru Creeks received AMD throughout the study period. In June 1981, a treatment plant began operations that significantly improved water quality in Coal Creek, thus allowing an assessment of reclamation success. Research done under grants G1105001 and G1115001 by the Colorado School of Mines. Available for reference at the Office of Assistant Director—Mining Research, Bureau of Mines, and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 206–83. Oxidation of Pyrite to Maghemite, by W. M. Roggenthen. October 1983. 143 pp. 54 figs. Investigation of the alteration processes of pyrite revealed that several magnetic chemical species are formed, depending upon oxygen and sulfur fugacities, temperature, and pH. Oxidation in both a dry and aqueous environment was studied. The primary purpose of the work included attempts to understand the processes wherein magnetic substances can be created from pyrite with the ultimate goal of aiding in the magnetic separation of pyrite, and hence sulfur from coal. This report presents a detailed description of the investigation. Research done under grants G1105047 and G1115461 by the South Dakota School of Mines and Technology. Available for reference at Bureau of Mines facilities in Avondale, MD, Twin Cities, MN, Rolla, MO, Albany, OR, and Salt Lake City, UT; and Office of Assistant Director—Mining Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 207(1)–83. Metal Organic and Inorganic Affinities in Strippable Fort Union Formation Coal. Volume 1, by F. E. Diebold and Douglas Drew. September 1983. 52 pp. 35 figs. The methodology for describing the geochemistry of elements in a coal seam was developed and has been applied to the Rosebud Coal Seam, an economically important member of the subbituminous coals of the Fort Union Formation in eastern Montana. The method development involved a detailed study of two popular techniques for determining the metal geochemistry of coal, namely, whole coal analyses and coal physical fractionation. The mathematically contrived element associations and the element concentration trends in the float and sink fractions are considered to lead to only qualitative conclusions

concerning the chemical associations of the elements in coals. Additionally, the processes taking place with the coal during low-temperature ashing in an oxygen plasma were experimentally investigated and shown to be of sufficient extent that the use of such low-temperature ash for deciphering element geochemistry is questionable. Volume 1 of this two-volume report presents a description of the study. Research done under grants G1105074 and G1195027 by the Montana College of Mineral Science and Technology. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; and Office of Assistant Director—Mining Research, Bureau of Mines, and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 207(2)–83. Metal Organic and Inorganic Affinities in Strippable Fort Union Formation Coal. Volume 2, by F. E. Diebold and Douglas Drew. September 1983. 139 pp. 35 figs. The methodology for describing the geochemistry of elements in a coal seam was developed and has been applied to the Rosebud Coal Seam, an economically important member of the subbituminous coals of the Fort Union Formation in eastern Montana. The method development involved a detailed study of two popular techniques for determining the metal geochemistry of coal, namely, whole coal analyses and coal physical fractionation. Volume 2 of this two-volume report contains maps and tables associated with the study. Research done under grants G1105074 and G1195027 by the Montana College of Mineral Science and Technology. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; and Office of Assistant Director—Mining Research, Bureau of Mines, and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 208–83. Derivation and Use of the Critical-Path-Method Diagram To Streamline Metallic Mining Premine Stage Requirements, by Joseph M. Pugliese and James P. Ludwig. 1983. 28 pp. 3 figs. The Bureau of Mines, through its contract research program, recently analyzed the mining and environmental requirements in the premining stage for copper mining in the northern highland of Wisconsin using the critical-path-method (CPM). However, a step-by-step derivation of the CPM diagram was beyond the scope of the effort. The Bureau's objective now is to show, step by step, how the original hand-computed CPM diagram was constructed. The streamlining (restructuring) of the diagram from the original effort is also summarized. The critical path time (longest time) through the original CPM diagram was 25.12 yr, excluding public liaison effort. The diagram showed the involvement of the regulatory agency, mining applicant, and public in the premining stage. Analysis of the diagram produced a streamlined version that reduced the critical path time by nearly 7 yr. The CPM construction methodology may be applied to mine planning for any mining operation. Research done by the Twin Cities (MN) Research Center. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Copies of this report will not be available for purchase.

OFR 209–83. Reverse Performance Characteristics of Main Mine Fans, by M. F. Dunn, S. Bhattacharya, and V. Rajaram. August 1983. 65 pp. 25 figs. During a mine fire or other emergency, it may be desirable to reverse the airflow in order to provide an escapeway or to isolate a fire. Also, in colder areas, the airflow may be reversed to prevent ice buildup. When reversing main mine fans, the mine operator usually does not know what operating characteristics of flow and pressure to expect. Laboratory and field tests of vane-axial main mine fans in the 7- to 9-ft-diam size range were conducted to establish forward and reverse performance characteristics under controlled conditions and at typical mine installations. The data obtained suggest that reverse performance characteristics are dependent upon the blade angle and the hub-to-tip ratio. There is also evidence that reverse performance can be predicted for a family of bland angles and a given hub-to-tip ratio. Generally, quantity of air is 30% to 65% less in reverse than when operating in the normal forward mode. Research done under contract J0308044 by Engineers International, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–143726; paper copy price code A04.

OFR 210–83. Achieving Uniform-High-Tensions in Mechanical-Anchor Bolts, by Anil Mahyera and A. H. Jones. November 1982. 122 pp. 158 figs. Toward the goal of achieving uniform high tensions in roofbolts to provide superior roof support for extended periods, mechanical anchor bolts were installed in a mine in eight different ways—under torque thrust control with and without hardened washers, belleville washers, and tension equalization; and in a conventional manner with and without hardened washers. The various bolt groups were analyzed in terms of tension uniformity and mean tension levels. Installing the bolts accurately with hardened washers under the bolthead, and with proper torque control, resulted in the most uniformly tensioned bolts—a coefficient variation of only 14%, an improvement three times over conventional installations. Also, these bolts maintained a high tension level—80% of the installation tension compared with 50% achieved conventionally. Research done under contract H0202006 by Terra Tek, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–143718; paper copy price code A06.

OFR 211–83. Recommendations for Human Factors Research and Development Projects in Surface Mining. by Ernest J. Conway and Mark S. Sanders. May 1982. 86 pp. 10 figs. To facilitate the planning of future research within the Bureau of Mines, 74 human factors research and development projects were identified for possible Bureau funding. The projects were based on (1) literature surveys, (2) reviews of accident statistics and reports, (3) interviews with equipment manufacturers, Mine Safety and Health Administration (MSHA) and Bureau personnel, and (4) site visits to 26 mines. The projects were divided into categories related to (1) mobile equipment, (2) maintenance shops and areas, (3) plans and mills, (4) organizational factors, (5) safety programs data, and (6) training. The projects were placed into three categories of priority and were rated by industry and MSHA people in terms of benefit to the industry. The highest priority contained 25 projects with 26 in category 2. and 23 projects in the lowest category. Research done under contract J0395080 by Canyon Research Group, Inc. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–143650; paper copy price code A05.

OFR 212–83. CMI Inert Gas Mine Firefighting System, by M. Paczkowski, G. A. Tracey, and A. Wojtyczka. February 1982. 58 pp. 23 figs. The use of inert gas systems to extinguish mine fires has been the subject of research for some time in the United States. In some European countries it is an established practice. Tests were conducted with the Central Mining Institute (CMI) Inert Gas System, which is being used by the Polish mining industry. This system utilizes a modified jet aircraft engine and afterburner as a compact source of combustion products with a very low oxygen content. Water injected into the combustion products stream provides evaporative cooling and forms a mist with a high cooling capacity. The CMI system was used under controlled conditions to extinguish coal pile fires at the Bureau of Mines Experimental Mine in Bruceton, PA. The tests results show that the CMI system can be used conveniently to extinguish fires quickly and to maintain an inert atmosphere in the fire zone to prevent reignition. Research done under contract J0318080 by CSE Corp. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Juneau, AK, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Surface Mining Library and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–142678; paper copy price code A04.

OFR 213–83. Slack and Overload Rope Protection System, by Holt L. Farley, Roger B. Fish, Robert L. Jeffcoat, and David L. Hoadley. January 1983. 327 pp. 71 figs. This report describes the development of an electronic system that detects unsafe slack and overload conditions in underground mine hoist ropes. The slack and overload rope protection system (SORPS) includes a fail-safe load cell inserted between the rope and the conveyance and an accelerometer mounted on the conveyance. Signals from these transducers are telemetered via a radio link to the hoist control room where they are combined with drum speed and chair status in a microprocessor-based decision and display unit. Abnormally high external force levels are detected as discrepancies between rope and tension and cage acceleration; conveyance weight is inferred continuously. Hazardous conditions and general hoist status are displayed to the hoist operator. The system has been tested in a working mine for approximately 2 years. The report contains specifications, design data, and field test experience generated under the SORPS program. Information on dynamic modeling, vibration environment, status of existing slack detection systems, and applicable control strategies are included. Research done under contract J0199008 by Foster-Miller Associates, Inc. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; National Mine Health and Safety Academy, Beckley, WV; and Office of Assistant Director—Mining Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–143460; paper copy price code A15.

OFR 214–83. Reclamation of Tailing Basins Resulting From Copper-Nickel Milling, by John P. Borovsky, David F. Grigal, and Ricki L. Strassman. August 1983. 149 pp. 34 figs. A 3-year study was conducted to evaluate the problems and benefits of using vegetation to stabilize tailing from a potential Minnesota copper-nickel milling operation with the major objective of developing a feasible method for revegetation. Secondary objectives were to (1) describe the physical and chemical characteristics of copper tailing and determine the potential influence of those characteristics on plant growth, (2) identify alternative plant species and soil management techniques useful in the revegetation of copper-nickel tailing, (3) evaluate the effects of vegetation establishment on the liberation of potentially toxic metals in tailing drainage water, and (4) assess the accumulation of potentially toxic metals in vegetation grown in copper-nickel tailing. Research done under contract J0205050 by Barr Engineering Co. Available for reference at Bureau of Mines facilities in Denver, CO, Twin Cities, MN, Pittsburgh, PA, and Spokane, WA; and Office of Assistant Director—Mining Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84–142587; paper copy price code A07.

OFR 215(1)–83. Basic Research on Coal Fragmentation and Dust Entrainment. Volume I—Technical Information, by Gary L. Stecklein, Ronald Branstetter, Roy Arrowood, David Davidson, James Lankford, Robert Lyle, and Carter Nulton. June 1982. 123 pp. 66 figs. This report summarizes the results of research into the areas of the fragmentation and entrainment of airborne respirable dust (ARD). The objectives of the program were fourfold: First, to review the present state of knowledge regarding ARD; second, to expand this state of knowledge through the identification of hypothetical microscopic mechanisms by which the coal is fragmented and the dust becomes entrained; third, to specify the informational requirements to verify or nullify

these hypotheses; and fourth, to relate experimental techniques that will produce that required information. Additionally, insights are provided regarding potential methods of extraction and/or treatment that may reduce the concentration of ARD. Volume I presents the technical information on the investigation. Research done under contract J0215009 by Southwest Research Institute. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; and Office of Assistant Director—Mining Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-143445; paper copy price code A06.

OFR 215(2)-83. Basic Research on Coal Fragmentation and Dust Entrainment. Volume II—Appendix Information, by Gary L. Stecklein, Ronald Branstetter, Roy Arrowood, David Davidson, James Lankford, Robert Lyle, and Carter Nulton. June 1982. 168 pp. 33 figs. This report summarizes the results into the areas of the fragmentation and entrainment of airborne respirable dust (ARD). The objectives of this program were fourfold: First, to review the present state of knowledge regarding ARD; second, to expand this state of knowledge through the identification of hypothetical microscopic mechanisms by which the coal is fragmented and the dust becomes entrained; third, to specify the informational requirements to verify or nullify these hypotheses; and fourth, to relate experimental techniques that will produce that required information. Additionally, insights are provided regarding potential methods of extraction and/or treatment that may reduce the concentration of ARD. Volume II contains the appendix. Research done under contract J0215009 by Southwest Research Institute. Available for reference at Bureau of Mines facilities in Tuscaloosa, AL, Denver, CO, Avondale, MD, Twin Cities, MN, Rolla, MO, Reno, NV, Albany, OR, Pittsburgh, PA, Salt Lake City, UT, and Spokane, WA; Mine Safety and Health Administration, Arlington, VA; and Office of Assistant Director—Mining Research, Bureau of Mines, and the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Order ONLY from NTIS: PB 84-143452; paper copy price code A08.

OFR 1-84. Elucidation of the Fundamental Chemistry and Recovery of Gold From Carbonaceous Ore Bodies, by James L. Hendrix, Frank G. Baglin, and John H. Nelson. Sept. 1983. 66 pp. 34 figs. Low-grade carbonaceous gold ore from eastern Nevada was characterized by a variety of analytical and spectroscopic techniques with emphasis on vibrational spectroscopy. It was found that no detectable amounts of humic acid materials or organic hydrocarbons were present in the samples. Different hydrometallurgical techniques were used in an attempt to extract gold values from the carbonaceous ores. The techniques included the use of thiourea, diethylamine, and ammonium thiosulfate. None of these achieved the extraction levels gained by the standard hydrometallurgical practice of oxidation pretreatment followed by cyanidation. This report contains published papers covering most of the results of the study. Research done under grants G1105039 and G1115322 by the University of Nevada—Reno. Available for reference at the following facilities: AD/MR, ALRC, AVRC, LIB, RERC, and SLRC. Copies of this report will not be available for purchase.

OFR 2–84. In Situ Mining of Bituminous Coal With Fluorinated Solvents, by Arnulf P. Hagen. June 1983. 58 pp. This project was designed to explore the suitability of using fluorinated inorganic materials as solvents for in situ mining of thin seamed, heavily overburdened coal; to build a data base for the selection of an inorganic solvent for use in coal cleaning; and to determine if fluorinated solvents will reduce the organic and inorganic sulfur contents of coal as well as to lower the ash content. The coal samples were combined with pure solvent and with aqueous solutions at atmospheric pressure and at increased pressure. The increased pressure experiments are important because they duplicate the conditions anticipated for an in situ cleaning and mining operation. Trifluoroacetic, difluorophosphoric (phosphorodifluoridic), and trifluoromethanesulfonic acids were found to be effective for cleaning high-sulfur, high-ash coal at 300° C and at atmospheric pressure. At pressures up to 20,000 psi the effectiveness of these reagents is not decreased. Research done under grants G1105043 and G1115401 by the University of Oklahoma. Available for reference at the following facilities: AD/MR, AVRC, DRC, LIB, OSM, PRC, RERC, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 3–84. Characterization of Subsidence Over Longwall Mining Panels—Rocky Mountain Coal Province, by John E. O'Rourke, Pamela H. Rey, and Kevin O'Connor. Sept. 19, 1982. 192 pp. 59 figs. This report documents the process of site selection, instrument installation, data acquisition, and preliminary data analysis followed to characterize the physical response of overlying strata to longwall mining. A system of surface, subsurface, and mine level instrumentation was installed at the Allen Mine in Weston, CO, where the overburden ranged from 600 to 900 ft thick. Survey monuments, automatic-recording strainmeters, multipoint rod extensometers, inclinometer-extensometers, stressmeters, and tap extensometer convergence stations were installed to monitor displacements and stress changes. A preliminary analysis of the data acquired up until project termination showed the system to be operative and strata response to be similar to that reported for other subsidence monitoring case histories. Recommendations for continued monitoring of the instrumentation systems are presented. Research done under contract J0333953 by Woodward-Clyde Consultants. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–142918; paper copy price code A09.

OFR 4–84. Blasthole Depth and Stemming Height Systems, by Calvin J. Konya and Duane R. Skidmore. Sept. 12, 1981. 75 pp. 15 figs. Overloaded blastholes and insufficient stemming are major factors in flyrock accidents at surface metal and nonmetal mines. Accurate measurement of blasthole depth, stemming height, and water depth would reduce the overload and the probability of blowout, flyrock, excessive ground vibration, and airblast. Problems result because current measuring systems are inaccurate and often difficult to use. A literature survey determined measurement techniques and blasting parameters prior to 1970. Similar data were gathered for current practices in 11 iron mines, 30 copper mines, and 92 quarries. Most operations used a cloth tape to measure borehole depth and stemming height; approximately 10 of the operations had dry blastholes. Alternate measurement techniques were evaluated and discussed. Candidate measuring techniques with best potential for improvement over the present weighted tape method are disposable tapes or string chains, automated readout tapes, modified sludge level indicators, and acoustic reasonance methods. Research done under contract J0208022 by Intercontinental Development Corp. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, OSM, PRC, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–142694; paper copy price code A05.

OFR 5–84. Design, Development and Validation of a Training System for Roof Bolt Equipment Operators, by William M. Hinton, Jr., George W. Menzer, Raymond E. Reilly, and Robert M. Baker. Apr. 10, 1982. 127 pp. 6 figs. The objective of this program was to design and produce a training sequence that would prepare roof bolter trainees for job performance. Data were collected and analyzed using the general procedures in Instructional Systems Development (ISD). Input data came from a previous roof bolter training analysis program. These data were expanded and structured through a series of ISD steps—objective hierarchies, media selection, syllabus, lesson specifications, and training materials development. The resulting program consisted of an ordered sequence of 15 lessons. The media mix for the lessons included lectures, slide-tape lessons, and hands-on instruction using operational roof bolters. Contents of all lessons were reviewed and approved by the Bureau of Mines. Research done under contract H0188039 by Allen Corp. of America. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–141886; paper copy price code A07.

OFR 6–84. Development of a Training Program for Shaft and Slope Construction Personnel, by Bryan R. Carmenati, Robert H. Trent, and Karen L. Sackett. July 1982. 128 pp. This report documents the need for formal health and safety and equipment operations training in the mine construction industry. The outlines, objectives, and training texts were developed based on the recommendation of needs of mine construction personnel and two contractors. The training materials contained herein, and under other contracts, are designed to improve the safety and production of those in mine construction. Research done under contract J0318020 by Mine Training Systems, Inc. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–143767; paper copy price code A07.

OFR 7–84. Ground Control Mechanisms in Multi-Seam Mining, by C. Haycocks, M. Karmis, Eddie Barko, John Carman, Brian Ehgartner, Steve Hudock, and Steve Webster. Oct. 1983. 328 pp. 156 figs. The objective of this research was to improve the design of underground mines to avoid or minimize the problems caused by the interaction of overlying coal seams. To evaluate past interaction effects and provide guidelines for future mine design, interactive ground control problems were categorized into four areas—pillar load transfer, massive inter-

seam shearing, subsidence, and pressure arching effects. The research was carried out using a two-pronged approach: (1) Modeling using finite elements, body-loaded low-modulus photoelastic and brittle models and (2) using results of field studies and detailed analyses of field observations. It became obvious early in the project that the geologic environment played a major role in interaction and interpretation of field data. Therefore, a review was made of the central Appalachian coalfields and geologic environment. The results of this review are presented in appendix 1. Research done under grants G1105050 and G1115511 by the Virginia Polytechnic Institute and State University. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 8–84. Control of Airblast and Excessive Ground Vibration From Blasting by Use of Efficient Stemming, by Calvin J. Konya, Duane Skidmore, and Francis Otuonye. June 1981. 199 pp. 62 figs. The objective of this study was to determine the relationships between borehole diameter and efficacious stemming type and length for a range of explosive pressures. A preferred material type and size was obtained after a detailed analysis of the data on minimum stemming lengths for retention acquired for limestone aggregate, crushed gravel aggregate, and Ottawa and river sands. Variables including the size, shape, and cohesive properties between the stemming particles and between stemming material and borehole walls were evaluated along with the strength of the rock. The study suggests that proper selection of stemming rock type and size distribution can reduce necessary stemming length, airblast levels, and ground vibration levels. Consequently, breakage can be improved and reductions realized for airblast, flyrock, and ground vibration. Research done under grant G5195034 by the Ohio State University. Available for reference at the following facilities: AD/MR, AVRC, LIB, OSM, and PRC/B. Copies of this report will not be available for purchase.

OFR 9(1)–84. Development of Models for Simulating Stormwater Runoff From Surface Coal Mined Lands. Volume I. Unit Hydrograph Models, by Michael E. Meadows, Kevin M. Howard, and Allen L. Chestnut. Nov. 1983. 173 pp. 39 figs. This study was designed to test the regional application of four popular synthetic unit hydrograph models. The performance of each model was evaluated with experimental watershed data from 38 watersheds in 14 States, 9 physiographic provinces, and 6 major coal-producing regions. The results provide insights to the regional application of each model and can be used to plan future hydrograph model development and calibration studies once an adequate surface mined land hydrologic data base is available. Research done under grants G1105070, G1115213, and G1195019 by the University of Kentucky and the University of South Carolina. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 9(2)–84. Development of Models for Simulating Stormwater Runoff From Surface Coal Mined Lands. Volume II. Finite Element Simulation of Overland Flow, by George E. Blandford, N. Peters II, and Michael E. Meadows. June 1983. 161 pp. 37 figs. Both Federal and State regulations require mining companies to develop specific plans for protecting the hydrological balance of a watershed, controlling sediment production, and diverting surface flows. Plan preparation requires predicting runoff volume, peak rate, and total hydrograph for design rainfall events. There is currently a very limited scientific basis for simulating the hydrological impact of surface mining activities. The purpose of this report is to present a scientifically (physically) based deterministic model to assess the hydrological impact of surface mined watersheds. Research done under grants G1105070, G1115213, and G1195019 by the University of Kentucky. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 10–84. Concurrent Establishment of Ground Cover and Hardwood Trees on Reclaimed Mineland and Unmined Reference Sites, by W. R. Byrnes, W. R. Chaney, and P. E. Pope. Dec. 1983. 13 pp. This research was conducted to assess reforestation success and ultimate productivity for areas reclaimed under the Surface Mining Control and Reclamation Act of 1977 (Public Law 95-87). The objectives were to (1) compare establishment success and productivity of ground cover and commercial hardwood trees planted concurrently and maintained under the same level of management on reclaimed mineland and unmined reference sites; (2) evaluate survival and growth of bareroot, containerized, and mycorrhizal inoculated hardwood seedlings; and (3) evaluate chemical plant control as a technique for concurrent establishment of hardwood tree species and low ground cover vegetation. Research done under grants G1105023 and G1115182 by Purdue University. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 11–84. Streamflow Estimation and Water Use Planning for Surface Mining in Northern Alaska, by S. Bandopadhyay, P. M. Fox, and R. F. Carlson. June 30, 1983. 72 pp. 16 figs. The primary objectives of this project were to improve methods to determine summer streamflow and stream response to surface mining activities in remote northern regions. A secondary objective was to provide a handbook describing techniques to estimate streamflow regimes and their accuracy for use by small-scale surface mining operators in the North. The project focused on developing standardized streamflow estimation procedures for different levels of surface mining activity versus differing availability of streamflow and climatic data. Decisions trees or flow diagrams based on data availability and size of mining operation were developed that will lead to a particular procedure to estimate streamflow for a particular mining operation. The flow diagrams were developed for each region because different stream regimes are anticipated within each region. The flow diagrams will provide standardized procedures to estimate streamflows (given a certain amount of data and the size of the mining operation), but also includes estimates of the risk inherent in the procedure used to estimate each parameter. All flow charts are based on the knowledge needed to successfully design and operate a long-term mine plan. Research done under grants G1105009 and G1115021 by the University of Alaska—Fairbanks. Available for reference at the following facilities: AD/MR, AVRC, DRC, LIB, PRC/B, SRC, and

TCRC. Copies of this report will not be available for purchase.

OFR 12-84. Survey of Ground, Surface Conditions Affecting Structural Response to Subsidence, by R. W. Bruhn, R. C. Speck, W. S. McCann, and O. S. Cecil. June 1983. 602 pp. 214 figs. The objective of this study was to examine the apparent influence of soil and near surface rock strata on the severity of damage experienced by surface structures subjected to mine subsidence. The report discusses (1) modes of ground movement that might complicate or be confused with mine subsidence, (2) prevailing concepts concerning mine subsidence in the Northern Appalachian Coalfield and Illinois Basin, (3) apparent influences of soil and near surface rock strata on the character of subsidence-related ground movements, (4) classifications and criteria for characterizing damage due to ground movements, and (5) types of subsidence damage experienced by homes above active mines in western Pennsylvania. A damage classification system that incorporates a severity index to characterize damage to homes with basements above active mines is presented. Also, a series of case histories illustrate subsidence damage to structures above active and abandoned mines. Research done under contract J0295014 by GAI Consultants, Inc. Available for reference at the following facilities: DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84-155860; paper copy price code A99.

OFR 13-84. Potash and Phosphate Demand, and Agricultural Supply Submodel, by Prospective Decision Models, Inc. Oct. 31, 1983. 149 pp. 3 figs. Potash and phosphate supply and demand computer submodels were developed and incorporated into the global macrodynamic simulation model, GloMaDyn, which represents 14 regions of the world. Each region is represented by submodels for demographics, economics, agriculture, energy, minerals, investment goods, aid, and trade. The objective of adding potash and phosphate representations to GloMaDyn was to analyze the interactions between the production of and agricultural demand for these minerals as productive inputs within an integrated, dynamic global framework. The enhanced model permits analysis of price changes, impacts of shortfalls in supplies, and other long-range events or policies that could affect the supply-demand balance. Research done under contract J0123067. Available for reference at LIB. Order ONLY from NTIS: PB 84-155878; paper copy price code A07.

OFR 14-84. Improved Crowd Limit Switches and Greenhorn for Electric Shovels, by Gary Choate, Fred O'Neil, Rudy Wachtler, and Cosmo Fazio. Sept. 30, 1983. 120 pp. 38 figs. The objective of this research was to develop and demonstrate appropriate system hardware for electric mining shovels that will prevent damage and downtime resulting from the shovel operator overextending the dipper handles when digging. The program began with a literature search and manufacturers product review to gather material as a basis for concept generation. Visits to three open pit mines provided information from operation and maintenance managers that was useful in preparing design concepts. These concepts were evaluated through laboratory tests and engineering analyses to select a final design concept. The improved greenhorn is designed to absorb the maximum energy generated by the greenhorn impacting the shipper shaft at maximum velocity with a loaded dipper. It consists of three shock-absorbing pads mounted on each side of the two dipper handles in a housing that bolts to the end of the dipper handle. The crowd limit control system is a nonmechanical device that senses the location of the dipper by counting the teeth of the pinion gear that drives the dipper handle and makes appropriate commands to the crowd motor to prevent greenhorn and shipper shaft collision. Research done under contract H0212019 by the Bendix Corp. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Copies of this report will not be available for purchase.

OFR 15-84. In-Mine Long Term Testing of Improved Truck Ladders, by J. L. Dahle, G. R. Gavan, and D. Strassel. Feb. 1983. 170 pp. 140 figs. This report describes in-mine tests that were conducted at eight mines in the United States to evaluate the novel pretensioned spring ladder design on haulage trucks. The design was initially developed by Woodward Associates, Inc., under a previously completed Bureau of Mines sponsored contract, Bureau of Mines OFR 87-81. The design is intended to improve ingress-egress for haulage truck operators as well as reduce maintenance of lower steps. Research done under contract J0295017 by Woodward Associates, Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-158831; paper copy price code A08.

OFR 16-84. Human Factors Analysis of Underground Metal and Nonmetal Mines, by Martin G. Helander and Gregory S. Krohn. Feb. 1983. 99 pp. 13 figs. The objective of this program was to research, develop, and validate a training program that will instruct miners in the proper preshift inspection, operating, and shutdown procedures for various types of major machines and equipment used in underground noncoal mines in order to reduce accidents and injuries. To identify human factors problems, unstructured interviews were performed with mine management, safety personnel, and mine workers. About 100 persons were interviewed at 9 mine locations, and work activities in each mine were inspected. Seventy-seven human factors problems were identified. A questionnaire was used to assign priorities to the research issues. The questionnaire was evaluated by human factors mining experts, MSHA inspectors, mine management personnel, and mine safety personnel. Of the 77 problems that were uncovered, 18 were selected for research and are described. Research done under contract H0308067 by Canyon Research Group, Inc. Available for reference at the following facilities: AD/MR, ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-158732; paper copy price code A05.

OFR 17-84. Evaluation of Geophysical Surface Methods for Measuring Hydrological Variables in Fractured Rock Units, by Robert W. Taylor. Nov. 1982. 146 pp. 73 figs. A simplified theoretical model for the use of electrical resistivity measurements to determine joint orientation and intensity was developed. A field procedure based on the theoretical model was applied to a physical model under laboratory conditions and at two field sites. The two field sites

were identical geologically but differed in that one site was intensely mined while the other was unmined. In all three cases, joint strike was determined within approximately 5° and the relative indications of joint intensity were correct. In addition to the electrical measurements, the anisotrophy associated with seismic velocity and attenuation was measured at each field site. The seismic measurements, in comparison with the electrical measurements, were much less informative and more difficult to interpret. A computer-automated system for the continuous monitoring of resistivity depth soundings was deployed at one of the sites. Continuous 48-h monitoring following a rainfall suggested that the downward movement of water could be detected. Research done under contract H0318044 by the University of Wisconsin—Milwaukee. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–158021; paper copy price code A07.

OFR 18–84. Fabrication and Test of an Articulated Remote Manual Roof Bolter, by R. E. Leyner and L. Brummert. Sept. 30, 1983. 34 pp. 14 figs. The objective of this investigation was to fabricate, laboratory test, and perform an underground test and evaluate a prototype articulating remote manual bolter for greater-than-seam-height bolting. The machine operator is located under supported roof approximately 5 ft from the bolt being installed. The results demonstrate that roof bolting with the articulating chassis and the operator approximately 5 ft from the bolting operation is feasible. Research done under contract H0202036 by the Bendix Corp. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–157866; paper copy price code A03.

OFR 19–84. A Study of Precalculation of Effect of Fires on Ventilation System of Mines, by Rudolf E. Greuer. Mar. 15, 1983. 293 pp. 25 figs. Two computer program sections to determine the fume or other contaminant exposures of underground miners were developed. One section deals with exposure at fixed points of the ventilation system, the other deals with the exposure of miners traveling along specified escapeways. The feasibility of combining the latter section with an existing mine evacuation program was investigated. Modifications were devised and the evacuation plan and contaminant exposure of 10 miners is presented. Based on the assumption that a nonsteady-state process can be approximated by a sequence of short-duration, steady-state processes, a new program for the nonsteady-state simulation of ventilation systems under the influence of mine fires was developed. Research done under contract J0285002 by the Michigan Technological University. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–159979; paper copy price code A13.

OFR 20–84. Feasibility Study of In-Mine Coal Preparation Facilities, by Dames & Moore and Roberts & Schaefer. 1982. 114 pp. 7 figs. This work examined the feasibility of in-mine coal preparation. The work included a survey of previous investigations and a preliminary analyses of the economic and technical feasibility on a selection of representative sites and degrees of cleaning. The preliminary analysis determined that in-mine preparation systems can be applied using currently available technology. The most likely mines for application will have shaft or slope access and be deeper than 500 ft. The refuse disposal systems technically feasible are (1) pneumatic placement of coarse refuse in room-and-pillar panels or longwall faces, (2) mechanical placement of coarse and fine fractions in room-and-pillar panels, and (3) hydraulic placement of fine fractions in room-and-pillar panels. The economic feasibility is much more dependent on the refuse disposal system than on the preparation system. It is estimated that the capital cost of an in-mine preparation and disposal system would be $6.00 per clean ton and the operating cost would be $1.24 per clean ton for a 1-million-clean-ton-per-year mine. Research done under contract J0333939. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–171347; paper copy price code A06.

OFR 21-84. Copper, Gold, Platinum, and Palladium Sample Results From the Klukwan Mafic/Ultramafic Complex, Southeast Alaska, by Jan C. Still. June 1983. 53 pp. 6 figs. The Klukwan mafic-ultramafic complex, located near Haines in southeast Alaska, was examined by Bureau of Mines personnel in 1981-82 to determine its potential for platinum-group metals, gold, and copper. The ultramafic portion of the complex and the alluvial fan below have long been recognized as a significant iron deposit. During this examination, over 400 rock, panned concentrate, and stream sediment samples were collected from an area 9 miles long by about 3 miles wide. Analyses of the samples indicate interesting values in platinum, palladium, gold, and copper at a number of locations throughout the area. Some of these values are located on Bureau of Land Management land open to claim staking and the remainder are located on patented mining claims. Research done by the Alaska Field Operations Center. Available for reference at the following facilities: AD/MDA, AFOC/A, AFOC/F, AFOC/J, and LIB. Copies of this report will not be available for purchase.

OFR 22–84. Economic Potential for Chromium, Platinum, and Palladium in the Mount Hurst Ultramafics, West-Central Area, Alaska, by William S. Roberts. Dec. 1983. 52 pp. 15 figs. Platinum, palladium, and chromite potential of the ultramafic rocks of Mt. Hurst, Ophir Quadrangle, west-central Alaska, was investigated in 1981 by the Bureau of Mines as part of a critical and strategic minerals program. Analyses of rock, stream sediment, soil, and panned concentrate samples indicate a low potential for lode and placer deposits of platinum, palladium, and chromite. The potential for paleoplacers is unknown. The ultramafic rocks consist of peridotites and pyroxenites of ophilitic origin. Comparison of these ultramafic rocks to other known occurrences provides a general framework for predicting size and quality of deposits. The upper limit for lode chromite ore is about 1 million tons; a greater probability exists for deposits containing less than 1,000 tons. The discontinuous character of the ultramafic rocks and the chemical variability of the chromite suggest the unlikelihood of economically significant platinum and palladium or chromite lode

deposits. Placer potential for these metals is limited because of the relative absence of alluvial deposits in the first order drainages. Placer potential in larger adjacent drainages is unknown except for the apparent negative results of historical prospecting. The detection of platinum and palladium in selected chromite and panned concentrate samples suggest a source for the nearby Boob Creek placer platinum occurrence reported by previous investigators. Research done by the Alaska Field Operations Center. Available for reference at the following facilities: AD/MDA, AFOC/A, AFOC/F, AFOC/J, and LIB. Copies of this report will not be available for purchase.

OFR 23–84. Cost-Effectiveness of Increasing Airflow at Any Location in Underground Coal Mines (Volume II—Appendices), by Sandip K. Mukherjee, Anthony W. Laurito, Muhammed O. Rahim, and Madan M. Singh. Feb. 1983. 122 pp. This report presents the results of the economic analyses of several applicable alternatives to increase airflow in four underground coal mines. Pressure and quantity surveys were conducted underground, and measurements were made at the main mine fans. The existing ventilation networks were modeled using a modified ventilation simulator, and the applicable alternatives were simulated. Performance data obtained from the simulation runs were utilized to conduct the cost-effectiveness analyses. Volume II, this report, contains the output of the computer simulation runs. Research done under contract J0100066 by Engineers International, Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Copies of this report will not be available for purchase.

OFR 24(1)–84. Mining and Rock Mechanics Research in Oil Shale and Nahcolite, Horse Draw Shaft, Colorado. Volume 1. Geotechnical Information, by Staff, Multi Mineral Corp. Aug. 1983. 249 pp. 77 figs. Horse Draw Mine, a facility owned by the U.S. Bureau of Mines, provides subsurface access to the nahcolite, dawsonite, and saline oil shale deposits in the Parachute Creek Member of the Green River Formation. The Bureau of Mines and the Bureau of Land Management entered into an agreement with the Multi Mineral Corp. (MMC) for a research program to be conducted by MMC at the facility to obtain mining, environmental, and geotechnical test data and bulk samples of the nahcolite, dawsonite, and oil shale. An extensive research program of core drilling, geology, rock mechanics, ventilation, and drilling and blasting tests was conducted. Processing studies included crushing, photosorting, heavy media separation, and flotation. The work is reported in detail in this seven-volume report. Volume 1 comprises geotechnical information. Research done under memorandum of agreement MOA14-09-0070-799. Available for reference at the following facilities: AD/MR, BLM, DRC, IFOC, LIB, MSHA, PRC/B, TCRC, and WFOC. Copies of this report will not be available for purchase.

OFR 24(2)–84. Mining and Rock Mechanics Research in Oil Shale and Nahcolite, Horse Draw Shaft, Colorado, Volume 2. Mine Operations Engineering, by Staff, Multi Mineral Corp. Aug. 1983. 338 pp. 63 figs. The Bureau of Mines and the Bureau of Land Management entered into an agreement with the Multi Mineral Corp. (MMC) for a research program to be conducted by MMC at the Horse Draw Mine in the Green River Formation to obtain mining, environmental, and geotechnical test data and bulk samples of the nahcolite, dawsonite, and oil shale. This volume comprises information on the current ventilation system and scheduled mine development and production for the program. Research done under memorandum of agreement MOA14-09-0070-799. Available for reference at the following facilities: AD/MR, BLM, DRC, IFOC, LIB, MSHA, PRC/B, TCRC, and WFOC. Copies of this report will not be available for purchase.

OFR 24(3)–84. Mining and Rock Mechanics Research in Oil Shale and Nahcolite, Horse Draw Shaft, Colorado. Appendix Volume A–1. Raw Data, by Staff, Multi Mineral Corp. Aug. 1983. 274 pp. 57 figs. The Bureau of Mines and the Bureau of Land Management entered into an agreement with the Multi Mineral Corp. (MMC) for a research program to be conducted by MMC at the Horse Draw Mine in the Green River Formation to obtain mining, environmental, and geotechnical test data and bulk samples of the nahcolite, dawsonite, and oil shale. This volume comprises rock mechanics test information and assay data. Research done under memorandum of agreement MOA14-09-0070-799. Available for reference at the following facilities: AD/MR, BLM, DRC, IFOC, LIB, MSHA, PRC/B, TCRC, and WFOC. Copies of this report will not be available for purchase.

OFR 24(4)–84. Mining and Rock Mechanics Research in Oil Shale and Nahcolite, Horse Draw Shaft, Colorado. Appendix Volume A–2. Core Hole 1840-UG-3 Data, by Staff, Multi Mineral Corp. Aug. 1983. 265 pp. 1 fig. The Bureau of Mines and the Bureau of Land Management entered into an agreement with the Multi Mineral Corp. (MMC) for a research program to be conducted by MMC at the Horse Draw Mine in the Green River Formation to obtain mining, environmental, and geotechnical test data and bulk samples of the nahcolite, dawsonite, and oil shale. This volume comprises test data on core hole 1840-UG-3. Research done under memorandum of agreement MOA14-09-0070-799. Available for reference at the following facilities: AD/MR, BLM, DRC, IFOC, LIB, MSHA, PRC/B, TCRC, and WFOC. Copies of this report will not be available for purchase.

OFR 24(5)–84. Mining and Rock Mechanics Research in Oil Shale and Nahcolite, Horse Draw Shaft, Colorado, Appendix Volume A–3. Drawing Index, by Staff, Multi Mineral Corp. Aug. 1983. 11 pp. The Bureau of Mines and the Bureau of Land Management entered into an agreement with the Multi Mineral Corp. (MMC) for a research program to be conducted by MMC at the Horse Draw Mine in the Green River Formation to obtain mining, environmental, and geotechnical test data and bulk samples of the nahcolite, dawsonite, and oil shale. This volume is an index of the drawings that are included in the report. Research done under memorandum of agreement MOA14-09-0070-799. Available for reference at the following facilities: AD/MR, BLM, DRC, IFOC, LIB, MSHA, PRC/B, TCRC, and WFOC. Copies of this report will not be available for purchase.

OFR 24(6)–84. Mining and Rock Mechanics Research in Oil Shale and Nahcolite, Horse Draw Shaft, Colo-

rado. Appendix Volume A–4. Surface Testing, by Staff, Multi Mineral Corp. Aug. 1983. 316 pp. 22 figs. The Bureau of Mines and the Bureau of Land Management entered into an agreement with the Multi Mineral Corp. (MMC) for a research program to be conducted by MMC at the Horse Draw Mine in the Green River Formation to obtain mining, environmental, and geotechnical test data and bulk samples of the nahcolite, dawsonite, and oil shale. This volume comprises data pertaining to the surface testing that was performed. Research done under memorandum of agreement MOA14-09-0070-799. Available for reference at the following facilities: AD/MR, BLM, DRC, IFOC, LIB, MSHA, PRC/B, TCRC, and WFOC. Copies of this report will not be available for purchase.

OFR 24(7)–84. Mining and Rock Mechanics Research In Oil Shale and Nahcolite, Horse Draw Shaft, Colorado. Appendix Volume A–5. Sample Log, by Staff, Multi Mineral Corp. Aug. 1983. 230 pp. 35 figs. The Bureau of Mines and the Bureau of Land Management entered into an agreement with the Multi Mineral Corp. (MMC) for a research program to be conducted by MMC at the Horse Draw Mine in the Green River Formation to obtain mining, environmental, and geotechnical test data and bulk samples of the nahcolite, dawsonite, and oil shale. This volume comprises the sample log. Research done under memorandum of agreement MOA14-09-0070-799. Available for reference at the following facilities: AD/MR, BLM, DRC, IFOC, LIB, MSHA, PRC/B, TCRC, and WFOC. Copies of this report will not be available for purchase.

OFR 25–84. A Summary of Data From the Sunnyside Single Entry Study—1971–80, by Elaine T. Bowers and Laurin N. Henton. May 12, 1983. 541 pp. 538 figs. The Sunnyside single-entry project pioneered the use of single entries for longwall development in this country. During the 10-year course of the project, an immense amount of information was gathered. Over 3 miles of entries were observed primarily through instrument groupings placed in strategically located areas or "rooms." Nearly 1,200 instruments were monitored to gain information on the behavior of coal entries during development stages and through the mining of two longwall panels. This was one of the most extensively documented projects undertaken by the Bureau of Mines. The data gathered has a great potential for scientific research, especially in the area of longwall mining. This report presents the ground control data gathered, in the form of computerized plots. Roof-to-floor deformation and load on cribs and roof bolts make up the bulk of the data, which is presented as load or deformation versus time. The plots are organized, generally, by the three main entries involved and, specifically, by the individual areas or rooms in those entries. No major attempt will be made in this paper to analyze data other than to identify the source and history. Research done by the Spokane (WA) Research Center. Available for reference at the following facilities: DRC, LIB, MSHA, NMH&SA, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 26–84. Preparation of Asbestos Substitute Multi-Strand Glass Fibers, by R. G. Simhan. Sept. 30, 1983. 20 pp. 2 figs. Several slate-slime glass fiber formulations were suggested as substitutes for asbestos in alkali environments. Different coatings were applied to determine their contribution to the alkali resistance of the system. The short fiberizing temperature range of the compositions precluded their fiberization with a 100-hole bushing. A single-hole bushing was used to obtain gram quantities for evaluation. This short fiberization range would preclude commercial-scale manufacture without further development. Research done under contract J0123050 by Manville Service Corp. Available for reference at the following facilities: ALRC, AVRC, LIB, MSHA, NMH&SA, PRC/B, and TCRC. Copies of this report will not be available for purchase.

OFR 27–84. Evaluation of Ceramic and Refractory Grade Raw Materials in Alabama: Gibbsite in Saprolites of East-Central Alabama. Phase II: Detailed Evaluation, by Mirza A. Beg. Sept. 30, 1983. 70 pp. 14 figs. Gibbsite occurs in soils and saprolites derived from feldspathic biotite and hornblend gneiss and layered amphibolite in Chambers County, AL. This region lies in a humid, subtropical climatic zone in the Piedmont physiographic province of east-central Alabama. Three target areas (I, II, and III) were selected on the basis of reconnaissance sampling carried out during the first phase of the study. Soil and saprolite samples were collected at 5-ft (1.52-m) intervals from shallow auger drill holes in the target areas. Gibbsite content of samples, as measured by differential scanning calorimeter (DSC), range from zero to 72 pct. Areas containing more than the average 10 pct gibbsite (DSC) are outlined for each target area and estimates of gibbsite tonnages were made for each. The gibbsite-rich saprolite blanket is usually within the first 20 ft (6.1 m) of the surface in the B and upper part of the C soil horizons. Gibbsite concentrations are richer where the depth of weathering is not more than 25 ft (7.62 m) because unweathered bedrock is conducive to internal drainage depending upon the mineralogy and orientation of rock structure. Estimated tonnage of 10 pct (DSC) or more gibbsite for target area I is 554,880 metric tons, target area II is 50,616 metric tons, and target area III is 309,729 tons. Research done under contract J0123066 by the Geological Survey of Alabama. Available for reference at the following facilities: ALRC, LIB, and TURC. Copies of this report will not be available for purchase.

OFR 28–84. Minerals Availability Manganese Deposit Abstracts, by Joseph S. Coffman, Catherine C. Kilgore, and Cesar M. Palencia. Dec. 1983. 118 pp. This report on manganese is one of a series of minerals availability commodity deposit abstracts. Nonconfidential information from the Minerals Availability Program data base covering domestic and foreign manganese properties and deposits has been abstracted for use in the report. Abstracts include applicable data on location, published reserves and resources, geology, mine beneficiation systems, and operational information. Research done by the Bureau of Mines Minerals Availability Field Office. Available for reference at the following facilities: AFOC/J, DMA, IFOC, LIB, and WFOC. Order ONLY from NTIS: PB 84–166164; paper copy price code A09.

OFR 29–84. Electrical Installations in Oil Shale Mines, by Bobby B. Gillenwater, Richard J. Kline, and Norbert Paas. Aug. 1983. 165 pp. 23 figs. This report presents recommended guidelines and regulatory changes applicable to electrical installations in underground oil shale mines. The recom-

mendations are based on information gathered from oil shale operators, government agencies, and other knowledgeable sources familiar with existing plans for mining systems and electrical installations, and on present understanding of the problems and hazards associated with oil shale mining. Additional discussions of specific electrical problems related to oil shale mining include ground fault current levels, permissible electrical wheel motors, permissible batteries and electrical starting systems, intrinsically safe instrumentation, and applicability of existing test standards. Research done under contract J0113061 by Foster-Miller, Inc. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-165794; paper copy price code A08.

OFR 30-84. Influence of Rock Discontinuities on Coal Mine Subsidence, by Kevin M. O'Connor, John E. O'Rourke, and James Carr. Sept. 10, 1983. 129 pp. 37 figs. This report documents the process of literature review, site selection, instrument installation, data acquisition, and preliminary data reduction performed to evaluate the influence of rock mass discontinuities on coal mine subsidence. A system of surface, subsurface, and mine level instrumentation ranged from 630 to 1,040 ft thick. Survey monuments, borehole pressure cells, full-profile borehole inclinometer-extensometers, mine level extensometers, stressmeters, and tap extensometer convergence stations were installed to monitor displacements and stress changes. Final design of the instrumentation system was based on (1) review of available information, (2) field mapping and analysis of areal photography, (3) drilling, and (4) borehole geophysics. The report contains the complete graphed data of stress and displacements accompanying the longwall mining of a 4,800-ft-long by 480-ft-wide coal panel. Research done under contract J0100087 by Woodward-Clyde Consultants. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84-166370; paper copy price code A07.

OFR 31-84. Ultrasonic Stress Transfer: A Direct Test of Rock Bolt Integrity, by G. R. Moulder, P. L. Howard, J. C. Hesler, and W. B. Tarpley, Jr. Aug. 1983. 84 pp. 15 figs. A device was developed that measures dynamic stress (ultrasonic energy) transfer through installed rock bolts, a measure that is directly proportional to the degree of grout bonding of the bolt to the mine roof structure and thus the ability of the bolt to bear static stress. The rock bolt bond tester (RBBT) is a handheld portable device that shows three ranges of bolt bond condition; i.e., one-third (bad bond), two-thirds (marginal), or fully bonded. These are shown respectively by a red, yellow, or green light that displays for 4 s. RBBT performance was verified with 2½- to 8-ft bolts installed in various types of mine roof structures (sandstone, shale, and boney coal-mud), and is now being tested by the Bureau of Mines in mines across the United States. The unit is about the size of a five-battery flashlight and contains the transducer, electronics, and battery pack. The RBBT is designed for extreme ease of operation, requiring only manual contact with the bolt and signal readout. The batteries are rechargeable and the package is designed for durability in a mine environment. Research done under contract J0295037 by the Energy & Minerals Research Co. Available for reference at the following facilities: DRC, LIB, MSHA, NMH&SA, SRC, and TCRC. Order ONLY from NTIS: PB 84-165802; paper copy price code A05.

OFR 32-84. Application of Draft Power Sensor (DPS) Concepts to Pan Scrapers, by H. S. Benson. Aug. 1983. 102 pp. 50 figs. This report describes the pan scraper wheel slip monitor (WSM), the function of which is to instantly warn the operator of wheel slip and thus allows for immediate corrective action. Knowledgeable pan scraper people recognize that the preponderance of scraper time damage and wear occurs during useless wheel slip when the operator attempts to increase machine draft beyond what traction will allow. The resultant shortened tire life has become very expensive. The WSM reported here provides the means for relieving the operator of attempting to judge wheel slip on tires out of view. Direct and intuitively understandable audible and flashing light warnings tell the operator which wheel is slipping and indicates the relative magnitude of the slip. Besides the WSM's patent utility as a real time operator aid, it has unique potential for application to extended term wheel slip history acquisition under field conditions. Research done under contract H0292016 by the Southwest Research Institute. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-166610; paper copy price code A06.

OFR 33-84. Appraisal of Deeper Soil Loosening Equipment for Use in Reclaiming Illinois Prime Farmland After Surface Coal Mining, by Yoginder P. Chugh and K. V. K. Prasad. Oct. 1983. 112 pp. 29 figs. This study appraises available deeper soil loosening equipment in the 1- to 4-ft-depth range, in the United States and abroad, that has potential for Illinois prime farmland reclamation. The appraisal was based on written and/or oral contacts with equipment manufacturers, reclamation experts, and visits with selected equipment manufacturers. The results indicate that several manufacturers in the United States, the Federal Republic of Germany, and England market static and vibratory deeper soil loosening equipment that may have potential for application in Illinois. Pertinent information concerning equipment with potential is presented in this report. Research done under contract J0225015 by Southern Illinois University—Carbondale. Available for reference at the following facilities: AD/MR, LIB, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84-166644; paper copy price code A06.

OFR 34-84. Evaluation of Branch and Horizontal Boreholes for In Situ Leach Mining, by D. W. Dareing, E. T. Wood, and D. H. Davidson. July 1980. 151 pp. 39 figs. Multiple-branch wellbores and horizontal holes, when applied to deep lying ore bodies, have the potential of significantly reducing total footage drilled per acre of well pattern. In addition, horizontal holes may increase sweep efficiency. Several drilling and completion concepts are given and evaluated in this report. The evaluation shows that there is economic incentive to further develop these concepts for field application to ore bodies 1,500 ft deep. Research done under contract J0199113 by Maurer Engineering Inc. Available for reference at the following facilities: ALRC, AVRC, DOE/M,

DRC, LIB, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-165869; paper copy price code A08.

OFR 35-84. Evaluation of Roof Trusses, Phase II. Use of Frequency of Vibration To Determine Chord Tension, by Clark P. Mangelsdorf. Jan. 1983. 58 pp. 27 figs. This report deals with efforts to develop a portable device suitable for underground use for the purpose of measuring the frequency of vibration of the horizontal chords of Birmingham roof trusses. Four devices were investigated and evaluated. An approximate empirical expression developed from a mathematical analysis provides a means of converting the frequency into tension. The method appears to be effective in mines with shale roof but requires some modification for other roofs. Research done under contract J0100070 by the University of Pittsburgh. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-166479; paper copy price code A04.

OFR 36-84. Development and Evaluation of Noise Control Techniques for Taconite Processing Equipment, by N. R. Dixon, A. R. Thompson, M. N. Rubin, and R. Madden . Feb. 1983. 160 pp. 97 figs. The objectives of this research were to assess worker noise exposure to taconite processing plants; identify major noise-generating equipment; and develop, install, and evaluate noise control treatments for those sources. Extensive noise and vibration meaurements were made on grinding mills in which the process parameters affecting mill noise were identified and the level of shell impact noise around the mill was defined. A multiplexing telemetry system was used to obtain shell vibration measurements from a rotating mill. Mill noise control methods were investigated and a partial mill barrier was built and tested on a semiautogeneous mill. A noise reduction of approximately 3 to 6 dBA was achieved on the falling side of the mill. The use of rubber mill liners on autogeneous mills was evaluated. Noise sources on fine screens were quantified and noise control measurements were developed. Noise reductions of 11 to 13 dBA were achieved at positions around the fine screen and some in-service testing was done. Noise measurements of crusher screens were obtained and noise control through resilient screen decks appears to hold the most promise. Additional benefits might be lower life-cycle cost because the service life of resilient decks is claimed to be longer than that of steel. Research done under contract H0377014 by Bolt Beranek and Newman Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-166198; paper copy price code A08.

OFR 37-84. Monitoring of a Phosphate Mining Area in Central Florida Using Landsat Satellite Data, by Michael Inglis and Thomas K. Budge. Mar. 1983. 67 pp. 34 figs. This report presents an investigation on the applicability of Landsat multispectral scanner satellite and simulated thematic mapper data to the phosphate mining area of central Flordia. An evaluation was made of the sensors as mine monitoring tools. The report describes the computer software and hardware used in the digital analysis of the scanner data, the theory of unsupervised classification, the methodology of image processing, and documents the classifications of selected mining and wetland areas. Conclusions are discussed and recommendations are made for future investigations. Research done under contract J0113099 by the University of New Mexico. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-165752; paper copy price code A04.

OFR 38-84. Handbook for State and Local Taxation of Solid Minerals, by George H. K. Schenck. Sept. 1983. 181 pp. 8 figs. This report provides a discussion of the appropriate procedures for conducting an economic analysis of proposed new taxes or changes in taxes on owners and operators of solid mineral deposits. Price elasticity of demand and supply are emphasized as key factors in determining the incidence of a mineral tax and the degree to which a mineral tax can be passed on by mine operators within a State to citizens of other States. Income, property, and severance taxes are the focus of the report; however, it is emphasized that the interrelationships between these taxes, their use at the several taxing levels (Federal, State, and local), and with other government-mandated charges should be incorporated as part of an analysis of tax changes. Constitutional provisions set important constraints on tax alternatives available to State and local governments. Principles guiding good tax practice are provided, and the relative advantages-disadvantages of the major taxes are discussed. Three analytical methods are described and several case studies are discussed. The cases, along with their detailed solutions, provide easily followed concepts. Research done under grants G1115423 and G5105046 by the Pennsylvania State University. Available for reference at the following facilities: AD/MDA, AD/MI, AVRC, LIB, OSM, and PRC/B. Order ONLY from NTIS: PB 84-166602; paper copy price code A09.

OFR 39-84. Postmining Results in Coshocton County, Ohio: Research on the Hydrology and Water Quality of Watersheds Subjected to Surface Mining, by U.S. Department of Agriculture and Ohio State University. May 1983. 176 pp. 53 figs. Watershed CO6 in Coshocton County, OH, was instrumented in 1976 as one of three watersheds established for the purpose of investigating surface mining and reclamation effects on local hydrology, sediment discharge, and water quality. Each watershed occupied approximately 50 acres in a unique geologic setting within southeastern Ohio. Surface runoff and ground water levels were monitored. Samples were taken for sediment determination and chemical analysis prior to mining. Monitoring and sampling continued through the period of watershed disturbance caused by mining and reclamation activities, which began in November 1976. A postreclamation period that followed the cessation of worker-machine activity on the watershed began in October 1978 and continued to the end of January 1981. Research done under contracts J0166054 and J0166055. Available for reference at the following facilities: LIB, OSM, SRC, and TCRC. Order ONLY from NTIS: PB 84-165893; paper copy price code A09.

OFR 40-84. Theoretical Noise and Propagation Models for Through-the-Earth Communication, by D. A. Hill

and J. R. Wait. May 1982. 52 pp. 12 figs. A survey of the literature on extremely low-frequency and very low-frequency atmospheric noise was made. Most measurements have concentrated on vertical electric field and the horizontal magnetic field rather than the vertical magnetic field, which is of interest in transmission between horizontal loops. The limited vertical magnetic field data indicate that the vertical component is generally 10 to 20 dB below the horizontal component. Three laterally inhomogeneous earth models were analyzed for conversion of horizontal to vertical magnetic field. The rough surface model examines surface effects, the inhomogeneous thin sheet model treats volume effects, and the buried cylinder model treats localized manufactured effects. All three models predict the possibility of significant conversion from horizontal to vertical magnetic field. A thin sheet model was also used to examine transmission from a buried magnetic dipole source. It was found that the predicted fields more nearly model the measured data than does the homogeneous half-space model. Research done under contract J0113058 by the National Telecommunications and Information Administration. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–166628; paper copy price code A04.

OFR 41–84. Recommended Guidelines for Oxygen Self-Rescuers—Volume IV—Underground Non-Coal Mining, by Randolph Berry and Donald W. Mitchell. June 1983. 176 pp. 26 figs. The Bureau of Mines initiated a contract for the development of guidelines for the storage and use of self-contained self-rescuers (SCSR) in underground noncoal mines. An SCSR is a device capable of supplying, in an emergency, 1 h of self-contained oxygen (no breathing of mine air). The information and recommendations in this report were developed primarily from three sources: discussions with mine representatives (including management, labor, and government), site visits in underground mines, and a detailed analysis of every reported noncoal accident that produced hazardous atmosphere during the 5-yr period 1976-80, plus 10 other major incidents from prior years. Research done under contract J0199118 by Foster-Miller, Inc. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–166636; paper copy price code A09.

OFR 42–84. Noise Control Techniques for the Design of Coal Preparation Plants, by M. N. Rubin, A. R. Thompson, R. K. Cleworth, and R. F. Olson. Dec. 1982. 135 pp. 51 figs. The purpose of this work was to document currently available noise control techniques that can be incorporated into new coal preparation plants during the design stage. This was accomplished by reviewing previous experience, conducting an extensive literature search, visiting operating coal preparation plants, and contacting various equipment manufacturers. The treatments addressed include equipment substitution, changes in plant layout, and retrofit treatments for existing equipment. Research done under contract J0100018 by Roberts & Schaefer Co. and Bolt Beranek and Newman Inc. Available for reference at the following facilities: DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84–166172; paper copy price code A07.

OFR 43–84. Noise Control of Rubber-Tired Front-End Loaders Used in Surface Mining, by N. R. Dixon and A. R. Thompson. June 1983. 52 pp. 28 figs. The objectives of this program were to assess and demonstrate retrofit noise control technology for front-end loaders. The treatments had to be practical, cost effective, and easily installed by mine personnel. The noise sources and acoustic paths that contribute to operator noise exposure were identified for two selected loaders. Retrofit noise control treatments were designed and installed on the loaders, and noise reduction of more than 10 dBA at the operator position were achieved on both machines. The retrofit packages are low cost and have been field tested in two mines for more than 2 yr. The results of the program were communicated to the mining industry through a series of workshops and a field manual. The workshops were given in 9 States across the United States, and more than 440 manuals were distributed. An audiovisual slide presentation was also developed that summarizes the program. Research done under contract J0395028 by Bolt Beranek and Newman Inc. Available for reference at the following facilities: DRC, LIB, MSHA, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84–166180; paper copy price code A04.

OFR 44–84. Use of Hazard Pictorials/Symbols in the Minerals Industry, by Belinda Lowenhaupt Collins. Sept. 1983. 193 pp. 52 figs. This report documents a multiphase research effort on the evaluation of the effectiveness of safety symbols and hazard pictorials for use in mining and milling operations. The first phase reviews applicable codes and standards, and documentation of typical mining hazards to determine relevant safety messages. In the second phase, visits were made to eight minesites to document existing sign practice and common mining hazards. In the third phase, the effectiveness of two sets of symbols for 40 different safety messages was evaluated with 267 miners from 10 sites at disparate geographical locations. The evaluation included an assessment of the effectiveness of six different symbol surround shapes and colors. The most effective symbols depicted both the person and the hazard or protective gear; these were more representational rather than highly abstract. Based on this research, a set of 40 symbols are suggested for further graphic refinement, additional evaluation, and eventual use. Research done under contract J0113020 by the National Bureau of Standards. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–165877; paper copy price code A09.

OFR 45–84. Evaluation of Surface Storage Facilities for Explosives, Blasting Agents and Other Explosive Materials, by J. Roth. June 1, 1983. 78 pp. 3 figs. The purpose of this study was to increase the safety of explosive storage. This was accomplished by (1) review of histories of recent and past magazine explosions to define causes and trends; (2) observation of present-day explosive storage and practices at active mines; (3) examination of Federal regulations on explosive storage to determine whether they address all conceivable safety problems, whether they contain redundant or obsolete standards, and whether their intent is clearly stated; and (4) recommendations for safety improvements and for revision and clarification of governmental regula-

tions. A recent increase in magazine explosion frequency must be attributed to an increase in deliberate (criminal or malicious mischief) explosions. Fires of various origins account for the remaining explosions of the past decade. During 1884–1926, several lightning-generated explosions occurred in nonmetal magazines, but it appears that a well-constructed metal magazine is immune to direct lightning strikes, regardless of whether it is grounded or not grounded. Grounding a metal magazine cannot be harmful, but it may well be superfluous. Magazines were observed at 34 widely separated mines, and storage problems were discussed with personnel at those mines. In general, storage conditions and practices were found to be satisfactory. Usually, only small quantities of explosives are stored on mine property since most explosives are brought in by suppliers when needed. Mine Safety and Health Administration and Bureau of Alcohol, Tobacco and Firearms standards on explosive storage appear to cover safety aspects adequately; however, certain revisions are recommended to clarify. Research done under contract J0318071 by Management Science Associates. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–168392; paper copy price code A05.

OFR 46–84. Development of a Phase Difference of Arrival Technique for Location of Trapped Miners, by W. G. Hopkins III, R. H. Church, and W. E. Webb. Aug. 27, 1983. 35 pp. 12 figs. The development of systems for location of miners who have become entrapped following a mine disaster is one of the major research goals in the Bureau of Mines. Current technologies for locating trapped miners from the surface are either simple direction finders or time difference pulse systems that have accuracy limitations. Developing technologies using full-vector field measurements at several receiving points are currently being studied. The necessity of measuring field strength with great accuracy can be a drawback in these systems. However, a system that operates with continuous-wave radio signals, with phase differences that can be measured accurately even in weak signal conditions, would greatly improve the location accuracy. A microcomputer could be used in conjunction with the system to gather and manipulate the data to automatically pinpoint the location of trapped miners. Comparison of this system with existing technology indicates a favorable accuracy-complexity ratio for the phase difference of arrival technique. Research done by the Tuscaloosa Research Center. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Copies of this report will not be available for purchase.

OFR 47–84. Noise Control of Large Track Dozers Used in Surface Mining, by R. Madden and M. Rubin. Apr. 1983. 58 pp. 35 figs. This report summarizes the development and demonstration of retrofit noise control treatments for large track dozers. Noise control treatments were installed on three demonstration dozers and field tested for more than 1 yr in surface mines. One dozer was equipped with a basic operator cab and the other two were equipped with rollover protective structures. The noise control treatments proved to be both effective and durable. As part of the project, a field manual describing the fabrication and installation of the treatments was also produced. The manual was distributed to mining industry representatives through a series of 1-day workshops across the United States. Forty-nine workshops were presented to over 800 people. As a result of the favorable reception of the workshops, an audiovisual slide presentation was also developed that summarizes the program. Research done under contract J0177049 by Bolt Beranek and Newman Inc. Available for reference at the following facilities: DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84–172477; paper copy price code A04.

OFR 48–84. Evaluation of Proposed Human Subject Certification Tests for Self-Contained Breathing Apparatus, by J. Frederick Stampfer, Alan L. Hack, and Andres Trujillo. Mar. 1983. 56 pp. The Bureau of Mines proposed a new series of human subject certification tests for self-contained breathing apparatus (SCBA) in 1977. Eight SCBA's, one open-circuit and seven closed-circuit, were worn by test subjects while performing the tests. The functioning of the apparatus was monitored continuously during the majority of the tests. The major conclusions were: (1) The proposed tests are not too physically demanding. (2) There should be a minimum test subject weight. (3) The important apparatus variables to be measured are breathing resistance, temperature, and CO_2 and O_2 concentrations of the inhaled gas. (4) Continuous monitoring should be employed. (5) New pass-fail criteria based on realistic estimates of the physiological requirements of the user, tempered by present and future engineering limitations, are needed. (6) Breathing machines should be used for the majority of certification testing when available. (7) A more realistic ergonomics test than that presently proposed is needed. (8) System gas leak and facepiece leakage tests are also needed. Research done under contract J0100068 by the Los Alamos National Laboratory. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–172212; paper copy price code A04.

OFR 49–84. Recommended Guidelines for Oxygen Self-Rescuers—Volume III—Escapetime Studies in Underground Coal Mines, by D. Randolph Berry, Diane M. Doyle, Eliezer Kamon, and Donald W. Mitchell. June 1983. 49 pp. 6 figs. The objectives of this project were to (1) determine escape speed in different mine conditions, (2) evaluate the performance of chemical oxygen self-contained self-rescuers (SCSR) under actual escape conditions, and (3) measure the physiological cost of mine escape. A special escapeway was established so that escape speeds and the use of SCSR's could be analyzed over a wide range of conditions, including travelway heights of 30 in to 7 ft. The average escape speeds ranged from 96 ft/min crawling to 264 ft/min for head-bent walking. The average life of six SCSR's was 60.8 min; those traveling faster consumed their SCSR's faster, although the total distance traveled before exhaustion of the SCSR was independent of speed and travel. Physiological data were also recorded. The average respiration rate was 41 L/min and the average oxygen consumption was 1.38 L/min. Research done under contract J0199118 by Foster-Miller, Inc. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and

TURC. Order ONLY from NTIS: PB 84–179506; paper copy price code A03.

OFR 50–84. Stress Analysis of Wire Hoist Rope, by George A. Costello and James W. Phillips. Sept. 30, 1983. 103 pp. 25 figs. A theoretical analysis is presented for the static and dynamic response of wire rope in deep-shaft mining operations. Expressions for the stresses in the individual wires of complex wire ropes are derived, and specific results for simple strands are presented for the case of ropes subjected to a combination of axial loading and bending over a sheave. Consideration is also given to the dynamic overloading associated with certain mining operations, such as dumping ore into a suspended skip and accelerating a fully loaded skip upward. Experiments to determine the axial stiffness of wire rope are described. Factors affecting the service life of wire rope, such as residual and contact stresses and fatigue behavior, are discussed. Specific research areas in need of further investigation are identified. Research done under contract J0100011 by the University of Illinois—Urbana-Champaign. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–172618; paper copy price code A06.

OFR 51–84. Contamination of Ground and Surface Waters by Uranium Mining and Milling. Volume III: Experimental Studies & Analytical Procedures, by D. D. Runnells, C. N. Gerlitz, A. Davis, R. D. Lindberg, R. Meglen, G. Swanson, L. Taylor, R. Sistko, and R. McNelly. Sept. 15, 1983. 229 pp. 71 figs. The objective of this study was to measure the degree of retardation of the important chemical species in fluid from a uranium tailings pile as the fluid passed through cores taken from underlying rock. The measurements indicated that pH was the dominant control on the behavior of these species, and that the pH was affected primarily by the calcite cement in the rocks. The most appropriate species for monitoring were sulfate, chloride, and selenium. An appendix provides a description of the advantages and disadvantages of the various analytical procedures used on these high-ionic strength solutions. Research done under contract J0295033 by the University of Colorado. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–172204; paper copy price code A11.

OFR 52(1)–84. Surface Coal Mine Spoil Stability Study, Eastern Coal Province. Volume I, by Paul G. Swanson, J. Christopher Giese, and John S. Jones, Jr. Aug. 25, 1983. 168 pp. 32 figs. The objective of this project was to quantitatively assess the slope stability problems associated with coal surface mining in the eastern coal province and to recommend spoil placement techniques that provide for slope stability. Data were collected for 11 minesites in Alabama, Kentucky, Ohio, Pennsylvania, Tennessee, and West Virginia. A site was selected in each of the six States on which a detailed investigation was conducted. The investigations included drilling through the slide into solid ground beneath, collecting samples at various depths for identification, and for laboratory tests. A topographic survey and field monitoring was conducted to determine field conditions at each slide. It was concluded that there are numerous factors related to the geologic and topographic conditions within the region that contribute substantially to the problems of spoil stability. The most significant factor appears to be the steep topography of the areas being mined. Research done under contract J0395011 by the Law Engineering Testing Co. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–178672; paper copy price code A08.

OFR 52(2)–84. Surface Coal Mine Spoil Stability Study, Eastern Coal Province. Volume II, by Paul G. Swanson, J. Christopher Giese, and John S. Jones, Jr. Aug. 25, 1983. 351 pp. 225 figs. The objective of this project was to quantitatively assess the slope stability problems associated with coal surface mining in the eastern coal province and to recommend spoil placement techniques that provide for slope stability. Data were collected from 11 minesites in Alabama, Kentucky, Ohio, Pennsylvania, Tennessee, and West Virginia. Volume II contains the field data of each site collected during the study. The data are presented in a separate section for each site. Each section contains a site description, a review of the applicable regulations at the time the site was mined and reclaimed, and a review of the mining and reclamation method. A review of the site geology, a stratigraphic section, and a geologic structure map is provided for each site. Research done under contract J0395011 by the Law Engineering Testing Co. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–178680; paper copy price code A16.

OFR 52(3)–84. Surface Coal Mine Spoil Stability Study, Eastern Coal Province. Manual of Practice, by Paul G. Swanson, J. Christopher Giese, and John S. Jones, Jr. Aug. 25, 1983. 41 pp. 17 figs. This manual is to be used in combination with volumes I and II of the study on spoil stability in the eastern coal province. The manual applies the predictive matrices developed in the parent study for use in evaluating the stability of typical mine spoil slopes. The values of internal friction and pore pressure coefficient are derived for many varied slope conditions. The results can be used in conventional stability analysis equations to assist mine operators or regulatory personnel in evaluating spoil stability from very limited information. Research done under contract J0395011 by the Law Engineering Testing Co. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–178698; paper copy price code A03.

OFR 53–84. Application of Tailings Flow Analyses to Field Conditions, by Samuel Bryant, James M. Duncan, and H. Bolton Seed. Aug. 1983. 312 pp. 134 figs. The purpose of this study was to develop procedures to measure Bingham flow properties for mine tailings and to use these procedures to predict the possible consequences of a hypothetical tailings flow failure at the Tenmile Tailings Pond at Climax, CO. Values of τ_y (Bingham yield shear strength) and η_p (plastic viscosity) were measured for 10 materials using results obtained from vaned coaxial viscometer and triaxial tests. It was concluded that the consequences of such a failure were minimal and the failure itself was highly unlikely. Re-

search done under contract J0285039 by the University of California—Berkeley. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-174184; paper copy price code A14.

OFR 54-84. Statistical Analysis of Wire Rope, by Richard C. Rice and Richard L. Jentgen. Feb. 16, 1983. 198 pp. 62 figs. The objective of this investigation was to determine from existing wire rope test data the effect of different operating parameters on rope life and to develop an optimum statistical methodology for the analysis of that data. Laboratory and field data for wire ropes typical of constructions used in underground mine hoisting were obtained, screened, encoded, and analyzed statistically. The analysis of hoist ropes retired from service showed that rope remaining strength or strength loss can be predicted with good accuracy if several nondestructive measures of rope damage are assessed. The outer-wire corrosion rating, the electromagnetic nondestructive inspection technique used for predicting strength loss, and the rope diameter reduction was found to be most important. Signs of rope deterioration such as broken wires or damage were also important indicators of strength loss. Based on the results of the investigation, a number of recommendations are presented that promise to yield better rope inspection and retirement criteria that will lead to improved safety and efficiency in underground mine hoist systems. Research done under contract J0215012 by Battelle, Columbus Laboratories. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-175934; paper copy price code A10.

OFR 55-84. Energy Conservation in Mining Operations, by E. K. Stanek and N. V. Suryanarayana. Dec. 1982. 117 pp. 27 figs. This study, performed on a case study basis, can be divided into two parallel thrusts: electrical and thermal energy conservation. In the electrical portion, five areas were addressed: optimal dispatching of on-site generation, high-efficiency motors, conductor selection, power factor correction, and high-efficacy lighting. In the case study mine, which has a multiple-unit on-site generation system, optimally dispatching units can save significant energy. The other four methods are difficult to justify on a retrofit basis owing to capital costs. In the thermal portion of the study, a thermodynamic analysis was performed on the reverberatory smelting process. Possible areas of energy conservation were identified as radiation and convection heat losses from the furnace arch and the dumping of high energy content smelting slag. It was determined that materials currently available can provide the means of reducing heat loss from the reverberatory furnace. It was also determined that a significant amount of energy may be recovered from the slag. However, these are both subject to further study and validation. Research done under contract J0113078 by the Michigan Technological University. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-175942; paper copy price code A06.

OFR 56-84. Personal Dust Exposure Monitor Based on the Tapered Element Oscillating Microbalance, by Harvey Patashnick and Georg Rupprecht. Apr. 1983. 89 pp. 27 figs. Current state-of-the-art microweighing technology represented by the tapered element oscillating microbalance (TEOM) is utilized as the basis for a new generation of personal dust exposure monitors (PDEM). Two design configurations are presented. The first is an end-of-shift analysis system that uses small TEOM-PDEM cannisters to replace the filter cartridges in the current PDEM system. All other components carried by the miner (cyclone preseparator and pump) are the same. After the shift, the TEOM cannister is plugged into an interface box that enables a minicomputer to automatically identify the unit, determine the dust mass increase during the shift, compute the shift average dust mass concentration, and print out and/or store the data. The second design is a real-time TEOM-PDEM system that is capable of operation over a 10-h shift and, on demand, display real-time dust concentration level, time-weighted average, and shift average concentration. A prototype end-of-shift analysis system was fabricated and delivered to the Bureau of Mines. A description of the system consisting of six TEOM cannisters, interface electronics, and a minicomputer is given. The system represents a significant advance in the dust monitoring program in terms of accuracy and automation. Research done under contract H0308106 by Rupprecht & Patashnick Co., Inc. Available for reference at the following facilities: AVRC, DRC, LIB, MSHA, NMH&SA, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84-173749; paper copy price code A05.

OFR 57(1)-84. Development of Guidelines for Rescue Chambers, Volume I, by John F. McCoy, D. Randolph Berry, and Donald W. Mitchell. Oct. 1983. 79 pp. 16 figs. The Bureau of Mines awarded a contract to develop guidelines for designing, constructing, stocking, and maintaining rescue chambers in underground mines. This report presents information and recommendations that could be used by a mine operator who desired to install a rescue chamber. Volume I covers atmospheric life support, configuration and construction, chamber location, power and lighting, equipment and supplies, communications, and psychological aspects and training. Research done under contract J0387210 by Foster-Miller, Inc. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-173723; paper copy price code A05.

OFR 57(2)-84. Development of Guidelines for Rescue Chambers, Volume II, Appendices, by John F. McCoy, D. Randolph Berry, and Donald W. Mitchell. Oct. 1983. 135 pp. 31 figs. The Bureau of Mines awarded a contract to develop guidelines for designing, constructing, stocking, and maintaining rescue chambers in underground mines. This report presents information and recommendations that could be used by a mine operator who desired to install a rescue chamber. Volume II, the appendices, covers the history of barricading, chamber pressurization considerations, diffusional infiltration of gas, compressed air storage, location examples, and psychological aspects. Research done under contract J0387210 by Foster-Miller, Inc. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, PRC/B,

RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-173731; paper copy price code A07.

OFR 58-84. Development and Analysis of Slurry Transport Systems in Longwall Mining of Coal, by Tuncel M. Yegulalp, Robert C. Knight, and Nicholas Marchi. Sept. 30, 1982. 127 pp. 14 figs. A preliminary systems analysis of coarse-particle coal slurry pipelines as a haulage method was performed. Two literature surveys on state-of-the-art longwall mining and slurry transport technologies were prepared. Two representative longwall systems were designed, one with conventional haulage and one with slurry haulage. The two systems were then compared on the basis of cost, safety, and reliability. It was concluded that for the case of a two-face longwall mine, a coarse slurry transport system does not have a clear-cut cost advantage over a conventional system. However, indications were that a cost advantage could occur under different analytical conditions such as (1) a larger scale mine, (2) if intangible benefits were quantified, and (3) if new generation technology rather than currently available technology were applied. Research done under contract J0333905 by Columbia University. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-173756; paper copy price code A07.

OFR 59-84. SPASID: A Computer Program for Predicting Ground Movement Due to Underground Mining; User Manual, by Jaan Kiusalaas and Eric K. Albert. Aug. 1, 1983. 201 pp. 44 figs. This report is a self-contained user manual for a computer program called SPASID (Subsidence Prediction and System Identification). The program has two primary functions: (1) precalculation of ground movements due to underground mining operations using the influence function method and (2) computation of influence function and site parameters from measured displacements. SPASID is written in FORTRAN and consists of four modules: (1) a preprocessor module that prepares and maintains surface and mine data bases, (2) a subsidence computation module that predicts movements of the surface, (3) a system identification module that is used to calculate the optimal influence function parameters, and (4) a postprocessor module for generating graphic displays of subsidence data. The last module is somewhat machine dependent but has internal documentation to indicate potential changes. All of the modules may be run in either batch or interactive mode. The manual does not assume previous knowledge of the influence function method or programing competence. Research done under contract J0295031 by the Pennsylvania State University. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-175074; paper copy price code A10.

OFR 60-84. Performance Criteria Guideline for Three Explosion Protection Methods of Electrical Equipment Rated Up To 15,000 Volts AC, by Larry Joe Linley and Alton B. Luper. Dec. 1982. 63 pp. 7 figs. This performance criteria guideline is an evaluation of three explosion protection methods of machines electrically powered with voltages up to 15,000 V ac. A sufficient amount of basic research has been accomplished to verify that the explosion-proof and pressurized enclosure methods can provide adequate explosion protection with the present state of the art up to 15,000 V ac. The routine application of the potted enclosure as a stand-alone protection method requires further investigation or development in order to clarify performance criteria and verification-certification requirements. A literature search, a series of high-voltage tests, and a design evaluation of the three methods performed at the White Sands Test Facility indicate that the explosion-proof, pressurized, and potted enclosures can all be used to enclose up to 15,000 V ac, if the performance criteria and verification-certification requirements recommended in this guideline are implemented. Research done under contract J0318081 by the National Aeronautics and Space Administration. Available for reference at the following facilities: AD/MR, DRC, LIB, MSHA, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84-172303; paper copy price code A04.

OFR 61-84. Role of Rock-Fluid Reactions in the Enhanced Recovery of Petroleum, by W. H. Somerton and C. J. Radke. Feb. 1, 1984. 121 pp. 43 figs. The objectives of this project were to evaluate the effects rock-fluid reactions in typical oil-producing formations may have on the success or failure of enhanced oil recovery (EOR) operations. Core samples were collected from a number of oil-producing formations that are undergoing or are potential candidates for EOR operations. The mineralogical-petrographic characteristics of the cores were evaluated. The cores were then subjected to fluid-flow tests in which sequences of flowing fluids, which might be used in EOR operations, were used to evaluate effects on flow capacity. Stabilizing agents were studied to determine their effectiveness in minimizing loss of flow capacity. Cores from formations in which steam injection operations are planned or were in progress were steamed to evaluate effects on rock behavior. Chemical loss studies were undertaken to evaluate rock-fluid reactions in chemical EOR operations. Research done under grants G1105015 and G5115063 by the University of California—Berkeley. Available for reference at the following facilities: AD/MR, AVRC, DOE/B, LIB, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 62-84. Processing of Dolomites for Refractory Applications, by G. L. Messing and R. C. Bradt. Dec. 1983. 122 pp. 42 figs. This report presents specific research pertinent to various aspects of dolomite processing. The concept of reactive phase calsintering evolved from research on raw material effects. This process allows for the densification of dolomite in a single-step process in which the dolomite is first mixed with an oxide that will form a liquid at elevated temperatures and a compact formed by processing. The compact is then heated in a controlled manner to 1,100° C to effect the decomposition of the dolomite. The decomposed material is rapidly heated from 1,100° C to the sintering temperature, where the liquid phase forms. The calsintering process is then extended to the sintering of calcium carbonate. The result of adding a chloride salt was investigated and determined to be deleterious to the calsintering of dolomite. It is believed that this is primarily an effect of the chloride salt on the decomposition product. To more fully understand this process, both chloride and fluoride salts were systematically added to dolomite, calcite, and magnesite and their effects on the decomposition

were studied. Research done under grants G1105044 and G1115421 by the Pennsylvania State University. Available for reference at the following facilities: AD/MMR, ALRC, AVRC, LIB, RORC, and TURC. Order ONLY from NTIS: PB 84–172345; paper copy price code A06.

OFR 63–84. Clay-Mineral Assemblages in Upper Cretaceous Shales in the Torreon Wash and Star Lake Coal Areas, Southeastern San Juan Basin, New Mexico, by Marc W. Bodine, Jr. Dec. 1983. 75 pp. 13 figs. This project was undertaken to characterize the mineralogy and chemical composition of clay-mineral assemblages in Upper Cretaceous shales in the southeastern part of the San Juan Basin in northwestern New Mexico and to determine their relations with episodes of coal deposition. The shales represent a range of depositional environments from marine, through near-shore mixed marine and continental, into fluvial and aeolean continental. Coal accumulation in the Torreon Wash and Star Lake areas occurs in both mixed marine and continental and fluvial continental facies. Research done under grants G1105077 and G1195030 by the New Mexico Institute of Mining and Technology. Available for reference at AVRC and LIB. Order ONLY from NTIS: PB 84–172352; paper copy price code A05.

OFR 64–84. Cobalt Behavior in Ammonia Leaching Systems, by K. Osseo-Asare and H. W. Pickering. Dec. 1983. 30 pp. 22 figs. The solution chemistry of the Fe- and Co-NH_3-H_2O-CO_3 systems was analyzed in terms of aqueous stability diagrams. Electrochemical techniques such as open-circuit potential and anodic polarization measurements were used to investigate the dissolution behavior of bulk and sintered Fe, Co, and Fe-Co alloys in ammoniacal ammonium carbonate solutions. The open-circuit and anodic polarization behaviors were studied in terms of alloy composition, heat treatment, solution composition, metal particle size, and sintering conditions. In addition, metallurgical characterization of the electrochemically treated solid surface was conducted by using various metallographic techniques, including X-ray diffraction and auger electron spectroscopy. The results indicate that the passivation behavior of Fe controls the dissolution behavior of Fe-Co alloys. Thus the electrochemical dissolution behavior of Fe-Co alloys may be, in part, responsible for the poor recovery of cobalt when the reductive-roast ammonia leach process is applied to ferruginous oxide ores. Research done under grants G1105045 and G1115422 by the Pennsylvania State University. Available for reference at the following facilities: AD/MMR, ALRC, AVRC, LIB, RERC, RORC, and SLRC. Order ONLY from NTIS: PB 84–172295; paper copy price code A03.

OFR 65–84. Geochemical Properties and Toxicological Effects of Aquatic Life of Coal Wastes, by William R. Roy, Thomas M. Skelly, Ivan G. Krapac, Robert A. Griffin, Donald R. Dickerson, Rudolph M. Schuller, John J. Suloway, and Neil F. Shimp. Jan. 1984. 166 pp. 19 figs. This investigation is comprised of interrelated physical, chemical, and biological analyses for a broad-based evaluation of the impact of abandoned spoil banks and coal solid wastes on the aquatic environment. The analytical synthesis of the data from this investigation would aid in control technology, development of reclamation, and determine the potential degree of toxicity of these wastes as required by the Surface Mine Control and Reclamation Act of 1977, Public Law 95–87. Research done under grants G1105002 and G5115002 by the Southern Illinois University—Carbondale. Available for reference at the following facilities: AD/MMR, AVRC, DRC, LIB, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 66–84. Structural Location and Role of Hydrogen Ions in Kaolinite and Its Products in Aluminum Removal, by R. A. Young, P. R. Suitch, and W. E. Moody. Dec. 1983. 24 pp. 8 figs. The objectives of this program were to (1) determine the mechanistic details by which the structural locations and ordering of the hydrogen ions in kaolinite affects its crystallinity, solubility, viscosity, processing, and use characteristics; (2) determine the intracrystalline mechanisms involved in the extraction of aluminum; and (3) better determine and control the characteristics of the siliceous byproducts of aluminum extraction in order that useful products may be created from them. X-ray and neutron powder diffraction data and the Rietveld method were used to refine the crystal structure of kaolinite specimens. The positions of the nonhydrogen atoms in dickite were similarly re-refined from X-ray powder data. In kaolinite, the rotation in the tetrahedral sheet is 7(1)°. The two inner hydroxyl O-H bonds are differently oriented; one points into an octahedral vacancy and the other points away. All six of the inner surface hydrogen atoms appear to be nearly equally involved in the hydrogen bonding between kaolinite layers in kaolinite. The process of dehydroxylation of the kaolinite was followed in detail with X-ray diffraction techniques. Dehydroxylation began at about 325° to 350° C and was more than half completed at 465° C. It was found that "half completed" means that one-half of the initial sample was completely dehydroxylated while the other one-half was not, retaining all details of its kaolinite structure. Research done under grants G1105019 and G1115131 by the Georgia Institute of Technology. Available for reference at the following facilities: AD/MMR, AVRC, and LIB. Copies of this report will not be available for purchase.

OFR 67–84. Citrate Process Flue Gas Desulfurization Demonstration Plant, by John M. Cigan. Sept. 1, 1983. 154 pp. 15 figs. An SO_2 emission control program at the St. Joe Minerals Corp.'s zinc smelter powerplant evolved into a cooperative program with the Bureau of Mines for the installation and initial operation of a citrate process flue gas desulfurization demonstration plant. The plant was operated on an intermittent basis from November 1979 to September 1982. The citrate process proved capable of absorption of greater than 90% of the SO_2 from the flue gas with ultimate conversion to elemental sulfur. However, in order to overcome problems that severely restricted process ontime, plant modifications were made that resulted in lower SO_2 absorption—generally 50% to 70%. Analysis of the operation identified equipment areas where redesign was needed for achieving high SO_2 removal with reasonable levels of process equipment ontime. The additional investment could not be justified by anticipated smelter revenues. The recent availability of a bubble concept by the environmental regulatory agencies permitted an SO_2 emissions compliance program that could be implemented on a more timely basis and preclude St. Joe Corp.'s continued involvement in the citrate process flue gas desulfurization development. Research done under contract S0261008 by the St. Joe Minerals Corp. Available for reference at the following facilities: ALRC, AVRC, LIB, PRC/B, RERC, RORC, SLRC, and TURC. Order ONLY

from NTIS: PB 84-176007; paper copy price code A08.

OFR 68-84. Improvement of On-the-Job Training Procedures Through Utilization of Modeling, Imitative and Other Learning Techniques, by Paul E. Loustaunau, Catherine Wetherby, and Richard Rosenblatt. June 30, 1983. 36 pp. This report describes a project in which three structured underground coal mine equipment operator training programs were developed. The project was carried out in two parts. In the first part, a study was conducted to determine how on-the-job training is currently conducted in industry, determine the overall effectiveness of current on-the-job training, and the possible application of the principles of the social learning theory to on-the-job training. In the second part, three on-the-job training programs were developed for shuttle car, roof bolter, and continuous miner operations. These programs were structured to eliminate the shortcomings of current industrial on-the-job training identified in the study and incorporated the application of relevant principles of the social learning theory. The programs are prototypes that underground coal mine training personnel can use as models to develop their own customized equipment operator training programs. Research done under contract H0308028 by the Human Resources Research Organization. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH-&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-180199; paper copy price code A03.

OFR 69-84. Gases in Hydrous Alteration Minerals: An Exploration Tool for Ore Deposits, by David I. Norman. Mar. 1984. 118 pp. 20 figs. The possibility of gases trapped in hydrous minerals and fluid inclusions as geochemical guides to sulfide ore deposits was studied. Techniques for analyzing structurally bound gases in hydrous minerals were developed. A survey of phyllosilicate minerals indicated that those associated with ore deposits had up to 10 times the amount of CO_2 and H_2S as similar minerals from nonore locals. Analyses of gases in altered, phyllosilicate-bearing rock samples from the Bingham, UT, and Copper Flat, NM, porphyry copper deposits indicated that the gas consumptions are related to the specific types of alteration and mineralization. Samples were collected from the surface of the Copper Flat deposit before it was disturbed by mining. Gases in phyllosilicates outlined the deposit that did not crop out. Samples were collected on the exposed portions of the St. Cloud-U.S. Treasury vein that crops out for about 1.5 km. There are no trace element anomalies either in the vein or wall rock over the silver-rich ore shoots that are in production. Both Co_2 content of inclusion gases as well as N_2-CO_2 ratios indicated the location of ore shoots. Research done under grants G1105040 and G1115351 by the New Mexico Institute of Mining and Technology. Available for reference at the following facilities: AD/MMR, AVRC, LIB, PRC/B, RERC, and SLRC. Copies of this report will not be available for purchase.

OFR 70-84. Revegetating Disturbed Areas To Protect the Environment, by Edward F. Redente, Norman E. Hargis, and Mario Biondini. Jan. 23, 1984. 97 pp. 10 figs. The purpose of this research was to develop guidelines for the efficient management of soil resources and for the production of rangeland vegetation, winter wheat, and alfalfa on surface mined areas in northwestern Colorado. The experimental soil management practices were four soil replacement thicknesses and ripping, disking, and fertilizing the overburden. The simple effects of soil thickness and cultural practices and their interaction were evaluated. Research done under grants G1105017 and G1115082 by Colorado State University. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 71-84. Flotation Recovery of Molybdenite From Porphyry Copper Ores, by Srinivasan Raghavan and Land L. Hsu. Dec. 1981. 47 pp. 25 figs. Investigations were conducted to characterize the surface chemical and flotation properties of molybdenite in aqueous environments typical of those that exist in the copper circuits of plants that process prophyry copper ores. The investigations showed that molybdenite and quartz particles are negatively charged at the pH commonly used for bulk sulfide flotation. While the adsorption of calcium ions reduces the magnitude of negative charge on molybdenite, the adsorption can reverse the surface charge on quartz particles when the calcium concentration in solution exceeds 1 by $10^{-3}M$. Heterocoagulation of molybdenite and quartz particles will thus be inevitable in solutions containing large amounts of lime and will impair the floatability of molybdenite. The deleterious effects of heterocoagulation can be somewhat overcome by an ultrasonic conditioning prior to flotation. Besides heterocoagulation, particle size is very critical for optimum molybdenite flotation. Coarse molybdenite particles float extremely rapidly and completely without being influenced by solution pH or heterocoagulation. The flotation of fine molybdenite particles is sensitive to the mean particle size and heterocoagulation. Results of tests conducted to assess the effects of overgrinding of molybdenite indicated that while there is no change in the crystal structure due to prolonged grinding, the floatability is significantly reduced due to the creation of rough surfaces. Research done under grant G5105011 by the University of Arizona. Available for reference at the following facilities: AD/MMR, ALRC, AVRC, LIB, RERC, and SLRC. Copies of this report will not be available for purchase.

OFR 72-84. Application of a Portable Device for Measuring Dragline Roller Circle Track Deviations and Roller Loadings, by R. Pallini, J. Rumbarger, D. Powell, H. Urbanek, J. Yankanich, and J. Sague. July 1982. 54 pp. 28 figs. The objective of this work was to develop and demonstrate an instrumentation system for measuring roller circle distortions and roller loads, and to develop methods for using elastomeric materials to reduce the loading on thrust rollers in walking draglines. A practical and portable device was developed and demonstrated on a walking dragline at the Falkirk Mine, Underwood, ND. The device performed reliably and provided data on the vertical (out-of-flat) and angular twist or warp of each dragline roller track. This information can identify whether the upper rotating frame structure, the tub structure, or both are the source of distortions. The combined distortion data can be used to calculate realistic roller loads, predict track service life, and assist in evaluating the cost effectiveness of potential field repairs (elastomeric cushioning materials) versus costly track and tub replacement. Research done under contract J0233919 by the Franklin Institute. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and

TURC. Copies of this report will not be available for purchase.

OFR 73–84. Testing of a Fragmentation System for a Hard Rock Mining Machine, by Thomas Brunsing and Robert Morin. Nov. 1983. 78 pp. 38 figs. The purpose of this program was to develop deep-kerfing and core-breaking techniques to be incorporated into the design of a field prototype hard-rock mining machine. The machine is designed to mine nonabrasive bedded deposits up to 20,000 psi in uniaxial compressive strength. The mining technique involves cutting approximately 2-ft-deep parallel kerfs spaced 2 ft apart in either a horizontal or vertical direction and subsequently breaking out the cores as defined. The program was aimed at minimizing the required kerf width, obtaining reliable breaking within that kerf width, and determining cutter blade requirements necessary to achieve a mining rate of 20 ft^3/min. Full-scale breaking and half-scale kerfing experiments were employed to evaluate the system. High-strength concrete test specimens were used to simulate the rock being cut and broken. The results indicate that the kerf-break technique can achieve the desired mining rate by utilizing two 7-ft-diam blades to cut 2-in-wide by 24-in-deep kerfs. A lateral load applied to the base of the kerf was selected at the core-breaking technique to be employed by the full-scale machine. Research done under contract J0100081 by Foster-Miller, Inc. Available for reference at the following facilities: AD/MR, ALRC, AVRC, DRC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–186394; paper copy price code A05.

OFR 74–84. Small Diameter Corrosion Resistant Pumps for In Situ Leaching, by Joe Puckett, John Murphy, and Kenneth Nixon. Dec. 1981. 70 pp. 18 figs. Reduced pump diameter allows use of smaller diameter wells and reduces drilling costs. This report describes pumping systems that can be used in smaller diameter wells at in situ leaching operations. Two 2-in monitor pumps were built and tested in 2-in wells, and two 3-in corrosion-resistant (production) pumps were built and tested in a 3.35-in well. The monitor pump was an 8-hp, 41-stage, centrifugal booster pump driving an injector located down in the well. The two pumps delivered 9.4 to 11.5 gpm, depending on the water level. The gasoline engines used 0.65 gph of gasoline. The performance of both pumps was unchanged after the test period. The production pump was a 40-hp, 12-stage, centrifugal booster pump driving an injector located down in the well. The two production pumps delivered 31 to 39 gpm against approximately 20 psi. The drive motors drew approximately 48 amp on a 420-V, 3-phase circuit. During the 40-h test run of each pump there was one shutdown that was caused by an overpressurization in the service line that caused the safety switch to cut out. The performance of both pumps was unchanged after the test period. Research done under contract H0292022 by the Kidde Co. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–186386; paper copy price code A04.

OFR 75–84. Movable Crusher System—Concepts and Applications, by R. N. Johnson, R. W. Utley, and E. S. Burkhardt. Dec. 1982. 178 pp. 48 figs. The objective of this report was to evaluate the feasibility and desirability of a movable in-pit crusher combined with conveyors to substantially reduce or eliminate truck or train haulage in large open pit nonfuel mineral mines. The report includes an introduction and summary of previous work, an analysis of movable crusher system components, a description of the selected system, a review of possible movable crusher system applications, and requirements for future work to bring about the general availability of such systems. Research done under contract J0295004 by Gard, Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–185297; paper copy price code A09.

OFR 76–84. Methodology Development for Mine Life Safety System Evaluation, by R. S. Nutter, N. S. Smith, W. R. Voltz, P. Klinkhachorn, and D. F. Tuthill. June 6, 1982. 428 pp. 82 figs. A methodology was developed for qualitative safety hazard evaluation and quantitative reliability analysis of mine monitoring and control systems. Detailed application of these techniques were made to two commercial monitor-control systems and to a microprocessor-based system. A controlled environmental test was conducted on a set of one of the commercial system's outstations. A software reliability evaluation methodology was also developed and applied. Research done under contract J0100057 by the West Virginia University. Available for reference at the following facilities: AD/MR, DRC, LIB, MSHA, NMH&SA, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84–182765; paper copy price code A19.

OFR 77–84. Alertness Monitor Evaluation, by John A. Stern, Robert Goldstein, and Barbara D. Strock. Dec. 31, 1983. 26 pp. 1 fig. Procedures were developed to evaluate the nature and timing of eye blinks and closures, and these variables were related to alterations in performance. Impaired performance is frequently indexed by alterations in these variables, suggesting that monitoring aspects of oculometric activity, such as the eye blink, may become useful predictors of impaired performance. What may be equally or more important is that such information can be used to alert equipment operators and prevent accidents. The analyses suggest that impaired performance is associated with the occurrence of eye closures, even in tasks where vision is not used, such as making judgments about durations of auditory stimuli. If such closures occur in conjunction with slow eye movements in the horizontal plane, the likelihood of signals being missed is further enhanced. Blinking during the period of stimulus presentation also results in an enhanced likelihood of a signal being missed. Research done under contract H0222012 by Washington University. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–183276; paper copy price code A03.

OFR 78–84. Development of a Conveyor Belt Service Machine, by James L. Eirls. Dec. 1983. 109 pp. 47 figs. A self-contained conveyor belt service machine was designed, developed, fabricated, and demonstrated for the Bureau of Mines. The

machine is battery-powered, rubber-tired, and capable of handling, storing, and transporting conveyor belting, wire rope, and associated structures for sectional conveyor belts. While moving the tail section to its next position, the machine discharges the belting, wire rope, and belt structures. The belting is elevated and separated to provide for the insertion of the structures with minimum manual effort. A hydraulic system provides the power for steering, braking, winding or unwinding belting and wire rope, and to operate a load-bed conveyor, connection hitches, and external hydraulic tools. A pneumatic system is available to operate air-impact tools. The machine can function in coal seams as narrow as 48 in, double-wind conveyor belting 42 in wide and 400 ft long, load or unload 3/4-in wire rope on two separate reels, and be controlled by two operators. A complete belt move using this machine requires only four persons. Successful underground demonstrations were conducted in coal mines in West Virginia and Kentucky. Research done under contract J0333926 by Tracor MBA. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-184845; paper copy price code A06.

OFR 79-84. Development of a Hydride Fuel System for Underground Mine Use, by Ned Baker and Frank Lynch. Apr. 15, 1983. 56 pp. 23 figs. Details are given of a hydride fuel system to provide 5 kg of H_2 to fuel a Caterpillar engine previously modified to operate on hydrogen fuel and intended to power an underground mining vehicle. The fuel system was installed onto the engine, and the engine-fuel system was tested under cold-start conditions and a full range of engine loads and speeds. Refueling tests were also performed. The fuel system will support full engine power and allow delivery of at least 3/4 power on a continuous basis from cold-start conditions. Research done under contract H0202034 by Eimco Mining Machinery International. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-182773; paper copy price code A04.

OFR 80-84. Development of a Mine Air Contaminant Measurement Program—Diesels and Explosives, by W. L. Wagner, D. E. Marano, K. L. White, B. F. Craft, and W. J. Kennedy. June 1983. 74 pp. 12 figs. This report presents a quality control approach to the derivation of strategies for monitoring a work environment; specifically, the environment in underground mines where diesel-powered equipment and blasting agents are used. The approach is presented as a series of 22 steps called the Monitoring Strategy Development Scheme. The scheme is an orderly method for selecting from a number of options a strategy or tactics to cost effectively meet the requirements of a chosen objective related to the monitoring of breathing zone air quality. The scheme provides a format to quantify many of the factors that influence the selection of one strategy or tactic over another, and to ensure that important considerations are not neglected. The premise that breathing zone air in a work environment can be considered to be a manufactured product and that conventional quality control approaches are applicable is introduced. Typical approaches to the quality control of manufactured products and how these approaches can be applied to the selection of monitoring strategies are discussed. Research done under contract J0100004 by the University of Utah. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-183078; paper copy price code A04.

OFR 81-84. Comminution and Simulation Using Rod and Ball Mills, by Douglas W. Fuerstenau. Dec. 1983. 82 pp. 47 figs. This report presents the results of an investigation of comminution in tumbling mills. Five topics involved with ball- and rod-mill grinding kinetics were studied, and the results were analyzed in terms of phenomenological size reduction and transport models. Continuous rod-mill grinding was found to be characterized by high Peclet numbers that permit simulation to be carried out by several methods. The dry-batch ball-mill grinding of mineral mixtures showed that the breakage rates of the components were composition-dependent but time-independent and were normalizable with specific energy. Locked-cycle tests on mineral mixtures showed that a grinding circuit may take a long time to attain steady state, during which time the composition of the mill holdings, and hence the breakage rate of the components, continuously changed. The study revealed that under plant conditions, grinding circuits can be in transience perpetually. The transport of mineral mixtures through drums showed complex size and/or density-dependent segregation, thereby simplifying the modeling of the continuous grinding of complex feeds. Wet-batch rod-mill grinding on single minerals showed that the normalization of breakage kinetics is valid for slurries of constant pulp density at different holdups but cannot be extended to slurries varying in pulp density. Research done under contracts J0113022 and J0123049 by the University of California—Berkeley. Available for reference at the following facilities: AD/MMR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-184746; paper copy price code A05.

OFR 82-84. Chromium Recovery From Tanning Wastes by Pyrolysis and Sulfuric Acid Leaching, by John Porter, Jr., Robert Lollar, Carl V. Huber, and Leo Devarenne. Sept. 1983. 136 pp. 12 figs. A study was conducted to evaluate the feasibility of recovering chromium from pyrolyzed tanning wastes by sulfuric acid leaching and reusing the final product in the tanning industry. Separate batches of tannery waste treatment sludge and finished leather and blue leather scraps were pyrolyzed in a batch furnace under varying temperature and atmospheric conditions. A bench-scale leaching evaluation was then conducted on each batch of pyrolyzed material to determine chemical composition and screen various leaching alternatives that could be pursued on a pilot scale. Next, chromium liquors were produced in a pilot-scale recovery system by sulfuric acid leaching. A tannage evaluation of these liquors was conducted on calfskin and pigskin. An additional batch of blue leather scrap was pyrolyzed in a rotary hearth furnace and leached on a bench scale to determine the effect a different pyrolysis process would have on chromium recovery. The tannage potential

of this liquor was also evaluated on calfskin and pigskin. The results indicated that chromium could be recovered from pyrolyzed tanning wastes with sulfuric acid; however, tannage with the resultant liquors was not acceptable. Comparable tannage results were obtained with the extract from the rotary hearth char; however, chromium recovery from this was lower. An economic analysis of this recovery method shows that it is not feasible or practical. Research done under contract J0113110 by the Tanners' Council of America, Inc. Available for reference at the following facilities: ALRC, AVRC, LIB, MSHA, NMH&SA, PRC/B, RERC, SLRC, and TURC. Copies of this report will not be available for purchase.

OFR 83–84. Preparation of Baseline Training Materials for Assisting Compliance and Accident Reduction in the Metal and Nonmetal Mining Industry, by J. H. Adkins, P. Krois, M. Hinton, J. Nussbaumer, and D. Leonard. Mar. 1983. 95 pp. 27 figs. The goal of this program was to produce a set of baseline health and safety training materials that could be used by the metal and nonmetal mining industry to reduce injuries and to comply with Federal training requirements. The materials developed are arranged in a two-level outline format. The first level provides the title, course goals, background, and topical outline. The second level provides a detailed outline of the course content. Each of the required units in the baseline guides have one or more self-checks. These are designed to be suggestive of evaluation techniques the users can develop for themselves. An instructor's guide and a mining terms glossary are included. Research done under contract J0308011 by the Bendix Corp. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–184852; paper copy price code A05.

OFR 84–84. Development and Trials of a Commercially Practical Roof Fall Warning System, by James E. Aplin, Dave Fish, and Arnis Mangolds. Mar. 1983. 157 pp. 63 figs. Previous studies have shown that fracturing of roof strata precedes ultimate failure, and that the fracture development causes an accompanying increase in apparent resistivity of the strata. Using this principle, a microprocessor-controlled resistivity roof fall warning system (RRFWS) was developed that automatically sequences through and records up to 32 electrodes that may serve as either voltage or current electrodes. This capability permits increased coverage with a minimal number of required electrodes. The data are stored in a nonvolatile memory and on an optional printout, making the system nonsusceptible to loss of mine power. To further save battery power, the system's electronics shut down between readings, except for a carbon molybdenum steel real-time clock. At a preprogramed interval, the RRFWS reactivates and repeats the sequence. If the absolute change or the rate of change of resistivity exceeds a predetermined limit, the system is capable of sounding an alarm. In addition to the monitor, a stainless steel modified split-set electrode was also developed that permits long-term, corrosion-free contact. Research done under contract H0202029 by Foster-Miller, Inc. Available for reference at the following facilities: AD/MR, ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–182807; paper copy price code A08.

OFR 85–84. Characteristics of a Radon Diffusion Chamber With Electrical Collection Using Plastic Nuclear Track Detectors, by Allen L. Frank and Eugene V. Benton. Sept. 1983. 17 pp. 5 figs. A portable radon diffusion chamber was tested with electrical collection of radon daughter nuclei for enhancement of sensitivity. The detector was small enough to be worn suspended from a belt. With a battery-supplied high voltage, the sensitivity was found to be 1.43 tracks/cm^2 per pCi-h/ℓ of ambient radon at 50% relative humidity. The track densities on the surfaces of the CR-39 plastic nuclear track detectors were found to be nonuniform, making the determinations of average densities with high accuracy difficult. The fabrication of electrets for use in the detector was investigated in accordance with published techniques with negative results. Research done under contract J0123037 by the University of San Francisco. Available for reference at the following facilities: AD/MR, ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–184209; paper copy price code A02.

OFR 86–84. Evaluation of the Safety of Underground Blasting Procedures, by W. G. Freeman, J. G. Babcock, M. L. Christo, G. P. Chitombo, and J. R. Biller. Nov. 1980. 139 pp. 31 figs. This study provides recommendations for improved safety in underground blasting procedures based on in-mine observations of blasting practices in 30 underground metal, nonmetal, and coal mines; analyses of blasting accidents since 1980; and existing State and Federal regulations pertaining to the storage and use of explosives. Results of these analyses and observations indicate that (1) blasting accidents have declined but are an important contributor to the hazards of underground mining; (2) existing regulations are essentially adequate; (3) greater emphasis should be placed on human errors, unsafe practices, and the enforcement of existing regulations; and (4) future revisions of these regulations and standards should be organized and their intent coordinated to eliminate ambiguities. Research done under contract J0199012 by International Mining Consultants, Inc. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–193838; paper copy price code A07.

OFR 87–84. Improvements to the Seismic Detection and Location Procedure, by Roy J. Greenfield. Dec. 1983. 49 pp. 20 figs. This report discusses three factors that relate to the seismic detection and location of trapped miners. (1) As part of the modeling procedure to explain the seismic waveforms observed on surface seismic subarrays, the force-time function of the source must be known. Accelerometer records of a source timber show the force is approximately one-half sinewave and that floor blows have a longer dwell time than roof bolt blows, leading to smaller amplitude for floor blows. (2) Comparisons were made between the least squares and MINER location methods using both statistical simulations and actual data. The comparisons showed the methods give similar accuracy for events inside the array with seven subarray

arrival times. However, for fewer subarrays, or for events outside the array, the least squares method is more accurate. (3) Refraction surveys to determine the rock velocity used for source location calculations should be approximately 1,200 ft long. To obtain accurate locations, small refraction surveys 165 ft long can and should be used to detect very slow soil layers under each subarray. Research done under contract J0318047 by the Pennsylvania State University. Available for reference at the following facilities: AD/MR, ALRC, AVRC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, AND TURC. Order ONLY from NTIS: PB 84-193713; paper copy price code A03.

OFR 88-84. Data Security for In-Mine Transmission. Final Report—Part II, by Jon G. Bredeson, Hossein Hashemi, and K. Sreedhar. Apr. 1982. 76 pp. 29 figs. Part I of this report contained a survey of noise measurements made by a number of researchers. This information was used to calculate bit error rates for mine communication systems. Part II, this report, examined available probability information of the noise envelope for noise measured in the mining environment. The exceedance probability distribution was averaged for available noise data and was shown to be modeled closely by Middleton's class B model. The noise power at the output of several communication links was scaled appropriately and together with the signal power a probability of burst error was calculated. The protocols were analyzed to determine the probability of undetected burst error for each communication system and then plotted versus distance. Various data communication protocols are used in equipment for the communication purposes. Some protocols are used very extensively in all types of communications systems, while others are designed for special systems. The report analyzes several protocols and gives recommendations for their use. Research done under contract J0308024 by the University of Oklahoma. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-185081; paper copy price code A04.

OFR 89-84. Feasibility of an Underground Hydraulic Coal Mine Near Wilkeson, Washington, by William C. Cooley, Arthur W. T. Grimley, and Walter W. Kaufman. Sept. 10, 1983. 174 pp. 35 figs. This report presents a technical and economic study of the feasibility of establishing an underground hydraulic coal mine in the Wilkeson, WA, quadrangle, 25 miles southeast of Tacoma. The deposit contains reserves of more than 200 million tons of metallurgical coal. It is found in nine seams of minable thickness in a complex set of anticlines, synclines, and faults. Typical dip angles are up to 60°, with minable seam thickness of 6 to 17 ft. A mine plan was made for a 200-million-ton-per-year clean mine using two shafts to access the deposit at a depth of 2,500 ft. The mining method uses water jets to break coal by sublevel retreat mining, fluming to a sump, and pumping the minus 0.25-in coal to a preparation plant on the surface. The plus 0.25-in coal is hoisted by skip. Cleaned coal is shipped by rail for export. A middlings product would be sold as thermal coal. Research done under contract J0133913 by Terraspace Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-184100; paper copy price code A08.

OFR 90-84. Predicting Mine Effluent and Ground Water Quality Prior to Mining, by William C. Hood. Mar. 20, 1984. 190 pp. 46 figs. A leaching column technique that produces effluent similar in quality to coal mine drainage in the eastern interior basin was developed. The columns are charged with 1,000 g of crushed overburden and cycled through the leaching process once a week for 12 weeks. Interrelationships among the important chemical constituents are very similar to those present in actual mine drainage waters, but the overall concentrations of ions are more dilute in the leachates. Multiplying the leachate concentrations by a factor of 4.5 gives values similar to mine waters. Available data suggest that each of the leaching cycles represents about 3 yr of natural weathering, so that the leaching technique can predict the evolution of the mine drainage water over a time span of nearly 40 yr. Use of the leaching technique with drill core samples should provide a method of approximating mine drainage quality in advance of mining and should be useful in identifying potentially toxic units in the overburden. However, the results should be considered to be a worst case situation because the technique does not consider the effects of reclamation. Research done under grants G1105065 and G1195014 by Southern Illinois University—Carbondale. Available for reference at the following facilities: AD/MR, AVRC, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84-189752; paper copy price code A09.

OFR 91-84. Development of Roof Control Criteria for Underground Longwall Mining, by S. S. Peng. Feb. 1984. 216 pp. 79 figs. The purpose of this study was to analyze the effects of strata behavior on longwall panels caused by mining. The study was focused on the weighting phenomena and their effects on front abutments, and the chain pillar stability and pillar design under various roof conditions. Using the three-dimensional finite element, the overburden depth, mechanical properties of the immediate roof and the main roof, panel width, and size of the chain pillar were analyzed. Four models were used to simulate various phases of panel production under various combinations of the above parameters. Model 1 simulated the beginning of panel mining, model 2 simulated the passage of the longwall face of more than half the panel length, model 3 simulated the completion of panel productions, and model 4 simulated the second panel mining. By applying the multiple-regression model to analyze the finite element results, the following were developed: (1) a formula that classifies the type of roof strata at the face area, (2) formulas that predict the first weighting and periodic weighting lengths, and (3) a formula that designs the chain pillar size. Research done under grants G111-5541 and G5105055 by West Virginia University. Available for reference at the following facilities: DRC, LIB, PRC/B, SRC, and TURC. Copies of this report will not be available for purchase.

OFR 92-84. The Environmental Consequence of Burial Depth of Toxic Spoils and of Excessive Compaction of Prime Land on the Growth of Plants, by Richard I. Barnhisel. Dec. 31, 1983. 200 pp. 5 figs. The objectives of this report were to (1) determine the minimum depth of soil, nontoxic spoils, or treated spoils re-

quired to control the environmental effects that toxic spoils may have on the growth of agronomic plants and (2) determine the consequence of excessive compaction (bulk density) on restored prime land on the yield of those plants. Timothy, alfalfa, corn, soybeans, and wheat were used in determining the effect of soil burial depth and liming; alfalfa, corn, soybeans, and wheat were the crops used in testing the effect of compaction on growth. From a chemical point of view, acidic spoils do not need to be buried by 120 cm or 4 ft of soil, provided that adequate lime is applied to these spoils as a barrier prior to placement of good-quality topsoil and that only forage crops are to be grown. The burial depth must be increased to as much as 75 cm when grain crops such as corn and soybeans are to be grown. A conventional farm tractor-mounted subsoiler increased yields of soybeans and corn the first 1 or 2 yr, but the effect was diminished with time. Subsoiling did not produce significant increases for alfalfa or wheat. However, ripping with a bulldozer produced significant yield responses, especially for corn and soybeans, that have lasted for at least 3 yr. The ripping effectively reduced the bulk density at least within the zones through which the ripper had passed. Liming the upper 20 cm of subsoil significantly increased yields of alfalfa, corn, and soybeans. There also appeared to be an interaction between this lime treatment and soil depth. Research done under grants G1105025 and G1115214 by the University of Kentucky. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 93–84. Survey of Electrostatic Hazards Detection and Minimization, by R. W. Courtney and R. W. Johnson. Mar. 1982. 116 pp. 23 figs. The objective of this study is to make a critical evaluation of the magnitude and extent of electrostatic hazards in typical U.S. mining operations and to assess the adequacy of techniques, materials, and equipment for detecting and minimizing these hazards. This was accomplished with an incident-accident survey, mine visits, literature search, and engineering analysis. It was concluded that it would be desirable to (1) utilize ground fault interrupters to minimize stray current from electrical utilities, (2) decrease the current and electrostatic sensitivity of electric detonators used in areas with a high incidence of lightning strikes or troublesome stray currents, (3) institute quality control and test standards for blasting material and protective devices, (4) establish an electrostatic monitoring program for loading ammonium nitrate and fuel oil in plastic-lined holes, and (5) establish risk criteria for operator exposure in mines. Research done under contract J0308113 by Hercules Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–186709; paper copy price code A06.

OFR 94–84. Methane Control in an Advancing Section of an Underground Coal Mine, by Danny W. Hagood, Richard C. Pate, and John W. Stevenson. Dec. 1983. 39 pp. 19 figs. The drilling of horizontal boreholes as a means of degasification in advance of mining was tried at the Jim Walter Resources, Inc., No. 4 Mine. In a joint venture with the Bureau of Mines, a series of horizontal boreholes were drilled in the panels of an advancing continuous miner section. The combined methane gas production rate ranged from 205,000 to 680,000 cfd with individual in-seam horizontal holes producing up to 332,000 cfd. The methane liberation from the ribs for the entire panel length decreased from an average 8.75 to 4.05 cfm per 100 ft of entry, a 54% reduction. The gas concentration as measured at the surface discharge point normally ranges from 85% to 95% methane. As a result of the significant reduction in methane liberation rates, a 50% increase in productivity from the section was realized. Research done under contract S0395033 by Jim Walter Resources, Inc. Available for reference at the following facilities: DRC, LIB, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84–185057; paper copy price code A03.

OFR 95–84. A Model for the Evaluation of Systematic Variability in Composition and Thickness of High Sulfur-High Ash Coals, by Alan C. Donaldson and John J. Renton. Feb. 1984. 108 pp. 64 figs. The purpose of this project was to provide a coal model to geographically describe the composition and thickness of a coal seam in sufficient detail to ensure an efficient and effective mining utilization and reclamation plan for coal before it is mined. The study focuses on high sulfur and high ash coals of the central and northern Appalachians. Data from approximately 500 cored wells of mainly Pittsburgh coal but also Redstone, Sewickley, and Waynesburg coals were provided by industry and used in the analysis. An additional 652 samples were collected and chemically analyzed. The coals were selectively examined using Mossbauer spectrometer analyses of pyrite-pyrrhotite; acid production when oxidized; and petrography by radiographs and an image scanner, scanning electron microscope, and reflected light. The report includes a better method than is presently used to predict acid mine waters and a method to improve the prediction of lateral coal-quality changes within a seam from limited samples. Research done under grants G1105090, G1115542, and G1195050 by West Virginia University. Available for reference at the following facilities: AD/MR, LIB, and OSM. Copies of this report will not be available for purchase.

OFR 96–84. The Use of Fe/Mn Oxide-Rich Fracture Coatings in the Geochemical Exploration for Precious Metal Deposits: A Comparison With Standard Rock and Soil Geochemistry, by Lawrence T. Larson, Robert H. Carpenter, and Walter C. Crone. Jan. 1984. 119 pp. 42 figs. The effectiveness of Fe/Mn oxide-rich fracture coatings as a geochemical medium for precious metals exploration is evaluated relative to conventional litho- and pedogeochemistry. Sampling of fracture coating, rock, soil, and stream sediments in areas of known disseminated gold in the Pinson Mine and Preble Prospect and potential bonanza-type near the Comstock Lode mineralization indicates that the technique is scientifically valid. Fracture coating samples contained an average of 18.8, 7.5+, 7.4, and 4.5 times more Sb, Au, As, and Hg, respectively, than rock samples at Pinson, and 10.2, 5.2+, 2.7, and 1.6 times more Sb, Au, As, and Hg, respectively, than rock samples at Preble. A higher contrast is obtained relative to soil and stream sediment samples. The geochemical halos obtained from fracture coating samples cover larger areas than those obtained from rock or soil samples and accurately reflect the locations of known mineralization. Larger exploration targets are defined as a result. Research done under grants G1105038 and

G1115321 by the University of Nevada—Reno. Available for reference at the following facilities: AD/MMR, AD/MR, AVRC, LIB, and RERC. Order ONLY from NTIS: PB 84-189653; paper copy price code A06.

OFR 97-84. Coal Waste Disposal Survey. Coal Refuse—An Increasingly Serious Problem for Colorado Plateau Production, by Susan M. White, W. Kent Ostler, and Cyrus McKell. July 1982. 67 pp. 26 figs. This study presents information on the nature of coal refuse and disposal practices on the Colorado Plateau. Samples were collected and analyzed to provide information to help formulate alternative methods for reclaiming refuse piles. The analyses were based on determining the capability of unmodified refuse to provide a suitable medium for plant growth. Local topsoils that would be used in reclamation were used as standards. Potential environmental hazards were also assessed. A general cost analysis was done for both surface and underground disposal and the advantages and disadvantages of each were assessed. Several problems were identified that, if solved, would increase the effectiveness of State regulatory programs. Research done under contract J0333931 by the Plant Resources Institute. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-185073; paper copy price code A04.

OFR 98-84. An Analog Device for Simulation of Hardrock Mine Ventilation, by H. Wright, R. Lundquist, and B. Murray. May 1983. 73 pp. 15 figs. The purpose of this report is to assess the feasibility of an analog "black box" approach to mine ventilation simulation in which electronic or mechanical elements are physically interconnected in order to model an underground ventilation network. The black box approach to ventilation simulation involves the use of electronic or fluid-mechanical elements that have the proper square law dependence between pressure and flow. These elements would be assembled in a configuration that represents the ventilation network. When activated, the flows or pressures can be measured. Branch resistances can be easily changed to simulate new test conditions such as a regulator readjustment or breakthrough between sections. Both the fluid-mechanical and analog electronic models can be made that have the capability to model nonlinear flow in networks such as mines. The fluid-mechanical device has a practical limitation of perhaps 25 to 30 branches and more design tailoring. The market for analog simulators is perhaps two to three hundred systems, and there is a noticeable price sensitivity above $5,000. Research done under contract J0318017 by Bolt Beranek and Newman Inc. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-185065; paper copy price code A04.

OFR 99-84. System for Handling Supplies in Underground Coal Mines, by Ani Chitaley and Ricardo A. Diaz. Apr. 22, 1983. 49 pp. 17 figs. A new method was developed to handle supplies in underground bituminous coal mines. A survey indicates industrywide implementation potential for the proposed method. Reduction of supply handling accidents by as much as 73% and improvements in the productivity of face operations by at least 3% are anticipated benefits. The new method is based on the palletization of daily supplies and the use of a forklift to carry out the handling tasks at the underground section. The forklift demonstrated several important features necessary for underground supply handling such as compactness, maneuverability, visibility, ease of control, and auxiliary attachments for hoisting, carrying timber, and pulling. Design improvements are recommended for future generation underground forklifts that relate to higher speed, increased battery duty cycle, higher payload, and modified traction steering to eliminate plowing of soft mine floors. Research done under contract H0188049 by Booz, Allen & Hamilton Inc. Available for reference at the following facilities: DRC, LIB, MSHA, NMH&SA, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84-186741; paper copy price code A03.

OFR 100-84. Research Study on the Technology for Control of Environmental Noise From Off-Road Haul Trucks, by John L. Dahle. Sept. 1983. 93 pp. 29 figs. This report documents research efforts that were undertaken to design, install, and test noise abatement devices for use on off-highway haul trucks operating in surface mines. The objective of the program was to reduce the environmental noise from haul trucks. The noise reduction devices that were developed utilized existing technology and were tested on a 50-ton haul truck. The work emphasized the reduction of noise emitted from the engine compartment, which included the use of side shields, sound absorbing material, improved radiator shroud design, and a modulating clutch fan. Noise tests were conducted using modified SAE test procedures for measuring sound levels around a stationary and moving machine, and inside the operator compartment. Test results showed a maximum of 4 dBA reduction measured 16 ft from the truck. Interior cab noise was reduced 6 dBA with the windows and vents closed. Research done under contract J0218020 by Woodward Associates, Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-186733; paper copy price code A05.

OFR 101-84. Development of a Multiple Unit Continuous Haulage System, by G. J. Hundman and P. W. Meisel. July 1983. 326 pp. 138 figs. The objective of this research was to design a method to continuously convey coal from a mining machine to a main haulage belt with the fewest operators. The multiple-unit, continuous-haulage (MUCH) system was designed to provide the capacity to convey the coal. The MUCH system has one operator who steers the lead vehicle, following the mining machine. All the remaining vehicles follow the path of the lead vehicle with their conveyors automatically lining up between the lead vehicle and mine section panel belt. This is accomplished by linkages on the vehicles that are interconnected by steering bars. An operator steers the discharge vehicle when outby travel is required. Surface tests indicate the system should track and retrack successfully in square-pillar underground room-and-pillar mines with 18-ft-wide entries and slopes up to 10 pct. For 60° pillar plans, the minimum entry width required is 15 ft. The tests also indicate the system will convey over 8 ton/min of coal around 90° corners without excessive spillage. Research done under contract J0333941 by Dresser Industries,

Inc. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-188630; paper copy price code A11.

OFR 102-84. A Feasibility Study for the Detection of Weak Electromagnetic Signal/Bursts With Hard-Limited Arrays, by M. Kanefsky and A. Q. K. Rajput. Nov. 1981. 138 pp. 30 figs. The objective of this report was to investigate the use of a noncoherent detector based on polarity-coincidence statistic. Two channel, polarity-coincidence and polarity-difference, statistics were analyzed. The signal, common to both channels, consists of sinusoidal bursts where the exact frequency of the signal is nearly known, but other parameters such as amplitude, phase, and pulse starting time are unknown. The noise inputs are dependent, narrow band, Markov processes. It is shown that the performance depends not only on the signal uncertainties, but on the precise shape of the cross-correlation functions between the noise inputs. By using two polarity-difference statistics in addition to the polarity-coincidence statistic, it is shown that the decrease in performance, as well as the cost of hard limiting due to correlated inputs, can be made small. Research done under contract J0318033 by the University of Pittsburgh. Available for reference at the following facilities: AD/MR, ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-188846; paper copy price code A07.

OFR 103-84. Investigation of the Interaction Between Acid Mine Water and Concentrator Wastes, by Frank E. Diebold and Dennis R. Jenke. Nov. 1982. 107 pp. 14 figs. The waste water treatment system of the Anaconda Mining Co. in Butte, MT, was physically and chemically characterized, modeled on a computer, and investigated with respect to alternate systems for economic heavy metal recovery. The system involves lime addition to a mixture of acid underground copper sulfide mine water, acid effluent water from the iron-induced precipitation of copper from acid leach solution, and basic suspensions of solid effluent from a concentrator plant. Experimental chemical analysis and predictive computer calculations show that the monosulfate and disulfate complexes of transition metals and alkaline earths are 40% of the total dissolved metal load of both acid streams. The suspended solids in the basic concentrator slurries are dominated by quartz and pyrite and also contain kaolinite, muscovite, biotite, and undissolved lime. The mixture of these three streams results in major reductions in concentrations of Al, Cu, Fe, Mg, Mn, Si, and Zn and a pH of >7, with Ca, Na, K, and SO_4^{-2} being the major dissolved ions. The treatment system was simulated in the laboratory and modeled on a computer. The computer program is capable of accurately predicting the amount of lime required to reach a desired effluent water. Preliminary research indicated the usefulness of electroprecipitation as a means of recovering the valuable metal load and providing an EPA acceptable effluent. Research done under contract J0295042 by the Montana College of Mineral Science and Technology. Available for reference at the following facilities: AD/MMR, ALRC, AVRC, DRC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Copies of this report will not be available for purchase.

OFR 104(1)-84. Volumes I Through III of Acquisition, Storage, and Classification of Engineering and Geological Data for Surface-Mine Design and Reclamation, by James C. Cobb, Konstanty F. Unrug, Alan D. Smith, and Richard A. Smath. June 1983. 471 pp. 77 figs. A computer-based information system for engineering and geological data pertaining to surface mining was developed. The information system is interactive, allowing the user to access all data, analyze data, input new data, and to obtain plots of programs on demand. Five computer programs were developed to access and analyze these data. The programs give results for all engineering tests for each rock type, plots of test results against depth, plots of test results against each other, and geologic descriptions of all cores sampled. A statistical analysis, using multiple-linear regression, hypothesis testing, power analysis, stepwise regression, and model building, was performed on the data generated by this project. Research done under grants G1105068 and G1195018 by the University of Kentucky. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, and PRC/B. Copies of this report will not be available for purchase.

OFR 104(2)-84. Volumes IV Through VI of Acquisition, Storage, and Classification of Engineering and Geological Data for Surface-Mine Design and Reclamation, by Edward A. Kryza, Joseph G. Turner III, and Roger L. Weinheimer. June 1983. 367 pp. 103 figs. Forty-seven samples from the Middle Pennsylvanian Breathitt Formation were examined petrographically to determine which shale attributes most directly influence slake durability. The study combined thin section examination with X-ray diffraction analyses of clay mineral orientation and clay mineralogy. Slake durability indices were obtained using a 60-min, one-cycle test and oven-dried samples. Multiple-linear regression indicates a high degree of correlation between slake durability indices and two measured shale characteristics, clay percent and clay mineral orientation. A discriminant function, using these two characteristics, proved successful in differentiating slakable from durable shales, correctly classifying 37 of the 47 tested samples. Research done under grants G1105068 and G1195019 by the University of Kentucky. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, and PRC/B. Copies of this report will not be available for purchase.

OFR 105(1)-84. Ground and Air Vibrations Caused by Surface Blasting. Volume I. Executive Summary, by Jaak J. K. Daemen, Ross C. Barkley, Amitava Ghosh, Clayton R. Morlock, and Sally A. Shoop. Sept. 1983. 121 pp. 46 figs. Ground and air vibrations induced by large surface blasts were monitored and the field results and a number of published results were used to assess the performance of existing predictors and for the development of improved prediction methods. Monitoring was performed with four seismographs giving complete wave records at limestone quarries, coal strip mines, and an open pit copper mine. Conventional analysis includes least square fitting of peak particle velocities and peak air overpressures with scaled distance formulations. Frequency content was analyzed and correlated with blast design. One new method to predict ground vibrations induced by blasting is an analytical predictor that accounts for inelastic attentuation and geometrical spreading, and calculates the peak velocity as a function of

charge weight and distance. Statistical analysis of case studies confirms the consistent improvement over conventional scaled distance predictors. A second new predictor is a computer program simulating blasts including blast geometry, charge distribution, and detonation sequence and simulating propagation of individual pulses to any point of interest where effects are summed. A complete blast vibration results, allowing prediction of frequency of content and duration as well as peak velocities. Research done under grants G5105010 and G5115041 by the University of Arizona. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, and TCRC. Order ONLY from NTIS: PB 84-191931; paper copy price code A06.

OFR 105(2)-84. Ground and Air Vibrations Caused by Surface Blasting. Volume II. Ground Vibration Monitoring and Assessment of Conventional Predictors, by Sally A. Shoop and Jaak J. K. Daemen. Sept. 1983. 193 pp. 86 figs. Thirty-seven blasts were monitored using either 3 or 4 seismographs at 4 coal strip mines and at a limestone quarry. Statistical analysis of the data shows that square root, cube root, and site specific scaling methods predict peak particle velocities with about the same degree of reliability. Some mines have peak particle velocities that are significantly lower or higher than the Bureau of Mines averages. This suggests that the option provided by the proposed regulations of the Office of Surface Mining in 1983 to adjust blast designs based on site specific measurements could be highly beneficial both to operators and to the public. The frequency spectra reveal that the predominant frequencies were generally less than 50 Hz, but several blasts had a significant amount of energy up to 125 Hz. In some cases the vibration energy was concentrated at frequencies corresponding to the delay intervals. Research done under grants G5105010 and G5115041 by the University of Arizona. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, and TCRC. Order ONLY from NTIS: PB 84-191949; paper copy price code A09.

OFR 105(3)-84. Ground and Air Vibrations Caused by Surface Blasting. Volume III. Computer Simulation Predictor of Ground Vibrations Induced by Blasting, by Ross C. Barkley and Jaak J. K. Daemen. Sept. 1983. 237 pp. 85 figs. A computer program was written to simulate ground vibrations induced by multiple-hole surface blasts. The program is an inexpensive and relatively easy to use tool for predicting the principal blast vibration characteristics that determine damage and annoyance potential: peak particle velocity, frequency content, and pulse duration. The program generates a complete ground motion history by superposing at any surface position the vibrations induced by each individual explosives charge. It requires specification of and allows accounting for the blast geometry, initiation sequence, position with respect to blast, pulse characteristics induced by each charge, and propagation laws. A methodology is outlined to determine the necessary variables either on the basis of site investigations or by backcalculation from measured blast vibration records. The latter procedure was applied to blasts from two coal strip mines. It was determined that the main difficulties are backcalculating individual pulses, propagation parameters, and delays. It was shown that a normal distribution of delays influences the results and the response of a single degree of freedom structure significantly. Research done under grants G5105010 and G5115041 by the University of Arizona. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, and TCRC. Order ONLY from NTIS: PB 84-191956; paper copy price code A11.

OFR 105(4)-84. Ground and Air Vibrations Caused by Surface Blasting. Volume IV. A New Analytical Predictor of Ground Vibrations Induced by Blasting, by Amitava Ghosh and Jaak J. K. Daemen. Sept. 1983. 315 pp. 28 figs. A new analytical formula for predicting ground vibrations induced by blasting is proposed. One factor accounts for geometrical spreading and one factor corresponds to inelastic attenuation. The geometrical spreading function is based on likely source geometries idealized as either square root, cube root, or site specific scaling and on the propagation characteristics of predominant wave types. The inelastic attenuation is approximated by an exponential function. The empirical constants in these functions are backcalculated from field measurements. Regression analyses were performed on 23 sets of measured data to determine the validity and effectiveness of the proposed method. In many cases, the proposed method gives better correlation than the conventional method. In most of the remaining cases, there was no difference between the two methods. Best-fit lines given by the proposed method fit the data trend very well, especially at large scaled distances. At large distances the proposed method gives a prediction much closer to the actual values than the conventional methods. The statistical analyses do not show much difference between square root, cube root, or site specific scalings. Research done under grants G5105010 and G5115041 by the University of Arizona. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, and TCRC. Order ONLY from NTIS: PB 84-191964; paper copy price code A14.

OFR 105(5)-84. Ground and Air Vibrations Caused by Surface Blasting. Volume V. Air Vibrations: Monitoring and Predictor Assessment, by Clayton R. Morlock and Jaak J. K. Daemen. Sept. 1983. 175 pp. 61 figs. Airblasts were monitored at four coal strip mines and at a limestone quarry. Thirty-seven production blasts were monitored with 3 seismographs resulting in 111 complete air pressure records. Instrumentation selection and use are described. Data analysis includes an assessment of the predictability of peak overpressures by means of the cube root scaled distance law. It was found that predictability for the cases studied is not good. An extensive discussion of possible explanations is included. A detailed analysis of the frequency content of the observed airblasts, of considerable importance in evaluating potential annoyance problems, was made for all records. A computer program was written to simulate airblasts induced by multiple-hole blasts. A series of small experimental blasts were detonated and monitored to allow an assessment of the program. It is clear that airblasts, especially when induced by very small charges and monitored at very close distances, are highly sensitive to detonation times. Retrofitting of airblast records occasionally was possible, but considerably improved fieldwork is required to validate or refute the computer model. Research done under grants G5105010 and G5115041 by the University of Arizona. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, and TCRC. Order ONLY

from NTIS: PB 84-191972; paper copy price code A08.

OFR 106-84. Testing Jet Fans in Metal/Nonmetal Mines With Large Cross-Sectional Airways, by Michael F. Dunn, Francis S. Kendorski, Mohammad O. Rahim, and Amitabha Mukherjee. July 1983. 132 pp. 55 figs. The objective of this work was to study the way in which jet fans are used to improve ventilation in metal and nonmetal mines with large cross-sectional areas and to develop guidelines for optimizing this performance. Two different sized jet fans and three separate mines were used in the study. The report gives guidelines on optimal fan location and attitude for ventilating open airways, face areas, and dead headings. The results are only for mines with initially low mean entry air velocities and should not be extrapolated to mines with higher air velocities. The appendix, "Using Auxiliary 'Jet Fans' in Large Underground Metal/Nonmetal Mines: A Handbook," is available also as a separate report, OFR 107-84. Research done under contract J0318015 by Engineers International, Inc. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-196393; paper copy price code A07.

OFR 107-84. Using Auxiliary "Jet Fans" in Large Underground Metal/Nonmetal Mines: A Handbook, by Michael F. Dunn, Francis S. Kendorski, Mohammad O. Rahim, and Amitabha Mukherjee. July 1983. 20 pp. 5 figs. This handbook was prepared to provide a quick reference for use by frontline supervisors, ventilation engineers, and mine planners in selecting and using jet fans in a variety of conditions in large underground metal and nonmetal mines. Discussions covering jet fan characteristics, selection and use criteria, and do's and don'ts for easier operation, safety, and performance are included. The handbook is based on research at three underground metal and nonmetal mines with cross-sectional areas of 900 to 2,000 ft^2. The handbook also appears in its entirety in OFR 106-84, "Testing Jet Fans in Metal/Nonmetal Mines With Large Cross-Sectional Airways." Research done under contract J0318015 by Engineers International, Inc. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-196401; paper copy price code A02.

OFR 108-84. Development of Sampling and Analytical Methods for Toxicants in Diesel Exhaust Streams, by K. T. Menzies, K. J. Beltis, and C. M. Wong. Mar. 15, 1983. 155 pp. 24 figs. The objective of this study was to develop and validate sampling and analytical methods for selected diesel exhaust contaminants. Three compound classes were studied including polynuclear aromatic hydrocarbons (PAH), light oxygenates (carbonyls), and heavy oxygenates (odorants). Sampling and analysis were developed and validated in a laboratory and evaluated in a diesel exhaust or mine air matrix. A high-performance liquid chromatographic (HPLC) method was evaluated for analysis of aldehydes and ketones in diluted diesel exhaust and mine air. Sampling schemes to collect carbonyls in these two matrices were also developed. A sampling method to collect odorants in diesel exhaust was developed by limited modification of available sampling schemes. The odorant analysis method evaluation is based on a diesel odor analysis system that utilizes liquid chromatography. The analytical methods developed for analysis of PAH utilized either a reverse phase HPLC or a capillary column gas chromatography-mass spectrometry technique coupled with various sample preparation steps. The developed procedures were found to be suitable for exhaust emission analyses. Interferences are minimal in all methods except for the HPLC analysis of PAH where PAH derivatives may interfere. The results of validation experiments indicate good recovery of specific compounds based on standard studies for individual methods. Research done under contract J0308005 by Arthur D. Little, Inc. Available for reference at the following facilities: DRC, LIB, MSHA, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84-196625; paper copy price code A08.

OFR 109(1)-84. Development of a Dewatering System for Controlling Fracture Dominated Inflow for Acid Mine Drainage Abatement, by Gerald Ahnell, David R. Buss, Robert M. Cohen, and Richard R. Parizek. May 1983. 210 pp. 48 figs. A mine dewatering strategy utilizing fracture sited wells drilled from the surface above a historically wet underground coal mine in Preston County, WV, successfully demonstrated the effectiveness of such a strategy to reduce mine water inflows and increase mine productivity through improved working conditions. The strategy has the potential to be cost effective by greatly reducing the total volume of water likely to enter the mine workings and require costly handling and treatment while minimizing the impact on shallower domestic water supplies. This report outlines five site-independent prerequisites for a cost-effective mine dewatering approach. Research done under contract H0202002 by Skelly and Loy. Available for reference at the following facilities: AD/MR, ALRC, AVRC, DRC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Copies of this report will not be available for purchase.

OFR 109(2)-84. Development of a Dewatering System for Controlling Fracture Dominated Inflow for Acid Mine Drainage Abatement, Appendices, by Gerald Ahnell, David R. Buss, Robert M. Cohen, and Richard R. Parizek. May 1983. 212 pp. 42 figs. A mine dewatering strategy utilizing fracture cited wells drilled from the surface above a historically wet underground coal mine in Preston County, WV, successfully demonstrated the effectiveness of such a strategy to reduce mine water inflows and increase mine productivity through improved working conditions. The strategy has the potential to be cost effective by greatly reducing the total volume of water likely to enter the mine workings and require costly handling and treatment while minimizing the impact on shallower domestic water supplies. This report, the appendices, contains several documents that present a preliminary assessment of the test minesite, a guide for exploration drilling at the site to evaluate the effectiveness of fracture sited wells, and raw data and interpretations of a variety of well tests performed at the demonstration site. Research done under contract H0202002 by Skelly and Loy. Available for reference at the following facilities: AD/MR, ALRC, AVRC, DRC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and

TURC. Copies of this report will not be available for purchase.

OFR 110(1)–84. Relationship of Underground Diesel Engine Maintenance to Emissions. Volume I, by Ronald Branstetter, Robert Burrahm, and Harry Dietzmann. Dec. 1983. 104 pp. 57 figs. Gaseous and particulate exhaust emissions from 20 diesel engines in service at 5 underground mines were measured with high-accuracy instrumentation. The engines were checked for faults or maladjustments. The vehicle and engine maintenance organization was studied at each mine and an idealized maintenance program was devised. Faults were induced in a new diesel engine to determine their effect on the characteristics of the exhaust emissions. The results, conclusions, and recommendations for this investigation are presented in volume I. Research done under contract H0292009 by the Southwest Research Institute. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–195510; paper copy price code A06.

OFR 110(2)–84. Relationship of Underground Diesel Engine Maintenance to Emissions. Volume II, by Ronald Branstetter, Robert Burrahm, and Harry Dietzmann. Dec. 1983. 217 pp. 59 figs. Gaseous and particulate exhaust emissions from 20 diesel engines in service at 5 underground mines were measured with high-accuracy instrumentation. The engines were checked for faults or maladjustments. The vehicle and engine maintenance organization was studied at each mine and an idealized maintenance program was devised. Faults were induced in a new diesel engine to determine their effects on the characteristics of the exhaust emissions. Volume II contains a discussion of mine vehicle maintenance, references, a bibliography, and the appendixes. Research done under contract H0292009 by the Southwest Research Institute. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–195528; paper copy price code A10.

OFR 111–84. Demonstration of Fresnel Lens Blind Area Viewers on Large Underground Mine Vehicles, by James L. Eirls. Feb. 1983. 44 pp. 32 figs. The low profile, fresnel lens, blind area viewer (BAV) developed for use on large haulage vehicles in open pit mines was evaluated to determine the BAV's adaptability to the underground environment. The safety potential was verified at two test mines where operators found the BAV useful in observing well-lighted objects in otherwise normally blind areas, although limited clearance for large vehicles in some areas caused damage problems. The limited vehicular traffic in the underground mines did not emphasize the inherent value or cost effectiveness of the BAV on underground haulage as it did on large vehicles in open pit mines. Research done under contract J0215029 by Tracor MBA. Available for reference at the following facilities: AD/MR, AFOC/J, DRC, IFOC, LIB, MSHA, NMH&SA, PRC/B, SRC, TCRC, and WFOC. Copies of this report will not be available for purchase.

OFR 112–84. Catalytic Chlorination of Alumina, by Y. K. Rao and M. K. Soleiman. Aug. 1983. 59 pp. 21 figs. This work is concerned with the kinetics of the chlorination process for making aluminum. The method investigated consisted of a conventional thermogravimetric unit comprised of a Cahn electrobalance and a vertical tube furnace. Small samples of Al_2O_3:3C mixtures were reacted with He-Cl_2 atmospheres under isothermal conditions. The reduction kinetics were deduced from the weight loss measurements. Temperature has a particularly strong effect on the reduction kinetics, suggesting that the chemical kinetic factors are very dominant in this system. The rate constant shows a first-order dependence on chlorine pressure at low temperatures (about 750° C), but the dependence becomes highly nonlinear at 900° C and above. The reaction kinetics were strongly improved by catalytic reagents, the foremost among these being the fluorides of sodium and calcium. The latter is inexpensive and potentially the most attractive of the catalytic additives found. The mechanism of catalysis involves complex mixed fluoride-chloride species acting as active intermediates. Research done under grants G1105054 and G1115531 by the University of Washington. Available for reference at the following facilities: AD/MI, AD/MMR, ALRC, AVRC, LIB, RERC, RORC, SLRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–196484; paper copy price code A04.

OFR 113–84. Processing of Mineral Fines by Column Flotation, by Kal V. S. Sastry. Sept. 30, 1982. 63 pp. 23 figs. Froth flotation is the most successful method of beneficiating mineral fines. The process is carried out in completely stirred vessels known as flotation cells. It was recently found that countercurrently operated flotation columns, with air bubbles uprising through downflowing slurry, show a definite potential to efficient and selective separation of fine particles. This report presents details and results from a research program that was directed toward understanding the principles governing the column flotation. Influence from a number of process variables was studied by using mixtures of finely ground dolomite and quartz. The column response was determined in terms of (1) recovery and grade of dolomite in the concentrate, and (2) holdup and solids concentration profiles within the column. The report includes a comprehensive analysis of the experimental results and the column flotation process. Research done under grant G1115062 by the University of California—Berkeley. Available for reference at the following facilities: AD/MMR, ALRC, AVRC, LIB, SLRC, TCRC, and TURC. Copies of this report will not be available for purchase.

OFR 114–84. Erodibilities and Eroded Size Distribution of Western Kentucky Mine Spoil and Reconstructed Topsoil, by B. J. Barfield, R. I. Barnhisel, J. L. Powell, M. C. Hirschi, and I. D. Moore. Dec. 1983. 205 pp. 38 figs. The objective of this study was to develop data on the erodibility and size distribution of eroded sediment from mine spoil and reconstructed topsoils and subsoils typical of western Kentucky surface mined lands. Standard erosion plots were constructed of shale, subsoil, and topsoil at the Alston surface mine of Peabody Coal Co. Rainfall was developed using a plot-sized rainfall simulator. Each plot was evaluated under tilled and compacted conditions. One compacted condition was developed with a wheeled compactor and another

with a dozer and scraper pan. Runoff, sediment yield, and size distribution data were collected for each plot. Complete descriptions of each plot and the test apparatus and instrumentation are given. A discussion of the experimental procedures and data analysis procedures are included, and the results and conclusions are summarized. Research done under grants G1105069, G1115211, and G5195021 by the University of Kentucky. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 115–84. Elastic Stress Wave Propagation in Underground Hardrock Mining, by John B. Ligon and R. L. Whipple. Dec. 1983. 218 pp. 109 figs. Blast-induced stress waves propagating along the surface of a drift of an underground hard-rock mine were recorded and analyzed. Resistance strain gauges, accelerometers, and a velocity pickup were used to make the measurements. Although a full face blast was recorded, the stress waves were initiated by single borehole blasts for the majority of the project. A special instrument trailer was designed, constructed, and utilized during the project. A reliable strain wave transducer was developed to measure the stress waves propagating on the drift surface. A correlation study between strain and acceleration signals for P-waves was made that agreed well with theory. The use of stemming was found to reduce strain and acceleration magnitudes as predicted. Research done under grants G1105030 and G1115261 by the Michigan Technological University. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 116–84. Performance and Test Criteria for DC Fuses—Phase I, by E. K. Stanek and D. O. Wiitanen. Mar. 1984. 177 pp. 46 figs. The goal of this research was the development and test criteria for dc fuses used in coal mines. Field tests were conducted in 10 coal mines in which transients were initiated on the dc system from which the parameters of the dc mine electrical power system could be determined. The data processing involved the use of a Fourier analyzer to filter noise and fit an exponential curve to the field waveforms. From this analysis it was possible to find the dc system resistance, inductance, and time constant. The survey of nationally recognized laboratories was conducted to establish that the recommended test criteria were practical. The development of test criteria for dc fuses used in mines was based on the measurement of parameters in the field, the survey of testing laboratories, literature searches, laboratory tests, etc. A computer program was written to analytically predict the parameters measured in the field. This approach has limitations but reasonable agreement with the results was obtained. A brief laboratory testing program was carried out to verify the practicality of the recommended criteria and establish the accuracy of the conclusions concerning dc fuse performance. Research done under contract J0328085 by Michigan Technological University. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-202662; paper copy price code A09.

OFR 117–84. Assesment of Dispersing Tracer Gas With Ventilation Air Stream To Detect Mine Fires, by Mervin D. Marshall. Oct. 1983. 69 pp. 25 figs. A remote heat-activated stench gas-tracer gas mine alarm system was developed to reduce the time between fire detection and personnel notification. The stench gas-tracer gas system contains ethyl mercaptan for personnel warning and a fluorocarbon for tracer gas detection by instrumentation. A system was also developed that can be interfaced with multiplex mine phones. In-mine tests were conducted and several systems were presently installed in a hard-rock mine. Research done under contract J0199031 by MSA Research Corp. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-202696; paper copy price code A04.

OFR 118–84. Stratiform Massive Sulfide Deposits in the Mt. Henry Clay Area, Southeast Alaska, by Jan C. Still. 1984. 65 pp. 8 figs. The Bureau of Mines in 1983 examined the Skagway B-4 Quadrangle in southeast Alaska for volcanic host rocks similar to those that host the stratiform world class Windy Craggy copper-cobalt-gold deposit located across the U.S.-Canadian border 50 miles to the northwest. Such rocks were found between the Jarvis and Boundary Glaciers in what is now called the Mt. Henry Clay area. This area was mapped and investigated for stratiform deposits similar to the Windy Craggy deposit. Investigations indicate that the Mt. Henry Clay area massive sulfide occurrences are stratiform, have a similar mineralogy, and are in a geologic setting similar to that of the Windy Craggy deposit. However, the Windy Craggy ore zone consists predominately of pyrrhotite-pyrite-chalcopyrite while the occurrences in the Mt. Henry Clay area consist predominately of barite-sphalerite-pyrite. During 1983 the Jarvis Glacier occurrences, which contain small amounts of cobalt, were discovered in the area by Bureau personnel; commercial mining personnel discovered the important Mt. Henry Clay zinc-copper-silver-gold deposit. Investigations indicate that the Mt. Henry Clay area is highly mineralized and a target for the discovery of stratiform massive sulfide deposits. Research done by the Alaska Field Operations Center. Available for reference at the following facilities: AD/MDA, AFOC/J, and LIB. Copies of this report will not be available for purchase.

OFR 119–84. Study of Availability and Composition of Metal Bearing Wastes, by R. Krishnaswamy. Apr. 13, 1984. 128 pp. 13 figs. Waste streams generated by mineral, metallurgical, and consumer industries carry in them recoverable metals or minerals of economic or strategic importance. This report summarizes the results of a study identifying the major waste streams, evaluating current practices of waste treatment, and their development requirements. Priorities are identified for the developmental work by assigning weightage factors from economic, strategic, and environmental importance as well as on the lead time that may be required for process development. The study covers the following industries and wastes in the United States: titanium extraction and fabrication, aluminum smelters, chromite-bearing refractory and foundry sand wastes, and spent and scrapped mercury batteries. Research done under contract J0134050 by N. H. Parker, P.E. & Associates. Available for reference at the

following facilities: ALRC, AVRC, DRC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-207091; paper copy price code A07.

OFR 120-84. Development of Foreign Economic Indices. Phase I for Philippines, by Alice M. Chieruzzi. Mar. 1983. 118 pp. 15 figs. This report presents the development of economic indices for the Philippines for the period from 1970 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair costs, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: ALRC, AVRC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-208883; paper copy price code A06.

OFR 121-84. Development of Foreign Economic Indices. Phase I for Zambia, by Alice M. Chieruzzi. Apr. 1983. 92 pp. 12 figs. This report presents the development of economic indices for Zambia for the period from 1970 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair costs, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: ALRC, AVRC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-208891; paper copy price code A05.

OFR 122-84. Low Glare Illumination System, by Charles W. Maus. Mar. 23, 1984. 88 pp. 25 figs. A low-glare illuminating system using fiber optics was developed for the Bureau of Mines. Fiber bundles transmit light from sources to luminaires. Light is from tungsten halogen lamps in two dichroic reflectors. Six lamps are housed together with a stepdown transformer in one enclosure. Three conceptual designs were made before development of the fiber optic concept. A fluorescent concept used two F8T5 lamps in a unique W-shaped reflector. The reflector gave the appearance of eight lamps. An incandescent concept used a rectangular solid plastic luminaire molded with a reflector and diffuse surface. A lamp enclosure was mounted on its end. The early fiber optic concept was changed for the final development. As finally produced, the luminaire had a lower profile and a curved underside for painting as a reflector. The top surface was abraded for diffusion. The lamp enclosure at first was for a single lamp. This was changed to six lamps in one enclosure for simplified wiring. Plastic fiber optic bundles were expensive to manufacture and economical glass fiber bundles were obtained. Nonelectrical fiber bundles make the system one of minimum electrical damage vulnerability. Research done under contract J0113006 by Mine Safety Appliances. Available for reference at the following facilities: ALRC, AVRC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-207935; paper copy price code A05.

OFR 123-84. Development of a Machine Mounted Respirable Dust Monitor, by Richard M. Spooner and John L. Bennett. Mar. 1978. 82 pp. 9 figs. This report encompasses the fabrication of a prototype respirable dust sampler and detector assembly for mining machine-mounted dust monitoring application, the design and fabrication of support electronics, and laboratory testing as defined in phase I of the work. The hardware was fabricated in accordance with the phase I design and modified to improve the performance and to comply with customer requests. Modifications involved the filter media, electronic flow controller, motorized and manual lift mechanisms for the transitional heads, speed reducer for the filter media transfer drive, a power supply for each Geiger-Muller tube, and a pressure-sensitive taper roller bracket revision. The functional and environmental testing indicated the prototype hardware functioned within the specified requirements. Research done under contract H0166186 by the Bendix Corp. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-207927; paper copy price code A05.

OFR 124-84. Theoretical Investigation of Seismic Waves Generated in Mines, by Roy J. Greenfield. Sept. 1982. 77 pp. 33 figs. Theoretical studies were performed on the propagation of seismic waves by trapped miners through the overburden of coal mines. These studies formed the basis for a geophone array and instrumentation design for the reception and recording of signals from a trapped miner. The studies, coupled with field tests, enable the performance of the trapped miner seismic system to be placed into a probablistic framework. The results show that the system should be capable of detecting the signal from a trapped miner for ranges exceeding 1,000 ft. Studies were also performed on the use of in-mine geophones for locating trapped miners. The results indicate that this approach may have an advantage over geophones placed on the surface of mines in the situation when either the mine is very deep or surface seismic noise is very high. Research done under grant G1055044 by Pennsylvania State University. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, IFOC, LIB, MSHA,

NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–207919; paper copy price code A05.

OFR 125–84. Feasibility of Gold and Copper Mining in the Chugach National Forest, Alaska, by Gary E. Sherman and Uldis Jansons. July 29, 1983. 55 pp. 8 figs. Preliminary economic mining feasibility studies of gold and copper deposits were conducted by the Bureau of Mines to estimate the mining costs in the Chugach National Forest, AK, in 1982. Lode and placer gold mines and open pit and underground copper mines were modeled. Cost data for the lode and placer gold mines were based on actual operating costs when available. Cost estimates for the copper mines were obtained using the Bureau's cost estimating system and may fall within ±25 pct of the actual costs. Underground gold mining appears economically feasible for a deposit with reserves of 100,000 tons containing greater than 0.5 oz per ton over a 4-ft mining width. A gold price of $456 per ounce is required for the operation to break even. Placer gold mining operations of 100, 500, and 1,000 yd^3 per day were modeled. At a gold price of $400 per ounce, these operations would break even at grades of 0.03, 0.012, and 0.009 per ounce of gold, respectively. An 11,000-ton-per-day open pit copper mine appears to be economically borderline at metal prices of $0.70 per pound of copper, $0.37 per pound of zinc, $400 per ounce of gold, and $10 per ounce of silver. A 1,650-ton-per-day underground copper mine would require a copper price of $0.75 per pound and a zinc price of $1.96 per pound to be economic. Research done by the Alaska Field Operations Center. Available for reference at the following facilities: AD/MDA, AFOC/A, AFOC/F, AFOC/J, IFOC, LIB, and WFOC. Copies of this report will not be available for purchase.

OFR 126–84. Investigation of Blast-Induced Underground Vibrations From Surface Mining, by Michael K. Phang, Thomas A. Simpson, and Robert C. Brown. Dec. 1983. 433 pp. 60 figs. The objective of this study is to evaluate an instrumentation and field monitoring program designed to record and monitor surface blasting effects on underground coal mine openings. Potential damage criteria and guidelines were developed by quantifying the relationship between identifying the nature and degree of underground vibrations and damage produced in a mine on the underground structure. To predict the characteristics of underground vibrations occurring from a surface blast, the propagation relations of underground vibrations from surface blasting were established through the use of measuring devices. Part of the study provides an approach to the design of an instrumentation and field monitoring program for use in investigating the damage criteria of surface blasting on underground coal mine openings. Research done under grants G5105008 and G5115011 by University of Alabama. Available for reference at the following facilities: AD/MR, DRC, IFOC, LIB, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 127–84. A Bibliography on Surface Mine Blasting, by Thomas A. Simpson and Michael K. Phang. Apr. 1984. 41 pp. The apparent rise in the use of explosives by the mining, quarrying, and construction industries over the past few years has prompted increased research in blasting and the attendant noise and vibrations accompanying detonation. Reliable information is needed to develop guidelines that will ensure adherence to blast designs made for protecting lives and property. This bibliography comprises many references that could be useful to researchers investigating blasting techniques and procedures. Research done under grant G1134101 by University of Alabama. Available for reference at the following facilities: AD/MR, LIB, OSM, PRC/B, and TCRC. Copies of this report will not be available for purchase.

OFR 128–84. Mining Properties Acquisition Costs: Kantishna Hills and Dunkle Mine Study Areas, Denali National Park, Alaska, by Dowl Engineers and PLANgraphics, Inc. 1983. 179 pp. 7 figs. This report describes the methodology and results of estimating the overall mineral resource value and the present cost of acquiring mineral property interests in the Kantishna Hills and Dunkle Mine study area of Denali National Park and Preserve in south-central Alaska. Previous studies have underestimated the value of acquiring these properties. The cost of acquiring both placer and lode claims based on current market value is estimated to be about $157.2 million. The acquisition cost includes the value of the patented surface estate. Research done under contract S0134043. Available for reference at the following facilities: AD/MDA, AFOC/A, AFOC/F, AFOC/J, and LIB. Copies of this report will not be available for purchase.

OFR 129(1)–84. 1983 Mineral Resource Studies: Kantishna Hills and Dunkle Mine Areas, Denali National Park and Preserve, Alaska. Volume I. Text, ed. by Vance V. Thornsberry, Calvin J. McKee, and William G. Salisbury. Apr. 1984. 251 pp. 55 figs. In 1983, mineral resource studies were conducted in the Kantishna Hills and Dunkle Mine study areas of the Denali National Park and Preserve, AK. Fieldwork included geologic mapping, geochemical and geophysical surveys, placer studies, and drilling. The Kantishna Hills area contains an estimated 688,000 oz of placer gold in 43 million cubic yards of gravels. The gold was probably derived by erosion of precious-metal vein deposits. Lode mineralization appears to be principally related to the Spruce Creek Sequence of metamorphosed- and volcanosedimentary deposits that contain modest reserves of antimony, gold, silver, lead, and zinc in vein and stratiform deposits. The area also contains black shale and volcanic environments exhibiting newly identified evidence of stratabound base- and precious-metal mineralization. Regional geochemical anomalies indicate other potentially mineralized areas. Mineralization of the Dunkle Mine study area appears to be related to an igneous complex and two regional structural zones hosted by sedimentary, metasedimentary, and metavolcanic rocks. Geochemical and geophysical evidence suggests the igneous complex is permissive for the formation of potentially large-tonnage breccia pipe deposits containing copper and gold, and for poryphyry-type deposits of copper and molybdenum. Numerous small structurally controlled base- and precious-metal deposits are present in the area but none has yet proven to be economic in character. Up to 350,000 tons of coal may be present in Tertiary sedimentary deposits. Production from the Kantishna Hills study area through 1983 totaled 85,000 oz gold, 265,000 oz silver, 540,000 lb lead, and 4,400,000 lb antimony. The Dunkle Mine area has produced approximately

64,000 tons of coal. Research done under contract S0134031 by Salisbury & Dietz, Inc. Available for reference at the following facilities: AD/MDA, AFOC/A, AFOC/F, AFOC/J, LIB, and PRC/B. Copies of this report will not be available for purchase.

OFR 129(2)–84. 1983 Mineral Resource Studies: Kantishna Hills and Dunkle Mine Areas, Denali National Park and Preserve, Alaska. Volume II. Appendices, by Jeffrey H. Levell, Vance V. Thornsberry, William G. Salisbury, and David A. Smith. Apr. 1984. 809 pp. 195 figs. In 1983, mineral resource studies were conducted in the Kantishna Hills and Dunkle Mine areas of the Denali National Park and Preserve, AK. Fieldwork included geologic mapping, geochemical and geophysical surveys, placer studies, and drilling. The Kantishna Hills area contains an estimated 688,000 oz of placer gold in 43 million cubic yards of gravels. The Dunkle Mine study area appears to be related to an igneous complex and two regional structural zones hosted by sedimentary, metasedimentary, and metavolcanic rocks. Volume II of this three-volume report contains the appendices. Research done under contract S0134031 by Salisbury & Dietz, Inc. Available for reference at the following facilities: AD/MDA, AFOC/A, AFOC/F, AFOC/J, LIB, and PRC/B. Copies of this report will not be available for purchase.

OFR 129(3)–84. 1983 Mineral Resource Studies: Kantishna Hills and Dunkle Mine Areas, Denali National Park and Preserve, Alaska. Volume III. Plates, by Salisbury and Dietz, Inc. Apr. 1984. 20 pp. In 1983, mineral resource studies were conducted in the Kantishna Hills and Dunkle Mine areas of the Denali National Park and Preserve, AK. Fieldwork included geologic mapping, geochemical and geophysical surveys, placer studies, and drilling. The Kantishna Hills area contains an estimated 688,000 oz of placer gold in 43 million cubic yards of gravels. The Dunkle Mine study area appears to be related to an igneous complex and two regional structural zones hosted by sedimentary, metasedimentary, and metavolcanic rocks. Volume III of this three-volume report contains plates to be used in conjunction with volumes I and II. Research done under contract S0134031. Available for reference at the following facilities: AD/MDA, AFOC/A, AFOC/F, AFOC/J, LIB, and PRC/B. Copies of this report will not be available for purchase.

OFR 130–84. Development of a Deep-Penetrating Borehole Geophysical Technique for Predicting Hazards Ahead of Coal Mining, Phase II, by Sidney A. Suhler, Oren Tranbarger, and Merle E. Converse. Aug. 14, 1981. 87 pp. 44 figs. The objective of this work was to develop a deep-penetrating borehole geophysical technique for predicting hazards ahead of coal mining. Various methods were evaluated to determine their potential for detecting geological and work-related hazardous conditions and their practicability of implementation. The study indicated that a borehole pulse electromagnetic reflectometer (radar) had the most promise as a viable field technique. Based on the results, a borehole monostatic baseband pulse radar was designed, developed, and tested in prototype form. Field tests of the prototype model showed that underground features were detectable by the technique. Follow-on developments included the design and construction of an engineering model radar that would overcome the problems associated with the prototype model and also provide enhanced detection capabilities. These developments lead to an advanced design borehole radar system providing a directional antenna in a 3-in-diam probe. The information reported herein relates to the theory of operation, operating instructions, and maintenance procedures for the advanced design engineering model radar system. Research done under contract H0252033 by Southwest Research Institute. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-239599; paper copy price code A05.

OFR 131–84. Design, Develop and Demonstrate the Use of Hollow Cutter Bars/Evaluation of Wet Bar Techniques, by Terry Muldoon, Ken Heller, Gary Anderson, and John McCoy. Dec. 1983. 139 pp. 70 figs. Three dust control systems for use in noncoal room-and-pillar mining were designed, fabricated, and evaluated. The first system, a hollow cutter bar, was designed to capture dust in the kerf at the cutting zone. The system was marginally effective in reducing dust levels because of the lack of control over other sources. Large quantities of material captured by the system made it operationally questionable. The second system, a machine-mounted exhaust system, was extremely effective in capturing virtually all of the dust generated in the heading. The captured dust was ducted out of the heading and exhausted downstream in the crosscut. However, exhausting the dust without scrubbing creates problems for personnel working downstream of the cutting machine. Successful application would require changes to the mine ventilation system and mining sequence. The third system injected foam from an on-board generator through a channel to the cutting zone at the tip of the bar. Results showed that foam, using one-third to one-half the total fluid quantity, was equally effective when compared with the mine's current system. Research done under contract H0308049 by Foster-Miller, Inc. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-215045; paper copy price code A07.

OFR 132–84. Extension of Low Coal Canopy Technology To Include Drilling and Cutting Machines, by Hanns Billmayer. Aug. 15, 1983. 56 pp. 31 figs. Low coal canopies have been a source of controversy since their introduction into the mining industry. Canopies have been designed to protect the operator from roof falls and contact with the roof. In many cases, however, this protection has been achieved at the expense of operator visibility and ease of ingress and egress. The intent of this program was to improve the operator protection from numerous hazards and to improve the visibility, comfort, and ability to get in and out of the operator compartment without difficulty. Canopy hardware was built for a cutter and a face drill. Design improvements are described herein. Research done under contract H0318007 by Wyle Laboratories. Available for reference at the following facilities: DRC, LIB, MSHA, NMH&SA, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84-215052; paper copy price code A04.

OFR 133–84. Subsidence Over a Room-and-Pillar Coal Panel in Southern West Virginia, by T. Z. Jones

and K. K. Kohli. Sept. 1983. 77 pp. 10 figs. This study was sponsored by the Bureau of Mines as part of its ongoing subsidence research program. The study involved installation of surface survey monuments over a room-and-pillar panel in southern West Virginia, eastern coal province. Monitoring was conducted for a period of 6 months. Maximum subsidence was 1.48 ft and occurred near the center of a two-panel span, one of which was monitored as part of the study and the other adjacent to it. This is equal to 31 pct of the extracted coal height. The angle of draw over the pillared panels was 24°. The width-to-depth ratio over the pillared panels was 0.85. A maximum surface horizontal strain of 0.003 was detected near the center of the monitored panel. The overburden lithology consists of interlayered sandstone, shales, and coal with 50 pct of the overburden being sandstone layers 5 ft thick or greater. Research done under contract J0382010 by West Virginia Institute of Technology. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–220177; paper copy price code A05.

OFR 134–84. Coal Mine Hazard Detection Using Synthetic Radar, by James C. Fowler. Dec. 1983. 74 pp. 48 figs. The objective of this investigation was to develop and field test a prototype synthetic pulse radar system for in-seam hazard detection. The system consists of three major components: (1) the control unit, (2) the transmitter and antenna, and (3) the receiver and antenna. The system employs a hetrodyne receiver and two synthetizers that are phase-locked together with a 1-MHz offset. A fiber optic link is used to help eliminate direct feedthrough. The transmitted frequencies are in the 20- to 160-MHz range, with a minimum frequency spacing of 100 kHz, providing a time window of 10,000 ns. The system is packaged with self-contained batteries for in-mine use. A secondary processor was designed and breadboarded to display data in the field. This processor, or any other minicomputer, can access the system using standard serial or parallel interfaces. The work was based upon the results of a previous Bureau of Mines contract, "Coal Mine Hazard Detection Using Synthetic Pulse Radar," OFR 79–81. This report summarizes the previous work, describes the results of four field tests, and discusses the advantages and disadvantages of this new type of radar. Research done under contract H0212016 by XADAR Corp. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84–220672; paper copy price code A04.

OFR 135–84. Development and Evaluation of Near-Mine Stimulation Techniques for Coalbed Degasification, by G. W. Murrie, J. T. Popp, C. M. McCulloch, and D. J. Steele. May 1984. 127 pp. 52 figs. The purpose of this project was to determine the effects of foam stimulation treatments on mining conditions in underground coal mines. Underground investigations were conducted to characterize the geological and mining conditions both before and after the holes were stimulated. Of 12 holes that were drilled at minesites in Kentucky, Pennsylvania, Utah, and West Virginia, 4 were mined through and mining progressed within 75 ft of a fifth before mining plans were altered because of unassociated reasons. The fracture fluids were tagged with fluorescing paint pigments to enable their underground pathways to be detected with an ultraviolet light and accurately mapped. At the holes that were intercepted by mining, the induced fractures were all contained within the coal seams. Horizontal fracturing at the seam-roof interface and along an inseam binder was more extensive than the vertical fracturing, which was confined primarily to the more friable portion of the seam. The mining conditions, roof, floor, and support requirements were unaffected by the stimulation treatments. Research done under contract J0333908 by Dames & Moore. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–220664; paper copy price code A07.

OFR 136–84. Ultralightweight Oxygen Container, by Ben Aleck. Nov. 1983. 32 pp. 15 figs. Technology to develop high-pressure gas cylinders that are 40 pct lighter than comparable fiberglass-wrapped aluminum cylinders was developed. The new cylinders were of cryobulged stainless steel overwrapped with a higher strength-to-weight ratio filament. Although a 40-pct decrease is significant, the weight savings on smaller cylinders, such as those used in escape apparatus, is very small and would not be cost effective. Open-circuit apparatus that use large bottles, such as for firefighting, would find weight savings worth pursuing. Research done under contract J0100043 by Grumman Aerospace Corp. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84–220730; paper copy price code A03.

OFR 137–84. Fundamental Investigation of Phosphate Bonding, by James F. Benzel. Nov. 1983. 72 pp. 25 figs. This investigation utilized single crystals to study phosphate bonding, eliminating surface area and particle shape as variables and allowing the effect of crystallographic orientation to be evaluated. The morphology of the reaction products when H_3PO_4 was reacted with alumina single crystals was related to the crystal face index. Star-shaped dendrites formed on the low index faces and equiaxed crystals formed on faces that did not correspond to low index planes and polycrystalline samples. The tensile strength of $(11\bar{2}0)$ and (0001) alumina bicrystals increased as their surface finish was improved. The tensile strength of $(11\bar{2}0)$ alumina bicrystals bonded with $NaH_2PO_4 \cdot H_2O$ or Glass H are greater than (0001) bicrystals produced under the same conditions. The tensile strength of $(11\bar{2}0)$ alumina bicrystals bonded with $NaH_2PO_4 \cdot H_2O$ varies with the amount of rotational mismatch between the crystals. Strength maximums occurred at 0° and 180° and a minimum of 90°. It appears that this strength pattern is related to the twofold symmetry of this plane. Combination of both rotational and tilt mismatch reduced the strength of $(11\bar{2}0)$ and (0001) bicrystals to almost zero. The strength decreases associated with these types of bicrystal mismatches could be related to differences in thermal expansion with direction or bond misalignment. Research done under contract J0123041 by Georgia Institute of Technology. Available for

reference at the following facilities: ALRC, AVRC, LIB, and PRC/B. Order ONLY from NTIS: PB 84–220748; paper copy price code A04.

OFR 138(1)–84. The Development of Guidelines for Closing Underground Mines: Executive Summary. by Allan M. Johnson, Linneas W. Laage, and Donald James Butler. Dec. 31, 1983. 40 pp. Case histories were used to document and evaluate deficiencies in underground mine closures that have resulted in postoperation problems such as subsidence shaft failures, acid or toxic water drainage, and others. Three underground mining districts in the United States were investigated: (1) An iron mining district in Michigan, (2) coal mining districts in eastern Ohio and southern Illinois, and (3) three metal mining districts in central Colorado. The studies show that problems from acid water drainage, subsidence, and inadequately protected mine shafts are the most severe and widespread. Suggestions of a technical nature are presented as partial solutions to some of these problems. It was determined that preclosure evaluations could result in the identification of some potential problems that may occur after a mine is closed. Early recognition of the problems would be an advantage because of the options available to mine operators to either prevent them or to plan for their occurrence. Mine closure and reclamation should be considered as a part of mining and be incorporated in the mining plan, which would result in reduced environmental impact and would be achieved at a lower overall cost. Research done under grants G1105033 and G1115262 by Michigan Technological University. Available for reference at the following facilities: AD/MR, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 138(2)–84. The Development of Guidelines for Closing Underground Mines: Colorado Districts, by Donald James Butler. 1983. 164 pp. 57 figs. The purpose of this research was to study mine-related problems in several underground mining districts with the goal of developing guidelines or suggestions for improved closing procedures for underground mines that would reduce or eliminate these problems. This report documents conditions of closed underground mines in three Colorado mining districts—Leadville, Westcliffe, and Cripple Creek-Victor. Research done under grants G1105033 and G1115262 by Michigan Technological University. Available for reference at the following facilities: AD/MR, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 138(3)–84. The Development of Guidelines for Closing Eastern Underground Coal Mines, by Linneas W. Laage. 1982. 143 pp. 41 figs. The purpose of this research was to study mine-related problems in several underground mining districts with the goal of developing guidelines or suggestions for improved closing procedures for underground mines that would reduce or eliminate these problems. This report documents conditions of closed underground mines in three eastern coal mine districts—two in Ohio and one in Illinois. Research done under grants G1105033 and G1115262 by Michigan Technological University. Available for reference at the following facilities: AD/MR, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 138(4)–84. The Development of Guidelines for Closing Underground Mines: Michigan Case Histories, by Allan M. Johnson. Dec. 1983. 132 pp. 51 figs. The purpose of this research was to study mine-related problems in several underground mining districts with the goal of developing guidelines or suggestions for improved closing procedures for underground mines that would reduce or eliminate these problems. This report documents conditions of closed underground mines in the Menominee Range of northern Michigan. Research done under grants G1105033 and G1115262 by Michigan Technological University. Available for reference at the following facilities: AD/MR, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 139–84. The Use of Coal Wastes for the Production of Alumina, by H. Y. Sohn. Dec. 29, 1983. 71 pp. 31 figs. The United States has become more and more dependent on foreign sources for bauxite, the primary source for aluminum at the present time, because its bauxite resources are considered inadequate as a long-range supply. However, domestic low-grade aluminum resources, including coal wastes, are considered unlimited. The development of a suitable method for using coal wastes for alumina extraction will also alleviate coal waste disposal problems. This report describes three methods of extracting alumina from domestic coal wastes using their carbon contents as a fuel and a reductant of silica contained therein. Research done under grants G1105089, G1115493, and G1195049 by the University of Utah. Available for reference at the following facilities: AD/MMR, ALRC, AVRC, LIB, RERC, and TURC. Order ONLY from NTIS: PB 84–223460; paper copy price code A04.

OFR 140–84. Development of Engineering and Cost Data for Foreign Gold and Silver Properties, by Robert E. Green and Derek J. Ottley. Jan. 7, 1983. 49 pp. This paper comprises 107 technical and profile reports on major gold and silver mines and deposits of the world, exclusive of the United States and the centrally controlled economy countries. The evolving mine and deposit lists and the accompanying criteria classifications are explained along with verifications and justifications for adding or deleting specific mines or deposits to the lists. Tabulated summaries of property data include reserves and resources, assays, production, and operating costs. Figures for specific mines and deposits are given in ranges of values to protect the confidentiality of individual owners and operators. Research done under contract J0215039 by Davy McKee Corp. Available for reference at the following facilities: AFOC/J, DRC, LIB, IFOC, SRC, and WFOC. Order ONLY from NTIS: PB 84–229004; paper copy price code A03.

OFR 141–84. Development of Environmentally Attractive Leachants. Volume II, An Experimental and Theoretical Study of Uranium and Pyrite Dissolution Kinetics, by Robert S. Schechter, Larry W. Lake, and Terry R. Guilinger. Feb. 29, 1984. 549 pp. 153 figs. This report describes the results of flow tests on the rate and ultimate yield of uranium and pyrite leaching

under conditions representative of carbonate in situ uranium leaching. The effects of cation type, pH, carbonate and oxygen concentrations, and flow rate were investigated for uranium leaching. Leachant cation, pH, and carbonate concentration had little effect on uranium leaching, but the leaching rate depended on oxidant concentration to ½ order. The insensitivity to cation type led to a new process whereby the leach solution is preceded by a preflush containing the chloride of the leaching cation. The preflush prevented permeability losses associated with carbonate precipitation and clay swelling caused by certain cations. The effects of leachant cation, pH, carbonate and oxidant concentration, and particle size were also studied for pyrite leaching. The reaction products were elemental sulfur, thiosulfate, sulfate, and an unidentifiable sulfur species. The fate of iron was geothite, amorphous iron, oxyhydroxides, and lepidocrocite. Research done under contract H0282016 by the University of Texas—Austin. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-232669; paper copy price code A23.

OFR 142–84. Effects of Longwall Mine Subsidence on Overlying Aquifers in Western Pennsylvania, by D. Pennington, J. G. Hill, G. J. Burgdorf, and D. R. Price. May 1984. 130 pp. 58 figs. Ground water levels and subsidence were monitored over a longwall panel of a deep coal mining operation in western Pennsylvania. The monitoring network includes 11 ground water monitoring wells completed to measure water level changes in separate shallow and deep aquifer zones and 50-ft surveyed subsidence stations parallel and perpendicular to the panel centerline. Monthly monitoring data were collected during the premining, mining, and postmining time periods. Aquifer testing and borehole geophysical logging were conducted during premining and postmining conditions to document any changes in aquifer properties and ground water flow patterns. Results indicate ground water declines were located with respect to the mining face and mined longwall panel. Dewatering of the deep aquifer zone caused a significant water level decline in deep wells; however, the shallow aquifer zone was isolated from major impacts by an aquitardal layer during the 1-yr period. Transmissivity data were greatly impacted by fracturing in the highly anisotropic aquifer system. Borehole geophysical logging indicated changes in ground water flow patterns and zones of increased fracturing from subsidence. Research done under contract J0199063 by SMC Martin Inc. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 84-236710; paper copy price code A07.

OFR 143–84. Development of Commercial Quiet Rock Drills, by Piyush K. Dutta and Peter W. Runstadler, Jr. Sept. 1983. 114 pp. 44 figs. This report describes the design, development, and manufacture of production stoper drills and the results of their field tests. It is shown that underground stoper drill noise level can be reduced from 118 dBA to below 100 dBA by using pneumatic drills. The design concept of these drills is a radical departure from the standard valved rifle bar type drill machine design to a drill featuring a valveless independent rotation system, use of an integral muffler, and a shroud tube. Six drills were manufactured in a standard commercial drill manufacturing setup and organization. The design and production technology proved that commercially viable quiet drills can be made available for mine use. Research done under contract J0177125 by Creare Products Inc. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, MSHA/P, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-232644; paper copy price code A06.

OFR 144–84. Low-Profile Portable Crusher for Underground Mining Applications: Construction and Testing, by H. Miller, S. Cobey, and J. Murphy. June 15, 1983. 126 pp. 45 figs. This report presents the results of a development and testing program for a portable low-profile crusher. The unit has an extremely low vertical profile considering its size and capacity. The crushing jaws that form the crushing chamber are inclined, with the lower jaw mounted for eccentric movement relative to the stationary upper jaw. This provides efficient crushing while also forcing material through the crushing chamber. As a result, the inlet feeder can be disposed horizontally. To facilitate correct processing of different materials, the size of the discharge opening and the action of the movable crushing jaw are variable. The unit also incorporates a feeder hopper and discharge conveyor that provides for efficient ore handling through the machine. Tests demonstrated the crusher's high capacity, efficiency, and reliability. During testing, the unit crushed over 120,000 tons of materials of up to 32,000 psi compressive strength at production rates in the 200- to 350-ton/h range. The unit operated smoothly under simulated low-headroom conditions and proved readily transportable. Research done under contract H0282037 by Eagle Crusher Co., Inc. Available for reference at the following facilities: AD/MR, ALRC, AVRC, DRC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-232578; paper copy price code A07.

OFR 145–84. National Prototype Copper Mining Water Management Plan, by Jacqueline V. Rich. Aug. 1, 1983. 153 pp. 17 figs. The objective of this study was to develop best management practices for the use of water at mines in the Globe-Miami, AZ, copper mining district. This paper, the concluding report in a series of 10, investigated the relationship between surface and ground water quality and copper mining. Methods to prevent, minimize, mitigate, or treat polluted water were identified and evaluated. Best management practices are incorporated in a recommended plan to manage the area's water quality. Research done under contract J0205039 by the Central Arizona Association of Governments. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-232586; paper copy price code A08.

OFR 146–84. Restoration of Groundwater Quality After In Situ Uranium Leaching, by Jerry R. Riding and Frank J. Rosswog. Aug. 1979. 363 pp. 63 figs. In situ solution mining of uranium has several environmental advantages over other mining techniques. The leaching of uranium, however, alters the

ground water in the aquifer where the leaching occurs. A requirement of the mining technique is the control of objectionable materials that are introduced into the water. This report reviews the state of the art in restoring ground water quality. Current restoration practices discussed include disposal wells and solar evaporation ponds. Sweeping techniques by producing waterflow from all wells during restoration and recirculating techniques by recharging water from a surface purification plant are evaluated. Methods for predicting the effectiveness and costs of current methods are presented. Possible alternatives for restoration of the ground water quality are described. Research done under contract J0275028 by Ford, Bacon & Davis Utah Inc. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-232875; paper copy price code A16.

OFR 147-84. Front-End Loader Training System, by Jane Applegate and Kristine Krupp. Dec. 1983. 110 pp. 45 figs. This report documents efforts to design, develop, and test a training approach that would assist front-end loader operators in the acquisition of skills and awareness to reduce the probability of their involvement in accidents in the mining environment. The goal of this project was to prepare and use, on a trial basis, a training method and materials that would be generally applicable to any loader and surface mining operation while at the same time be adjustable by mine personnel to meet the specific needs of each mining operation. This resulted in the Front-End Loader Training System, a structured, performance-based training approach with diverse instructional aids and classroom and on-machine training experiences. Validation of the system at a large western mine demonstrated the utility and flexibility of the training approach and materials. Research done under contract H0308034 by Woodward Associates, Inc. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-232594; paper copy price code A06.

OFR 148-84. Roof Bolt Anchorage Quality Indicator/Tension Decay Equalizer, by Anil Mahyera and A. H. Jones. Nov. 1983. 158 pp. 131 figs. This report presents the results of a laboratory and field research program to design and develop a torque-thrust controlled bolter with the capability to (1) predict the "quality of anchorage" attained while installing mechanical anchor roof bolts and (2) improve the uniformity and tension levels achieved among a group of roof bolts. The prediction accuracy of the anchorage quality algorithm ranged from low to moderate because of the complexity and variability of the phenomena involved. The best roof support with mechanical anchor bolts was achieved by simply installing them under proper torque-thrust control with a hardened washer under the bolthead. The results showed a threefold uniformity improvement and a 75% increase in mean tension levels over conventionally installed roof bolts. Research done under contract H0282047 by Terra Tek, Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 84-231455; paper copy price code A08.

OFR 149-84. Development and Validation of a Training Program for Operators of Underground Non-Coal Equipment, Volume I, by Chuck Semple. Feb. 1984. 98 pp. 4 figs. This report describes the development of training materials for the operators of underground mining equipment in the underground metal and nonmetal mining industry. The objective was to determine the effectiveness and acceptability of these training materials and to provide the validated training materials to the industry. Ten modules were developed, based on industry need according to accident frequency, accident severity, and exposure to equipment. The final modules were an average 20 min long and used slides with synchronized narration on cassette tapes. Testing materials are included for use by the mines. Research done under contract H0308067 by the Canyon Research Group. Available for reference at the following facilities: AD/MR, ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-237205; paper copy price code A05.

OFR 150-84. Monitoring and Control of Mine Air Diesel Pollutants: Tailpipe Emissions Measurements, Aftertreatment Device Evaluation and Quantification of Diesel and Coal Fractions of Particulate Matter With Raman Spectroscopy, by John H. Johnson, David H. Carlson, Mark D. Osborne, Edward O. Reinbold, Bahne C. Cornilsen, and Veeryooth Lorprayoon. Nov. 15, 1982. 182 pp. 56 figs. The objective of this research was to provide engineering guidelines and methodologies for the control of air quality in dieselized underground mines. The work includes investigations of the interrelationship between ventilation and diesel operational and control parameters, develops measurement technology and methods, and evaluates emission control devices specific to the operation of diesels in dead-end entries. The report includes a description of the emissions measurement apparatus, monitoring methods and evaluation, evaluation of on-board CO_2 monitors, selective analysis for diesel soot in coal mine dust samples, exhaust control techniques using a mine air quality laboratory, and technical papers. Research done under contract J0199125 by Michigan Technological University. Available for reference at the following facilities: AD/MR, ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 84-239151; paper copy price code A09.

OFR 151-84. Placement and Evaluation of High-Modulus Backfill, by Koehler Stout, Leroy Friel, Edward Van Eeckhout, and Brian Woodward. Aug. 11, 1983. 208 pp. 94 figs. Previous work indicates that hydraulically placed backfill can be strengthened severalfold by various placement methods. Sunshine mill tailings were tested by these placement methods and strength increases up to 30 times over the ordinary placement methods were achieved. A computer simulation study of the test stope in the Sunshine Mine showed that a high-modulus fill absorbs up to 27 pct of normal stresses versus 7 pct for normal fill while reducing maximum convergence 28 pct versus 8 pct for normal fill. Although high-modulus fill was not placed in the test stope during this research, various instrumentation was pur-

chased, designed, and built to record necessary data in the stope. Stress gauges were placed in the pillars and recorded data corresponded closely with theoretical projections. Research done under contract J0295052 by Montana College of Mineral Science and Technology Alumni Foundation. Available for reference at the following facilties: AD/MR, DRC, LIB, MSHA, NMH&SA. OSM, PRC/B, and TCRC. Order ONLY from NTIS: PB 84-239144; paper copy price code A10.

OFR 152-84. Minerals Availability Directory of Mineral Deposits for 23 Strategic Mineral Commodities, by Luis V. Coppa and Carl A. DiFrancesco. May 1984. 216 pp. 7 figs. This Bureau of Mines open file report is a directory of 23 major mineral commodities, both foreign and domestic. Nonconfidential information from the Advanced Deposit Information and Tracking System data base covering worldwide market economy country mineral properties being evaluated by the Division of Minerals Availability have been abstracted for use in this report. Abstracts include applicable data on location, commodities present, company name, mining method, and operational status. Research done by the Division of Minerals Availability. Available for reference at the following facilities: AFOC/J, IFOC, LIB, and WFOC. Order ONLY from NTIS: PB 84-239185; paper copy price code A10.

OFR 153-84. Development of Foreign Economic Indices. Phase I for Australia, by Alice M. Chieruzzi. Dec. 1982. 171 pp. 20 figs. This report presents the development of economic indices for Australia for the period from 1965 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair costs, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-103703; paper copy price code A08.

OFR 154-84. Development of Foreign Economic Indices. Phase I for Bolivia, by Alice M. Chieruzzi. Dec. 1983. 114 pp. 5 figs. This report presents the development of economic indices for Bolivia for the period from 1970 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair parts, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight fctors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-103687; paper copy price code A06.

OFR 155-84. Development of Foreign Economic Indices. Phase I for Canada, by Alice M. Chieruzzi. Dec. 1982. 44 pp. 4 figs. This report presents the development of economic indices for Canada for the period from 1965 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair parts, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-104321; paper copy price code A08.

OFR 156-84. Development of Foreign Economic Indices. Phase I for Chile, by Robert Smith. Oct. 1983. 141 pp. 8 figs. This report presents the development of economic indices for Chile for the period from 1970 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair parts, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-104495; paper copy price code A07.

OFR 157-84. Development of Foreign Economic Indices. Phase I for Germany, F.R., by Alice M. Chieruzzi. Jan. 1983. 103 pp. 12 figs. This report

presents the development of economic indices for the Federal Republic of Germany for the period from 1965 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair parts, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-104446; paper copy price code A06.

OFR 158-84. Development of Foreign Economic Indices. Phase I for Greece, by Alice M. Chieruzzi. Dec. 1983. 97 pp. 13 figs. This report presents the development of economic indices for Greece for the period from 1970 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair parts, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-103695; paper copy price code A05.

OFR 159-84. Development of Foreign Economic Indices. Phase I for Guatemala, by Robert Smith. Dec. 1983. 77 pp. 6 figs. This report presents the development of economic indices for Guatemala for the period from 1970 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair parts, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-106854; paper copy price code A05.

OFR 160-84. Development of Foreign Economic Indices. Phase I for Japan, by Alice M. Chieruzzi. May 1983. 88 pp. 11 figs. This report presents the development of economic indices for Japan for the period from 1970 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair parts, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-152445; paper copy price code A05.

OFR 161-84. Development of Foreign Economic Indices. Phase I for Jordan, by Alice M. Chieruzzi. Dec. 1983. 129 pp. 17 figs. This reports presents the development of economic indices for Jordan for the period from 1970 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair costs, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-107688; paper copy price code A07.

OFR 162-84. Development of Foreign Economic Indices. Phase I for Morocco, by Clifford F. Zinnes. Dec. 1982. 148 pp. 11 figs. This report presents the development of economic indices for Morocco for the period from 1965 through 1981. The work was

done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair parts, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. OFR 163-84. Development of Foreign Economic Indices. Phase I for Peru, by Robert Smith. Oct. 1983. 144 pp. 9 figs. This report presents the development of economic indices for Peru for the period from 1970 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair costs, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-105914; paper copy price code A07.

OFR 164-84. Development of Foreign Economic Indices. Phase I for South Africa, by Alice M. Chieruzzi. Dec. 1982. 178 pp. 18 figs. This report presents the development of economic indices for the Republic of South Africa for the period from 1965 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair costs, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-106540; paper copy price code A09.

OFR 165-84. Development of Foreign Economic Indices. Phase I for Sweden, by Alice M. Chieruzzi. May 1983. 85 pp. 9 figs. This report presents the development of economic indices for Sweden for the period from 1970 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair parts, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-152452; paper copy price code A05.

OFR 166-84. Development of Foreign Economic Indices. Phase I for Syrian Arab Republic, by Robert Smith. Dec. 1983. 84 pp. 4 figs. This report presents the development of economic indices for the Syrian Arab Republic for the period from 1970 through 1981. The work was done through the Bureau of Mines Minerals Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair costs, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-107027; paper copy price code A05.

OFR 167-84. Development of Foreign Economic Indices. Phase I for United Kingdom, by Clifford F. Zinnes. May 1983. 94 pp. 10 figs. This report presents the development of economic indices for the United Kingdom for the period from 1970 through 1981. The work was done through the Bureau of Mines Miner-

als Availability Program under contract. The contract calls for the development of 12 index time series describing factor input costs in the mining sector of 95 countries. The index time series describe the costs of (1) mining wages, (2) construction wages, (3) equipment and repair parts, (4) bits and related steel, (5) timber and lumber, (6) fuel, (7) powder and blasting agents, (8) tires, (9) construction materials, (10) industrial materials, (11) transportation, and (12) electrical power. The indices were developed primarily for use in the Bureau's Minerals Availability Program in assessing the worldwide availability of nonfuel minerals and, when combined with weight factors being developed by Bureau personnel, will be used to perform instantaneous updates of all costs relating to the mining industry. Research done under contract J0225001 by Phoenix Associates, Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, OSM, and WFOC. Order ONLY from NTIS: PB 85-103745; paper copy price code A05.

OFR 168-84. Geostatistics for Resource/Reserve Estimation, by Luis V. Coppa, Eric K. Green, and Choon K. Quan. June 1984. 116 pp. 43 figs. Since its inception in 1910, the Bureau of Mines has been the principal Federal agency involved in ore reserve estimations using such traditional methods as polygons of influence and variations of inverse distance weighting. While adequate for estimating the average ore grades in a mining block or section, these methods do not provide a consistent way of quantifying the reliability of the estimates. This report describes a technique for enhancing ore reserve estimations using geostatistics, the methodology of which combines the spatial and random aspects of geologic phenomena into a formal theoretical framework for deriving the estimation variance of ore reserves. Correctly used, geostatistics enables confidence intervals to be placed around ore reserve estimates calculated from drill hole data. A geostatistical software system was obtained from the U.S. Geological Survey and installed, after slight modifications, on the Bureau's Wang computer. System testing and validation were conducted using a simple textbook-type example. This was then followed by variogram analysis, point kriging, and block kriging of data from a previously worked section of a uranium mine. Kriging provides the best linear unbiased estimator in the sense that its estimation variance (kriging variance) is a minimum. The kriging variance then determines the accuracy of a reserve estimate and the risk associated with a financial decision based on that estimate. Research done by the Division of Minerals Policy and Analysis and the Division of Minerals Availability. Available for reference at the following facilities: AD/MDA, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-105781; paper copy price code A06.

OFR 169-84. The Development of Engineering and Cost Data for Foreign Graphite Properties, by Thomas P. Oxford. Feb. 1984. 19 pp. Natural graphite is used in a wide variety of applications where its unique physical, thermal, and electrical properties are exploited. Availability products are broadly classified as either crystalline or amorphous. The Sonora district of northwestern Mexico is the most important supplier of amorphous graphite to the United States. Crystalline flake varieties are available from Canada, Brazil, Madagascar, India, the Republic of Korea, Mexico, Norway, the Federal Republic of Germany, and Zimbabwe. Lump graphite is available from Sri Lanka. Ore is retrieved from both underground and open pit sources, and froth flotation is the primary upgrading process. This report summarizes studies on graphite completed under contract and is presented as a project overview. The number and description of various technical reports that were prepared and submitted are outlined. Various property list changes implemented by contract modifications are noted. Methods of data acquisition and analyses are described and useful findings of the studies are discussed. Difficulties and problems experienced during the project are highlighted, providing hints for improvement to future Minerals Availability Program commodity studies. Research done under contract J0225019 by Zellars-Williams, Inc. Available for reference at the following facilities: AD/MDA, AFOC/J, IFOC, LIB, and WFOC. Order ONLY from NTIS: PB 85-103737; paper copy price code A02.

OFR 170-84. Development of Engineering and Cost Data for Foreign Fluorspar Properties, by Robert B. Fulton III, Gill Montgomery, Mary L. Pearson, and Richard Waissar. May 1984. 43 pp. This report presents summaries of data and estimates for 52 fluorspar properties in Mexico, Thailand, China, Morocco, Tunisia, Italy, Spain, the Republic of South Africa, France, the United Kingdom, Kenya, Namibia, and the Federal Republic of Germany. Data include deposit type, resource tonnage and grades, mining and beneficiation methods, annual production, fluorspar products and byproducts, work force requirements, and capital and operating cost estimates. For operating properties, engineering and cost data were developed for present and anticipated levels of production. Hypothetical operations were assumed for undeveloped deposits. Research done under contract J0225010 by Dames & Moore. Available for reference at the following facilities: AFOC/J, IFOC, LIB, and WFOC. Order ONLY from NTIS: PB 85-103729; paper copy price code A03.

OFR 171-84. Minerals Availability Nickel Deposit Abstracts, by William L. Rice. July 1984. 451 pp. This Bureau of Mines open file report on nickel is one of a series of minerals availability commodity deposit abstracts. Nonconfidential information from the Minerals Availability Program data base covering domestic and foreign nickel properties and deposits has been abstracted for use in the report. Abstracts include applicable data on location, published reserves and resources, geology, mine and beneficiation systems, and operation information. Research done by the Western Field Operations Center. Available for reference at the following facilities: AFOC/J, IFOC, LIB, and WFOC. Order ONLY from NTIS: PB 85-107613; paper copy price code A20.

OFR 172-84. Characterization of Georgia Kaolins as Ores of Aluminum, by John E. Husted. Sept. 1983. 178 pp. 256 figs. Quantities of kaolin in Georgia in contiguous or single bodies were established by previous work to be sufficient for an alumina industry. The need for characterization of this kaolin to determine its suitability as an ore of aluminum resulted in the studies described herein.

It was determined in an area about 7 by 27 miles, known as the Wren district, that approximately 5.9 billion short tons of kaolin averaging 35.55 pct Al_2O_3 exists in an essentially continuous clay body. The Macon-Sandersville district consists of discontinous kaolin bodies averaging 35.28 pct Al_2O_3 with an average thickness of 28 ft. Tonnages for this district were not available. One hundred and twenty core samples of kaolin were analyzed for K_2O, CaO, MgO, Al_2O_3, TiO_2, Cr_2O_3, Fe_2O_3, SiO_2, P_2O_5, and F. The P_2O_5 and F were analyzed by wet chemistry methods, and the others were analyzed by electron microprobe. Seventy-nine of the samples were from the Wrens district, 40 were from the Macon-Sandersville district, and 1 was from the Andersonville district. Emission spectroscopic analyses were made to qualitatively determine all elements present for each core. X-ray diffraction studies were made of each core to determine mineral species present. Scanning and transmission electron microscope pictures are given for each core sample. Elevations, overburden thickness, and kaolin thickness are given for each core site as well as map locations. Isopachs for overburden and kaolin thickness are given for the Wren district. Research done under contract J0188120 by Georgia Institute of Technology. Available for reference at the following facilities: ALRC, AVRC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Copies of this report will not be available for purchase.

OFR 173–84. Stream Sediment, Float, and Bedrock Sampling in the Porcupine Mining Area, Southeast Alaska, by Jan C. Still. 1984. 20 pp. 3 figs. The Bureau of Mines in 1983 collected stream sediment, float, and bedrock samples in the Porcupine mining area near Haines in southeastern Alaska. The samples were collected for possible indications of massive sulfide mineralization similar to that found at the world class Windy Craggy copper-cobalt-gold deposit near the United States-Canadian border, 50 miles to the northwest. Such indications were found at several locations. Samples collected in the Mosquito Lake vicinity contained up to 360 ppm Pb, 210 ppm Co, 0.033 ppm Au, and 1.437 ppm Ag; samples collected in the Porcupine Road vicinity contained up to 1,300 ppm Zn, 280 ppm Pb, 100 ppm Co, 0.092 ppm Au, and 1.437 ppm Ag; samples collected at scattered locations between the Tsirku River and Jarvis Glacier contained up to 770 ppm Zn, 1,400 ppm Cu, 310 ppm Pb, 310 ppm Co, 0.186 ppm Au, and 3.686 ppm Ag. Also, a sample collected in Little Boulder Creek contained 870 ppm Zn, 400 ppm Cu, and 100 ppm Pb while a sample collected in Muncaster Creek contained 1,500 ppm Cu, 360 ppm Co, 0.165 ppm Au, and 1.881 ppm Ag. Research done by the Alaska Field Operations Center. Available for reference at the following facilities: AFOC/J, IFOC, LIB, and WFOC. Copies of this report will not be available for purchase.

OFR 174–84. Columbium in the Gold- and Tin-Bearing Placer Deposits Near Tofty, Alaska, by D. D. Southworth. 1984. 25 pp. 5 figs. The Tofty mining district, near Manley Hot Springs in north-central Alaska, has been the scene of placer gold mining since 1906 and has produced more than 100,000 tr oz of gold and several hundred tons of byproduct tin, in the form of placer cassiterite. Although opencut mining methods are currently employed, drift-mining methods were formerly utilized to mine the gold- and tin-bearing gravels. As part of the current Bureau of Mines Alaska-wide assessment of critical and strategic minerals, splits of concentrate samples collected in the 1950's from 11 tailings piles representative of the presently inactive Tofty drift mines were reanalyzed in 1983 for tantalum and columbium (niobium). Most of these concentrates contained between 0.2 and 4.5 pct Nb. Tantalum was detected, but not measured, in only three samples. Relatively higher average niobium values from tailings piles on either side of a small hill suggest a possible intrusive source there at shallow depth. Niobium occurs in the Tofty area in the mineral columbite that could be recovered as a byproduct during placer mining of gold and/or tin. An estimated 100,000 lb of recoverable Nb_2O_5 are inferred to be present in the Tofty placer deposits. Research done by the Alaska Field Operations Center. Available for reference at the following facilities: AFOC/J, ALRC, IFOC, LIB, RERC, and WFOC. Copies of this report will not be available for purchase.

OFR 175–84. Cobalt-Bearing Deposits Related To Mineral Terranes of Alaska, by William S. Roberts. 1984. 10 pp. 1 fig. Cobalt minerals or anomalous concentrations of cobalt associated with sulfide minerals have been identified in 21 deposits in Alaska. Undoubtedly other deposits exist, but there has been little economic incentive to search for cobalt in Alaska and none has been produced. In the known deposits, cobalt occurs in trace amounts recoverable only if the deposit is mined for other minerals and if the cobalt can be concentrated during mining and milling. Two of the known cobalt occurrences (Brady Glacier and Yakobi Island) are in large copper-nickel deposits. A third (Bornite) is associated with a large copper sulfide deposit. A fourth occurrence (Jarvis Glacier) was recently discovered in a geologic setting possibly favorable for massive sulfide deposits similar to the Windy-Craggy copper-cobalt deposit in nearby British Columbia, Canada. Seventeen of the known cobalt occurrences are in mineral terranes that have been mapped as favorable for finding cobalt. Four of the occurrences are in areas where information had been too scanty to map terranes. This emphasizes both the lack of data on Alaskan mineral resources and the need to periodically update the mineral terrane maps. Research done by the Alaska Field Operations Center. Available for reference at the following facilities: AD/MDA, AFOC/J, ALRC, IFOC, LIB, RERC, and WFOC. Copies of this report will not be available for purchase.

OFR 176–84. Geologic and Geochemical Investigation of the "Nail" Allochthon, East-Central Alaska, by D. D. Southworth. 1984. 26 pp. 1 figs. The "Nail" allochthon, east-central Alaska, was investigated by the Bureau of Mines in cooperation with the State of Alaska, Div. of Geological and Geophysical Surveys', as part of an effort to develop more definitive information on Alaska's critical and strategic mineral reserves. The peridotites and former peridotites in the vicinity of the vertical angle bench mark Nail constitute an approximately 8-mile-long, 2,000-ft-thick thrust sheet of probable Permian age that overlies a complex assemblage of Paleozoic(?) greenschist-facies metamorphic rocks. An extensive zone of carbonate alteration is present at the base of the ultramafic thrust sheet. The mineralized zone contains up to 17 pct MgO. The remote location and inaccessibility of the zone render it subeconomic at this time. Although the peridotites at Nail Ridge usually contain 2 to 4 pct chromite, metallurgical tests by the Bureau's Albany Research

Center indicate it to be a high-magnesium, high-aluminum chromite of submarginal grade. Neither platinum-group metals nor gold in significant amounts are present either in the bedrock or as placer concentrations in the streams draining the study area. Research done by the Alaska Field Operations Center. Available for reference at the following facilities: AFOC/J, ALRC, IFOC, LIB, RERC, and WFOC. Copies of this report will not be available for purchase.

OFR 177–84. Substitution of Platinum Metal Crucibles Used in the Glass Industry, by Mir Akbar Ali. Aug. 1984. 56 pp. 24 figs. A research and development study was conducted wherein commercial tin oxide (SnO_2) was evaluated as crucible material for melting optical-quality glasses. Several sintering aids for SnO_2 were examined. Laboratory-scale SnO_2 crucibles were fabricated by dry pressing, slip casting, and isostatic pressing processes. Corrosion resistance, surface characteristics, and the forming process itself were evaluated using the scanning electron microscopy technique. Research done under contracts J0113098 and J0123056 by Glass & Ceramics International, Inc. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 85-106888; paper copy price code A04.

OFR 178–84. Chromite Occurrences in the Kaiyuh Hills, West-Central Alaska, by Jeffrey Y. Foley, Toni Hinderman, Donald E. Kirby, and Cheryl L. Mardock. 1983. 27 pp. 5 figs. Chromite occurrences in poorly exposed ultramafic rocks in the Kaiyuh Hills area, west-central Alaska, were investigated. This report describes the local geology, chromite occurrences, and results of chemical analyses on 32 samples and metallurgical tests that were performed on 4 deposits in the area. Total estimated reserve potential for the four deposits is between 17,000 and 37,000 tons of contained Cr_2O_3. One 3-ft-wide nearly massive band that contains between 50 and 60 pct chromite is estimated to have a strike length of almost 300 ft. This deposit is estimated to contain between 2,000 and 5,000 tons of Cr_2O_3 in high-chromium chromite. Numerous other low-grade occurrences with between 3 and 10 pct chromite contain discontinuous bands up to several inches wide over areas measuring tens of feet wide and up to several hundred feet long. Three of the larger low-grade occurrences that contain between 3 and 4 pct chromite are estimated to contain between 15,000 and 32,000 tons of Cr_2O_3 in high-chromium and high-iron chromite. Potential exists for additional chromite in buried occurrences and in placer deposits in streams that drain the area. Research done by the Alaska Field Operations Center and C. C. Hawley and Associates, Inc. Available for reference at the following facilities: AFOC/J, ALRC, IFOC, LIB, RERC, and WFOC. Order ONLY from NTIS: PB 85-106219; paper copy price code A03.

OFR 179(1)–84. Guidelines for Open-Pit Ore Pass Design. Volume I, by D. F. Hambley, W. G. Pariseau, and M. M. Singh. Sept. 1983. 169 pp. 36 figs. The objective of this investigation was to develop a manual for the design, construction, and maintenance of vertical and inclined ore pass systems for use in underground haulage from open pit mines. The work included an extensive information search, novel analyses in rock flow theory, cost and time estimation for shaft and raise construction methods, and development of design criteria for the ore pass proper, dump point, and draw point. Research done under contract J0205041 by Engineers International, Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-106425; paper copy price code A08.

OFR 179(2)–84. Guidelines for Open-Pit Ore Pass Design. Volume II—Design Manual, by D. F. Hambley and M. M. Singh. Sept. 1983. 139 pp. 34 figs. The objective of this investigation was to develop a manual for the design, construction, and maintenance of vertical and inclined ore pass systems for use in underground haulage from open pit mines. The manual is comprehensive and deals with all aspects including location, design, construction, and operating considerations. In the construction section, all applicable raising and shaft sinking methods are considered and cost estimates and advance rates are provided for each. The design process is divided into several sections—rock flow requirements, support design, dump point design, and draw point design. Use of this manual provides open pit planning engineers with a means of designing and assessing the feasibility of ore passes for their operations. Research done under contract J0205041 by Engineers International, Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-106433; paper copy price code A07.

OFR 180–84. Remote Manual Control Roof Bolter, by Peter de Bakker. Dec. 1983. 155 pp. 49 figs. The objective of this investigation was to determine the feasibility of remote installation of roof support and the capabilities and limitations of the operator to perform simple functions needed in providing reliable, economical, remote-control roof bolting. The bolter was to be capable of placing longer-than-seam-height bolts up to 10 ft long, from a seam height of 36 to 72 in, while keeping the operator under canopy and supported roof. The machine, called the REM bolter, is a low-profile unit that utilizes a flexible shaft roof drill, a roof bolt inserter, and a newly designed roof bolt lifter-torquer. Efforts were made to strike a successful compromise between automation and manual control. In a controlled laboratory environment, the REM bolter remotely installed 1,000 bolts. The machine was tested in an operating coal mine where 500 holes were drilled and bolts were installed over a 4-month period. All tests show that the operator of a machine of this kind can quickly and repeatedly install roof bolts remotely from the operator compartment about 8 ft away from the drilling-bolting action. Research done under contract H0202009 by Foster-Miller, Inc. Available for reference at the following facilities: ALRC, DRC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 85-106201; paper copy price code A08.

OFR 181–84. Innovative Recontouring of Abandoned Surface Coal Mined Lands, by Peter Bowen, Glenn Philips, Graham Mathieson, Gene Consalis, and Gus Tausan. Sept. 1983. 123 pp. 10 figs. The purpose of this investigation was to identify innovative materials-handling systems suitable for spoil bank

recontouring applications on abandoned coal mine lands. Nine specific sites, considered typical of abandoned mine lands in the United States, were examined. Recontouring costs for the sites were estimated first using conventional reclamation equipment (dozers, scrapers, etc.) as a base case, and second using large dragline stripping equipment for comparison. Using the cost and efficiency data generated during the studies, five innovative techniques were devised and applied to appropriate sites for cost estimation. The techniques involved an examination of the effects of modifying recontouring plans to reduce costs, the use of special bulldozer blade equipment, the use of special bucket pullback types of excavation systems, the application of hydraulicking, and the application of cast blasting to recontour highwall material. Research done under contract J0295048 by Golder Associates, Inc. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-106870; paper copy price code A06.

OFR 182-84. Field Test of a Post-Disaster Communication System, by M. P. Ristenbatt, E. K. Holland-Moritz, and K. Metzger. Dec. 1983. 51 pp. 14 figs. A new postdisaster communication and location system using through-the-earth electromagnetic wave propagation was tested at the Bureau of Mines Lake Lynn Experimental Mine. Successful detection of the signal, estimated to be at a signal-to-noise ratio (SNR) of −30 dB, was accomplished using a coherent integration time of 4.46 min. The transmitted waveform consisted of a repeating pseudonoise maximal length sequence phase modulating a 1,950-Hz carrier. The receiver used a sliding-window matched filter, optimal for signal known exactly except for phase and starting time, implemented via a special purpose processor. Parallel processing permits adaptive signaling where the detection (integration) time is determined by the actual input SNR encountered. The field test demonstrates a trapped miner detection system that is about 36 dB more sensitive than the current pulsed system. The increased sensitivity permits some desired combination of increased range, shorter detection time, and reduced transmitter power or antenna size. The combination of pulse-compression-type signal, coherent integration, parallel processing, and output peak-detection algorithms permits implementation of an ultrareliable detection system. The same combination is compatible with digital pulse position modulation and emitter position location strategies. Research done under contract J0123030 by University of Michigan. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-109270; paper copy price code A04.

OFR 183-84. Mine Power System Safety and Reliability Improvement. Part II, by Herman W. Hill, Jr., and Elmer W. Collins. Sept. 1983. 21 pp. 3 figs. This report describes field tests that were performed to determine hazard rates for four critical mine power system components: the molded-case circuit breaker, the undervoltage relay, the ground check monitor, and the ground fault relay. Techniques of data analyses are given along with the experimental method and calculations of hazard rates. Detailed descriptions are given of all observed failures. Recommendations are made for improving the reliability of these devices. Research done under contract J0199119 by West Virginia University. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-109288; paper copy price code A02.

OFR 184-84. Oil Shale Creep Testing at Elevated Temperatures, by Krishna P. Sinha, Thomas F. Borschell, and John F. Schatz. July 6, 1983. 162 pp. 90 figs. An investigation was made to determine the creep behavior of oil shale at elevated temperatures. Work done on creep behavior of geological materials was reviewed and triaxial creep tests on oil shale were planned. Tests at temperatures up to 250° C and axial stress up to 3,000 psi were conducted at no confinement and at confining pressures equal to one-third and two-thirds of axial stress. Wide variations in the elastic properties as well as creep characteristics are exhibited. Creep deformation is more pronounced at elevated temperature but no definite quantitative remarks can be made regarding effect of grade of oil shale due to wide scatter and limited number of data points. Primary creep can be described by a power law. Secondary creep seems to be an experimental function of deviatoric stress. Tertiary creep was not observed within the test period. Research done under contract J0205013 by Terra Tek Inc. Available for reference at the following facilities: AD/MR, DRC, LIB, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 85-106417; paper copy price code A08.

OFR 185-84. Ground-Water Monitoring in the Tucson Copper Mining District, by Pima Association of Governments. July 1983. 99 pp. 43 figs. Ground water tailings pond monitoring in the Upper Santa Cruz Basin Mines Task Force Special Studies Area was performed to determine the nature and extent of aquifer contamination from copper tailings pond recharge in the basin. A monitoring program for each of three mining areas (Mines A, B, and D) was developed. Analyses of data show that recharge from Mine A ponds caused increased hardness, sulfate, and total dissolved solids in local ground water. However, pumpage in the area has controlled most of the water's movement. Pond recharge from Mine B led to similar conditions, and the degraded water is moving towards a local public-supply well. Pumpage from Mine D interceptor wells is controlling some, but not all, of the movement of recharge seepage from ponds in that area. Recommendations include the need for enhanced monitoring programs at each current minesite, development of a monitoring program for the Mine C area, development of water budgets for all mines, investigation of tailings pond compaction and sliming, establishment of mine closure plans for containment of recharged pond water, and the need for additional interceptor wells in several locations. Research done under contract J0215006. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, IFOC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-106862; paper copy price code A05.

OFR 186-84. The Economic Effects of Subsidence From Underground Coal Mining on Agricultural Land in Illinois, by Harold D. Guither. Jan. 30, 1984. 60 pp.

2 figs. The objective of this study was to determine the economic impact of subsidence from underground coal mining on agricultural lands in Illinois. In a survey of Illinois agricultural extension advisers, the presence of subsidence from underground coal mining was reported in 31 counties. The most frequently reported problems were the presence of depressions or potholes, standing water in depressed areas, surface drainage disruption, broken tile lines, and reduced crop yield. The most frequently reported attempts to restore productivity from subsidence damage were to dig surface drainage ditches, haul in fill dirt, fill in depressions with tractor and blade or land leveler, and replace tile lines; success was varied. Positive identification of all subsidence occurrences and measurement of the area affected is very elusive. Probably about 2 pct of the agricultural land that overlies underground mines is affected, but on specific farms and specific fields, occurrences may affect much more of the land. Farmland with subsidence occurrences is usually appraised at a lower value, sells at a discount, and is assessed for real estate taxes at a lower rate. Research done under contract H0222010 by University of Illinois—Urbana-Champaign. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC, SRC, and TCRC. Order ONLY from NTIS: PB 85-109296; paper copy price code A04.

OFR 187(1)–84. Erodibility and Related Soil Properties of Three Reclaimed Surface Mined Soils, by Otto Robert Stein, Jr. May 1983. 133 pp. 5 figs. A study was conducted to determine erodibilities of different reclamation treatments and an unmined soil at three Indiana strip mine sites. A rainfall simulator was used to artificially erode plots constructed within seven treatment categories and the unmined soil. Soil erodibility was assessed in terms of the universal soil loss equation (USLE) K factor. Values for K calculated from field data were compared with values predicted from independently measured soil properties. Differences in soil erodibility between treatments were site specific. Unmined soil had the highest calculated erodibility at one site, but at two other sites soils having reclaimed A horizons were highest. Shaley overburden treatments had the lowest calculated erodibility. Predicted soil erodibility was usually lower than that calculated from field data. Site specific slope gradient factors were developed for reclaimed A horizon treatments. Research done under grants G1105022 and G1115181 by Purdue University. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 187(2)–84. Erodibility of Reclaimed Surface Mined Land, by D. T. Hahn, O. R. Stein, Jr., C. B. Roth, J. K. Mitchell, and W. C. Moldenhauer. May 1983. 20 pp. Adequate and cost effective erosion control is an important component in most plans for reclamation of surface mined land. Despite the fact that much is known about erosion of agricultural lands, insufficient conclusive knowledge is available about erosion of reclaimed surface mined land. This study was conducted to characterize the erodibility of reclaimed surface mine land relative to unmined cropped land and to evaluate the accuracy of the universal soil loss equation in estimating erosion from reclaimed soils. A rainfall simulator was used to measure runoff and erosion rates from plots at three Indiana surface mines. The relation of erosion of the reclaimed soils was not completely constant with that from the cropped soils. Significant differences in erodibility were observed between reclaimed and nonreclaimed topsoils as well as reclaimed topsoils and reclaimed subsoils. Research done under grants G1105022 and G1115181 by Purdue University. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Copies of this report will not be available for purchase.

OFR 188–84. The Development of Engineering and Cost Data for Foreign Sulfur Properties, by Thomas P. Oxford. Feb. 1984. 17 pp. Iron pyrite, recovered from massive pyrite deposits or as a byproduct of the flotation of complex sulfide ores, is an important feedstock in many local areas. Its use has diminished substantially over the past decade owing to increased availability of sulfur recovered from petroleum refining or from the smelting of metal sulfide concentrates. Outside the United States, but within other market economy countries, the important Frasch sulfur deposits are in Mexico and Iraq. Deposits amenable to exploitation by the Frasch method are those that can be melted and extracted by injection of hot water and compressed air. Data concerning both Frasch and pyritic sulfur properties are summarized herein. The report summarizes the results of work completed under contract and is presented as a project overview. The number and descriptions of the various technical reports prepared and submitted are outlined. Various property list changes implemented by contract modifications are noted. Methods of data acquisition and analyses are described and useful findings of the study are discussed. Difficulties and problems experienced during the project are highlighted. Research done under contract J0225020 by Jacobs Engineering Group Inc. Available for reference at the following facilities: AD/DMA, AFOC/J, IFOC, LIB, and WFOC. Order ONLY from NTIS: PB 85-107159; paper copy price code A02.

OFR 189–84. Adaptive-Noise-Cancellation Techniques for Through-the-Earth Electromagnetics. Volume II, by Frederick H. Raab. Sept. 1983. 121 pp. 63 figs. An electromagnetic (EM) system to locate trapped miners at coal mine depths was investigated. The use of such a system in deep mines requires transmission at extremely low frequencies (ELF) and a reduction in the effective noise level beyond that which can be obtained by acceptable integration times. Automatic-noise-cancellation (ANC) techniques reduce the effective noise level by combining several received signals that contain correlated noise. The signals can be obtained from either a remote magnetic antenna or a local electric antenna. This report presents the results of a simulation of the use of ANC techniques in a through-the-earth EM system. A multicomponent ELF noise model that incorporates impulsivity, direction of arrival, and ground characteristics was developed. Nonlinear processors (NLP) for ELF noise were compared and the adaptive clipper was found to be preferable. Direct-matrix-inversion (DMI) and least-mean-square ANC techniques were compared and the DMI algorithm was preferable. The performance of the combined NLP-ANC system was evaluated by simulation, and effective noise reductions between 5 and 30 dB were obtained for typical ELF-noise conditions. While improvements of the individual systems were not additive, maximum noise reduction was obtained when both were included. Research

done under contract J0318070 by Green Mountain Radio Research Co. Available for reference at the following facilities: AD/MR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-111409; paper copy price code A06.

OFR 190-84. Coal Injector for Coarse Slurry Transport, by Mackenzie Burnett, Leslie S. Rubin, Andrew Harvey, John C. Roberge, Robert L. Cardenas, and Hans Hug. Dec. 1983. 262 pp. 91 figs. An inducer-type pump, capable of injecting dry coal into a hydraulic transport pipeline was developed and installed in a specially designed and fabricated slurry injector vehicle. The full-scale prototype injector system can deliver up to 11 ton/min of coal into an 8-in pipeline at pressures up to 95 lb/in^2. The injector operates on centrifugal principles with flow passing axially through a helical-pitched conical rotor. Water is delivered to the pump through an annular slot at the atmospheric pressure coal inlet. The spinning rotor maintains an air-core vortex of water that pressurizes the discharge housing. A screw feeds coal through the open inlet into the vortex. The inner radius of the vortex contracts as pressure is increased, giving a limiting maximum pressure that is proportional to the square of the rotor speed. Below this limit, flow rate, discharge pressure, and rotor speed are independent variables. The self-powered, 42-in-high slurry injector vehicle follows and receives run-of-mine coal from a continuous miner, reduces the top size to 3 in, and delivers the sized coal to the injector feed screw for slurry formation and pumps it through a mobile hose attached to the vehicle's outby end. Research done under contract J0333914 by Foster-Miller, Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-149441; paper copy price code A12.

OFR 191-84. The Effectiveness of Organization and Management Training on Safety and Productivity in Metal/Non-Metal Underground Mining, by Fred E. Fiedler, Cecil H. Bell, Jr., Martin H. Chemers, and Dennis Patrick. Nov. 17, 1983. 296 pp. 25 figs. A demonstration project on the feasibility and effectiveness of two management interventions—management training and organization development—for improving productivity and safety in metal and nonmetal mines was investigated. The management training intervention was conducted at Texasgulf Co.'s trona mine, using three nearby trona mines as controls. The organization development intervention took place in Hecla Mining Co.'s Lucky Friday Mine, using the highly similar Star Mine as control. The two management interventions seemed about equally effective in reducing accidents and injuries, as well as Mine Safety and Health Administration citations, and the management intervention at the Texasgulf mine also appeared to have led to substantial improvement in mine productivity. Research done under contract J0387230 by Perceptronics, Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-163285; paper copy price code A13.

OFR 192-84. Technique for In Situ Leach Simulation of Uranium Ores, by David C. Grant, Don C. Seidel, and Ivan L. Nichols. May 1984. 66 pp. 26 figs. In situ uranium mining offers the advantages of minimal environmental disturbance, low capital and operating costs, and reduced mining development time. It is becoming an increasingly attractive mining method for the recovery of uranium from secondary ore deposits. To better understand the process, a laboratory technique was developed and used to study and simulate both the chemical and physical phenomena occurring in ore bodies during in situ leaching. The simulation technique was used to determine effects of leaching variables on permeability, uranium recovery, and postleach aquifer restoration. This report describes the simulation system and testing procedure in sufficient detail to allow the construction of the system and to perform the desired leaching tests. Research done under contract H0262004 by Westinghouse Electric Corp. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-145902; paper copy price code A04.

OFR 193-84. Summary of a Technique for Heap Leach Simulation on Uranium Ores, by Hal D. Peterson, Don C. Seidel, and Ivan L. Nichols. Apr. 1984. 43 pp. 15 figs. A technique was developed for simulation of heap leaching uranium ores in 2-ft-diam columns constructed such that ores as coarse as minus 4-in could be treated in bed depths from 8 to 18 ft with test condition variations. The technique consisted of the separate steps of ore preparation, column loading, charge wetting, leaching, washing, and residue recovery. For the ores studied, sulfuric acid was found to be generally superior to alkaline lixiviants. The rate of uranium extraction by acid leaching proved to be primarily a function of percolation rate, alkalinity of the ores, and oxidant requirements of the ores. Column leaching was closely comparable to field-scale heap leaching terms of uranium extraction rate and recovery results. Acid and oxidant requirements were lower for the field-scale operation. All column tests, as well as the field-scale heap, achieved in excess of 96-pct uranium extraction on a Bear Creek, WY, ore. Research done under contract H0252022 by Colorado School of Mines Research Institute. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-145811; paper copy price code A03.

OFR 194-84. Minerals Availability Cobalt Deposit Abstracts, by William L. Rice. Sept. 1984. 374 pp. The Bureau of Mines report on cobalt is one of a series of minerals availability commodity deposit abstracts. Nonconfidential information from the Minerals Availability Program data base covering domestic and foreign cobalt properties and deposits has been abstracted for use in the report. Abstracts include applicable data on location, published reserves and resources, geology, mine and beneficiation systems, and operation information. Research done by Western Field Operations Center. Available for reference at the following facilities: AFOC/J, IFOC, LIB, and WFOC. Order ONLY from NTIS: PB 85-114643; paper copy price code A16.

OFR 195–84. Practices for Protecting and Enhancing Fish and Wildlife on Coal Surface-Mined Land in Central and Southern Appalachia, by Richard E. Ambrose, Charles R. Hinkle, and Calvin R. Wenzel. Mar. 1983. 223 pp. 51 figs. This handbook contains information on the best current practices to minimize disturbances and adverse impacts of surface mining on fish and wildlife resources. Current State and Federal legislation was reviewed to determine those practices that were most compatible with the best technology currently available, fish and wildlife plans, and reclamation plans for the central and southern Appalachia region of the United States. The information presented includes risks, limitations, approximate costs, and maintenance and management requirements of each practice. Plans for the restoration of specific habitats, according to the best current practices, are also included. Research done under contract J0100089 by Science Applications, Inc., as a result of an interagency agreement between the Fish and Wildlife Service and the Bureau of Mines. Available for reference at the following facilities: AFOC/J, ALRC, AVRC/DRC, IFOC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC and WFOC. Order ONLY from NTIS: PB 83-237073; paper copy price code A10.

OFR 196–84. Practices for Protecting and Enhancing Fish and Wildlife on Coal Surface-Mined Land in the Green River-Hams Fork Region, by Bettina R. Proctor, Richard W. Thompson, Jane E. Bunin, Kenneth W. Fucik, George R. Tamm, and Edward G. Wolf. Mar. 1983. 256 pp. 47 figs. This handbook contains information on the best current practices to minimize disturbances and adverse impacts of surface mining on fish and wildlife resources. Current State and Federal legislation was reviewed to determine those practices that were most compatible with the best technology currently available, fish and wildlife plans, and reclamation plans for the Green River-Hams Fork region of the United States. The information presented includes risks, limitations, approximate costs, and maintenance and management requirements for each practice. Plans for the restoration of specific habitats, according to the best current practices, are also included. Research done under contract J0100089 by Science Applications, Inc., as a result of an interagency agreement between the Fish and Wildlife Service and the Bureau of Mines. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 83-252064; paper copy price code A12.

OFR 197–84. Practices for Protecting and Enhancing Fish and Wildlife on Coal Surface-Mined Land in the Powder River-Fort Union Region, by Bettina R. Proctor, Richard W. Thompson, Jane E. Bunin, Kenneth W. Fucik, George R. Tamm, and Edward G. Wolf. Mar. 1983. 261 pp. 46 figs. This handbook contains information on the best current practices to minimize disturbances and adverse impacts of surface mining on fish and wildlife resources. Current State and Federal legislation was reviewed to determine those practices that were most compatible with the best technology currently available, fish and wildlife plans, and reclamation plans for the Powder River-Fort Union region in the United States. The information presented includes risks, limitations, approximate costs, and maintenance and management requirements for each practice. Plans for the restoration of specific habitats, according to the best current practices, are also included. Research done under contract J0100089 by Science Applications, Inc., as a result of an interagency agreement between the Fish and Wildlife Service and the Bureau of Mines. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 83-237081; paper copy price code A12.

OFR 198–84. Practices for Protecting and Enhancing Fish and Wildlife on Coal Surface-Mined Land in the Southcentral U.S., by Richard E. Ambrose, Charles R. Hinkle, and Calvin R. Wenzel. Mar. 1983. 243 pp. 52 figs. This handbook contains information on the best current practices to minimize disturbances and adverse impacts of surface mining on fish and wildlife resources. Current State and Federal legislation was reviewed to determine those practices that were most compatible with the best technology currently available, fish and wildlife plans, and reclamation plans for the south-central region of the United States. The information presented includes risks, limitations, approximate costs, and maintenance and management requirements of each practice. Plans for the restoration of specific habitats, according to the best current practices, are also included. Research done under contract J0100089 by Science Applications, Inc., as a result of an interagency agreement between the Fish and Wildlife Service and the Bureau of Mines. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 83-252049; paper copy price code A11.

OFR 199–84. Practices for Protecting and Enhancing Fish and Wildlife on Coal Mined Land in the Uinta-Southwestern Utah Region, by Bettina R. Proctor, Richard W. Thompson, Jane E. Bunin, Kenneth W. Fucik, George R. Tamm, and Edward G. Wolf. Mar. 1983. 264 pp. 44 figs. This handbook contains information on the best current practices to minimize disturbances and adverse impacts of surface mining on fish and wildlife resources. Current State and Federal legislation was reviewed to determine those practices that were most compatible with the best technology currently available, fish and wildlife plans, and reclamation plans for the Uinta-southwestern region of the United States. The information presented includes risks, limitations, approximate costs, and maintenance and management requirements of each practice. Plans for the restoration of specific habitats, according to the best current practices, are also included. Research done under contract J0100089 by Science Applications, Inc., as a result of an interagency agreement between the Fish and Wildlife Service and the Bureau of Mines. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, ad WFOC. Order ONLY from NTIS: PB 83-252056; paper copy price code A12.

OFR 200–84. The Development of Engineering and Cost Data for Foreign Potash Properties, by Thomas P. Oxford. Feb. 1984. 18 pp. Potash concentrate is used as an agricultural fertilizer material, typically at grades in excess of 95 pct KCl (potassium chloride). The term "potash" is commonly accepted to include KCl, potassium sulfate, and certain mixed

salts that include magnesium as well as potassium. The primary application of these products is agricultural use. At present, the largest producer in market economy countries is Canada, and production is intended almost entirely for export. The balance of the market economy production outside the United States is accounted for by Europe and the Near East (specifically, through brine recovery from the Dead Sea). This report summarizes studies completed on potash under contract and is presented as a project overview. The number and descriptions of the various technical reports prepared and submitted are outlined. Property list changes implemented by contract modification are noted. Methods of data acquisition and analyses are described and useful findings are discussed. Difficulties and problems experienced during the project are highlighted. Research done under contract J0225011 by Jacobs Engineering Group Inc. Available for reference at the following facilities: AFOC/J, IFOC, LIB, and WFOC. Order ONLY from NTIS: PB 85-119410; paper copy price code A02.

OFR 201-84. Recovery of Manganese From Low-Grade Domestic Sources, by S. Malhotra, S. Margolin, R. F. Machacek, V. Vejins, W. S. Kelly, and M. Laurila. Sept. 1984. 166 pp. 7 figs. The objectives of this study were to evaluate existing data on low-grade domestic ores, classify the various deposits, determine applicability of promising new beneficiation technologies to these ores, review extraction processes for manganese recovery of these sources, rank the extraction process against each deposit, and examine the cost and profitability of the three most promising processes. Of the 23 districts or deposits that were investigated, 8 were identified as having recoverable resources of manganese exceeding 1 million metric tons. Based on state-of-the-art technology, 16 processes were evaluated for detailed cost evaluation studies. The three most promising processes were (1) the Leute-Dean ammonia-leaching process that solubilizes the manganese as a carbamate complex, (2) the Nossen nitric acid process that forms a soluble manganese nitrate, and (3) the sulfur dioxide process that forms manganese sulfate for recovery. A 35-pct manganese concentrate was used for evaluation and the size of the plant was assumed at 1,000 tons per day. Of the three processes evaluated, the Nossen nitric acid process appears to be the most promising for further development. Research done under contract H0222005 by Arthur D. Little, Inc. Available for reference at the following facilities: AD/MMR, AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-119378; paper copy price code A12.

OFR 202-84. Preliminary Investigations on Solvent Extraction Kinetics, by D. J. MacDonald and C. H. Elges. Sept. 1984. 15 pp. 3 figs. As a contribution to Bureau of Mines research on the fundamentals of liquid-liquid extraction applied to extractive metallurgy, a preliminary investigation was made on the kinetics of solvent extraction. Equipment was designed and constructed for measurement of rates of solvent extraction. Equipment was designed and constructed for measurement of rates of solvent extraction by the rising drop and Lewis cell methods. The report includes a bibliography on solvent extraction kinetics in extractive metallurgy. Research done by the Reno (NV) Research Center. Available for reference at the following facilities: AD/MMR, ALRC, AVRC, LIB, PRC/B, RERC, RORC, SLRC, TCRC, and TURC. Copies of this report will not be available for purchase.

OFR 203-84. Research To Improve Health and Safety Programs in the Mining Industry. Volume I, by Louis Schaffer and Donna Atchison. Apr. 1983. 260 pp. 62 figs. The objectives of this research were to determine whether a model health and safety program could be defined in terms that would enable its application to mines of all types and, if such a model program could be defined, to determine through evaluations in two mining companies whether it would achieve measurable improvements. This report describes the model, how it was applied in the field, and how it was evaluated. Anecdotal data to illustrate common kinds of safety problems and their solutions are included. Research done under contract H0308076 by Woodward Associates, Inc. Available for reference at the following facilities: AD/MR, DRC, LIB, MSHA, NMH&SA, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 85-151009; paper copy price code A12.

OFR 204-84. Treatment of Mine Drainage From Abandoned Mines by Biological Iron Oxidation and Limestone Neutralization, by Richard L. Harris, Thomas O. Tiernan, John Hinders, Joseph G. Solch, Brent E. Huntsman, and Michael L. Taylor. May 1984. 113 pp. 61 figs. To treat or mediate small flows from acid mine drainage (AMD) sources, a low-cost and low-maintenance treatment method was developed and field tested at an AMD site in Ohio. Phase I studies commenced in June 1982 using a portable bog with five chambers of *Sphagnum* moss (41.3 ft^3) to one of limestone (8.3 ft^3). AMD flow rates ranged from 2 to 18 $gal \cdot h^{-1}$(0.12 to 1.1 $L \cdot min^{-1}$). Phase II studies began in July 1983 during which the chamber ratio of 5:1 for *Sphagnum* to limestone was altered to 4:2. AMD flows averaged 22 $gal \cdot h^{-1}$ (1.4 $L \cdot min^{-1}$). During phase II, the first chamber length of 12 linear ft (8.3 ft^3) of *Sphagnum* moss was found to reduce on average 88% of the ferrous iron at a rate of 5.5 $mg \cdot L^{-1} \cdot h^{-1}$ (1.8 $mg \cdot L^{-1} \cdot ft^{-3}$ of moss). Four chamber lengths or 48 linear ft (33.0 ft^3) of moss reduced on average 50% to 60% of the total iron concentrations in the AMD water at a rate of 1.8 $mg \cdot L^{-1} \cdot h^{-1}$ (0.6 $mg \cdot L^{-1} \cdot ft^{-3}$ of moss). After passage through the limestone bed, pH of the treated AMD water increased up to 0.8 pH unit. Acidity was reduced from 12% to 43% at a rate of 74 $mg \cdot L^{-1} \cdot h^{-1}$ $CaCO_3$ through one 12-linear-ft chamber length (8.3 ft^3) of limestone. Once the AMD flow was stabilized, the portable bog was found to be effective in treating the low-flow AMD by increasing pH and reducing the acidity, ferrous iron, and total iron concentrations. Research done under contract J0113033 by PEER Consultants, Inc. Available for reference at the following facilities AD/MR, ALRC, AVRC, DRC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Copies of this report will not be available for purchase.

OFR 205-84. Explosion Proofing of Large Vehicles, by Norbert Paas. May 1984. 275 pp. 116 figs. This report presents a novel non-water-consuming method for explosion-proofing the exhaust system of large diesel vehicles for gassy mines. Recommendations for modifications of the present regulations and procedures for testing and certification are based on a comprehensive study of regulations and practices of mining and nonmining industries around the world. Research done under contract J0113070 by Foster-Miller, Inc. Available for reference at the following facilities: AD/MR,

DRC, LIB, MSHA, NMH&SA, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 85–145803; paper copy price code A12.

OFR 206–84. Analysis of Economic Impact of Fatal/Nonfatal Accidents in Surface Coal and Metal/Nonmetal Mines, by Daniel G. Di Canio. Nov. 1983. 145 pp. 44 figs. This report describes a computer-based accident cost indicator model (ACIM) for estimating tangible costs of occupational injuries, illnesses, and fatalities in the U.S. mining industry. The report includes studies performed to expand the scope of the ACIM to all mining sectors and validation of ACIM cost element estimation algorithms with actual costs of mining-related injuries and illnesses. A study of the effect of a fatal accident on production in surface coal and metal-nonmetal mines, based on samples of 15 fatalities in underground and surface mines, is presented. Evidence of significant long-term decline in postfatality production at six of eight underground samples is included. The average loss is shown to be 1.8% of annual mine production. A study of accident costs in U.S. mining from 1975 through 1981 using the ACIM indicates that total annual costs increased from $180,000,000 in 1975 to $379,000,000 in 1981, a 15% annual increase after adjusting for inflation, with mining companies bearing 45% of the total and expected wage losses to mining families accounting for 42%. The study shows total costs of $12,400 per accident and $674,000 per fatal accident for 1981. Research done under contract J0113005 by SRI International. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85–145787; paper copy price code A07.

OFR 207–84. Accident Cost Indicator Model Reference and User Manual, by Daniel G. Di Canio. Aug. 1983. 148 pp. 38 figs. This manual contains reference information and instructions for using the Bureau of Mines accident cost indicator model (ACIM) software as implemented on the VAX-11/780 computer with the virtual memory system (VMS). The objective of the manual is to provide the following capabilities: (1) execution of ACIM search and display procedures from the VAX-VMS command level by nonprogramming ACIM users, (2) access to the mine accident cost data bases for all mining sectors and file-management procedures by developers of private software, and (3) annual updating of the mine accident cost data bases by the ACIM manager. Research done under contract J0113005 by SRI International. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, MSHA, NMH&SA, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85–145795; paper copy price code A07.

OFR 208–84. Erosion and Reclamation Plots: Research on the Hydrology and Water Quality of Watersheds Subjected to Surface Mining, by J. V. Bonta and P. Sutton. Dec. 1983. 62 pp. 14 figs. An erosion and reclamation experiment was conducted on a geologic site in east-central Ohio to determine the effect of slope and reclamation treatments on hydrologic, sediment loss, and vegetative variables. Analyses of the fallow plot data showed that a topsoiled surface significantly decreased soil loss, but was of borderline significance in affecting peak flow when compared with spoil. The application of 1 and 2 tons of mulch reduced soil loss 3.8 to 10 times, respectively, compared with no-mulch plots, but was of borderline significance in explaining runoff and peak flow changes. Treatment effects on vegetative establishment and growth were measured over a 2-year period. Mulch rates increased plant growth and vegetative canopy cover of the soil surface most during the vegetative established period. When plots were compared and seeded a second time, plant growth differences were smaller. Research done under contracts J0166054 and J0166055 by the U.S. Department of Agriculture and Ohio State University. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 85–145845; paper copy price code A04.

OFR 209–84. Results in Jefferson County, Ohio: Research on the Hydrology and Water Quality of Watersheds Subjected to Surface Mining, by C. R. Amerman, J. V. Bonta, T. J. Harlukowicz, G. F. Hall, N. E. Smeck, W. A. Dick, J. R. Page, and A. C. Razem. Dec. 1983. 177 pp. 51 figs. Watershed J11 in Jefferson County, OH, was instrumented in 1977 as one of three watersheds established for the purpose of investigating surface mining and reclamation effects on local hydrology, sediment discharge, and sediment and water quality. Each watershed was less than 50 acres in size, and was in a different geologic setting within southeastern Ohio. Surface runoff and ground water levels were monitored. Samples were taken for sediment determination and chemical analyses prior to mining. Monitoring and sampling continued throughout the period of watershed disturbance caused by mining and reclamation activities that began in May 1980. A pseudo-postreclamation period followed the initial cessation of human-machine activity on the watershed. A second reclamation effort occurred in the fall of 1981. A true final postreclamation period was not monitored at this site because the erosion control practice failed after each reclamation. Research done under contracts J0166054 and J0166055 by the U.S. Department of Agriculture and Ohio State University. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 85–149276; paper copy price code A09.

OFR 210–84. Final Report: Research on the Hydrology and Water Quality of Watersheds Subjected to Surface Mining, by C. R. Amerman, J. V. Bonta, T. J. Harlukowicz, G. F. Hall, N. E. Smeck, W. A. Dick, J. R. Page, D. L. Forster, P. Sutton, A. C. Razem, and R. W. Jeppson. Jan. 1984. 35 pp. 3 figs. An investigation was begun in 1976 on the impact of surface mining and reclamation on the hydrology and water quality of surface and subsurface waters. The study was conducted in the Ohio coal surface mining region and considered three different coalbeds of Pennsylvanian age. The basic research unit at each site consisted of a watershed of less than 50 acres with an accompanying sediment pond and instrumentation for monitoring climatic variables. The watershed was instrumented to monitor ground water levels and surface water flow and to collect samples of both for water quality analyses. Each site was monitored throughout an approximate 5-year period that included a premine subperiod, a mining and reclamation subperiod, and a subperiod consisting of the initial years of the postreclamation condition. After regrading of spoil was complete

at one of the sites, a number of 72.6-ft-long plots were instrumented on spoil and topsoiled areas. Four different slopes were used to study erosion processes and the effectiveness of reclamation treatments on the establishment of vegetative cover on a reclaimed surface. The treatments consisted of different topsoil and different mulching depths. Concurrent with the watershed and plot studies, an investigation was conducted on the economics of complying with reclamation laws in Ohio and the development or adaptation of surface and subsurface hydrology simulation models for conditions in the region under study. Research done under contracts J0166054 and J0166055 by the U.S. Department of Agriculture and Ohio State University. Available for reference at the following facilities: AD/MR, DRC, LIB, OSM, PRC/B, SRC, and TCRC. Order ONLY from NTIS: PB 85–149292; paper copy price code A03.

OFR 211–84. Evaluation and Comparison of Linear and Branching Delivery Systems, by Jerry A. Wichser. Aug. 1984. 102 pp. A series of linear programmed instruction modules was developed in the general subject areas of blasting technology and explosives safety and electrical training. The programs (modules) were developed in the form of tape and slide plus workbook materials, while the branching format evolved from the Lincoln terminal system from the Massachusetts Institute of Technology, through several other teaching machines and microcomputers, and finally settling on Radio Shack TRS-80 microcomputer models I and III. Initial validation figures indicate that essentially the same results are attained from both methods, with the most noticeable difference being an approximate 25% savings in study time with the branching modules. Research done under contract J0387234 by AMAX Coal Co. Available for reference at the following facilities: ALRC, AVRC, DRC, LIB, MSHA, NMH&SA, PRC/B, RERC, RORC, SLRC, SRC, TCRC, and TURC. Order ONLY from NTIS: PB 85–149078; paper copy price code A06.

OFR 212–84. Guideline Manual for Hopper/Crusher/Conveyor Systems Used With Front-End Loaders, by James W. Martin, Thomas J. Martin, Donald W. Gentry, Matthew J. Hrebar, and Thomas P. Bennett. Aug. 1982. 186 pp. 55 figs. This user's manual analyzes the application, selection, and performance of hopper-crusher-conveyor systems used with front-end loaders in surface mining operations. It is designed to be used in conjunction with its companion manual, "Guideline Manual for Front-End Loader Load-and-Carry Applications," OFR 169–82. Aspects of the application are covered as well as design considerations of the hopper-crusher-conveyor units. Lists of equipment manufacturers and crusher specifications, together with a series of checklists, are included for preliminary analyses. Research done under contract J0205045 by Martin Consultants, Inc. Available for reference at the following facilities: AFOC/J, ALRC, AVRC, DRC, IFOC, LIB, OSM, PRC/B, RERC, RORC, SLRC, SRC, TCRC, TURC, and WFOC. Order ONLY from NTIS: PB 85-139954; paper copy price code A10.

OFR 213–84. Concentrations of Cobalt and Other Metals in the Western Crazy Mountains, Interior Alaska, by James C. Barker. Aug. 8, 1984. 44 pp. 12 figs. The U.S. Bureau of Mines made a reconnaissance in the western Crazy Mountains for cobalt and associated metals as part of the Alaska-wide critical and strategic metals program. The area, located about 75 miles north of Fairbanks in central Alaska, is underlain by complexly faulted, predominantly clastic sedimentary rocks bordering the Tintina Fault system. Above background metal concentrations were found to occur in altered fault zones, tectonic breccias, soils, and ground water seeps and precipitates that either cut or are derived from the faulted clastic sedimentary rocks. Up to 0.115 pct cobalt and more than 2.0 pct zinc were detected in soil samples. Spring precipitates contained up to 1.3 pct zinc, 0.037 pct tungsten, and other metals. Some locations lacked cobalt but contained anomalous amounts of copper, lead, zinc, silver, and other metals. No outcropping of primary metallic minerals was located because of colluvium and vegetation cover and extensive deep leaching. Therefore, whether the metal values encountered are due to primary deposits with economic development potential or are the results of concentration by ground water from low-grade sources is unknown. The presence of cobalt, nickel, and zinc, and the identification of minor tin and tungsten indicate that further investigation is warranted. Research done by the Alaska Field Operations Center. Available for reference at the following facilities: AFOC/J, ALRC, IFOC, LIB, RERC, and WFOC. Copies of this report will not be available for purchase.

OFR 214–84. Regional Distribution of Critical and Strategic Minerals in the Kantishna Hills Area, Denali National Park and Preserve, Alaska, by Rodney E. Jeske. Oct. 16, 1984. 97 pp. 57 figs. In 1984, the U.S. Bureau of Mines studied the abundance and distribution of critical and strategic minerals in the Kantishna Hills study area of the Denali National Park and Preserve, AK. The study is a continuation of the 1983 mineral resource study of the area mandated by Section 202(3)(b) of the Alaska National Interest Lands Conservation Act. Several areas containing anomalous critical and strategic minerals were identified. Analytical results for reconnaissance placer, panned concentrate, and stream sediment samples for the 1983 study were statistically treated and anomalous samples and their distribution identified. The elements evaluated were cobalt, chromium, gallium, germanium, manganese, palladium, platinum, nickel, tin, tantalum, titanium, tungsten, and columbium. Anomalies exist within areas of known mining activity and mineral occurrences as well as in areas with no previously known mining or mineral occurrences. Ten main anomalous areas identified for tin, tungsten, tantalum, titanium, columbium, cobalt, nickel, and germanium should be considered target areas for future critical and strategic mineral exploration. Research done by the Alaska Field Operations Center. Available for reference at the following facilities: AFOC/A, AFOC/F, AFOC/J, ALRC, IFOC, LIB, and WFOC. Copies of this report will not be available for purchase.

OFR 215–84. Strategic and Critical Mineral Development Potential of the Chugach National Forest, South-central Alaska, by Robert B. Hoekzema. 1984. 64 pp. 11 figs. This report is one of several Bureau of Mines reports concerning mineral development potential of the Chugach National Forest, AK. Anomalous data for selected strategic and critical minerals including antimony, chromium, cobalt, fluorspar, gallium, manganese, nickel, quartz crystals, tin, and

tungsten were compiled from previously published Bureau reports and unpublished Bureau data. Deposits containing anomalous quantities of these commodities were identified and given mineral development potential ratings. Moderate mineral development potential exists for two manganese, three nickel, and one cobalt deposit. Cobalt, gallium, and nickel could be produced as byproducts should copper deposits such as those on Latouche and Knight Islands be developed. Low mineral development potential exists for antimony, chromium, fluorspar, and tungsten, and other cobalt, manganese, and nickel deposits. The mineral development potential for tin and quartz is unknown. Research done by the Alaska Field Operations Center. Available for reference at the following facilities: AFOC/J, ALRC, IFOC, LIB, and WFOC. Copies of this report will not be available for purchase.

COMPUTER TAPE

The following computer tape and documentation are available only from the National Technical Information Service, U.S. Department of Commerce, Springfield, VA 22161. Checks or money orders should be made payable to the U.S. Department of Commerce. NTIS also accepts American Express, MasterCard, and VISA credit cards in payment for all services. NTIS prices are subject to change; therefore, price codes are given. Contact NTIS for a current copy of the domestic or foreign order price schedule.

CT 1–83. Modernization of the BMINES Computer Code. Volume I: User's Guide. Volume II: Methodology, by David E. Van Dillen, Richard W. Fellner, Robert D. Ewing, and Thomas J. R. Hughes. Sept. 23, 1981. This is a static, two- and three-dimensional, nonlinear, finite element computer program for the analysis of structural and geological systems and is designed specifically for application to the mining problems involving the simulation of excavation in construction sequences. The program is intended for practical analysis, and an effort was made to foresee difficulties in using it. The program uses the direct stiffness method of structural analysis. Degrees of freedom are defined at nodal points and element stiffnesses are assembled to form a symmetric, banded global stiffness matrix. Nodal point forces, which include external loads and internal resisting forces, are expressed in a global load vector. Incremental displacements are obtained from the global load vector and global stiffness matrix by a banded triangulation of the global stiffness matrix, reduction of the load vector, and then back substitution of the reduced load vector into the triangulated stiffness matrix. Part of the reduction operations are performed in local double precision to reduce error propagation, and size limitations have been eliminated. The program includes the capability of prescribing initial states and stress. The output available includes both printed and plotted responses. A restart capability for the calculation phase is included so that large problems may be split into several runs. An attempt was made to lengthen the useful life of the program by making it simple to add new elements, to expand the material model descriptions, and by making the program efficient for and compatible with a wide variety of computers. The model is written in Fortran 4 and is currently operational on a CDC Cyber 176 computer. Approximately 131K words of memory are required with 3 overlays. Source tape is in ASCII character set. Character set restricts preparation to 9-track, ½-inch tape only. Identify recording mode by specifying density only. Call NTIS Computer Products (703–487–4763) if you have any questions. Research was done under contract H0282022 by Agbabian Associates. NOTE: NTIS lists this under the title. **"BMINES: Static, Three-Dimensional, Nonlinear, Finite Element Computer Program for Application to Mining Problems."** Order computer tape with documentation from NTIS: PB 83–221572, price code T14. Documentation only may be obtained from NTIS by ordering PB 83–221564 to obtain the 616-page user's guide in volume I (paper copy price code A99) and PB 83–221556 to obtain the 45-page methodology in volume II (paper copy price code A03).

MINERAL LAND ASSESSMENTS

The following reports, part of a continuing series of Mineral Land Assessment reports, are available for consultation at the Bureau of Mines, Field Assessment and Evaluation Program Staff, Washington, DC, and at the Natural Resources Library, U.S. Department of the Interior, Washington, DC. Specific reports are also available at the field office indicated following their titles.

1981

MLA 1–81. Summary of Mineral Resources of the Lake Fork RARE II Area (Study Area 6290) Baker and Wallowa Counties, Oregon, by Martin D. Conyac. 1981. 9 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 2–81. Mineral Resources of the John Muir Wilderness; Fresno, Inyo, Madera, and Mono Counties, California, by Frederick L. Johnson, Horace K. Thurber, Richard W. Morris, Thomas J. Peters, and D. S. Lindsey. 1981. 18 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 3–81. Mineral Resources of the Big Butte-Shinbone (5145), East Fork (5226), Murphy Glade (5298), and Wilderness Contiguous (5137) RARE II Proposed Additions to the Yolla Bolly-Middle Eel Wilderness, Trinity, Tehama, and Mendocino Counties, California, by Warren D. Longwill. 1981. 13 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 4–81. Summary Report on Mineral Resources of the West Pioneer RARE II Area, No. 1–006, Beaverhead County, Montana, by John R. Benham. 1981. 12 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 5–81. Mineral Resources and Potential of Goat Rocks RARE II Areas, No. 6036, Parts A, C, and D, Lewis and Yakima Counties, Washington, by Thomas J. Peters and J. Mitchell Linne. 1981. 9 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 6–81. Mineral Resources of the Hyalite-Porcupine-Buffalo Horn Wilderness Study Area (RARE II Areas No. 1–158 G, Gallatin Divide; and H. Hyalite), Gallatin and Park Counties, Montana, by Terry J. Close, J. Douglas Causey, Spencee L. Willett, and Clayton M. Rumsey. 1981. 11 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 7–81. Mineral Resources of the Tepusquet Peak RARE II Area (No. 5–116), Santa Maria County, California, by Dale William Avery. 1981. 6 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 8–81. Mineral Resources of the Carson-Iceberg Area (RARE II C-4–986, C-5–986, B-5–986 North, and B-5–986 South), Alpine and Tuolumne Counties, California, by Michael Miller. 1981. 16 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 9–81. Mineral Resources of the Cuyama RARE II Study Area 5–135, Santa Barbara and Ventura Counties, California, by Lucia Kuizon. 1981. 11 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 10–81. Mineral Resources of the Domeland Addition (5207) and Woodpecker (5206) RARE II Areas, Tulare and Kern Counties, California, by James M. Spear and Robin McCulloch. 1981. 11 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 11–81. Mineral Resources of the Windigo Theilson RARE II Area, No. 6132, Douglas and Klamath Counties, Oregon, by John R. Benham. 1981. 6 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 12–81. Mineral Resources of the Caney Creek Wilderness Area, Polk County, Arkansas, by Maynard L. Dunn, Jr., and Donald K. Harrison. 1981. 33 pp. 10 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 13–81. Mineral Resources of the Shining Rock Wilderness; Haywood County, North Carolina, by Maynard L. Dunn, Jr. 1981. 17 pp. 3 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 14–81. Mineral Resources of the Granite Chief RARE II Area (A5–261), Placer County, California, by Francis E. Federspiel, Eric E. Cather, and Douglas F. Scott. 1981. 13 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 15–81. Mineral Resources of the Gee Creek Wilderness Area, Polk and Monroe Counties, Tennessee, by Gertrude C. Gazdik and Paul T. Behum. 1981. 31 pp. 6 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 16–81. Mineral Resources of the Linville Gorge Wilderness and Additions, Burke and McDowell Counties, North Carolina, by Gertrude C. Gazdik and Donald K. Harrison. 1981. 34 pp. 6 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 17–81. Mineral Resources of the Lye Brook Wilderness, Bennington and Windham Counties, Vermont, by Donald K. Harrison. 1981. 21 pp. 4 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 18–81. Mineral Resources of the Bristol Cliffs Wilderness Areas, Addison County, Vermont, by Peter C. Mory. 1981. 15 pp. 5 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 19–81. Mineral Resources of the Sipsey Wilderness and RARE II Areas, Lawrence and Winston Counties, Alabama, by Peter C. Mory, Robert B. Ross, Jr., and Paul T. Behum. 1981. 42 pp. 9 figs.

Intermountain Field Operations Center, Denver, Colo.

MLA 20–81. Mineral Resource Potential of the Upper Priest Lake RARE II Area (A1–123), Bonner County, Idaho, by David K. Denton, Jr. 1981. 9 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 21–81. Mineral Resources of the Blue Joint Mtn. RARE II Area (No. 1–941), Ravalli County, Montana, by John R. Benham. 1981. 8 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 22–81. Mineral Resources of the Buttermilk RARE II Area (No. 5–038), Inyo County, California, by Stephen R. Iverson. 1981. 7 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 23–81. Mineral Resources of the Little Frog Mountain RARE II Area, Polk County, Tennessee, by Gertrude C. Gazdik. 1981. 15 pp. 2 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 24–81. Mineral Resources of the Dinkey Lakes RARE II Area (No. 5244), Fresno County, California, by Francis E. Federspiel, Harry W. Campbell, Douglas F. Scott, and James M. Spear. 1981. 14 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 25–81. Mineral Resources of the Fisher Gulch RARE II Area (No. A5299), Trinity County, California, by Eric E. Cather and Joseph L. Ritchey. 1981. 10 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 26–81. Mineral Resources of the Black Butte RARE II Area (No. 5102), Monterey County, California, by Scott A. Stebbins. 1981. 9 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 27–81. Mineral Resources of Belle Starr East RARE II Further Planning Area and Belle Starr West RARE II Further Planning Area; Scott and Sebastian Counties, Arkansas, by Lyle E. Harris. 1981. 25 pp. 6 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 28–81. Mineral Resources of the James River Face Wilderness; Rockbridge and Bedford Counties, Virginia, by Robert B. Ross, Jr., and Gertrude C. Gazdik. 1981. 16 pp. 3 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 29–81. Mineral Resources of Ellicott Rock Wilderness Area and Additions; Oconee County, South Carolina, Macon and Jackson Counties, North Carolina, and Rabun County, Georgia, by Gertrude C. Gazdik. 1981. 45 pp. 4 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 30–81. Mineral Resources of the Natural RARE II Further Planning Area; Baker County, Florida, by Thomas M. Crandall. 1981. 22 pp. 3 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 31–81. Mineral Resource Potential of the Arnold Mesa RARE II Further Planning Area, Yavapai County, Arizona, by Robert A. McColly and Stanley L. Korzeb. 1981. 11 pp. 2 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 32–81. Mineral Resource Investigation Burden Falls RARE II Further Planning Area; Pope County, Illinois, by Robert M. Thompson. 1981. 13 pp. 3 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 33–81. Mineral Resources of Troublesome Further Planning Area; McCreary County, Kentucky, by Robert B. Ross, Jr., and Richard W. Hammack. 1981. 21 pp. 5 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 34–81. Mineral Resources of the La Panza RARE II Area (No. 5109), San Luis Obispo County, California, by Donald J. Barnes. 1981. 10 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

1982

MLA 1–82. Mineral Resources of the Lost Cove and Harper Creek RARE II Further Planning Areas; Avery and Caldwell Counties, North Carolina, by Robert B. Ross, Jr., and Thomas M. Crandall. 1981. 61 pp. 7 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 2–82. Mineral Resources of the Mt. Henry RARE II Area (No. 1–666), Lincoln County, Montana, by Martin D. Conyac. 1981. 7 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 3–82. Mineral Resources of the Los Machos Hills RARE II Area (No. 5111), San Luis Obispo County, California, by David K. Denton, Jr. 1981. 8 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 4–82. Mineral Resources of the Raymond Peak RARE II Area (No. 4985), Alpine County, California, by Francis E. Federspiel, Douglas F. Scott, and Eric E. Cather. 1981. 18 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 5–82. Mineral Resources of the Kings River (B5–198) and Rancheria (C5–198) RARE II Areas, Fresno County, California, by Warren D. Longwill. 1981. 25 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 6–82. Mineral Resource Investigation Lusk Creek RARE II Further Planning Area; Pope County, Illinois, by Robert M. Thompson. 1981. 28 pp. 7 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 7–82. Mineral Resources of the Log Cabin Saddlebag (5052), Hall Natural Area (5051), Horse Meadow (5049), Tioga Lake (5050), RARE II Study Areas Mono County, California, by Francis E. Federspiel, Douglas F. Scott, Eric E. Cather, Nicholas T. Zilka, and Andrew M. Leszcykowski. 1981. 16 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 8–82. Mineral Resources of the Garcia Mountain RARE II Area (No. 5107), San Luis Obispo County, Cali-

fornia, by David A. Lipton. 1981. 9 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 9–82. Mineral Resources of the La Brea RARE II Area (No. 5117), Santa Barbara County, California, by John R. Benham and Robin B. McCulloch. 1981. 9 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 10–82. Mineral Resources of the Trail Lake RARE II Area (No. B5–095), Lassen and Plumas Counties, California, by Joseph L. Ritchey and Eric E. Cather. 1981. 7 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 11–82. Mineral Resources of the Reservoir-North RARE II Area (No. H1–485), Teton County, Montana, by Lawrence Y. Marks. 1981. 6 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 12–82. Mineral Resources of the Long Swamp RARE II Area (No. A6024), Okanogan County, Washington, by John R. Benham. 1981. 6 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 13–82. Mineral-Resource Potential of the Lower San Francisco RARE II Further Planning and Wilderness Recommendation Areas, Greenlee County, Arizona, Grant and Catron Counties, New Mexico, by Michael E. Lane. 1981. 7 pp. 1 fig. Intermountain Field Operations Center, Denver, Colo.

MLA 14–82. Mineral Resources of the Oat Mountain RARE II Area (No. 5197), Fresno County, California, by James M. Spear. 1981. 9 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 15–82. Mineral Resources of the Lake Eleanor RARE II Area (No. 5807), Trinity County, California, by Eric E. Cather and Joseph L. Ritchey. 1981. 10 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 16–82. Mineral Resources of the Santa Lucia Wilderness, San Luis Obispo County, California, by Charles Sabine and Leon E. Esparza. 1981. 6 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 17–82. Mineral Resources of the Welcome Creek Wilderness, Granite County, Montana, by Terry J. Close. 1981. 15 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 18–82. Mineral Resources of the Big Snowies Wilderness Study Area (RARE II 1–739) Fergus and Golden Valley Counties, Montana, by Francis E. Federspiel and James D. Huffsmith. 1981. 8 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 19–82. Mineral Resources of the Agnew RARE II Area (No. 5199), Fresno County, California, by James M. Spear. 1982. 9 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 20–82. Mineral Resources of the North Fork American River (5–262) RARE II Study Area, Placer County, California, by Francis E. Federspiel, Andrew M. Leszcykowski, and Frederick A. Spicker. 1981. 17 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 21–82. Mineral Resources of the Black Mountain RARE II Area (No. 5108), San Luis Obispo County, California, by Peter N. Gabby. 1981. 12 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 22–82. Mineral Resources of the Three Sisters Wilderness, Deschutes, Lane, and Linn Counties, Oregon, by J. Douglas Causey and Spencee L. Willett. 1981. 12 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 23–82. Mineral Resources of the Diamond Peak Wilderness and Proposed Addition, Lane and Klamath Counties, Oregon, by Philip R. Moyle and Clayton M. Rumsey. 1981. 10 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 24–82. Mineral Resources of the Anaconda Pintlar Wilderness, Beaverhead, Deer Lodge, Granite and Ravalli Counties, Montana, by Terry J. Close, Francis E. Federspiel, J. Douglas Causey, Spencee L. Willett, Richard W. Morris, and James R. Huffsmith. 1982. 23 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 25–82. Mineral Resources of the Additions to the Ventana Wilderness, Monterey County, California, by Leon E. Esparza and Charles Sabine. 1982. 9 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 26–82. Mineral Resources of Beaver Creek Wilderness; McCreary County, Kentucky, by Richard W. Hammack and Robert B. Ross, Jr. 1982. 40 pp. 12 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 27–82. Mineral Resources of Jobildunk RARE II Further Planning Area; Grafton County, New Hampshire, by Robert A. Welsh, Jr., and Lyle E. Harris. 1982. 17 pp. 3 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 28–82. Mineral Resource Investigation of Allegheny Front and Hickory Creek RARE II Further Planning Areas; Warren County, Pennsylvania, by Vaughn P. Girol. 1982. 26 pp. 5 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 29–82. Mineral Resources of the Whipple Mountains Wilderness Study Area, San Bernardino County, California, by James Ridenour, Phillip R. Moyle, and Spencee L. Willett. 1982. 34 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 30–82. Mineral Resources of the Emmet Wash Wilderness Study Area, Coconino County, Arizona, by Michael E. Lane. 1982. 5 pp. 2 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 31–82. Mineral Resources of Overflow Further Planning Area, Rabun County, Georgia, and Macon County, North Carolina, by Michael P. Davis. 1982. 16 pp. 3 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 32–82. Mineral Resources Investigation of Rainbow Lake Wilderness Area and Flynn Lake Wilderness Study Area, Bayfield County, Wisconsin, by Maynard L. Dunn, Jr., Gertrude C. Gazdik, and James J. Hill. 1982. 29 pp. 8 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 33–82. Mineral Resources of the Gearhart Mountain Wilderness and RARE II Area 6225, Klamath and Lake Counties, Oregon, by James Ridenour. 1982.

6 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 34–82. Mineral Resources of Devils Den RARE II Further Planning Area, Rutland and Windsor Counties, Vermont, by Andrew E. Sabin and Jay G. Jones. 1982. 16 pp. 3 figs. Western Field Operations Center, Spokane, Wash.

MLA 35–82. Mineral Resource Potential of the Dragoon Mountains RARE II Further Planning Area, Cochise County, Arizona, by Terry J. Kreidler. 1982. 9 pp. 3 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 36–82. Mineral Resources of the Domeland Wilderness, Kern and Tulare Counties, California, by Andrew Leszcykowski, Clayton Morlock, and Spencee Willett. 1982. 5 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 37–82. Mineral Resources of the Mount Hood Wilderness, Clackamas and Hood River Counties, Oregon, by J. Douglas Causey. 1982. 13 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 38–82. Mineral Resources of the Mount Washington Wilderness, Deschutes, Lane, and Linn Counties, Oregon, by J. Douglas Causey. 1982. 6 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 39–82. Mineral Resource Investigation of Cornplanter RARE II Further Planning Area; Warren County, Pennsylvania, by Robert A. Welsh, Jr., and Roy H. Grau III. 1982. 24 pp. 4 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 40–82. Mineral Resources of Upper Buffalo Wilderness Area and Buffalo Addition RARE II Wilderness Area; Newton County, Arkansas, by Michelle K. Armstrong and Maynard L. Dunn, Jr. 1982. 19 pp. 5 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 41–82. Mineral Resources of the Hells Canyon Study Area, Adams, Idaho, and Nez Perce Counties, Idaho, and Wallowa County, Oregon, by Terry J. Close, Francis E. Federspiel, and Andrew Leszcykowski. 1982. 32 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 42–82. Mineral Resources of Snowbird RARE II Further Planning Area; Graham County, North Carolina, by Mark L. Chatman. 1982. 18 pp. 3 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 43–82. Mineral Resources of Shinbone Creek and Adams Gap RARE II Further Planning Area; Clay County, Alabama, by Donald K. Harrison and Michelle K. Armstrong. 1982. 19 pp. 5 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 44–82. Mineral Resources of the Freel Peak RARE II Area (No. 5271), El Dorado County, California, by Thomas J. Peters and Francis E. Federspiel. 1982. 11 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 45–82. Mineral Resources of the Square Butte Instant Wilderness Study Area, Chouteau County, Montana, by Charles E. Larson. 1982. 7 pp. 1 fig. Western Field Operations Center, Spokane, Wash.

MLA 46–82. Mineral Resources of Farles Prairie and Buck Lake RARE II Further Planning Areas; Marion County, Florida, by Thomas M. Crandall. 1982. 20 pp. 4 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 47–82. Mineral Resources of Cohutta Wilderness Area, Big Frog Wilderness Study Area, and Hemp Top and Big Frog Additions RARE II Areas, North-Central Georgia and Southeastern Tennessee, by Gertrude C. Gazdik and Maynard L. Dunn, Jr. 1982. 31 pp. 4 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 48–82. Mineral Resources of Sandy Creek RARE II Further Planning Area, Adams County, Mississippi, by Richard F. Bitar and Thomas M. Crandall. 1982. 18 pp. 5 figs. Intermountain Field Operations Center, Denver, Colo.

MLA 27–84. Mineral Investigation of the Starvation Point Wilderness Study Area, Mohave County, Arizona and Washington County, Utah, by Albert D. Harris and George S. Ryan. 1984. 14 pp. 2 figs. Intermountain Field Operations Center, Denver, CO.

MLA 28–84. Mineral Investigation of the Bristol/Granite Mountains Wilderness Study Area (BLM No. CDCA-256), San Bernardino County, California, by Charles Sabine. 1984. 21 pp. 4 figs. Western Field Operations Center, Spokane, WA.

MLA 29–84. Mineral Resources of the Morongo Wilderness Study Area (BLM No. CDCA-218), San Bernardino County, California, by Lucia Kuizon. 1984. 10 pp. 1 fig. Western Field Operations Center, Spokane, WA.

MLA 30–84. Mineral Resources of the Sawtooth Mountains B Wilderness Study Area (BLM No. 060–024B), San Diego County, California, by Eric Cather. 1984. 13 pp. 1 fig. Western Field Operations Center, Spokane, WA.

MLA 31–84. Mineral Investigation of the Mount Trumbull Wilderness Study Area, Mohave County, Arizona, by John R. McDonnell, Jr. 1984. 7 pp. 2 figs. Intermountain Field Operations Center, Denver, CO.

MLA 32–84. Mineral Investigation of the South Providence Wilderness Study Area (BLM No. CDCA–262), San Bernardino County, California, by Steven R. Munts. 1984. 31 pp. 2 figs. Western Field Operations Center, Spokane, WA.

MLA 33–84. Mineral Resources of the Pit River Canyon Wilderness Study Area (BLM No. CA–020–103), Lassen County, California, by Harry W. Campbell. 1984. 11 pp. 2 figs. Western Field Operations Center, Spokane, WA.

MLA 34–84. Mineral Investigation of the Hack Lake Wilderness Study Area, Garfield County, Colorado, by Steven E. Kluender. 1984. 7 pp. 2 figs. Intermountain Field Operations Center, Denver, CO.

MLA 35–84. Mineral Resources of the Mecca Hills Wilderness Study Area (BLM No. CDCA–343), Riverside County, California, by Harry W. Campbell. 1984. 17 pp. 2 figs. Western Field Operations Center, Spokane, WA.

MLA 36–84. Mineral Resources of the Funeral Mountains Wilderness Study Area (BLM No. CDCA–143), Inyo County, California, by Terry R. Neumann. 1984. 19 pp. 2 figs. Western Field Operations Center, Spokane, WA.

MLA 37–84. Mineral Investigation of the Hack Canyon Wilderness Study Area, Mohave County, Arizona, by John R. McDonnell, Jr. 1984. 15 pp. 3 figs. Intermountain Field Operations Center, Denver, CO.

MLA 38–84. Mineral Resources of the Picacho Peak Wilderness Study Area (BLM No. CDCA-355A), Imperial County, California, by Arel B. McMahan and Clayton M. Rumsey. 1984. 31 pp. 3 figs. Western Field Operations Center, Spokane, WA.

MLA 39–84. Mineral Resources of the Indian Pass Wilderness Study Area (BLM CDCA-355), Imperial County, California, by Clayton M. Rumsey and Arel B. McMahan. 1984. 31 pp. 3 figs. Western Field Operations Center, Spokane, WA.

MLA 40–84. Mineral Resources of the El Paso Mountains Wilderness Study Area (BLM No. CDCA-164), Kern County, California, by Richard S. Gaps. 1984. 18 pp. 2 figs. Western Field Operations Center, Spokane, WA.

REPORTS AVAILABLE FROM THE NATIONAL TECHNICAL INFORMATION SERVICE

Bureau of Mines publications and open file reports are available from the National Technical Information Service (NTIS) in two forms: paper cover copies and microfiche. Price codes are listed for paper copies of each publication. Contact NTIS for a copy of the current price schedule for domestic orders (any order going to Canada, the United States, or Mexico) or the current schedule for foreign orders (any order going to a country other than Canada, the United States, or Mexico). Microfiche copies (price code A01) of each publication are available on request unless otherwise indicated. Quotations on quantity purchases of a single title are available on request. Purchases may be made by check or money order payable to the National Technical Information Service, or charged on a VISA, MasterCard, or American Express credit card. Address requests to—

National Technical Information Service
U.S. Department of Commerce
Springfield, VA 22161

or call 703–487–4650.

CUMULATIVE INDEX

This index lists all Bureau of Mines publications placed with the National Technical Information Service during calendar years 1980–84. Listing is by Bureau series and number and NTIS accession number. Three other indexes, by Bureau series and number, can be found in the 5-year lists of Bureau of Mines publications for the calendar years 1965–69, 1970–74, and 1975–79.

ARTICLES IN OUTSIDE PUBLICATIONS

The following are articles by Bureau of Mines personnel in non-Bureau publications that came to our attention. In addition to Bureau authors, this section may contain some non-Bureau coauthors. Copies of these articles are NOT available from the Bureau of Mines.

1980

OP 1–80. Identification and Quantification of Asbestos and Other Mineral Particulates, by William J. Campbell. Proc. Symp. on the Impact of Federal Health, Safety, and Environmental Regulations on the Ceramic Industry, 81st Ann. Meeting, Am. Ceram. Soc., Cincinnati, Ohio, Apr. 30–May 1, 1979, December 1979, pp. 55–66. Optical and electron microscopic methods are compared for their identification and quantification of fibrous particles in air, water, and bulk samples. Limitations of the Federal regulatory optical counting procedures for asbestos are considered when applied to materials of interest to the ceramic industry.

OP 2–80. Impact of Recent Cobalt Supply Situation on Magnetic Materials and Applications, by G. Y. Chin, S. Sibley, J. C. Betts, T. D. Schlabach, F. E. Werner, and D. L Martin. IEE Trans. on Magnetics, v. MAG–15, No. 6, November 1979, pp. 1685–1691. In 1978, the cobalt market was thrown into a state of great uncertainty, with soaring prices, limited supply, and accelerating demand. A critical shortage threatened to develop but never really materialized. To a great degree, the prices cobalt commanded on the free market induced Zambia, after consultation with other producers, to hike its prices. The effect was self-perpetuating, with each pricing-tier increase, producer and free market, encouraging the other to escalate. In each instance, Zaire followed suit. These developments took place against a background of a lack of readily available effective substitutes. Barring unforeseen developments that could greatly reduce the available supply, such as a previous production shutdown that lasted for several months, the supply of cobalt is likely to remain tight, but not critically short, for the next several years. Prices are expected to remain relatively high. Over the long term, 1985 and beyond, prospects are good for more readily available cobalt at more reasonable prices. Domestic production of cobalt and mining of deep sea cobalt-bearing manganese nodules could satisfy domestic demand and eventually result in lower prices. Thus, the short-term outlook is rather pessimistic, while over the long term the present precarious situation could be reversed.

OP 3–80. Development of a Mine Shaft Fire and Smoke Protection Prototype System, by Guy A. Johnson. Proc. 3d West Virginia University Conf. on Coal Mine Electrotechnology, Morgantown, W. Va., Aug. 4–6, 1976, pp. 20–1—20–4. This report describes the efforts by the Bureau of Mines and FMC Corp. to define the mine shaft fire and smoke hazard problem, then design, fabricate, and in-mine test prototype hardware for a system that better protects miners and the mine than the shaft-collar rings now commonly used. The resulting mine shaft fire and smoke protection system involves both thermal and smoke detectors, remotely controlled smoke doors at the shaft station, and remotely controlled sprinklers. The system was successfully demonstrated by an actual fire test in the Silver Summit shaft near Wallace, Idaho, in the spring of 1975. Long-term, in-mine testing of alternative system designs is currently being conducted to show that the system has credibility as a reasonably priced, reliable piece of improved mining health and safety hardware.

OP 4–80. Fused-Salt Electrowinning and Electrorefining of Rare-Earth and Yttrium Metals, by E. Morrice and M. M. Wong. Miner. Sci. Eng., v. 11, No. 3, July 1979, pp. 125–136. Increasing demands for rare-earth and yttrium metals in the preparation of special alloys and other uses have greatly enhanced their status as industrial metals. In this paper, a review is made by the Bureau of Mines of fused-salt electrowinning of individual rare-earth metals, yttrium metal, and mischmetal from the respective chlorides and oxides. Preparation of alloys of yttrium metal and rare-earth metals by fused-salt electrolysis and electrorefining of yttrium metal is also included in this review. Particular attention is devoted to the problems encountered in the electrolysis and progress made in the development of the technology.

OP 5–80. Chemical Monitoring of the In Situ Leaching of a South Texas Uranium Orebody, by R. W. Potter II, M. A. Clynne, J. M. Thompson, V. L. Thurmond, R. C. Erd, N. L. Nehring, K. A. Smith, P. J. Lamothe, J. L. Seeley, D. R. Tweeton, G. R. Anderson, and W. H. Engelmann. U.S. Geol. Survey Open File Rept. 79–1144, 1979, 54 pp. The Federal Bureau of Mines and the U.S. Geological Survey measured the changes in formation water chemistry during the initial stages of in situ uranium leaching at a site in south Texas, using $(NH_4)_2CO_3$ as the leach solution. Cores and ground water were analyzed before leaching. Water samples were taken from test wells between injection and recovery wells as leach solution replaced the ground water. Measurements were made at least daily of temperature, pH, U, Na, K, Ca, Mg, SiO_2, NH_4, HCO_3, CO_3, SO_4, and Cl. The data were needed for developing and verifying a computer simulation model of the geochemical reactions involved in in situ uranium leaching.

OP 6–80. Acoustic Emission Techniques Applied to Slope Stability Problems, by Raymond M. Stateham and Robert H. Merrill. Rockslides and Avalanches Vol. 2. Engineering Sites, ed. by B. Voight; ch. 16 in Development in Geotech. Eng., v. 2, No. 14B., 1979, pp. 577–593. Techniques and instru-

ments used to detect instability in rock masses around underground mines have been refined and applied to the detection of instability in rock slopes. From the number and magnitude of the acoustic emissions in the rock mass, engineering estimates of slope instability can be made. The electronic apparatus has advanced from early tube-type circuitry to solid-state circuitry capable of amplifying the output of accelerometers, velocity gages, and pressure gages used to detect acoustic emissions (rock noises). Some of the techniques, instruments, and results at four open pit mines are described. The results of these studies show that the techniques can be used to predict failure, monitor the progress of the failure, and provide evidence that earthquakes can affect the stability of a pit wall.

OP 7–80. Magnetic Properties of Mischmetal-(Co,Cu,Fe,Mg) Alloys, by J. W. Walkiewicz and M. M. Wong. IEEE Trans. on Magnetics, v. MAG-15, No. 6, November 1979, pp. 1757–1759. To relieve the dependence for critical and strategic minerals through conservation and substitution, the Bureau of Mines investigated alloys containing mischmetal (MM), cobalt, copper, magnesium, and iron for use in permanent magnets in place of the scarce samarium-cobalt alloys. The magnetic properties of selected MM-Co-Cu-Mg and MM-Co-Cu-Mg-Fe alloys were evaluated. Magnets were fabricated by powder metallurgy that consisted of arc-melting the metals, crushing and grinding the resultant alloy, alining and compacting the powder, and sintering the green compacts.

OP 8–80. Inhibition of Pyrite Weathering by Recycling of Selected Effluents, by Fraser M. Walsh, Robert L. Stone, and William H. Engelmann. Proc. Underground Coal Mining Symp., Coal Conf. and Expo V, Louisville, Ky., Oct. 23–25, 1979, pp. 139–146. Pyrite weathering is responsible for the large loads of acid and iron in streams associated with coal mine regions of Appalachia. This paper is derived from a study funded by the Bureau of Mines and describes briefly (1) the work done to verify the mechanics of weathering of pyrite entrained in fresh coal mine face material, (2) the importance of iron bacteria in catalyzing pyrite weathering, and (3) the successful laboratory test of a method for inhibiting these bacteria. Preliminary results of the ongoing laboratory tests are described. These results show that iron bacteria catalyze pyrite weathering by a factor of 4 and this catalysis can be stopped by increasing the iron concentration of water influent to the mine face material to 100 ppm. The technical basis for a practical field method for reducing by 80 percent the acid and iron loads from coal mine operations is described.

OP 9–80. Electron Radon Daughter Dosimetry, by John Durkin. Health Phys., v. 37, December 1979, pp. 757–764. Daily exposure of uranium mining personnel to ^{222}Rn daughters has established the need for a device that will continually monitor an individual's exposure. Such a device has been built and tested with promising results. The device is an electronic dosimeter using both a solid-state detector and circuitry, and is a personal instrument worn throughout the working shift. Since the instrument is in close proximity to the miner and measures continually, it provides a more accurate account of total cumulative exposure, and avoids the errors caused by the present technique of spot checking the environment. The system permits the measurement of cumulative exposures to airborne radon progeny, expressed in units of working level hours.

OP 10–80. Research on a More Effective Use of Mineral Resources—A Mission of the United States Bureau of Mines, by T. A. Henrie and F. Block. Proc. 2d Internat. Symp. on the Mineral Resources Potential of the Earth, Hannover, Federal Republic of Germany, Apr. 18–20, 1979, pp. 24–38. The standard of living in the United States and other industrialized nations depends heavily on mineral resources, particularly metals. Per capita consumption of metals is high, and it increases each year. The growth rate is most rapid in those countries that are just beginning to industrialize, which means greater competition for mineral resources than ever before. Therefore, it is imperative to conserve these resources by the most efficient use possible. This paper discusses some of the new mineral-processing technologies investigated by the Bureau of Mines in this vital mission.

OP 11–80. Wear-Resistant Materials for Coal Conversion Components, by J. E. Kelley and H. W. Leavenworth, Jr. Proc. 4th Ann. Conf. on Materials for Coal Conversion and Utilization, Gaithersburg, Md., Oct. 10–12, 1978, pp. III–32—III–37. The need for improved wear-resistant materials for valves, nozzles, and other wear-prone components has been demonstrated by frequent failures in gasification and liquefaction pilot plants. The key to the development or selection of improved materials is a thorough understanding of the behavior of existing materials in both laboratory and pilot plant environments. This Bureau of Mines paper presents results of research to evaluate materials in these environments, recommendations on the best currently available materials, and the use of accumulated data to develop better materials.

OP 12–80. Citrate Process Demonstration Plant—Construction and Testing, by Richard S. Madenburg, Laird Crocker, Laurance L. Oden, John M. Cigan, and R. Dean Delleney. Proc., Symp. on Flue Gas Desulfurization, Regenerable Processes Session, Las Vegas, Nev., March 1979, EPA-600/7-79-167b, v. 2, July 1979, pp. 761–791. This Bureau of Mines paper discusses the construction of the citrate process demonstration plant, the mechanical and prestartup testing, and the test and evaluation program. A brief description of the process, recent material evaluations, and an assessment of application of citrate technology to other industrial SO_2-emitting sources are presented.

OP 13–80. Demonstration of SO_2 Scrubbing of Flue and Stack Gases by Citrate Absorption, by William A. McKinney and W. I. Nissen. Pres. at Am. Min. Cong. Min. Conv., Los Angeles, Calif., Sept 23–26, 1979, 14 pp. The Bureau of Mines citrate process for scrubbing SO_2 from industrial waste gases comprises absorption of SO_2 from cooled and cleaned gases in a solution of sodium citrate, citric acid, and sodium thiosulfate, followed by reacting the absorbed SO_2 with H_2S to precipitate elemental sulfur and regenerate the citrate solution for recycle. Laboratory investigations established process parameters; then pilot plant testing at a copper smelter and a lead smelter confirmed process, operational, and performance parameters and established the design basis of commercial demonstration of the citrate process. The demonstration plant represents a joint Government-industry effort to apply the citrate process to an existing 60-Mw coal-fired, electricity generating powerplant. Construction of the demonstration plant was scheduled to be completed in August 1979, and acceptance testing was to start immediately afterwards. Following the plant accept-

ance test, plans call for the test and evaluation of the plant operation for 1 year.

OP 14–80. Projections and Forecasts of U.S. Mineral Demand by the U.S. Bureau of Mines, by V. Anthony Cammarota, Jr., William J. Mo, and Barry W. Klein. Proc. 109th AIME Ann. Meeting, Las Vegas, Nev., Feb. 24–29, 1980, pp. 69–71. The Bureau of Mines forecasting system consists of statistical and contingency analyses. Ordinary least-squares regression analysis is the statistical technique used to obtain U.S. demand projections for mineral commodities by end use categories in the year 2000. The year 2000 projections for the independent or explanatory variables used in these linear regressions are based on the Data Resources, Inc., macroeconomic model that forecasts gross national product and detailed Federal Reserve Board industrial production indexes. Among the resulting regression lines that best explains the variation in the dependent variable is the one that is chosen and its associated end use projection in 2000 is published in the Bureau's Mineral Commodity Profile series. The other important component of the Bureau of Mines forecasting system is contingency forecasting that takes into account the judgmental factors. The effects on demand from such factors as technological advances, environmental issues, government policies and regulations, and consumer tastes are considered.

OP 15–80. Evaluation of the Methane Gas Content of Coalbeds: Part of a Complete Coal Exploration Program for Health and Safety and Resource Evaluation, by William P. Diamond. Proc. 2d Internat. Coal Exploration Symp., Denver, Colo., Oct. 1–4, 1978; Coal Explor., v. 2, 1979, pp. 211–222. The explosion hazard of methane-air mixture has become an increasingly serious problem in mine planning. As mining progresses to greater depths or develops in new, previously unmined areas, an advance assessment of methane gas potential can be essential for a safe and economic mine development program. The Bureau of Mines, as part of its Coal Mine Health and Safety Program, has developed a simple, inexpensive test to accurately measure the methane content of coal samples obtained from exploration cores. The gas content of the coal per unit weight determined by this "direct method" test can be used as a basis for a preliminary estimate of mine ventilation requirements and to determine if degasification of the coalbed in advance of mining should be considered. The test results also can be used to estimate the methane resources of coalbeds in specific geographic areas. With the eventual decline in conventional domestic gas production and increased price of natural gas, commercial production of coalbed gas will become a reality.

OP 16–80. Directional Drilling for Coalbed Degasification in Advance of Mining, by William P. Diamond and David C. Oyler. Proc. 2d Ann. Symp. on Methane Recovery From Coalbeds, Pittsburgh, Pa., Apr. 18–20, 1979, pp. 162–176. The Bureau of Mines has conducted research in directional drilling for degasification in advance of mining since 1973. This technique is designed to combine the highly successful underground horizontal degasification drilling technology with surface drilling methods. The use of directional drilling techniques will be particularly useful in areas where access to gassy coalbeds is not possible underground, and where topography makes multiple sites for vertical degasification holes impractical or prohibitively expensive. This report presents the development of the directional drilling technique in detail along with a description of the Bureau's current directional drilling program at the Emerald mine near Waynesburg, Pa.

OP 17–80. Ferric Chloride Leach-Electrolysis Process for Production of Lead, by M. M. Wong, F. P. Haver, and R. G. Sandberg. Proc. 1980 World Lead-Zinc Symp., Las Vegas, Nev., Mar. 27–29, 1980, pp. 445–454. The Bureau of Mines, under a cooperative research agreement with lead producers, is conducting a feasibility study of a process to minimize pollution caused by sulfur oxide and lead. The process involves ferric chloride leaching of galena to produce lead chloride and fused-salt electrolysis of the lead chloride to produce lead and chlorine. The chlorine produced by electrolysis is used directly to regenerate ferric chloride in the leach solution. The study is being conducted in a process development unit designed to produce about 500 pounds per day of lead metal, operating on an integrated basis. This report describes the equipment and operating procedures, and presents a preliminary evaluation of the results with respect to process performance, equipment corrosion, impurity buildup, and air monitoring.

OP 18–80. Production and Uses of Zinc, by V. Anthony Cammarota, Jr. Ch. in Zinc in the Environment. John Wiley & Sons, Inc., New York, pt. 1, 1980, pp. 1–38. The organization of the zinc industry is discussed with details given on mining, milling, smelting, and refining of zinc by various processes. The geology of major deposits are described. Environmental and economic factors in the industry are given. World mine and smelter data have been tabulated since 1950 to indicate trends in world production. The United States was the largest producer of zinc metal from 1901 to 1971, but has lost this position as smelters closed. Since 1951, U.S. production has shifted from the Western States to the Eastern States, with the result that a higher proportion of zinc is being extracted from zinc ores rather than mixed ores. The use of zinc as a metal, dust, and in compounds is described. U.S. demand is expected to grow at an annual rate of about 2 percent to the year 2000. After about 1990 zinc batteries for automobile propulsion and electrical load leveling could become important.

OP 19–80. Alaska's Minerals: A Look at 1979, by David Carnes. Alaska Construct. & Oil, January 1980, pp. 40–43. This article outlines mineral exploration, mining, and petroleum activity that occurred in Alaska during 1979. Small placer mines, located in the State's known gold placer districts, increased total production during the year, but reduced production from the leading gold producer caused an overall decline in total gold production. Sand and gravel production, coupled with crushed stone, produced the largest revenues in the mineral industry. Coal production was limited to a single operation that produced approximately 730,000 short tons of coal. Mineral exploration was at a slightly reduced level compared with the previous year. Major companies explored on the Seward Peninsula, the De Long Mountains, Brooks Range, Interior Alaska, and Southeastern Alaska. Extensive exploration for outlining ore body configuration occurred at Greens Creek and Quartz Hill. Daily oil production during 1979 reached over 1.4 million barrels per day, putting Alaska in 2d place among the 50 States for daily oil production. The proposed natural gas line received approval by the Department of the Interior, but actual construction is running

into financial difficulties. The first oil and gas lease sale since 1974 was conducted during 1979.

OP 20–80. Recovery of Byproduct Heavy Minerals From Sand and Gravel Operations in Central and Southern California, by J. M. Gomes, G. M. Martinez, and M. M. Wong. Proc. Mineral Resource Potential of California Conf., Sacramento, Mar. 27–28, 1980, pp. 54–70. The Federal Bureau of Mines has investigated the occurrence and recovery of byproduct heavy minerals from sand and gravel operations as a means of assessing the Nation's resources. Sand samples from 63 locations in central and southern California were treated to yield heavy mineral concentrations. The mineral compositions of the concentrates were characterized by chemical and mineralogical examinations. Additional large quantities of concentrates were prepared from selected deposits that contained significant quantities of heavy minerals. Beneficiation studies were performed on these concentrates to recover individual mineral products. Gold was recovered by amalgamation; platinum-group metals and radioactive minerals were recovered by flotation; and magnetite, ilmenite, and chromite were recovered by magnetic and high-tension separation techniques.

OP 21–80. Recovering Byproduct Heavy Minerals From Sand and Gravel Operations in Northern California, by J. M. Gomes, G. M. Martinez, and M. M. Wong. Proc. Aggregate, Sand and Gravel Conf., Reno, Nev., May 5–9, 1979, pp. 4–33. The Bureau of Mines, as part of an effort to maximize minerals and metals recovery from domestic resources, has investigated sand and gravel, placer gold, and industrial mineral operations in northern California. Sand samples from about 50 locations were treated by gravity separation to yield heavy mineral concentrates (black sands). Mineral compositions of the concentrates were determined by chemical analysis and mineralogical examination. Individual zircon, ilmenite, magnetite, platinum-group metals, thoria, and silica products were prepared from heavy mineral concentrates by selective separation using low- and high-intensity magnetic, high-tension, and flotation equipment.

OP 22–80. Pneumatic Beneficiation of Mica Ores, by C. E. Jordan, G. V. Sullivan, and B. E. Davis. Pres. at Soc. Min. Eng., AIME, Ann. Meeting, Las Vegas, Nev., Feb. 24–28, 1980, SME Preprint 80–7, 8 pp. The Bureau of Mines, as part of its effort to maintain an adequate supply of minerals and metals to meet national economic and strategic needs, is conducting research on the pneumatic recovery of coarse mica. A system of crushers, screens, and zigzag air classifiers is used to concentrate coarse liberated mica particles from mica ore and from the waste tailings of abandoned mica operations. The plus 0.21-mm-size mica is effectively recovered by this method. The mica concentrates produced contain over 90 pct mica. The method recovered up to 78 pct of the mica in the samples. As a dry concentration method, the pneumatic beneficiation technique may be advantageous to areas of limited water resources.

OP 23–80. Recycling of Waste Magnesite-Chrome Refractories, by E. Martin and A. V. Petty, Jr. Pres. at TMS-AIME Ann. Meeting, Las Vegas, Nev., Feb. 24–28, 1980; TMS Paper Selection A80–40, March 1980, 15 pp. The Bureau of Mines, as part of its program to conserve mineral resources through secondary resource recovery, determined the feasibility of recycling magnesite-chrome refractories from copper and steel furnaces. Physical and chemical beneficiation processes were investigated to remove contaminants prior to recycling. Samples of the beneficiated material were formed into briquets, and modulus of rupture data were determined.

OP 24–80. A Bureau of Mines for the 80s, by Lindsay D. Norman. Min. Cong. J., Reprint, December 1979, 4 pp. The paper presents a general explanation of the recent reorganization of the Bureau of Mines and attempts to convey a meaningful understanding of the new organization. New purposes and principal ways in which the Bureau can more effectively serve the public interest are described along with an idea of the Bureau's objectives and the importance of individual efforts in attaining them.

OP 25–80. Criterion of Failure for Design of Rock Mass Structures as Determined by Borehole Shear Tests, by Louis A. Panek. Proc. 4th Cong., Internat. Soc. for Rock Mechanics, Montreux, Switzerland, Sept. 3–7, 1979, pp. 509–515. To meet the need for improved field test instruments, hardware and procedures were developed for rapidly determining the in-place shear strength of coal and rock. The hydraulically operated device is permissible, portable, and can be used in 3-inch boreholes at depths up to 100 feet. Field tests in a number of mines, coal, nonmetallic, and hard rock, show that the tester is practical for mine use, especially where recovery of unbroken core for laboratory tests would be difficult. In addition to eliminating the "good rock only" bias inherent in laboratory testing, the tester offers the advantages that many tests can be quickly performed in a single borehole and the results are available immediately. A technical paper presented to an international meeting in 1979 shows that the test data obtained for four different coals and four rock types are equivalent to those for conventional triaxial tests, the best laboratory strength test. The shear strength of coal and rock is important in determining pillar crushing, floor heaving, overburden collapse, roof bolt anchorage, and cutability and drillability of the materials.

OP 26–80. Recovery of Barite From Tailings Ponds and Bypassed Mining Waste, by G. V. Sullivan and W. E. Lamont. Pres. at Soc. Min. Eng., AIME, Ann. Meeting, Las Vegas, Nev., Feb. 24–28, 1980, 5 pp. As part of its program to conserve domestic mineral resources through advancing mineral resources technology, the Bureau of Mines conducted investigations to determine the feasibility of recovering high-grade barite concentrates, suitable for use as well-drilling mud, from current and old waste pond materials and materials bypassed in present mining operations. Flotation studies of waste pond samples from Missouri and Nevada yielded barite concentrates containing over 95 pct $BaSO_4$ with recoveries of 86 and 96 pct, respectively, of the barite in the flotation feed. Flotation studies of a hard-rock sample from Georgia, currently bypassed in mining, yielded a barite concentrate containing 97 pct $BaSO_4$ with an attendant recovery of 97 pct of the barite.

OP 27–80. Preparation of Dilution-Stable Aqueous Magnetic Fluids, by Sanaa E. Khalafalla and George W. Reimers. Pres. at 2d Internat. Conf. on Magnetic Fluids, Orlando, Fla., Mar. 24–27, 1980; IEEE Trans., v. MAG-16, No. 2, March 1980, pp. 178–183. The extension of the Bureau-developed peptization technique for kerosine-base fluids to the

preparation of the aqueous variety was possible when oleic acid was replaced by dodecylamine. The fluids thus prepared were, however, not stable toward dilution. When dodecanoic (lauric) acid was used instead of dodecylamine as the dispersing agent, the resulting aqueous magnetic fluid was found to be more stable toward dilution with water. In this second generation water-base magnetic fluid, the dodecanate anionic dispersing agent is superior to the commonly used dodecylamine cationic dispersing agent. Chemisorption of dodecanate anion on the magnetite surface proper by chemically bonding to surface iron atoms is contrasted to the mere adsorption of a cationic surfactant on the solution side of the electric double layer.

OP 28–80. Characteristics of a Potassian Winchite-Asbestos From the Allamoore Talc District, Texas, by Ann G. Wylie and Charles W. Huggins. Can. Mineral., v. 18, February 1980, pp. 101–107. Asbestos from the Diablo prospect, Allamore talc district (Texas) has cell dimensions a 9.944(5), b 17.951(6), c 5.271(4) A, β 104.41(5)° (powder-diffraction data); the data are consistent with space groups $C2$, Cm, or $C2/m$. Chemical analyses indicated a potassian winchite-asbestos, $(K_{0.43}Na_{0.02})$ $(Na_{1.12}Ca_{0.68}Mg_{0.20})$ $(Mg_{4.82}Al_{0.11}Fe^{3+}_{0.07})$ $(Si_{7.99}Al_{0.01})$ $O_{21.55}(OH_{1.88}F_{0.51})$. Low indices of refraction, $n\alpha' = 1.576$ to 1.596, $n\gamma' = 1.590$ to 1.600, are probably related to the presence of fluorine and the low Ca and Fe contents. EDAX indicates that their variability is related to Na, K, Ca, and Mg contents. In composition, this asbestos probably ranges from a potassian richterite to a potassian winchite. The asbestos habit is here well developed: fibers are composed of fibrils 200 to 400 A wide, oriented with c axes parallel, but with no preferred orientation of a and b. This fibril-bundle structure explains the optical properties of parallel extinction and anomalous interference figures. This asbestos is considered a product of low-temperature metasomatism of a siliceous dolomite. The chemical and physical characteristics described here are consistent with this interpretation.

OP 29–80. Electrical Energy Required to Cut and Deliver Coal Out of a Continuous Miner Section, by George J. Conroy and James H. Green. Trans. Soc. Min. Eng., AIME, v. 266, 1980, pp. 1929–1935. Results of a long-term program of electrical parameter measurements in underground coal mine working sections, performed by the Pennsylvania State University under Bureau of Mines sponsorship, are utilized as the basis for an analysis of the electrical energy requirements during operation. A model section is hypothesized, developed from the average or most representative characteristics as determined from tabulations of the measurements. Performance factors of the model section's machine complement are then analyzed, particularly with regard to the energy required per ton of raw coal cut and delivered from the section. Results are given in kilowatt-hours per ton.

OP 30–80. Gearing Up To Control Trace Elements During Mineral Processing, by Thomas A. Henrie. Min. Cong. J., v. 66, No. 4, April 1980, pp. 18–20. Gearing up to control trace elements during mineral processing involves obtaining all the information available about the operations of the various processors. This Bureau of Mines paper describes the need for precise terms and methodology needed for trace minerals, the environmental impact of polutants not documented, a matrix to identify problems, properties of chemical compounds and how they differ from component elements, and the confusion in assessing the need for environmental controls. The paper also describes why it is important for processors to know about the compounds at each step and how they can add body to existing knowledge.

OP 31–80. A Transient Dust-Flame Model: Application to Coal-Dust Flames, by Edward J. Kansa and Henry E. Perlee. Combust. Flame, v. 38, 1980, pp. 17–36. A transient model of dust combustion is presented in which processes such as solid pyrolysis, gaseous combustion, solid-gas combustion, radiation transport, mass and thermal diffusion, and convection have been considered. It is assumed that each dust particle and its immediate-gaseous envelope do not influence their nearest-neighboring similar systems. Application of this model to coal dust-air mixtures yields results in good agreement with the experimental observations of other researchers.

OP 32–80. Vegetative Stabilization Tests on an Acidic Copper Tailing, by W. R. McDonald and M. B. Shirts. Pres. at SME-AIME Fall Meeting and Exhibit, Tucson, Ariz., Oct. 17–19, 1979, SME Preprint 79–321, 8 pp. The Bureau of Mines conducted field tests on acidic copper tailing as part of its program to devise, improve, and demonstrate technology for stabilizing mining and mineral processing wastes. Results are presented from successful 1/8- and 1-1/2-acre demonstration revegetation plots established in 1973–74 on an abandoned copper tailing pond located on public land adjacent to Holden Village, Wash. The tailing was neutralized with treatments of either dolomitic lime or limerock and fertilized with processed sewage sludge and/or commercial fertilizer. Plant growth covering 60 percent of the surface was achieved on both test plots. Regar brome, Tegmar intermediate wheatgrass, and tall wheatgrass provided the best plant growth and surface coverage. In neutralizing the tailing, the pH of 6.8 was not achieved; however, good plant growth occurred in areas where the pH ranged from 2.9 to 5.8.

OP 33–80. Preparation of Specialty Ferrochromium (9 Wt. %C) From a Domestic Chromite, by Philip E. Sanker, Ralph H. Nafziger, and George H. Reynolds. J. Metals, v. 32, No. 1, March 1980, pp. 49–52. An example of studies by the Bureau of Mines to develop technology to tap domestic sources of critical minerals is presented. Ferrochromium containing 62.5 wt-pct Cr and 9.1 wt-pct C was produced from a domestic chromite using an open-bath technique in an electric furnace. The high-carbon ferrochromium product in powder form was successfully tested in fusion welding processes for hardfacing.

OP 34–80. Dewatering Fine-Particle Suspensions With Direct Current, by Richard H. Sprute and Dennis J. Kelsh. Pres. at Soc. Min. Eng., AIME, Meeting, Las Vegas, Nev., Feb. 24–28, 1980; proc. Fine Particles Processing Symp., American Institute of Mining, Metallurgical, and Petroleum Engineers, Inc., New York, v. 2, ch. 91, May 1980, pp. 1828–1844. Slow-setting, fine-grained suspensions can often be dewatered and densified by applying direct current between buried electrodes. Although water removal rates and power expenditures depend on physical and chemical properties of the treated slurries, metal mine tailings from Idaho, Colorado, and Mexico have responded well in laboratory testing, as have 29 samples of ultrafine coal waste from

mines in nine States. This Bureau of Mines report reviews field tests at two Idaho metal mines and describes the recent installation at the Henderson molybdenum mine near Empire, Colo., and the treatment of coal sludge at a Clinchfield Coal Co. preparation plant near Dante, Va.

OP 35–80. Underground Mine Evacuation Plans Analyzed by Computers, by Douglas Tesarik, David Nicholson, and A. B. Boghani. Mine Safety and Health, Mining Safety and Health Administration, v. 4, No. 5, October-November 1979, pp. 14–16. The most important element in escaping from an underground mine during fires and other emergencies is an effective evacuation strategy and plan. The Bureau of Mines has developed a computer program to evaluate and construct mine evacuation procedures and plans. The paper illustrates the program's application for practical use by the mining industry.

OP 36–80. ROPS Field Performance—A Status Report, by Jack L. Woodward and Stephen Swan. Pres. at Earthmoving Industry Conf., Central Illinois Section, Peoria, Ill., Apr. 14–16, 1980; SAE Tech. Paper 800679, 9 pp. The question, "Are ROPS providing adequate operator protection?" is addressed by conducting analyses of rollover accidents and reviewing ROPS certification test data. It was found that ROPS generally exceed structural performance requirements and do reduce the number of injuries and deaths due to rollovers on mining and construction machines. It was also determined that the severity of rollovers vary widely between different types of machines, that quality control during ROPS fabrication is very important, and the chances of surviving a rollover are enhanced substantially by wearing a seat belt.

OP 37–80. Drilling Long Horizontal Coalbed Methane Drainage Holes From a Directional Surface Borehole, by William P. Diamond and David C. Oyler. Pres. at SPE/DOE Symp. on Unconventional Gas Recovery, Pittsburgh, Pa., May 18–21, 1980, SPE Preprint 8968, pp. 341–346. Three primary horizontal methane drainage holes totaling 2,428.4 meters (7,967 feet) have been completed in the Pittsburgh coalbed from a directional surface borehole. Directional control and sidetracking techniques developed during the project increased the horizontal drilling rate from 24.4 meters (80 feet) per day initially to 64.9 meters (213 feet) per day on the third horizontal hole. Drilling data indicate that horizontal holes can be drilled substantially longer than the maximum 977 meters (3,207 feet) achieved.

OP 38–80. Influence of Coalbed Characteristics and Geology on Methane Draining, by Gerald L. Finfinger, Leonard J. Prosser, Jr., and Joseph Cervik. Pres. at SPE/DOE Symp. on Unconventional Gas Recovery, Pittsburgh, Pa., May 18–21, 1980, SPE Preprint 8964, pp. 319–324. Methane drainage in advance of mining using horizontal holes continues to expand. Interpretation of coalbed characteristics and geology in relation to drilling procedures and gas flows will provide additional information for further development of this technique. A study conducted in the Pittsburgh coalbed at Bethlehem Mines Corp., Marianna mine 58, showed the effect of coalbed discontinuities, such as clay veins and sandstone channels, on drilling of horizontal boreholes, and on gas flows. It has shown the need to adapt drilling techniques to the varying degrees of hardness encountered within the same coalbed.

OP 39–80. Ilmenite Reduction by a Carbon Injection Technique, by R. H. Nafziger and R. R. Jordan. 37th Electric Furnace Conf. Proc., AIME, Detroit, Mich., Dec. 4–7, 1979, v. 37, July 1980, pp. 178–189. Declining domestic reserves of high-grade ores have stimulated interest in the efficient use of more plentiful materials such as ilmenites and titaniferous magnetites for the production of pigment-grade TiO_2 and raw materials for steelmaking operations. Materials containing high levels of TiO_2 cannot be used in blast furnace operations, owing to the formation of titanium carbide and/or nitride. These deposits increase the viscosity of the slag so that reduction reactions occur with difficulty. Success was achieved by reducing titaniferous materials in an electric-arc furnace under carefully controlled conditions. Traditionally, the preparation of charge materials for the reduction of titaniferous ores and concentrates in an electric-arc furnace was accomplished either by mixing the carbonaceous reductant with the charge or by pelletizing the reductant with the ore. In most cases, carbon utilization ranging from 29 to 39 pct were realized when coke was used with or without woodchips. Reserves of domestic coking coals were limited. Therefore, use of alternate byproduct or readily available reductants should be encouraged. In addition, conventional techniques for adding carbonaceous reductants to electric-arc furnaces often result in undesirable environmental degradation.

OP 40–80. Methane Drainage From the Mary Lee Coalbed, Alabama, Using Horizontal Drilling Techniques, by John H. Perry, Leonard J. Prosser, Jr., and Joseph Cervik. Pres. at SPE/DOE Symp. on Unconventional Gas Recovery, Pittsburgh, Pa., May 18–21, 1980, SPE Preprint 8967, pp. 335–340. The Bureau of Mines has developed several techniques for draining methane from coalbeds in advance of mining. Drilling long horizontal holes from an underground location is one of these techniques which has been successfully demonstrated in the Pittsburgh and Sunnyside coalbeds. A similar project was successfully conducted in the Mary Lee coalbed at Jim Walter Resources Inc., No. 4 mine. In a year about 1.13 million m^3 (40 MMcf) of methane was recovered from the coalbed.

OP 41–80. Completion Techniques and Production Data From Vertical Methane Drainage Boreholes, Jawbone Coalbed, Dickenson County, Virginia by Peter F. Steidl, Michael A. Trevits, and William P. Diamond. Pres. at SPE/DOE Symp. on Unconventional Gas Recovery, Pittsburgh, Pa., May 18–21, 1980, SPE Preprint 8965, pp. 325–328. Five vertical methane drainage boreholes have been completed in the Jawbone coalbed at the Clinchfield Coal Co. McClure No. 1 mine in Dickenson County, Va. Foam stimulation treatments were used to increase gas production from the boreholes. After 15 months the cumulative gas production from the first hole was 310,000 cu m (11 MMcf) with production averaging 700 cu m/d (25,000 cu ft/d).

OP 42–80. Determining the Feasibility of Using Vertical Boreholes to Drain Gas From the Pocahontas No. 3 Coalbed, Buchanan County, Va. by Michael A. Trevits, Walter L. Richards, and Hilmar A. Von Schonfeldt. Pres. at SPE/DOE Symp. on Unconventional Gas Recovery, Pittsburgh, Pa., May 18–21, 1980, SPE Preprint 8966, pp. 329–334. In July 1979, a project was established to determine the feasibility of using vertical boreholes to degasify the Pocahontas No. 3 coalbed in advance of mining. To date, three

methane gas drainage boreholes have been completed near the Virginia Pocahontas No. 5 mine in Buchanan County, Va. Various coalbed reservoir tests and in situ stress determinations have been performed. Hydraulic stimulation treatments were designed and implemented at two boreholes, followed by preliminary gas and water production testing.

OP 43–80. Influence of Graphite Morphology on the Damping Properties of Selected Cast Iron Structures, by A. Visnapuu, B. A. Betts, and L. A. Neumeier. 37th Electric Furnace Conf. Proc., AIME, Detroit, Mich., Dec. 4–7, 1979; July 1980, pp. 304–306. Increasing attention has been directed toward a need for better structural materials to reduce equipment noise in metallurgical and other industries in compliance with imposed noise restrictions. One of the goals of the Bureau of Mines is to minimize the undesirable environmental conflicts, impacts, and occupational hazards associated with mining and mineral processing operations. Toward this goal, the Bureau of Mines has investigated damping and other properties of experimental cast irons. It was shown that damping capacity and toughness intermediate to high-damping, brittle gray cast iron and low-damping, tough ductile cast iron can be installed in "hybrid" cast iron with a compacted graphite structure intermediate to the flakes of gray cast iron and the nodules of ductile iron. Damping capacity of ductile iron can also be enhanced by hot working reduction. Comparative damping data are given for hybrid cast iron, conventional gray and ductile cast irons, and steels containing various amounts of carbon and subjected to a variety of heat treatments.

OP 44–80. Oil Mining, by Richard A. Dick and Sheldon P. Wimpfen. Sci Am., v. 243, No. 4, October 1980, pp. 156–161. Conventional drilling and pumping removes less than half of the oil in an average petroleum reservoir. As the price of oil rises, mining it underground or at the surface becomes economically more attractive. This report discusses the size of this potential resource and methods for its recovery.

OP 45–80. Diffraction Jig for Philips Electronics Diffractometers, by Charles W. Huggins and Stephen D. Cramer. Norelco Rep., v. 27, No. 1, April 1980, p. 40. An X-ray diffraction jig for use on Philips electronics diffractometers was designed and fabricated at the Avondale Research Center primarily for use on corrosion research using 3/8-in-diam metal electrodes that were covered with corrosion films and geothermal scales. The jig was constructed of an aluminum alloy and will handle a variety of sample sizes and shapes up to 1.5 by 2.0 cm. The jig dimensions and a sample illustration are given in the paper.

OP 46–80. Thermal Decomposition of Monomethylamine Nitrate, by Yael Miron. J. Hazardous Mater., Elsevier Scientific Publishing Co., Amsterdam, the Netherlands, v. 3, 1980, pp. 301–321. Monomethylamine nitrate (MMAN), was used during World War II as an ingredient for bomb and shell loading. Now it is used as a component in some water gel formations. Knowledge of its dissociation and/or decomposition mode would be desirable, but none was found in the open literature. MMAN decomposition was observed through differential scanning calorimetry, thermogravimetric analysis, and mass spectrometry. The effect of small amounts of iron oxide, rust, and copper on MMAN decomposition was also assessed. These compounds have shown catalytic activity in the decomposition of ammonium and hydrazine nitrates.

OP 47–80. The Bureau of Mines Shaft and Research Facility in the Oil Shales of Colorado, by Stephen Utter. Pres. at 83d National Western Min. Conf., Denver, Colo., Feb. 6–8, 1980; pub. in 1980 Mining Yearbook. Colorado Mining Association, Denver, June 1980, pp. 164–170. As part of a program to assess the environmental problems that would attend the mining of oil shale, the Bureau of Mines blind-bored a 10-ft-diam shaft to a depth of 2,371 feet in the Piceance Creek Basin and installed an 8-ft-diam steel casing to a depth of 2,352 feet. This pioneer shaft penetrates two aquifers, the rich Mahogany oil shale zone, and virtually the full thickness of oil shale and accessory minerals in the Parachute Creek member of the Green River Formation. A surface plant consisting of a headframe, hoist, and support facilities was erected, and the shaft was equipped with hoisting, ventilating, pumping, and service systems. Cutouts or windows were made in the shaft lining, and stations were opened on the 1,844- and 2,079-foot levels. A 10- by 10-foot entry was driven on the 2,079-foot level, and bulk samples of oil shale, dawsonite, and nahcolite were mined for processing tests. Problems with methane gas and ground water were encountered, and grouting was required.

OP 48–80. Environmental Assessment of an Oil Shale Installation, by Stephen Utter. Proc. 6th Ann. UMR-DNR Conf. on Energy, Rolla, Mo., Oct. 16–18, 1980, v. 6, pp. 481–485. The Bureau of Mines constructed a research facility in the oil shale deposits of the Piceance Creek Basin in northwestern Colorado. The purpose of the installation is to identify the environmental effects that could be expected from future commercial oil shale mines and to develop technology needed to resolve or mitigate environmental problems. This report describes the installation, outlines the research program for which the environmental assessment was made, and presents the findings of the assessment.

OP 49–80. W Recovery From Searles Lake by Ion Exchange, by P. B. Altringer and P. T. Brooks. Tungsten News, v. 18, No. 3, Summer 1980, pp. 3–4. An effective ion exchange operation to remove tungsten from Searles Lake brines using a pilot unit that has been operating since July 1979 at the Kerr-McGee Corp., Trona, Calif., is described. The extractive technique, developed by the Bureau of Mines, is based on a new tungsten-selective resin designated QRF. The objectives of the investigation includes (1) proving the operational viability during seasonal changes in brine properties, (2) providing a tungsten-rich solution to enable completion of tungsten recovery research, and (3) supplying data for system escalation to enable recovering nearly 227,000 kg per year of tungstic oxide.

OP 50–80. Theoretical Evaluation of Radon Emanation Under a Variety of Conditions, by John C. Edwards and Robert C. Bates. Health Phys., v. 39, August 1980, pp. 263–274. A cylindrical coordinate mathematical model to calculate ^{222}Rn flux and movement was developed considering ^{222}Rn production, decay, and diffusion in a multilayered, porous, permeable matrix. Air movement, transporting radon through the media, satisfies Darcy's law and is influenced by the air (barometric) pressure applied at the surface. Two zones of porous material have been defined, one with ^{222}Rn production term (the uranium ore zone) and the other without this

term to simulate shotcrete or concrete ground support. A provision is made to evaluate the effect of a pinhole in an otherwise impermeable sealant. Comparisons are made between field measurements and predicted values. Specific examples are given of ^{222}Rn losses through pinholes for cases of linearly varying and static barometric pressures. The results suggest factors to consider in uranium mine radon control. For example, pinholes are not a serious problem since it appears that several thousand 2-mm-diam pinholes per square meter are required to cause a significant loss of a barrier coating's effectiveness.

OP 51–80. Consolidation of Industrial Clay Wastes, by B. J. Scheiner, J. R. Zatko, and A. G. Smelley. Proc. Environmental Symp. '80, New Orleans, La., Apr. 7–10, 1980, pp. 477–486. The Bureau of Mines is developing a dewatering technique for phosphatic clay slime waste produced in Florida phosphate facilities. The technique consists of mixing the slime waste with a flocculant, polyethylene oxide, and dewatering the resulting agglomerate on a rotary screen. Slimes containing a nominal 3 wt-pct solids have been dewatered to solids contents of 20 to 30 pct. This paper describes a series of laboratory investigations applying the Bureau-developed dewatering technique to a variety of ultrafine waste materials.

OP 52–80. Thermodynamic Properties of $KAlO_2$, by R. P. Beyer, M. J. Ferrante, and R. R. Brown. J. Chem. Thermodynamics, v. 12, 1980, pp. 985–991. As part of a goal to advance mineral technology, to reduce energy use, and to abate pollution, the Bureau of Mines generates thermodynamic quantities on various minerals and metals. This study on potassium aluminate was undertaken to further this aim. Although of possible importance to the cement and ceramic industries, the current interest in potassium aluminate is its role in magnetohydrodynamic (MHD) power generation. Potassium, in the form of a seed material used to enhance the electrical conductivity of the high-temperature MHD generator plasma, reacts with alumina. Alumina is a major constituent of coal slag and a material of construction in MHD power generators. A better understanding of the potassium and alumina interaction will help with the problems of corrosion, seed material recycling, etc.

OP 53–80. Testing and Development of Materials for Catalytic Coal Gasification Process Equipment, by H. Heystek and N. S. Raymon. Proc. 5th Ann. Conf. on Materials for Coal Conversion and Utilization, Gaithersburg, Md., Oct. 7–9, 1980, pp. IV-1—IV-7. Catalytic coal gasification (CCG), one of the most promising third generation coal conversion processes, is based on reaction of coal and steam in the presence of an alkali metal catalyst to achieve high production of methane at a rate equivalent to second generation high British thermal unit process, but at lower temperatures and pressure. Additional advantages include reduced energy requirements, the elimination of a separate methanation reactor, and the ability to process caking coals. At present, few data are available to aid in selecting metal and refractory materials for reliable, low-cost services under the conditions prevailing in the CCG reactor itself. The objectives of this research are to determine the effect of CCG environments on metal and refractory materials of construction by exposure to CCG reactor conditions in a laboratory simulator and to identify the attack mechanisms of CCG environments on metals and refractories so that materials offering improved performance at lower cost can be identified.

OP 54–80. Retreatment of Tailings To Recover Barite, by W. E. Lamont, E. G. Davis, and G. V. Sullivan. Proc. 7th Miner. Waste Utilization Symp, Chicago, Ill., Oct. 20–21, 1980, pp. 26–33. The feasibility of recovering barite by retreatment of tailings was demonstrated in investigations by the Bureau of Mines. The investigation was part of the Bureau's program to conserve domestic mineral resources through advancing mineral resources technology. A primary objective was to produce concentrates that would be suitable for use in oil well drilling mud applications. Two samples of tailings were received from Nevada that represented the fine and very fine fractions of waste from an operating plant. Concentrates containing over 96 pct $BaSO_4$ were readily obtained from each. Barite recovery was 96 pct for the fine tailings and 86 pct for the very fine tailings. Treatment of a low-grade Missouri tailing by sizing and flotation resulted in a concentrate containing 96 pct $BaSO_4$ and an 86 pct recovery of the barite. A Georgia material responded in similar fashion with the concentrate containing 97 pct $BaSO_4$ and a barite recovery of 82 pct. All flotation concentrates had specific gravities in excess of the 4.20 specification for drill mud applications.

OP 55–80. Cobalt and Nickel Recovery From Missouri Lead Ores, by D. L. Paulson, W. M. Dressel, and R. M. Doerr. Proc. 7th Miner. Waste Utilization Symp., Chicago, Ill., Oct. 20–21, 1980, pp. 127–134. In its continuing effort to improve the utilization of domestic resources, the Bureau of Mines is developing procedures to recover up to 2.5 million pounds of cobalt and 3.5 million pounds of nickel lost annually in processing Missouri lead ores. The procedures include a physical method for producing a Co-Ni enriched product from a commercial lead mill Pb-Cu flotation rougher concentrate and a hydrometallurgical process for treating the enriched product and/or Co-Ni bearing lead smelter mattes and drosses. In the physical separation process, the Pb-Cu rougher concentrate is separated by wet high-intensity magnetic separation and the magnetic fraction (chalcopyrite concentrate) is reground and floated to produce a high-grade copper concentrate and a tailing product containing over 3.5 pct cobalt and 5 pct nickel. In the hydrometallurgical process, both the Co-Ni bearing tailing product and lead smelter mattes are leached with manganese dioxide and sulfuric acid to obtain cobalt, nickel, copper, lead, manganese sulfates, and elemental sulfur. At 85° to 100° C, the cobalt, nickel, and copper are solubilized as sulfates leaving a residue of $PbSO_4$, sulfur, and gangue. The residue can be returned to a smelter for lead recovery and the soluble metals are recovered from the leach solutions by caustic purification (removal of arsenic and iron) and sequential sulfide precipitations. The products are copper sulfide (62 pct copper) and Co-Ni sulfide (up to 50 pct combined cobalt and nickel). The manganese is reclaimed from the leach liquor as manganese oxide to be used for recycling.

OP 56–80. Surface Charge Heterogeneity in Amphibole Cleavage Fragments and Asbestos Fibers, by Joseph E. Schiller, Sequoyah L. Payne, and Sanaa E. Khalafalla. Pres. at ACS National Meeting, Washington, D.C., Sept. 9–14, 1979; pub. in Science, v. 209, Sept. 26, 1980, pp. 1530–1532. Aspect ratio and electrophoretic mobility data for amphibole particles reveal that short fibers and blocky cleavage

fragments have a smaller net change than highly elongated particles. Asbestos fibers and cleavage fragments of the same dimensions exhibit the same net negative surface charge but positively charged ends and negatively charged lateral surfaces.

OP 57–80. Time-Dependent ^{222}Rn Samples Loss From Small Samples, by Robert C. Bates. Health Phys., v. 39, November 1980, pp. 799–801. A research plan was prepared to measure the effect of moisture on the ^{222}Rn emanation coefficient in small uranium ore samples. One version of the plan called for the sealed can to be counted after a long storage and then opened to let the free radon escape. However, a question arose about the information on many emanation coefficient measurements (for example, Ha36, Ki32, Sh70, St57, and Wa51). Reported values for ^{219}Rn, ^{220}Rn, and ^{222}Rn generally differ by less than a factor of 10, which is considerably less than expected from linear diffusion theory (1, 3.7, 290, for ^{219}Rn, ^{220}Rn, and ^{222}Rn, respectively) (Ta78). This small difference suggests that radon escape is very rapid, and hence the steady-state flux might be reached within tens of seconds. None of the papers, however, specifically address the question; therefore, the Bureau of Mines performed the analytical study reported in this note.

OP 58–80. Challenges of the 1980's From the Perspective of the U.S. Bureau of Mines, by Ralph C. Kirby and Donald G. Kesterke. Proc. 8th Ann. Min. and Met. Div. Symp. and Exhibit, Phoenix, Ariz., May 14–16, 1980 (pub. as Instrumentation in the Mining and Metallurgy Industries), v. 7, pp. 19–26. This paper covers some of the underlying factors and forces that will shape the mining and metallurgical industries during the 1980's. The discussion includes what the Bureau of Mines plans to do about these forces and the Bureau's present reaction.

OP 59–80. Industrial Wastes, by S. L. Law. McGraw Hill Encyclopedia of Environmental Science. McGraw-Hill Book Co., Inc., New York, 2d. ed., 1980, pp. 387–396. Approximately 334 million metric tons of industrial processing residues are generated annually with 10 to 15 percent being classified as hazardous by the U.S. Environmental Protection Agency. Problems arising from improper disposal of these wastes are discussed along with several highly publicized examples including Love Canal in Niagara Falls, N.Y., and Valley of the Drums in Stump Gap Creek, Ky. Hazardous wastes are broken down by geographic regions and by industry. Waste waters and gaseous wastes are discussed as well as solid wastes. Sections on waste recycling, waste exchange, waste disposal options, and industrial discharges to publicly owned treatment works are included.

OP 60–80. Adapting Conventional Sputtering Equipment for Coating Long Tubes and Strips, by R. L. Lincoln and R. Blickensderfer. J. Vac. Sci. Technol., v. 17, No. 5, September–October, 1980, pp. 1252–1253. A method for adapting conventional sputtering equipment to coat long tubes and strips was devised at the Albany (Oreg.) Research Center, Bureau of Mines. This research was part of an effort to meet the Bureau's goal of minimizing the need for critical minerals through conservation, using coatings of metals applied by techniques such as sputtering, cladding, or surface alloying.

OP 61–80. Water Recovery and Disposal of Clay Waste Slimes, by B. J. Scheiner and A. G. Smelley. Proc. 1980 Symp. on Surface Mining Hydrology, Sedimentology and Reclamation, Lexington, Ky., Dec. 1–5, 1980, pp. 249–253. As part of research conducted in its mission to effect pollution abatement, the Bureau of Mines is developing a dewatering technique that allows for disposal of mineral wastes, for reuse of water now lost with these wastes, and for reclamation of mined land. The technique utilizes a high-molecular-weight nonionic polyethylene oxide polymer that has the ability to flocculate and dewater materials containing clay wastes. A variety of different clay wastes have been successfully dewatered in laboratory experiments. Coal-clay waste was consolidated from 4 to 57 wt-pct, potash-clay brine waste from 20 to 62 wt-pct, phosphatic-clay waste from 16 to 49 wt-pct, uranium mill tailings from 15 to 67 wt-pct, and talc tailings from 10 to 53 wt-pct. The consolidated materials can be handled by mechanical devices such as trucks and conveyors for disposal in mined-out areas.

OP 62–80. Contact Filtration of Asbestos Fibers With Magnesium Oxide, by Joseph E. Schiller and Sanaa E. Khalafalla. Pres. at 109th AIME Ann. Meeting, Las Vegas, Nev., Feb. 24–28, 1980, SME Preprint 80–108, pp. 1–7 As part of its research on identification of asbestos fibers, the Bureau of Mines discovered a method to remove asbestos fibers from water. The process and its theory of operation is described in this report. The surface charge of amphibole minerals in potable water was negative and, in common with most other silicate minerals, the isoelectric point of amphibole asbestos fibers is in the pH range 4 to 6. Magnesia is one of the rare oxides with a high isoelectric point of about 11. The surface of magnesium oxide will be positively charged in water at pH 6 to 8, while the electric charge on amphibole asbestos fibers is negative. Because of the electrical attraction of these oppositely charged solids, it was possible to remove negatively charged asbestos fibers by percolating water that contained suspended asbestos through a porous bed of magnesium oxide particles. Scanning electron photomicrographs indicated that essentially complete removal of the fibers was accomplished. Other materials tested as contact filter media and found to be effective or partially effective were sand, calcite, carbon, diatomaceous earth, and cellulose. Acidic aluminum collected amphibole fibers but not chrysotile fibers.

1981

OP 1–81. Fire-Fighting Mini, by Donald N. H. Chi and Henry E. Perlee. Datamation Mag., September 1980, pp. 217–220. Research computer systems usually begin by filling several critical needs and then expand as demand develops among other groups in the laboratory. This paper describes the computer network used by the Bureau of Mines at the Pittsburgh Research Center in conducting and overseeing research related to health and safety in mines and in mine environmental technology.

OP 2–81. Preventing Frictional Ignitions, by Welby G.

Courtney. Coal Min. & Proc. J., v. 8, No. 1, January 1981, pp. 48–58. This article reviews the history of frictional ignitions in U.S. Coal mining operations, laboratory studies of the problem, and specific remedial measures that can be implemented by mine operators to alleviate the frictional ignition problems.

OP 3–81. Health and Safety, by Robert Marovelli. Compress. Air (subarticle in Coal's Future: The Experts' Views), v. 85, No. 10, October 1980, pp. 14–15. Since the oil embargo of 1974, there has been less growth in the demand and consumption of coal than previously forecasted. Concern about the importation of oil brought a strong move toward increasing the consumption of coal during 1974–77, and a large amount of coal mining equipment was sold. But the mining producers overbought equipment, and the slackening-off of the market has produced a significant amount of unused equipment. This article discusses how this slackening-off of the market has affected the coal industry and the advantages and disadvantages of expanding the coal industry in the United States.

OP 4–81. Cobalt: A Strategic and Critical Resource for Industrialized Nations, Supplied by Developing Nations, by Scott F. Sibley. Natural Resources Forum, United Nations, v. 4, No. 4, October 1980, pp. 403–413. In 1978, the world cobalt market was abruptly thrust into a state of great uncertainty, with soaring prices, limited supply, and accelerating demand. A critical shortage threatened to develop but never really materialized. However, this situation dramatized Western nations' vulnerability to supply disruption. A number of factors, including limited natural occurrence, unfavorable market conditions, and accelerating demand for cobalt, combined to bring about these unstable conditions.

OP 5–81. Field Stress Corrosion Tests in Brine Environments of the Salton Sea Known Geothermal Resource Area, by J. P. Carter and S. D. Cramer. Mater. Performance, v. 19, No. 9, 1980, pp. 13–16. Corrosion research is being conducted by the Federal Bureau of Mines to determine suitable construction materials for geothermal resource recovery plants. As part of this research, a 30-day stress corrosion test was conducted at the Salton Sea Known Geothermal Resource Area on seven iron- and nickel-base alloys in four brine and steam process streams using wellhead brine from geothermal well Magmamax 1. The tests showed transgranular cracking of AISI 316L stainless steel and intergranular and transgranular cracking of AISI 430 stainless steel in all four process streams. E-Brite 26–1 exhibited intergranular and transgranular cracking in three of the four process streams. Carbon steel, Inconel 625, and Hastelloys G and C-276 show no evidence of stress corrosion cracking.

OP 6–81. Coal Liquefaction, by Franklin D. Cooper. Encyclopedia of Energy, McGraw-Hill Book Co., Inc., New York, 2d ed., 1980, pp. 136–139. This article discusses four direct-liquefaction processes, two indirect-liquefaction processes, and developing third-generation processes. Also discussed are production constraints, prospects and issues, hydrogen for liquefaction processes, costs, and modifications of second-generation direct liquefaction processes.

OP 7–81. Corrosion in Geothermal Brines of the Salton Sea Known Geothermal Resource Area, by S. D. Cramer and J. P. Carter. Geothermal Scaling and Corrosion, ed. by L. A. Casper and T. R. Pinchback, ASTM STP 717, 1980, pp. 113–141. Corrosion research is being conducted by the Bureau of Mines to determine suitable construction materials for geothermal resource recovery plants. High chromium-molybdenum iron-base alloys, nickel- and titanium-base alloys, and titanium-zirconium-molybdenum alloy exhibited good resistance to general, crevice, pitting, and weld corrosion and stress corrosion cracking in laboratory tests in deaerated brines of the Salton Sea Known Geothemal Resource Area (KGRA) type at 232° C and in brine containing dissolved carbon dioxide and methane. Only titanium-base alloys were resistant to corrosion in oxygenated Salton Sea KGRA-type brine. Copper adversely affected the resistance to general corrosion of low-alloy steels in deaerated brine, whereas chromium, nickel, silicon, and titanium improved it. Carbon steel, type 4130 steel, and types 410 and 430 stainless steels exhibited poor corrosion resistance in field tests in five brine and steam process streams produced from geothermal well Magmamax 1. These alloys were highly susceptible to pitting and crevice corrosion. General corrosion rates were high for carbon and type 4130 steels.

OP 8–81. Eastern Cement Kiln Dust Characterization, by B. W. Haynes, S. L. Law, and J. A. Jolly. Met. Soc., AIME, TMS Paper Selection A81–39, February 1981, 10 pp. Cement kiln dust (CKD) is a waste product that accumulates at the rate of 12 million tons per year in the United States. In proposed hazardous waste guidelines in 1978, the Environmental Protection Agency (EPA) placed CKD in the "Special Wastes" category pending more information on the composition, characteristics, and degree of hazard posed by this waste. In 1980, the Special Wastes category was removed, but a 3-year study of the hazard potential of CKD has been proposed by EPA. An exploratory evaluation of the resource recovery potential and environmental effects of the metals present in the dust has been underway during this period at the Bureau of Mines Avondale Research Center. Results of the first phase of this research—CKD from the east coast—will be discussed including major, minor, and trace element concentrations; mineralogy; iron chromatographic and thermal information; and EPA hazardous waste leach test results.

OP 9–81. Surface Subsidence Due to Underground Longwall Mining in the Northern Appalachian Coal Field, by K. K. Kohli, S. S. Peng, and R. E. Thill. Pres. at SME-AIME Ann. Meeting, Las Vegas, Nev,, Feb. 24–28, 1980. SME Preprint 80–53, 8 pp. Since the adoption of the Surface Mining Reclamation and Control Act of 1977 there has been a sudden rise in demand on guidelines for minimizing surface subsidence and its associated structural damages. A 10-month survey resulted in a collection of surface subsidence surveys that was conducted by coal companies in the Northern Appalachian coal field over the past 20 years. This paper presents the preliminary results of the longwall subsidence data

OP 10–81. Vibration and Air Blast Noise From Surface Coal Mine Blasting, by Patrick Linehan and John F. Wiss. Pres. at SME-AIME Fall Meeting and Exhibition, Minneapolis, Minn., Oct. 22–24, 1980, SME Preprint 80–336, 6 pp. Vibration and air blast noise from blasting were evaluated during a research program sponsored by the Bureau of Mines. Blast variables were studied using small-scale model tests to evaluate specific variables as well as interactive effects, followed by experiments

with production blasts at the surface coal mines. Experimental data showed that the primary variables affecting the ground vibration amplitude are the charge weight per delay and the length of the delay interval. Blast variables with a significant affect on the overpressure amplitude include the charge weight per delay, the length of the delay, burden and spacing, stemming amount and type, direction of initiation, charge depth, and amount of detonating cord and cover.

OP 11–81. Dust Control Systems, by John N. Murphy. Proc. 3d Ann. Min. Institute, University of Alabama, Apr. 15–17, 1980, 30 pp. This paper presents an overview of the Bureau of Mines Respirable Dust Control Program. Completed and ongoing developments in the areas of dust generation, ventilation, scrubbers, personal protection, and instrumentation are discussed.

OP 12–81. Damage to Residential Structures From Surface Mine Blasting, by David E. Siskind. Pres. at SME-AIME Fall Meeting and Exhibition, Minneapolis, Minn., Oct. 22–24, 1980, SME Preprint 80–362, 17 pp. The Bureau of Mines has studied the problem of cracking in residential structure walls from vibrations produced by blasting in surface mines. Direct observations were made of blasting damage consisting primarily of cosmetic cracking in plaster and gypsum board walls. Measurements of structure response and also application of the response spectra analysis single-degree-of-freedom model were used to quantify the frequency dependence of the safe level criteria. An overall summary analysis was performed and data obtained from nine previous studies, including the three analyzed earlier by the Bureau for Bulletin 656 published in 1971. Separate analysis of the high- and low-frequency damage cases, structural response, and two types of construction resulted in the establishment of safe vibration levels ranging from 12 mm/sec to 50 mm/sec (0.5 in/sec to 2.0 in/sec).

OP 13–81. Hypothetical Mine Models and Input-Output Requirements for Copper-Nickel Mining in Minnesota, by David L. Veith. Pres. at SME-AIME Fall Meeting and Exhibition, Minneapolis, Minn., Oct. 22–24, 1980, SME Preprint 80–330, 21 pp. As the basis for the State of Minnesota's Regional Copper-Nickel Study environmental evaluation, hypothetical mine models were developed ranging in ore capacity from 5.35 to 2.00 x 10^6 mtpy. Open pit and underground mining operations were defined utilizing conventional methods of ore extraction. Processing of the copper-nickel sulfide material involved conventional bulk flotation of the valuable minerals, with maximum water recycle and tailing disposal. Flash smelting and electrolytic refining of the concentrate resulted in 0.10 x 10^6 mtpy copper plus nickel metal, plus associated cobalt and precious metals. Variations in model parameters allowed environmental trade-offs to be identified.

OP 14–81. Seepage Through Partially Saturated Soils Below a Uranium Tailings Pond, by E. G. Zahl and G. L. Bloomsburg. Proc. 1st Internat. Conf. on Uranium Mine Waste Disposal, Vancouver, British Columbia, Canada, May 19–21, 1980; American Institute of Mining, Metallurgical, and Petroleum Engineers, Inc., New York, ch. 30, December 1980, pp. 445–455. A finite-element computer program, UNSAT2, that simulates unsaturated flow is described and applied to a tailings pond near East Gas Hills, Wyo. Information necessary to run the program are tables of relative conductivity versus moisture content and capillary pressure versus moisture; porosity and saturated conductivity; and initial pressures, boundary conditions, and spatial coordinates for each nodal point. A 10-year simulation is made of the tailings pond based on existing field data and assumptions and interpolations where field data are lacking. The final phreatic surfaces through the cross section are similar but higher than measured values, probably due to limitations in assigning boundary conditions. UNSAT2 program results simulate actual conditions much better than saturated flow analysis. Limitations of applying the program to typical tailings ponds are lack of historical data, cost, and difficulty in obtaining representative data to determine relative conductivity—capillary pressure—moisture content relationships, and assigning realistic boundary conditions compatible with the program. Further work on the program could make it an effective method of analyzing flow beneath new, properly instrumented, tailings ponds.

OP 15–81. An Overview of Materials and Corrosion in Geothermal Systems, by J. P. Carter, S. D. Cramer, and R. K. Conrad. Pres. at Energy-Sources Technol. Conf. and Exhibition, New Orleans, La., Feb. 3–7, 1980 (pub. in Materials and Corrosion Problems in Energy Systems, ed. by W. J. Lochmann and M. Indig), pp. 17–1—17–10. For the past several years the Bureau of Mines has been involved in the development of the geothermal mineral resources of the Imperial Valley, Calif. The brines produced from geothermal reservoirs in this area are extremely corrosive. Furthermore, the brines readily form complex scales during processing that complicate the corrosion process and interfere with process operations. This paper presents examples of corrosion and materials problems encountered at some of the major geothermal systems presently being developed.

OP 16–81. Infrared Pyrometers for Measuring Dust Explosion Temperatures, by K. L. Cashdollar and M. Hertzberg. Modern Utilization of Infrared Technol. VI, SPIE, v. 253, 1980, pp. 254–260. This paper describes the design of two infrared optical pyrometers used to study dust explosions. One is a six-wavelength pyrometer that can measure both dust particle temperature and gas temperature by observing continuum and gas band emission in the 1- to 5-μm infrared region using PbSe detectors. The second pyrometer measures particle continuum emission in the 0.8- to 1.0-μm region of the near infrared using Si detectors. Temperature data are presented for both laboratory- and full-scale mine explosions.

OP 17–81. The Corrosion Behavior of Niobium in Hydrochloric Acid Solutions, by B. S. Covino, Jr., J. P. Carter, and S. D. Cramer. Corrosion, v. 36, No. 10, October 1980, pp. 554–558. Studies to better understand the corrosion behavior of niobium in hydrochloric acid solutions have been conducted as part of the Bureau of Mines effort to conserve mineral resources in the United States. A study of the general corrosion behavior of niobium as a function of acid concentration, time, oxygen, and added ferric ion is reported. Weight loss (corrosion) tests were performed in air saturated (agitated and static) and helium saturated (agitated) hydrochloric acid solutions ranging from 1*N* to 10*N* at temperatures from 35° to 100° C and exposures up to 60 days. The 30-day corrosion rates ranged from

0.0 μm/y in 35° C air saturated (agitated) 1*N* HCl to 230 μm/y in air saturated (static) 9.8*N* HCl at 85° C. Although the corrosion rates decreased rapidly for times up to 30 days, the rates for 30 and 60 days were essentially identical. The presence of air did not affect the corrosion rate of niobium, while the presence of only 70 ppm of ferric ion reduced the corrosion rate in most air saturated 5*N* and 10*N* HCl solutions.

OP 18–81. An Overview of Sulfur-Extended Asphalt Usage, by W. C. McBee, T. A. Sullivan, and D. Saylak. Pres. at FAA Eastern Region Airport Eng. Seminar, Hershey, Pa., Mar. 3, 1980; pub. in Asphalt Pavement Construction: New Materials and Techniques, ed. by J. A. Scherocman, ASTM STP 724, pp. 39–63. Interest in the use of sulfur in highway pavement construction has been stimulated by unpredictable increases in cost and by uncertainty as to the future availability of asphalt cement as a result of the current "energy squeeze." As a consequence, bid prices for asphalt cement, which have almost tripled over the past 3 years, are expected to rise even more. Recent studies and experimental field tests have shown that sulfur can, under certain circumstances, replace as much as 35 vol-pct of the asphalt cement used in asphaltic concrete mixes. The unique properties of sulfur, both alone and when blended with asphalt, have also shown potential for use in recycling old bituminous pavements. This paper attempts to put into perspective the state-of-the-art in design, preparation, placement, and performance evaluation of sulfur-extended asphalt (SEA) pavement mixtures. Various methods of binder preparation are discussed and, where possible, compared on the basis of their physical and engineering properties. The status of three domestic experimental field trials utilizing these methods is reviewed. The potential use of SEA binder to recycle old bituminous pavements is also presented. Theoretical in-service performance predictions of SEA pavement materials are compared with conventional asphalt cement on the basis of their rutting potential, resistance to cracking, slope variance, and serviceability index. Finally, recommendations for future work are discussed.

OP 19–81. Electrochemical Determination of Thermodynamic Properties of Molybdenite (MoS_2), by S. C. Schaefer and N. A. Gokcen. High Temp. Sci., v. 12, 1980, pp. 267–276. As part of the Bureau of Mines effort to provide thermodynamic data for the advancement of mineral technology, thermodynamic properties of molybdenite (MoS_2) were determined with high-temperature galvanic cells employing stabilized zirconia as the electrolyte.

OP 20–81. Recovery of Molybdenum and Rhenium From Concentrates by an Electrooxidation-Solvent Extraction—Carbon Adsorption Technique, by B. J. Scheiner and D. L. Pool. Pres. at Internat. Cong., Inst. Min. Eng., Santiago, Chile, Nov. 23–29, 1980; Anales Congr. Cincuentenario Min. Cobres Porfidicos, v. 2, pp. 122–148. The Bureau of Mines has demonstrated an electrooxidation-solvent extraction-carbon adsorption technique for recovering molybdenum and rhenium from offgrade concentrates in a process research unit (PRU) operating at a feed rate of 3.4 to 4.7 lb of concentrate per hour. The flow sequence consists of metal values by electrooxidation, liquid-solid separation by thickening, acidification and chlorate ion removal by sulfur dioxide treatment, solvent extraction to concentrate the molybdenum and rhenium, separation of molybdenum and rhenium by carbon adsorption, and metal recovery by crystallization. Molybdenum and rhenium were recovered as ammonium paramolybdate and ammonium perrhenate. Based on PRU results, an industrial-sized cell was constructed and tested for extraction of metal values from offgrade molybdenite concentrates.

OP 21–81. Dewatering of Thickened Phosphate Clay Waste From Disposal Ponds, by B. J. Scheiner and A. G. Smelley. Pres. at AIME Ann. Meeting, Chicago, Ill., Feb. 21–26, 1981, TMS Paper Selection A81–6, 9 pp. The Bureau of Mines, as part of its mission to effect pollution abatement, conducted research to develop a technique for dewatering phosphate clay waste from disposal ponds. Phosphate clay waste was dewatered from 11.8 pct to greater than 20 pct solids using 0.53 lb of polyethylene oxide (PEO) per ton of dry solids. Dewatering was accomplished by mixing the clay waste with PEO and treating the resulting flocs on a static screen followed by further treatment on a rotating trommel screen. Discharge from the trommel screen, when placed in a column 23 inches in diameter and 11 feet in height, continued to dewater to greater than 28 pct solids in 90 days.

OP 22–81. Methanol Synthesis Catalysts From Thorium-Copper Intermetallics. Preparation and Evaluation, by Elizabeth G. Baglin, Gary B. Atkinson, and Larry J. Nicks. I&EC Prod. Res. and Develop., v. 20, No. 1, March 1981, pp. 87–90. Bureau of Mines research into the use of intermetallic compounds as catalytic materials has shown catalysts prepared from binary alloys of copper and thorium to be active for the synthesis of methanol from carbon monoxide and hydrogen. Activation of the alloys resulted in oxidation of the thorium yielding high surface area catalysts containing copper interspersed on thoria. For example, catalysts prepared from $ThCu_x$ alloys by air oxidation at 400° C had surface areas as high as 35 m^2/g and produced up to 6.7 times as much methanol as a traditional $Cu/ZnO/Al_2O_3$ catalyst from $16H_2$:CO synthesis gas in a continuous-flow microreactor at 280° C and 60 atm pressure. Standard inlet space velocity was 31,000 h^{-1}.

OP 23–81. A Drop Impact Sampler, by Lung Cheng and Warren G. Cross. Environ. Sci. Technol., v. 15, No. 4, April 1981, pp. 459–463. The drop impact sampler developed by the Bureau of Mines is based on the stain technique for measuring airborne drops. The stain technique requires a calibration curve to relate stain and drop diameters at a known impact velocity, usually the terminal value. However, physical constraints limit sampler location, making it difficult to attain the terminal value and thereby introducing complications; extrapolation of a calibration curve based on the spherical quiescent model to large drops results in an erroneously large diameter. The new sampler eliminates these difficulties and makes it possible to determine rates of depositions and spatial concentrations. The sampler can measure drop diameters ranging from 0.005 to 2.5 mm and is suitable for water sprays, raindrops, and carry-over drops such as from cooling towers. Laboratory tests have shown that the sampler is reliable, rugged, lightweight, and easy to use.

OP 24–81. Direct Flotation of Potash From Insoluble-Slime-Bearing Sylvinite and Carnallite Ores, by Donald G. Foot, Jr., and Jerry L. Huiatt. Pres. at AIME Ann. Meeting, Chicago, Ill., Feb. 22–26, 1981, SME Preprint 81–74, 8 pp. The Bureau of

Mines devised a direct flotation method for treating low-grade carnallite ($KCl\text{-}MgCl_2 \cdot 6H_2O$) and sylvinite (a mixture of KCl and NaCl) ores characterized by a high content of water-insoluble impurities. The procedure consists of (1) flocculation-depression of the insoluble slimes, (2) decomposition leach (carnallite only), (3) potash rougher, cleaner, and recleaner flotation, and (4) final product leaching. The technique eleminates the necessity of removing the water-insoluble slimes by mechanical or flotation desliming. Laboratory results demonstrated that the direct flotation procedure, when compared with conventional techniques, yielded equivalent or improved flotation results with equal or less reagent consumptions. The direct flotation method recovered 81.6 pct of the solid-phase KCl from carnallite ore and 79.7 pct of the KCl from sylvinite ore in final products containing 60.5 pct and 60.9 pct K_2O. A flowsheet incorporating the described flotation procedure is presented.

OP 25–81. Biogeochemistry of Acid Mine Drainage and a Method to Control Acid Formation, by R. L. P. Kleinmann, D. A. Crerar, and R. R. Pacelli. Min. Eng., v. 33, No. 3, March 1981, pp. 300–305. A bacterium, *Thiobacillus ferrooxidans*, is of prime importance in the formation of acid drainage from pyritic material. Above pH 4.5, *T. ferrooxidans* increases initial acidification; below pH 4.5, it allows acidification to continue by oxidizing Fe^{2+}. Below a pH of approximately 2.5, the activity of Fe^{3+} is significant and results in steady-state cycling between oxidation of pyrite by Fe^{3+} and bacterial oxidation of Fe^{2+}. Laboratory and field tests demonstrate that inhibition of *T. ferrooxidans* by controlled release of anionic detergents can inexpensively reduce pyrite oxidation and acid formation.

OP 26–81. Computer Program To Aid in Adjusting Particle Size Distribution, by Arthur V. Petty, Jr., and D. B. Nevin. Am. Ceram. Soc. Bull., v. 60, No. 4, April 1981, pp. 506–507. Numerous situations in which particle size must be matched to a predetermined distribution or the distribution of a sample must otherwise be altered. Normally, this alteration requires screening the entire sample into various mesh sizes and recombining to form the desired distribution, or using extensive and time-consuming iterative calculations. A computer program to aid in these calculations was developed by the Bureau of Mines for use on a basic processing system. The program determines the quantity of material that must be added to a sample to adjust its size distribution to approximate that of a standard. Operating in an interactive mode, the program will accept up to 20 size fractions as input or will use a standard $\sqrt{2}$ distribution, depending on input commands. Also required as input are the particle size distributions of the standard and the sample to be adjused, the limit of error on the adjustments, and the mass (in grams) of the sample to be prepared.

OP 27–81. Platinum-Group Minerals in Alluvial Deposits, by J. Sjoberg and J. M. Gomes. Pres. at Precious Metals Conf., Reno, Nev., Nov. 17–20, 1980; pub. in California Geol., v. 34, No. 5, May 1981, pp 91–98. The Bureau of Mines is investigating the recovery of byproduct heavy minerals from California sand and gravel deposits as a means of more effectively utilizing these mineral resources. In one phase of the study different platinum-group metal (PGM) minerals are being identified to determine if variations in their geograhical distribution exist. Platinum-group mineral concentrates were recovered containing up to 1,000 oz/ton PGM. More than 20 PGM minerals were identified by SEM/microprobe analysis of samples from 12 areas of northern and central California. Major minerals identified were ferroplatinum, sperrylite, and osmiridium. Several mineral phases not previously reported in the literature as occurring naturally were tentatively identified. There are indications of the existence of variations in the geographical distribution of the major PGM minerals. The history, occurrence, geology, and uses of the platinum-group metals are discussed.

OP 28–81. Regeneration of Waste Chromic Acid Etching Solutions in an Industrial-Scale Research Unit, by L. C. George, D. M. Soboroff, and A. A. Cochran. Proc. 3d EPA/AES Conf. on Advanced Pollution Control for the Metal Finishing Industry, Kissimmee, Fla., Apr. 14–16, 1980; v. EPA-600, No. 2-81-028, February 1981, pp. 33–36. Substantial amounts of chromium are lost in various surface-finishing operations and pollution problems are created when spent solutions containing hexavalent chromium and sulfuric acid are discarded. Laboratory research has shown that these spent etching solutions can be regenerated in a diaphragm cell. When the spent solution is placed in the anode chamber, most of the Cr^{3+}, produced during etching operations, is oxidized to Cr^{6+}. Impurity metals dissolved during the etching operation are transferred to the catholyte. When waste brass etchants are treated, about one-third of the copper and zinc is removed. The energy consumption is less than 9 kwhr/kg of sodium dichromate regenerated. Similar results are obtained with spent printed-circuit-board etchants and rinse waters from plastic etching operations. An industrial-scale research unit capable of oxidizing up to 0.5 kg/hr of trivalent chromium has been operated to demonstrate the viability of the recycling techniques. Regenerated brass etchants evaluated by two companies equaled or exceeded the performance of fresh etchants.

OP 29–81. State-of-the-Art Guideline Manual for Design, Quality Control, and Construction of Sulfur-Extended-Asphalt (SEA) Pavements, by W. C. McBee, T. A. Sullivan, and J. O. Izatt. Fed. Highway Admin., U.S. Dept. Trans., FHWA-IP-80-14, August 1980, 52 pp. Interest in the use of sulfur in highway pavement construction has been stimulated by unpredictable increases in cost and the relative uncertainty as to the future availability of asphalt cement (A/C) along with the potential surplus of sulfur in the near future. These events have led to the development of a new binder: a sulfur-extended-asphalt (SEA) binder. This new binder replaces some of the asphalt with sulfur in conventional asphalt paving plants. The mix material can be transported, laid, and compacted with standard paving equipment. Studies of SEA pavements indicate that their properties are comparable and in some cases may prove to be superior to those of conventional asphalt pavements. The manual presents state-of-the-art guidelines for design, quality control, safety factors, and construction of these newly developed pavements. A nonproprietary, direct mixing method and four proprietary methods of producing the SEA mixtures are described.

OP 30–81. Role of Sulphur in SEA Pavements, by W. C. McBee, P. A. Romans, T. A. Sullivan, and R. R. Uhde. Pres. at Sulphur-81 Internat. Conf., Calgary, Alberta, Canada, May 25, 1981;

pub. in Sulphur Res. & Develop., v. 4, pp. 5–12. As part of the Bureau of Mines Sulfur Utilization Program, paving materials were developed in which sulfur replaced up to 35 pct of the asphalt binder volume. These sulfur-extended asphalt (SEA) materials, along with those developed by private concerns, have been used to construct experimental highways in 20 States. Very little information has been obtained on the behavior of the materials during in-service aging. The sulfur microstructural features of core samples obtained from highways constructed using all existing SEA technologies are described. In addition, the activation energy for diffusion and solubility limits of sulfur in asphalt were determined for a typical paving asphalt. A mechanism for nucleation and growth of crystalline sulfur in the pavement is presented and related to the structure developed in the material.

OP 31–81. Dewatering of Coal-Clay Waste Using Polyethylene Oxide as a Flocculant, by B. J. Scheiner, Annie G. Smelley, and Jalna Zatko. Proc. Progress in the Dewatering of Fine Particles Conf., University of Alabama, Apr. 1–2, 1981, 20 pp. The Bureau of Mines is developing a dewatering technique for coal-clay wastes. The technique consists of mixing coal-clay waste with the flocculant polyethylene oxide (PEO) and dewatering the resulting flocs on a hydrosieve screen followed by further dewatering on a rotary trommel screen. Coal-clay waste slimes containing from 7 to 28 weight-percent solids have been consolidated up to 50 weight-percent solids using about 0.5 lb of PEO per ton of dry solids.

OP 32–81. Application of a Dewatering Technique to Industrial Wastes, by Annie G. Smelley and B. J. Scheiner. Proc. Progress in the Dewatering of Fine Particles Conf., University of Alabama, Apr. 1–2, 1981, 13 pp. In research conducted as part of its mission to effect pollution abatement, the Bureau of Mines has developed a specialized flocculation dewatering technique that may have wide application in the disposal of industrial wastes. This method allows for reuse of water previously lost with the wastes, eliminates or reduces the need for storage ponds, and facilitates recovery of mineral values. The flocculants used are high molecular weight polymers such as polyethylene oxide and polyacrylamides that can form strong, tough flocs with the wastes.

OP 33–81. Effect of Ion Exchange on Dewatering Phosphate Clay Waste With Polyethylene Oxide, by D. A. Stanley, P. M. Brown, and B. J. Scheiner. Proc. Progress in the Dewatering of Fine Particles Conf., University of Alabama, Apr. 1–2, 1981, 14 pp. As part of its mission to provide technology to assure a continuing supply of minerals, the Bureau of Mines conducted research to obtain a better understanding of how clays are flocculated by polyethylene oxide (PEO). The Bureau is presently developing a dewatering technique in which PEO is used to flocculate phosphatic clay waste and the resulting flocs dewatered on static and rotary screens. During the field testing of this technique, a clay waste was encountered that could not be dewatered readily. Studies indicated that the clay contained trace amounts of sulfides and that a portion of the exchange ions on the clay were probably hydrogen ions. Replacement of the exchange ions with calcium ions and agitation of the clay to oxidize the sulfides reduced the PEO requirements, which resulted in the clay being readily dewatered in both laboratory and large-scale field tests.

OP 34–81. The Limits of Flammability of Pulverized Coals and Other Dusts, by Martin Hertzberg, Kenneth L. Cashdollar, and Charles P. Lazzara. Proc. 18th Internat. Symp. on Combustion, Ontario, Canada, Aug. 9, 1980; The Combustion Institute, 1981, pp. 717–729. The limits of flammability of pulverized coals and other dusts were measured in a 7.8-liter system that provided accurate control of the significant experimental variables. The data are consistent, reproducible, and reliable, and the system is recommended as the standard for dust flammability studies.

OP 35–81. Inhibition of Acid Mine Drainage Formation: The Role of Insoluble Iron Compounds, by John W. Nebgen, William H. Engelmann, and Douglas F. Weatherman. Pres. at Inst. Environ, Sci. Ann. Meeting, Philadelphia, Pa., May 11–14, 1980; pub. in J. Environ. Sci., v. 24, No. 3, May-June 1981, pp. 23–27 This paper contains findings and conclusions from a 2-year study concerning chemical agents for the inhibition of acid mine drainage (AMD) formation. Three materials containing pyrite were evaluated in detail, but only one was a strong producer of AMD. Analysis of the experimental results strongly suggest that the rate at which pyrite is oxidized can be lowered substantially if the iron products from pyrite oxidation are kept insoluble. Analysis of the data does not distinguish between the lack of availability of soluble ferric ion as an oxidant or the exclusion of air by a ferric oxide coating. Either mechanism is compatible with the experimental data. Thus, methods to keep aqueous ferric ion minimized, for example, through insolubilization or maintaining high Fe^{++}/Fe^{+++} ratios, appear to be important in the chemical inhibition of AMD formation.

OP 36–81. Estimating Mine Pillar Strength From Compression Tests, by L. A. Panek. Trans. Soc. Min. Eng., AIME, v. 268, 1981, pp. 1749–1761. Using an approach based on the theory of similitude, a general equation and related concepts were developed that provide new insights to an old problem. The load-bearing capacity (strength) of a square, rectangular, or cylindrical prism of a brittle material such as rock, coal, or concrete is expressed as the mathematical product of a size effect, a shape effect, and a function of the mechanical properties (deformability, cleat-joint spacing, and friction) of the pillar, roof, and floor materials. Through an application of multivariate statistical analysis, the results of assorted tests (laboratory and in situ) and observations of failed pillars can be combined into a fundamental scaling equation, which provides a unified, consistent approach to the estimation of mine pillar strength. The form of the equation is sufficiently general to be able to incorporate refinements in the characterization of the structural parameters, as they become available through future analysis and experimentation. Analysis of the published test data suggests that pillar compressive strength (per unit of area) is proportional to the cube root of the pillar width, and that the height effect can be described as the superimposing of a variable size effect (characteristic of the material) on the constant width effect.

OP 37–81. Prereduction and Melting of Domestic Chromites, by Ralph H. Nafziger, Phillip E. Sanker, Jack E. Tress, and Robert A. McCune. Proc. 38th Electric Furnace Conf., Iron and Steel Soc., AIME, Pittsburgh, Pa., Dec. 11–12, 1980, pp. 27–45. The Bureau of Mines has prereduced domestic chromites to provide a suitable charge material for

the production of ferrochromium in an electric arc furnace. As part of the Bureau's goal to economically and efficiently recover metal values from domestic resources, this investigation has shown that prereduction of domestic chromites increases productivity and decreases electric energy consumption, compared with results where unreduced materials were used. Approximately 75 pct chromium metallization and 75 pct total metallization were realized when high-iron chromites from Montana were prereduced with coal char and coke breeze in a batch rotary kiln. Chromium and total metallizations near 95 pct were obtained when a metallurgical-grade chromite was prereduced. Satusfactory ferrochromium for the production of stainless steel was produced in an electric arc furnace from all of the prereduced materials.

OP 38–81. Deformation and Cracking of a Concrete-Lined Tunnel in a Rock Mass Subjected to a Changing State of Strain, by Louis A. Panek. Proc. 22d U.S. Symp. on Rock Mechanics, Cambridge, Mass., June 29-July 2, 1981, pp. 328–334. As part of an investigation of ground movements around a zone of caving ground, measurements were made of the deformation of a 90-meter length of mine tunnel. The tunnel lay astride the path of an approaching caved zone 64 meters wide, which eventually undermined the tunnel. The approach of the caving zone caused the rock mass around the tunnel to expand laterally and downward toward the cave, resulting in a gradual sinking of a portion of the tunnel and distortion of the tunnel section, which led to the fracturing of the concrete lining. Longitudinal extension and bending of the axis of the tunnel were measured, as well as the distortion of the tunnel cross section, using extensometers and tiltmeters of simple design. The approach was to monitor basic deformation components that could be conveniently measured by mine personnel, making maximum use of off-the-shelf hardware, to show that definitive data can be generated thereby. Especially notable was the demonstrated capability to determine from a triangular configuration of cross tunnel extensometer measurements the principal directions of deformation within the surrounding rock mass. By increasing the number of gage points from 2 to 3, three times as much information is obtained as by measuring roof-to-floor convergence.

OP 39–81. Effects of High Pressure, High Temperature Steam-Containing Environments on Alumina Refractory Concretes, by Leon Y. Sadler III, Nancy S. Raymon, Kenneth H. Ivey, and Hendrik Heystek. Am. Ceram. Soc. Bull., v. 60, No 7, July 1981, pp. 703–706. This paper describes results obtained in a study of the response of alumina-based refractory concretes to coal dry-ash gasifier environments. The investigations were designed to determine the relationship between observed refractory property changes after exposure to dry-ash gasifier environments and variables such as exposure temperature, steam partial pressure, gas velocity, aggregated and cement composition, and the presence of alkalis. Both commercially available and laboratory-formulated refractory concrete compositions, ranging from 45 to 95 pct alumina and containing low, intermediate, and high-purity calcium aluminate cements were studied. The refractories were exposed to environments at pressures ranging from 2.9 to 7.0 MPa (400 to 1,000 psig) and at temperatures ranging from 760° to 1,000° C. In some exposures, alkalis were introduced into the exposure environment. The steam-induced volatilization and vapor-phase transport of silica from the refractories under a variety of conditions were also studied.

OP 40–81. Smoke Characteristics of Coal-Lined Tunnel Fires, by Kenneth L. Cashdollar, Joseph M. Singer, Calvin K. Lee, and Charles D. Litton. Fire and Mater., v. 5, No. 2, 1981, pp. 47–51. Characteristics of smoke particulates generated from a coal fire in a ventilated model tunnel were investigated by laser optical transmission and by electron microscopy. Average particle diameter and mass concentration of the smoke were determined as a function of the temperature and stoichiometry of the coal tunnel fire. Smoke particle sizes ranged from 0.2 to 0.9 μm, with larger particle sizes associated with higher smoke concentrations. These coal smoke data are relevant to several aspects of underground mine safety including the development and location of smoke detection instruments, the understanding of the fire (toxic fume) hazards, and the development of new fire protection and control techniques.

OP 41–81. Potential Production Capacity of Metallurgical Coke, by Franklin D. Cooper. Iron and Steel Eng., v. 58, No. 9, September 1981, pp. 52–57. A method for determining the annual potential production capacity (ppc) for captive blast furnace coke is described together with examples relating battery age to productivity, time, and worker hour distributions for coke-oven operations and production costs. Based on a practical best fit combination of known operating variables involving more than 140 captive oven batteries, the study shows that the U.S. steel industry currently has blast furnace coke ppc equivalent to about 62 to 64 million tons annually of coke-related finished steel shipments.

OP 42–81. Bureau of Mines New Stopping Designs—An Update, by Edward D. Thimons and Fred N. Kissell. Min. Cong. J., v. 67, No. 7, July 1981, pp 1–4. Conventional stoppings of concrete block or wood walls covered with mortar-type sealants, urethane foams, or heavy brattice cloth work well in many mining applications, but the time and cost of constructing and maintaining them can make them impractical, especially when only temporary stoppings are needed. They do not lend themselves to use at or near the working faces of mines where heavy blasting is done because of the damage they incur. This paper describes the parachute stopping, quick-fix blowout stopping, and damage-resistant brattice, recently developed by the Bureau of Mines, that are much more suitable for such applications.

OP 43–81. Preparation of Cell Feed Materials for Aluminum and Magnesium Production, by James A. Barclay. Pres. at Workshop on Electrochemistry Applied to Processing of Lunar Materials, Houston, Tex., Sept. 12, 1979; Space Solar Power Review, v. 12, 1981, pp. 259–269. Magnesium chloride for electrolysis to magnesium in a fused-salt bath is made by reacting seawater with milk of lime to precipitate magnesium hydroxide, separating the latter from the barren seawater, dissolving the hydroxide in hydrochloric acid, and crystallizing and drying the compound $MgCl_2 \cdot 1.5H_2O$. Solar evaporation of Great Salt Lake brine, followed by spray drying, also is practiced. Dolomite may be calcined and ground to a fine powder to be mixed with ferrosilicon for reduction to magnesium in vacuum retorts by a nonelectrolytic process. Alumina for smelting to aluminum in Hall-Heroult cells is pre-

pared from bauxite by pressure digestion with strong NaOH solution, thickening, and filtration to separate a waste "red mud," and crystallization of $Al_2O_3 \cdot 3H_2O$ in the presence of seed crystals. The $Al_2O_3 \cdot 3H_2O$ then is calcined to Al_2O_3. The Bureau of Mines and other research on the recovery of alumina from nonbauxitic aluminous materials is discussed, and possible applications of acid leaching, alkaline sinter-caustic leaching, and carbochlorination processes to lunar materials are briefly evaluated.

OP 44–81. Potential "Met" Coke Production Capacity: The Case Is Anything But Closed, by Franklin D. Cooper. 33 Metal Producing, v. 19, No. 9, September 1981, pp. 65–67. A method for determining the annual potential production capacity (ppc) for captive blast furnace coke is described together with examples of relating battery age to productivity, time, and work-hour distributions for coke-oven operations and production costs. Based on a practical best fit combination of known operating variables involving more than 140 captive oven batteries, the study shows that the U.S. steel industry currently has blast furnace coke ppc equivalent to about 62 million to 64 million tons annually of coke-related finished steel shipments.

OP 45–81. The Error in Working-Level Hour. Calculations When the α-Energy From the Radon Daughters Is Not Discriminated, by John Durkin. Health Phys., v. 41, No. 3, September 1981, pp. 477–481. Exact working-level hour cumulative exposure measurements require knowledge of all the potential α energy in 1 liter of air, with this α energy coming from the decay of RaA and RaC' daughters. This can be done by measuring α emission from the daughters with a system that also determines the energy of the α particle, and is, therefore, able to determine which daughter decayed. However, simple counting of total α emission and the assignment of a predetermined energy to the α particle whose value is prescribed from statistical studies of typically found daughter ratios, allow acceptable accuracies in working-level hour measurements.

OP 46–81. Determination of Ground Pressure Existing in a Viscoelastic Rock Mass by Use of Hydraulic Borehole Pressure Cells, by Paul H. Lu. Proc. Internat. Symp. on Weak Rock, Tokyo, Japan, Sept. 21–24, 1981, 7 pp. Accurate magnitude of the biaxial ground pressures existing in a viscoelastic rock mass can be determined by pressure convergence tests with a combination of one cylindrical and two flat hydraulic pressure cells installed in a single hole drilled into that rock mass. Consequently, the triaxial ground pressures can be measured by drilling a pair of orthogonal holes for such instrumentation. Unlike most of the known methods of in situ stress determination that determine the magnitude of the stress indirectly from the elastic stress-strain relation by measuring strain or displacement in place and modulus of deformation in the laboratory, this method directly measures the in situ stress without any knowledge of the value of modulus of deformation. Furthermore, the complete state of stress existing in the viscoelastic rock mass also can be determined by this method if other techniques are supplemented for determining the directions of the principle stresses. In this paper, the theoretical background, measuring equipment, and measurement procedure are discussed. Validity of tions of the principal stresses. In this paper, the are demonstrated by the in situ measurements conducted for a variety of rock types.

OP 47–81. A Comparison of American Safety Performance to Other Countries, by Robert L. Marovelli. Min. Con. J., August 1981, pp. 45–51. Comparisons are made of indicators of safety performance in the United States and primarily the European coal-producing countries of the United Kingdom and the Federal Republic of Germany. Caveats are made that safety performance for U.S. room-and-pillar mining is being compared with European longwall mining and that even a comparison confined to U.S. longwall mining versus European longwall mining would be indirect at best due to important differences in mine development (e.g., U.S. multiple entries versus European single entries) and mining operations.

OP 48–81. Thermodynamic Properties of Aluminum Sulfide (Al_2S_3), by M. J. Ferrante, J. M. Stuve, H. C. Ko, and R. R. Brown. High Temp. Sci., No. 14, 1981, pp. 91–108. Research done at the Bureau of Mines has produced calorimetric data for the low temperature heat capacity from 12 to 312 K and the high temperature relative enthalpy from 400 to 800 K for aluminum sulfide (Al_2S_3). The heat capacity measurements yielded $S°_{298} = 27.927 \pm 0.05$ cal K^{-1} mol^{-1} for the standard entropy at 298.15 K (1 cal = 4.1840 J). The standard enthalpy of formation at 298.15 K, $\Delta Hf°_{298} = 155.6 \pm 0.9$ kcal mol^{-1}, was determined by hydrochloric acid solution calorimetry. The results were combined with the published data for pure aluminum and sulfur to obtain a complete set of thermodynamic data for Al_2S_3 from 0 to 900 K at appropriate temperature intervals.

OP 49–81. Thermodynamic Properties of Cuprous and Cupric Sulfides, by M. J. Ferrante, J. M. Stuve, and L. B. Pankratz. High Temp. Sci., v. 14, 1981, pp. 77–90. Low-temperature heat capacities of Cu_2S(c) and CuS(C) have been measured from 5 to 310 K with an adiabatic calorimeter. The results yielded $S°_{298} = 27.76$ for Cu_2S and $S°_{298} = 16.05$ for CuS, where $S°_{298}$ is the standard entropy at 298.15 K in cal $K^{-1}mol^{-1}$ (1 $cal_{th} = 4.184$ J). High-temperature relative enthalpies have also been measured with a copper-block calorimeter from 298 to 1,600 K for Cu_2S and from 298 to 780 K for CuS. Two solid-solid transitions have been observed for Cu_2S upon heating, the first at 376 K with an isothermal heat absorption of 865 cal mol^{-1}, and the second at 720 K with an isothermal absorption of 280 cal mol^{-1}. The enthalpy of fusion at 1,400 K was 3,070 cal mol^{-1}. No solid-solid phase transitions were observed for CuS from 5 to 780 K. All related thermodynamic properties have been tabulated.

OP 50–81. An Algorithm for Multidimensional Combusting Flow Problems, by Edward J. Kansa. J. Comput. Phys., v. 42, No. 1, July 1981, pp. 152–194. Mathematical effort in combusting fluid flow has been limited due to the numerical difficulties associated with the highly nonlinear processes such as Arrhenius chemical kinetics, radiation, and turbulence superimposed upon fluid flow. Traditional explicit schemes become inefficient in typical combustion problems because the stability requirement is more stringent than the accuracy requirement. The approach taken in this paper is to combine the best features of the block implicit (BI)-ADI partial differential equation (PDE) scheme with the best features of the stiff ordinary differential equation (ODE) schemes and the damped Newton-Raphson and steepest descent nonlinear equation schemes. The resulting algorithm for the highly nonlinear

PDE's for combustion problems is very robust and efficient over a wide range of phenomena.

OP 51–81. Selective Extraction of Metals From Pacific Sea Nodules With Dissolved Sulfur Dioxide, by S. E. Khalafalla and J. E. Pahlman. J. Metals, v. 33, No. 8, August 1981, pp. 37–42. A rapid and efficient—almost instantaneous and quantitative—method was devised to differentially leach manganese, nickel, and cobalt to the exclusion of copper and iron from deep sea nodules. In this method, a given weight of raw sea nodules ground to -200 mesh in an aqueous slurry is contacted for 10 min at room temperature with a specified quantity of SO_2. An independent leaching parameter, R, was defined as the ratio of the number of moles of SO_2 in the leaching solution to the weight of sea nodules. Variation of metal extraction with R generates sigmoidal curves characteristic of the metals extracted. A threshold value of R is required to initiate the leaching of a given metal from the mixed oxides. Once the threshold is reached, the metal recovery can rise above 95% in less than 10 min. For increasing value of R the extractability of various metals from Pacific sea nodules by SO_2 follows the order: Mn > Ni > CO >> Fe, AL, Cu. Disparity in the R values permits a variety of selective leaching systems and metal separations simply by changing the quantity of SO_2 in the contact solution.

OP 52–81. The Determination of Chrysotile in Insulation Samples Using Combined TGA–GCA, by John V. Scalera. Proc. North Am. Thermal Analysis Soc. Conf., New Orleans, La., Oct. 19–21, 1981, v. 2, No. 51, pp. 303–309. The identification and quantification of asbestos in insulation materials was investigated by the Bureau of Mines Particulate Mineralogy Unit. One of the objectives is to provide technical assistance on mineral particulate-related problems to other Federal agencies. Quantification of the asbestos content in insulation and construction materials is necessary for the U.S. Environmental Protection Agency to evaluate the potential health risk from exposure to airborne fiber. Gas chromatographic analysis (GCA) of the effluent gases from a thermogravimetric analysis (TGA) balance can provide quantitative data concerning the composition of insulation samples. The GCA peak related to the dehydration of chrysotile occurs within the temperature range of 560° to 660° C. Using chrysotile standards, a linear relationship is obtained relating the summation of the peak heights for water evolved within this 100° C range and the mass of chrysotile present in the sample. The use of a narrow 100° C range to acquire the dehydration data for chrysotile minimizes interferences from hydrates that decompose at lower temperatures and amphiboles that decompose at higher temperatures, for example, gypsum and amosite. GCA data also allow avoiding misinterpreting TGA thermograms for chrysotile when actual $CaCO_3$ decomposition is involved by resolving weight losses in the dehydration range of chrysotile into components of water and CO_2.

OP 53–81. Alumina From Nonbauxitic Resources, by R. C. Kirby and J. A. Barclay Proc. Internat. Committee for the Study of Bauxite, Alumina, and Aluminum, ISCOBA-AIM Conf., Cagliari, Italy, Sept. 26–28, 1979, No. 16, 1981 v. 11, pp. 1–12. Although the United States produces nearly one-third of the world's primary aluminum, it must import more than 90 percent of the bauxite and alumina needed. To test and improve various raw material-process technology alternatives to the Bayer-bauxite process for alumina production, the Bureau of Mines is engaged in an extensive research and development effort. Information thus obtained will be used for decisionmaking on further large-scale testing of the process showing the greatest potential for producing alumina from a domestic nonbauxitic resource. The paper discusses recent research in the Bureau's alumina miniplant project, miniplant support research, and contract studies leading to the preliminary design of a 20-ton-per-day alumina pilot plant.

OP 54–81. Improved Fire Resistance Test Method for Belt Materials, by J. M. Kuchta, M. J. Sapko, F. J. Perzak, and K. E. Mura. Fire Technol., v. 17, No. 2, May 1981, pp. 120–130. A moderately scaled apparatus was developed for determining the fire resistance characteristics of mine conveyor belts and similar type materials. The test method overcomes the limitations of existing laboratory-scale methods and provides a measure of both ignitability and flammability in quantative terms. Data are presented for nine belt materials, and fire resistance ratings are proposed in terms of the flame spread rate, heat release rate, and critical ignitor heat flux.

OP 55–81. Modified-Sulphur Concrete Technology, by William C. McBee, Thomas A. Sullivan, and Bing W. Jong. Proc. Sulphur-81, Internat. Conf. on Sulphur, Calgary, Alberta, Canada, May 25–28, 1981, pp. 367–388. As part of a program to find uses for plentiful resources, the Bureau of Mines has developed a sulfur concrete technology in which chemically modified elemental sulfur is utilized with suitable mineral aggregates to formulate durable, corrosion-resistant materials of construction. This paper describes the chemical, physical, and mechanical characteristics of both sulfur cement and concretes, and the current state-of-the-art for the manufacture of the materials. Specialized use applications in chemical and metallurgical process environments and current performance data are described.

OP 56–81. Recovery of Zinc From Wastewater Treatment Sludge, by J. B. Stephenson, E. R. Cole, and D. L. Paulson. Res. and Conservation, v. 6, No. 3–4, November 1981, pp. 203–210. Preliminary laboratory work done under a Memorandum of Agreement between the Bureau of Mines Rolla Research Center and the Harrison Radiator Div., General Motors, Corp., has indicated that zinc can be recovered from wastewater treatment sludges generated at the Harrison plant at Lockport, N.Y. The method developed at the Rolla Research Center, Rolla, Mo., for extracting zinc from the sludge involves roasting, leaching-purification, and electrowinning. Roasting to combust the organic fraction and leaching with H_2SO_4 to stabilize the zinc proceeded routinely. Purification and electrowinning followed standard practice for a commercial zinc electrowinning plant, but because of the large amounts of deleterious impurities coextracted with the zinc, as much as 50 times greater than normally encountered in a commercial operation, an extensive modification of the purification procedure was necessary. Zinc was electrowon with good current efficiency and deposit morphology. Residues are being characterized to determine the feasibility of recovering valuable constituents prior to disposal in an environmentally acceptable manner.

OP 57–81. Gasification Pilot Plant Evaluation of CVD Coated Hardware, by J. B. Stephenson and H. O. McDonald. Proc. 8th Internat. Conf. on Chemical Vapor Deposition 1981, Chantilly-Gouvieux, France, Sept. 15–18, 1981, v. 81–7, November 1981, pp. 642–652. The Bureau of Mines, under an interagency agreement with the U.S. Department of Energy (DOE), investigated the feasibility of coating the critical surfaces of valves by chemical vapor deposition (CVD). The purpose of the research was to increase the wear resistance of the valves for use in the abrasive and erosive environment of coal conversion and utilization processes. In-service testing of the CVD-tungsten ball seat was conducted at the DOE Morgantown Energy Technology Center (METC) in Morgantown, W. Va. Tungsten CVD coatings were reproduced on nickel-plated carbon steels and stainless steels by the hydrogen reduction of the tungsten hexafluoride at 325° to 600° C. Tungsten-coated 6-, 10-, and 12-inch (0.15-, 0.25-, and 0.30-meter) ball valve seats were prepared for METC evaluation in their low-Btu coal gasification pilot plant. Use of the CVD-tungsten coated ball valve seat as a seal surface was determined to be satisfactory by METC under their process conditions. Little or no significant wear, other than a lapping effect, was noted on the valve seal surface after 1,230 cycles of operation.

OP 58–81. Recovery of Barite From Tailings Ponds and Bypassed Mining Waste, by G. V. Sullivan and W. E. Lamont. Min. Eng., v. 33, No. 11, November 1981, pp. 1632–1634. As part of its program to conserve domestic mineral resources through advancing mineral resources technology, the U.S. Department of the Interior, Bureau of Mines, conducted investigations to determine the feasibility of recovering high-grade barite concentrates, suitable for use as well-drilling mud, from current and old waste pond materials and materials bypassed in present mining operations. Flotation studies of waste pond samples from Missouri and Nevada yielded barite concentrates containing over 95% $BaSO_4$ with recoveries of 86% and 96%, respectively, of the barite in the flotation feed. Flotation studies of a hard-rock sample from Georgia, currently bypassed in mining, yielded a barite concentrate containing 97% $BaSO_4$ with an attendant recovery of 97% of the barite.

1982

OP 1–82. Methane Control on Longwall—European and U.S. Practices, by Joseph Cervik. Pres. at Soc. Min. Eng., AIME, Ann. Meeting, New Orleans, La., Feb. 18–22, 1979; ch. 9 in Longwall-Shortwall Mining, State of the Art, 1981, pp. 75–80. Common methods of controlling gob gas in U.S. mines are by means of ventilation of gob areas and gas drainage through surface boreholes. Costs of drilling surface gob holes increase as deeper coalbeds are mined. Where gob holes cannot be drilled because of topography, ventilation is the only means of control. Even then, sufficient air may not be available to dilute methane in the bleeder entries to acceptable levels. Thus, new methods of gob gas control need to be developed that are independent of surface topography, and of the mine ventilation system, less costly than present systems. Except for slight variations in procedures and equipment, Great Britain, the Federal Republic of Germany, France, Belgium, Poland, and Czechoslovakia use a common methane control method that is different from the systems generally used in the United States. This Bureau of Mines paper reviews European mining methods, mining conditions, and methane control technology and discusses their applicability to U.S. mines.

OP 2–82. Recovery of Gold and Other Heavy Minerals From Alluvial Deposits: Equipment and Practices, by J. M. Gomes and G. M. Martinez. Proc. Internat. Gold/Silver Conf., Reno, Nev., May 21–23, 1981, 12 pp. The potential for recovering gold and other heavy mineral byproducts from sand and gravel operations is discussed. The Bureau of Mines recently completed a study to determine heavy minerals present in the west coast sand and gravel deposits. Methods and equipment used for the recovery of gold and other heavy minerals in the deposits are discussed. Flowsheets for the recovery of gold and for the possible recovery of other heavy mineral byproducts are shown.

OP 3–82. Comparative Anatomy of a Pottsville Lithic Arenite and Quartz Arenite of the Pocahontas Basin, Southern West Virginia: Petrogenetic, Depositional, and Stratigraphic Implications, by David W. Houseknecht. J. Sediment. Petrol., v. 50, No. 1, March 1980, pp. 3–20. Appalachian carboniferous stratigraphy remains controversial partly because of unclear petrogenetic, depositional, and stratigraphic relationships displayed by Pottsville sandstones, which have been interpreted as being of either alluvial or barrier-beach origin. Two associated sandstones of the New River Formation of southern West Virginia provide the setting for a detailed examination of this problem. The Lower Raleigh lithic arenite consists of elongate and lobate, dip-oriented bodies that display erosional bases, interfinger laterally with shales, fine upward at the top, and are unidirectionally trough cross-bedded basinward. The Upper Raleigh quartz arenite consists of elongate, dip-oriented bodies updip in the basin and elongate and lobate, strike-oriented bodies downdip. The quartz arenites display erosional bases, interfinger laterally with shales, fine upward at the top, and are unidirectionally planar cross-bedded basinward. Evidence suggests that Lower Raleigh detritus was derived from a southeasterly metamorphic-sedimentary source terrane and deposited in high-constructive lobate deltas. Upper Raleigh quartzose detritus may have been derived from coarse-grained alluvial facies equivalents of Lower Raleigh deltaic facies and deposited in deltas whose margins were modified by marine processes. It appears that the Lower and Upper Raleigh sandstones are not deltaic and barrier-tidal facies equivalents, thus negating gross regional stratigraphic relationships implied by the barrier model. Additionally, these conclusions suggest that use of quartz arenite as a unique lithogenetic rock type for predictive purposes is prone to error.

OP 4–82. Anticipating Coal Mining Problems in Hartshorne Formation, East-Central Oklahoma, Using Sedimentary Facies Analysis, by David W. Houseknecht and Anthony T. Iannacchione. Am. Assoc. Pet. Geol. Bull., v. 64, May 1980, p. 724; Okla. Geol. Notes, v. 40, No. 5, October 1980, p. 209. This study of sedimentary facies associated with the Hartshorne coalbeds of east-central Oklahoma provides an oppor-

tunity for preventive planning to minimize mining problems

OP 5–82. Methane Production Potential From Hartshorne Coal Beds in Deep Parts of Pittsburg, Coal, and Hughes Counties, Oklahoma, by Anthony T. Iannacchione and David W. Houseknecht. Am. Assoc. Pet. Geol. Bull., v. 65, No. 8, August 1981, pp. 1499–1500. This paper discusses the methane production potential investigation performed by the Bureau of Mines of the Hartshorne coalbeds in the Arkoma Basin, Okla.

OP 6–82. Predicting Zones of Potentially Unstable Coal Mine Roof Based on Consideration of Sedimentary Facies: A Case Study, by Anthony T. Iannacchione, James P. Ulery, Frank E. Chase, David M. Hyman, and Donald G. Puglio. Pres. at 1980 Ann. Meeting, Geol. Soc. of America, Atlanta, Ga., Nov. 17–20, 1980, abs. with Programs, v. 12, No. 7, p. 453. This study demonstrates the use of geological data in prediction of slickensided transition zones and will aid in projecting main entries under the most competent roof and in planning an effective roof support system for advancing sections of a coal mine.

OP 7–82. Mineral Industries, by Thomas G. Langton and Phillip N. Yasnowsky. The Encyclopedia of Mineralogy, Encyclopedia of Earth Sciences. ed. by K. Frve. Hutchinson Ross Publishing Co., Stroudsburg, Pa., v. 4B, 1981, pp. 258–270. This encyclopedia article gives a brief and general discussion of the development of the mineral industry to its present state and its role in the national economy. Selected mineral data, with an accompanying textual discussion on reserves, production, import reliance, and consumption are provided.

OP 8–82. New Closure Rate Instruments for Retreat Mining Operations, by James R. McVey and Wayne L. Howie. Min. Eng., v. 33, No. 12, December 1981, pp. 1699–1700. The Bureau of Mines Spokane Research Center has constructed an intrinsically safe closure-rate instrument that provides the mine operator a means for predicting an imminent roof fall during pillar robbing. This improves operator and machine safety and prevents delays in digging out equipment. The instrument system consists of two rugged retrievable extensometers connected by long electrical cables to a digital readout unit for reading closure and closure rate. Once a predesignated closure rate is reached, the extensometer is retrieved by pulling it from the imminent roof fall area by the electrical cable. The equipment and mine personnel are also pulled back to await the fall, which usually occurs within minutes after the designated rate is reached. Although the unit is primarily designed for retreat mining operations, it can be used for any activity requiring measurement of displacement or rate of displacement with a measurement range of zero to 6 inches with 0.1 percent accuracy for openings 4½ to 12 feet.

OP 9–82. Stop #21. Steeply Dipping Upper Freeport Coal, by D. G. Puglio and A. T. Iannacchione. Proc. 9th Internat, Cong. of Carboniferous Stratigraphy and Geology, Urbana, Ill., May 10–June 2, 1979; pub. in Geology of the Northern Appalachian Coal Field, Guidebook, Field Trip No. 2, ed. by J. Donahue and H. B. Rollins, pp. 27–28. Coalbeds that dip nearly vertically have not previously been seen in Pennsylvania west of the Allegheny Front. This paper discusses some steeply inclined coalbeds that were observed during a field trip west of West Bolivar, Westmoreland County, Pa.

OP 10–82. High-Constructive, Tidally Influenced Deltaic Sedimentation in Arkoma Basin: Desmoinesian Hartshorne Sandstone, by D. W. Houseknecht, Mark A. Kuhn, Albert P. Matteo, Jr., David J. Steyaert, John F. Zaengle, and Anthony T. Iannacchione. Am. Assoc. Pet. Geol. Bull., v. 65, No. 8, August 1981, p. 1499. This paper describes the probable origin of the Hartshorne Sandstone and associated fine-grained facies of the Arkoma basin located in Arkansas and Oklahoma. Understanding the genesis of these delta plain facies reportedly will enhance petroleum and coal exploitation efforts within the Hartshorne of the Arkoma basin.

OP 11–82. Occurrence and Recovery of Rutile From Western Copper Mill Tailings, by G. V. Sullivan and T. O. Llewellyn. Pres. at SME-AIME Fall Meeting and Exhibit, Denver, Colo., Nov. 18–20, 1981, SME Preprint 81-333, 7 pp. The Federal Bureau of Mines examined tailings samples from 13 western copper operations to determine the potential for recovering rutile. Results showed that six of the samples contained sufficient liberated titania to be considered potential sources. One sample contained 0.75 percent TiO_2 or 0.40 percent liberated rutile. Batch flotation studies developed a procedure that recovered 70 percent of the liberated rutile at a grade of 34.7 percent TiO_2. Sulfuric acid leaching studies on 12 of the samples dissolved 100 to 2,200 grams Cu per ton of tailings; leaching of the slimes showed slightly more copper was dissolved, 1,800 to 3,300 grams Cu per ton of minus 10-micrometer material. Bulk sulfide flotation of nine of the samples resulted in concentrates that contained 0.38 to 2.0 percent Cu and 0.7 to 2.1 and 6.9 to 42.9 grams per ton Au and Ag, respectively.

OP 12–82. Improved Optical Probe for Monitoring Dust Explosions, by R. S. Conti, K. L. Cashdollar, and I. Liebman. Rev. Sci. Instr., v. 53, No. 3, 1982, pp. 311–313. An improved optical probe was developed to monitor dust-cloud concentration in explosions even in the presence of dust flame radiation. Principal features of the probe include a pulsed light-emitting diode and a photodetector with optical interference filter to reduce flame radiation. The probe has a U-shaped configuration and air jets to keep the windows dust free. Experimental data are presented for a coal dust explosion.

OP 13–82. Retractable Core Bit Drilling System, by W. C. Larson, W. W. Svendsen, J. F. Hoffmeister, and R. E. Cozad. Pres. at SME-AIME Ann. Meeting, Las Vegas, Nev., Feb. 24–28, 1980, SME Preprint 80–116, 16 pp.; Min. Eng., v. 34, No. 2, February 1982, pp. 163–170. This paper presents the background, history, and current development of a retractable core bit for a wireline drilling system. Design criteria, concept development, and system of the retractable bit system are discussed, including laboratory test results.

OP 14–82. Computer Simulation of Zirconium-Hafnium Separation by Countercurrent Extraction, by D. J. MacDonald. Sep. Sci. Technol., v. 16, No. 10, 1981, pp. 1355–1371. In carrying out research and development on an improved method for production of reactor-grade zirconium oxide, the Bureau of Mines has prepared a computer program capable of accurately predicting the stage-by-stage performance of a multistage countercurrent solvent extraction system for separation of zirconium from hafnium using a tertiary amine extractant. The results were used to plan laboratory experiments using a multistage countercurrent mixer-settler unit. The number of

extractor stages, number of scrubber stages, feed solution concentrations, scrubber solution concentration, feed flow, scrubber flow, and organic-phase flow are the significant variables. The computer simulation indicates the effects of changes in the pertinent variables and makes it possible to locate the best combination of variables without a prohibitively large number of time-consuming experiments.

OP 15–82. Development of an In-Line Water Spray Cooler, by J. F. McCoy, A. Whillier, K. S. Heller, and E. D. Thimons. J. Mine Vent. Soc. S. Afr., v. 35, No. 1, January 1982, pp. 1–6. This paper describes an experimental program financed by the Bureau of Mines for the development of an in-line cooler using direct water-to-air contact heat exchange. The direct water-to-air contact design eliminates problems of dust buildup on cooling surfaces, a frequent problem of fin-coil coolers in mines. While direct-contact coolers such as spray chambers are relatively tolerant to dust loading, their thermal performance, in practice, has not been viewed in the United States as competitive with counter-flow, fin-coil-type exchangers. This is believed to be due to the negligible experience with the direct water-to-air coolers in North American mines. The purpose of this paper is to describe a successful experience with a water spray-type cooler. The program consisted of resolving initial specifications, design, development of the cooler including laboratory testing, and in-mine testing at the Homestake Gold Mine in South Dakota.

OP 16–82. Insoluble Crosslinked Starch Xanthate as a Selective Flocculant for Sulfide Minerals, by S. C. Termes, R. L. Wilfong, and P. E. Richardson. Pres. at AIME Ann. Meeting, Dallas, Tex., Feb. 14–18, 1982, Reprint 82–171, 8 pp. This paper discusses recent Federal Bureau of Mines research on the selective flocculation of various minerals with insoluble crosslinked starch xanthate (ISX). ISX is insoluble, has a shelf life of over a year when kept cold, and has a higher molecular weight due to crosslinking than the soluble noncrosslinked starch xanthate used in previous flocculation studies on nonsulfide minerals. ISX readily flocculates a number of sulfide mineral fines but not silicious gangue. Floc formation, floc size, and settling rate are strongly dependent on pH, with the pH dependence differing for each mineral. Bornite has been selectively flocculated from bornite-quartz mixtures, and the bornite containing flocs were separated from the unflocculated quartz using decantation and washing procedures.

OP 17–82. Engineering Properties of Coal Measure Rocks, by Richard E. Thill and James A. Jessop. Pres. at 111th SME-AIME Ann. Meeting, Dallas, Tex., Feb. 14–18, 1982, SME Preprint 82–146, 26 pp. Engineering properties of rock are essential in most phases of mining from site reconnaissance through mineral processing. Review of the literature indicates, however, that property data is scarce for most coal measure rocks in the United States. The Bureau of Mines has undertaken a wide-ranging testing program to provide more complete property data for coal strata in the U.S. coal basins. The property data are expected to have applications in geophysical exploration, development of premining and hazard detection probes and instrumentation, mine design, engineering and rock mass classification, subsidence engineering, and ground control. This paper describes the comprehensive program encompassing in situ geological, geophysical, and geotechnical properties and laboratory determinations of acoustic, electromagnetic, physical, mechanical, and index properties and discusses results for 500 feet of coal measures at a mine site in the northern Appalachian, eastern coal province.

OP 18–82. A Review of Potential Domestic Raw Materials as Substitutes for Refractory-Grade Bauxite, by Dale E. Wittmer. Proc. 111th AIME Ann. Meeting, Dallas, Tex., Feb. 14–18, 1982; pub. in Light Met., 1982, pp. 23–35. The Bureau of Mines characterized foreign and domestic bauxites and domestic high-alumina grogs with respect to chemical and mineralogical analyses and refractory properties. Domestic raw materials such as ferruginous bauxites, saprolites, and zunyite were evaluated as substitutes for imported refractory-grade bauxite (RGB). Available data on ferruginous bauxite reserves are insufficient to evaluate the potential of upgraded ferruginous bauxite as a RGB substitute. Saprolite deposits of the southeast were evaluated as a source of gibbsite, but results indicate that simple beneficiation procedures would not produce a suitable RGB substitute. Initial evaluation of a synthetic magnesium aluminate spinel produced from aluminum dross as a RGB substitute was encouraging.

OP 19–82. Microbial Processes for Removal of Suspended Clays From Selected Industrial Wastewaters, by Carole L. Brierley, Guy R. Lanza, and Bernard Scheiner. Biotechnology and Bioengineering Symp. John Wiley & Sons, Inc., New York, No. 11, 1981, pp. 507–520. Finely divided clays, generated by beneficiating phosphate, are impounded for up to several decades to effect dewatering. Under contract to the Bureau of Mines, several microbiological processes were tested for aggregating suspended clays. Polymers, isolated from *Leuconostoc mesenteroides*, *Xanthomonas sp.*, and *Beijerinckia indica*, flocculated dilute phosphatic clay-slime at a rate comparable to polyethylene oxide; however, biopolymer-flocculated clays produced turbid supernatants. *Cladosporium cladosporioides*, enriched from phosphatic clay-slimes, produced a bioflocculant, and agitated incubation of *C. cladosporioides* spores, sugar, and yeast extract with phosphatic clay-slimes induced clay-fungus pelletization. Microbiologically mediated clay removal may have application in industrial wastewater clarification.

OP 20–82. An Industrial Application of Sulfur Concrete, by R. H. Funke, Jr., and W. C. McBee. Ch. 12 in Sulfur: New Sources and Uses, ed. by M. E. D. Raymont. ACS Symp. Series 183, 1982, pp. 195–208. In cooperation with the U.S. Department of the Interior, Bureau of Mines, and the Sulphur Institute, ASARCO Incorporated tested components of sulfur concrete, both precast and poured in place, in corrosive environments of sulfuric acid. Favorable endurance of these samples led to a full-scale cooperative demonstration project, which was the rehabilitation of an electrolytic zinc cellhouse basement floor of approximately 21,000 square feet. Sulfur concrete utilizing an aggregate gradation of minus 3/8-inch and minus 1/8-inch materials was produced in a portable asphalt patch mix plant. Mixing and placing operations were conducted without problems. Economics of sulfur concrete versus portland cement concrete are highly variable. Total costs were approximately 15 pct higher than for portland cement. Potential uses are electrolytic cells, holding tanks and vats, and floor and basin areas exposed to acidic environments.

OP 21–82. A Simulation Model for Predicting the Performance of Vibrating Screens, by Douglas C. Grant, Kevin Hennings, Thomas Bobick, and Roy Bartholomae. National Limestone Inst. Operations Day Program Booklet, 1982, pp. 57–72. Replacing a woven wire deck on a vibratory screen with one of another type raises questions as to how screening performance may be expected to vary. This paper describes the development of a digital computer model capable of predicting screen performance and the testing done to provide a data base for correlation and verification. Within the range of operating conditions tested, the simulation model in its present state is generally capable of predicting separation efficiency to within ±2 percentage points. Also, predicted sieve analyses of the underproduct and overproduct are in good agreement with those measured.

OP 22–82. Demonstration of Technology To Recycle Chromic Acid Etchants at Gould, Inc., by Glenn L. Horter and L. C. George. Proc. 4th Recycling World Cong. and Exposition, New Orleans, La., Apr. 5–7, 1982, pp. M/3/5/1—M/3/5/13. The process research unit for the regeneration and recycling of chronic acid-sulfuric acid etching solutions developed by the Bureau of Mines was demonstrated in cooperation with Gould, Inc., in Niles, Ill. The process research unit continuously regenerated and recycled etching solution from a brass etching circuit during normal production throughput for 17 days. Evaluation of the data obtained during the demonstration shows that the etching solution was maintained at an acceptable level of performance, consumption of sodium dichromate was reduced by 68 pct, generation of waste was reduced by 76 pct, and the cost of the operation was reduced by 70 pct.

OP 23–82. Canister Concept Provides Early Fire Warning in Mines, by Mervin D. Marshall, Edward D. Thimons, David W. Kneebone, and Stanley Gross. Min. Cong. J., v. 68, No. 4, April 1982, pp. 64–69. Presently, many metal-nonmetal mines have fire-warning systems that make use of a stench gas, which is released from the surface into the compressed-air lines and/or ventilation air. Usually the stench gas is the volatile liquid ethyl mercaptan, mixed with either Freon 11 or Freon 22 to render it inert. Time delays for the stench gas to reach underground mine personnel and the uncertainty of effectively distributing the gas throughout the mine are disadvantages of these surface-release stench systems. To avoid these problems, MSA Research Corp. and the Bureau of Mines have developed a stench gas canister with a heat-fusible release for use in mine locations susceptible to fire. In the event of a fire near the canister, the heat-fusible alloy melts, releasing the gas into the ventilation air and warning all miners downstream of the fire. With appropriate detectors on the mine exhaust, the tracer gas can provide warning of a fire during off-duty shifts or when no mine personnel are downstream of the release.

OP 24–82. Conservation of Chromium in the Tanning Industry, by Jean J. Tancous and Lawrence C. George. Proc. 4th Recycling World Cong. and Exposition, New Orleans, La., Apr. 5–7, 1982, pp. M/3/2/1—M/3/2/17. The tanning industry uses trivalent chromium in the form of water soluble chromium sulfate for the tanning of hides and skins that are byproducts of the meat industry. The U.S. total demand for dichromate in 1976 was 161,00 tons and the tanning industry used 17% or one-sixth of this amount. The waste generated was 9% or one-eleventh of the U.S. total demand. Because of the concern about chromium usage and waste, the Bureau of Mines and Tanners Council of America Inc. made a study of conservation of chromium in the tanning industry. The chromium wasted is present in leather trimmings and shavings, in the effluents from process procedures, and in sludge generated. Ways to recycle the effluent chromium and to recover the chromium from solid waste will be discussed including the possibility of using the chromium-bearing shavings and trimmings with pelletized stainless steel waste in the steel mill. From bench-scale experiments conducted, it was determined that the most economically feasible way to recover chromium from solid waste is by incineration.

OP 25–82. Characterization — Characterization of Bulk Samples, by U.S. Bureau of Mines. Paper in Characterization, Recovery and Recycling of Electric Arc Furnace Dusts, Lehigh University, Bethlehem, Pa., sec. III, February 1982, pp. III.B–1—III.B–4. Bulk chemical analyses including the EP Toxicity Test were undertaken by the Avondale Research Center. As expected, the alloying elements chromium, nickel, and molybdenum show up prominently in the stainless steel and specialty alloy dusts. The amounts of these elements are sufficient to make recovery a viable activity. Carbon steel dusts are richer in zinc (up to 28 wt-pct) and lead (up to 3.8 wt-pct) because of the greater use of galvanized and other coated products in the melt.

OP 26–82. Chemical and Physical Separation—Bulk Specimens—Task B—Chemical Extraction, by U.S. Bureau of Mines. Paper in Characterization, Recovery and Recycling of Electric Arc Furnace Dusts, Lehigh University, Bethlehem, Pa., sec. IV, February 1982, pp. IV.A–1—IV.A–24. One large representative sample of carbon steel dust and one large representative sample of stainless steel dust were given a series of chemical dissolution or leaching tests by the Rolla Research Center. From the results, it would appear that because of the relatively high unit value of the Cr, Ni, Mo, etc., arc furnace dusts from stainless and specialty steelmaking can best be treated pyrometallurgically for recycle by techniques such as in-plant greenballing and recycling to the furnace, or centralized processing to produce master alloy for recycle.

OP 27–82. Chemical and Physical Separation—Bulk Specimens—Task B—Physical Separation, by U.S. Bureau of Mines. Paper in Characterization, Recovery and Recycling of Electric Arc Furnace Dusts, Lehigh University, Bethlehem, Pa., sec. IV, February 1982, pp. IV.C–1—IV.C–13. One large sample of carbon steel dust and one large sample of stainless steel dust were given physical separation tests by the Twin Cities Research Center. The tests showed that physical separation was of no value in treating high-chromium dust from stainless steelmaking. However, physical separation using wet processing has potential value for treating high-zinc dust from carbon steelmaking. Because of the very small particle size and high specific surface area, separation methods requiring adsorption of chemical reagents are not economically feasible with the present technology and the particle size is too small for specific gravity-based techniques. Low-intensity wet magnetic separation is the most practical method of physical separation. Separation with a typical ceramic permanent magnet wet drum separator yields a low-zinc ferromagnetic product and a zinc-enriched product.

OP 28–82. Reconnaissance of Rare-Metal Occurrences Associated With the Old Crow Batholith, Eastern Alaska-Northwestern Canada, by James C. Barker. Short Notes on Alaskan Geology, 1981. Alaska State Department of Natural Resources, College, Alaska, Geol. Rept. 73, 1982, pp. 43–49. Evidence suggests that the emplacement, tectonics, and chemical composition of the Old Crow batholith, located in eastern Alaska and western Yukon Territory, Canada, are favorable for the occurrence of tin, tungsten, uranium, tantalum, niobium, and other rare metals. This evidence is reinforced by findings of uranium, tin, rare-earth oxides, and base metals during the 1976–80 field seasons.

OP 29–82. Alkaline Igneous Rocks in the Eastern Alaska Range, by Jeffrey Y. Foley. Short Notes on Alaskan Geology, 1981. Alaska State Department of Natural Resources, College, Alaska, Geol. Rept. 73, 1982, pp. 1–5. Previously unreported, alkaline igneous rocks occur in the eastern Alaska Range as two dike swarms, one near the West Fork of the Robertson River and another to the east near the Tok River. These rocks intrude the underlying Precambrian and possibly younger, crystalline metamorphic terrane and are believed to be the youngest igneous rocks in the area. A single potassium-argon age date (69.2 ± 1.5 million years) on biotite indicates that a local, Late Cretaceous thermal event was associated with a stage of alkaline magmatism.

OP 30–82. Method for Automatically Rounding Data on the Wang 2200 in Basic Computer Language, by Scott F. Sibley. Geophys. Res. Ltrs., v. 9, No. 2, February 1982, pp. 120–123. The method described permits any set of numbers within an allowable range to be rounded to any number of significant figures. This is accomplished by generation of an array (rounding position) data bank, which is unique for each combination of the following variables: (1) Chosen decimal position, (2) number range of the number to be rounded, and (3) number of significant figures to which this number is to be rounded. It is especially useful as a subroutine in programs that generate large quantities of figures (such as reserve or resource tonnages) that require rounding.

OP 31–82. Consideration of Overburden Lithology for Subsidence Prediction, by Sathit Tandanand and Larry R. Powell. Proc. Workshop on Surface Subsidence Due to Underground Mining, Morgantown, W. Va., Nov. 30–Dec. 2, 1981, pp. 17–33. Geological differences among various coalfields restrain the applicability of subsidence prediction using existing European methods. To modify these methods for domestic conditions, the Bureau of Mines developed a method of assessment to evaluate the lithological effects on subsidence in the northern Appalachian basin by examining data collected from 16 longwall panels in the coalfield. The assessment is partially completed, and the results to date show that the ratio of maximum subsidence to the extraction thickness, known as the subsidence factor, can be expressed in terms of the width-to-depth ratio by a simple exponential equation that has a coefficient tentatively considered as the subsidence index. This index varies with the lithology of a particular site and can be expressed in terms of the percent distribution of weak and strong rocks in the overburden.

OP 32–82. Thermal Energy Recovery for Deep Mines, by Edward D. Thimons and Robert N. Torbin. Pres. at 1st Mine Ventilation Symp., University of Alabama, Tuscaloosa, Ala., Mar. 29–31, 1982; Eng. and Min. J., v. 183, No. 5, May 1982, pp. 98–99. High temperatures and humidities in deep mines make a comfortable working environment difficult and expensive to maintain. Large quantities of refrigeration water must be carried down long, vertical pipelines. The electrical costs of this refrigeration are rising owing to increased demand and rising kilowatt-hour costs. Converting the energy of falling water into useful work is a well-developed engineering concept. Much of the electric power consumed in the United States is generated this way. Water that flows down long, vertical pipelines into deep mines could be used to operate a turbine at the bottom of the pipeline.

OP 33–82. Identification and Quantification of Asbestos in Construction Materials Using Polarized Light Microscopy: The Need for Standards, by R. L. Virta, K. B. Shedd, and W. J. Campbell. Proc. NBS/EPA Asbestos Standards Workshop, Gaithersburg, Md., Oct. 1–3, 1980; NBS SP 619, March 1982, pp. 34–43. The Bureau of Mines Particulate Mineralogy Unit, in cooperation with the Environmental Protection Agency (EPA), conducted a round robin program to evaluate the reliability of analyses of asbestos-containing building materials by polarized light microscopy. This microscopic technique was selected by EPA as the principal analytical method for asbestos identification and quantification in their program to evaluate the potential health risks from exposure to airborne asbestos in public buildings. Results of the round robin show a need for monomineralic reference samples of asbestos and nonasbestos components of these materials to aid in identification training. Also necessary are bulk standards containing known amounts of asbestos to be used in verification and quality control of quantification techniques.

OP 34–82. Selective Extraction of Tungsten From Searles Lake Brines, by P. B. Altringer, P. T. Brooks, and W. A. McKinney. Sep. Sci. Technol., v. 16, No. 9, 1981, pp. 1053–1069. Tungsten was successfully extracted from the brines of Searles Lake, Calif., in a demonstration unit based on 9 years of laboratory research conducted by the U.S. Department of the Interior, Bureau of Mines. Pilot-scale operation was initiated in July 1979 at the Westend facility of the Kerr-McGee Chemical Corp. at Trona, Calif. The extractive method, based on a novel ion exchange resin, resulted from research supporting one of the Bureau's goals: helping to insure an adequate supply of minerals to meet national economic and strategic needs. The objectives met during pilot testing included proving operational viability during seasonal changes in brine properties, concentrating the tungsten to enable concluding tungsten recovery research, supplying escalation data necessary for commercialization, and confirming earlier small-scale laboratory work. The demonstration unit typically removed 92 percent of the tungsten from alkaline brine using QRF (8-hydroxyquinoline-resorcinol-formaldehyde) resin beads produced by the Bureau. A "merry-go-round" system was employed whereby two 12-inch-diameter resin beds were loaded in series while a third bed was eluted. Testing was concluded after treating over 500,000 gallons of brine. Tungsten, isolated in the primary ion exchange system, was reconcentrated in a secondary ion exchange system. Several tungsten products were produced from tungsten-rich solutions.

OP 35–82. The Effectiveness of Overpressure Ventilation: A Mathematical Study, by Robert C. Bates

and John C. Edwards. Ch. 24 in Radiation Hazards in Mining: Control, Measurement, and Medical Aspects, ed. by M. Gomez. Pub. by Society of Mining Engineers of AIME, New York, 1981, pp. 149–154. Results are given of a mathematical study by Bureau of Mines personnel of overpressurization ventilation effects in underground uranium mines. The mathematics and computer codes make it possible to analyze many facets of transient and steady-state radon diffusion with Darcy flow. Rapid changes in radon flux occur after imposing a pressure differential across the model. Flux into the model mine drops to near zero and then increases to the steady-state level, while the sink flux increases rapidly and then drops slightly to the steady-state level. Magnitudes of mine flux decreases and sink flux increases are dependent upon the distance from the mine to sink, permeability, and amount of overpressure. Current work on more complex models is also described.

OP 36–82. A Plan for Modeling Uranium Radon Daughter Concentrations, by Robert C. Bates and John C. Edwards. Ch. 38 in Radiation Hazards in Mining: Control, Measurement, and Medical Aspects, ed. by M. Gomez. Pub. by Society of Mining Engineers of AIME, New York, 1981, pp. 256–259. Modeling uranium mine radiation control methods and natural environmental radon variations is an extremely complex endeavor. A number of authors have examined particular facets of the problem and have proposed models for their area of interest. Bureau of Mines personnel brought together many of these individual studies, and from them have attempted to develop a coordinated plan for modeling radon daughter concentrations in the uranium mine environment. This approach is described.

OP 37–82. Ventilation Cost Impact of Reduced Radon-Daughter Working Levels, by Robert C. Bates. Ch. 159 in Radiation Hazards in Mining: Control, Measurement, and Medical Aspects, ed. by M. Gomez. Pub. by Society of Mining Engineers of AIME, New York, 1981, pp. 1066–1070. Published information on costs of radon-daughter control in uranium mines was analyzed to develop estimates of the cost per ton for any level of radiation exposure control. All data were converted to 1967 cost of living index to provide a common analysis base. Results of the analysis show that the cost per ton increases exponentially as the radiation level is lowered. A linear relationship with the cost of living index is assumed, and equations and graphs are provided to estimate control cost per ton for any exposure control level and cost of living index.

OP 38–82. Evaluation of Recent Developments in Radon Progeny Measurements, by T. B. Borak, E. Franco, K. J. Schiager, J. A. Johnson, and R. F. Holub. Ch. 66 in Radiation Hazards in Mining: Control, Measurement, and Medical Aspects, ed. by M. Gomez. Pub. by Society of Mining Engineers of AIME, New York, 1981, pp. 419–425. The evaluation of grab sampling methods for monitoring exposure to radon progeny is presented. Each method is examined individually according to accuracy, precision, and uncertainties attributed to human errors. An analysis of procedures that are common to all measurement methods is included.

OP 39–82. Bureau of Mines Statement of Principles, by John A. Breslin. Ch. 6 in Radiation Hazards in Mining: Control, Measurement, and Medical Aspects, ed. by M. Gomez. Pub. by Society of Mining Engineers of AIME, New York, 1981, pp. 15–16. Control of radiation hazards in mines is only one of many goals of the Bureau of Mines. Radiation research is only a small part of the Bureau's mine health and safety research program. This paper describes the mission and programs of the entire Bureau of Mines, with emphasis on the mine health and safety program of which the Bureau's radiation research is a part.

OP 40–82. Sandcasting Titanium and Zirconium, by J. M. Burrus and R. K. Koch. Foundry M&T, v. 110, No. 5, May 1982, pp. 43–51. Research conducted at the Bureau of Mines Albany Research Center on alternatives to the rammed-graphite molding process currently used in industry is described. With the alternative molding processes developed in this research, the cost of titanium castings could be reduced to allow cast titanium to substitute for chromium-, nickel-, and cobalt-containing alloys in the transportation and chemical processing industries.

OP 41–82. Instrumentation for Measuring Uranium Miner Exposure to Radon Daughters, by Robert F. Droullard. Ch. 51 in Radiation Hazards in Mining: Control, Measurement, and Medical Aspects, ed. by M. Gomez. Pub. by Society of Mining Engineers of AIME, New York, 1981, pp. 332–338. The U.S. Bureau of Mines has investigated instrumentation and methods for measuring exposure to radon daughters in underground mine atmospheres. Both personal and area monitors have been studied through in-house and contract research. A field study in uranium mines identified some reliability problems that required additional work for the personal dosimeter systems. Improved versions of continuous working level detectors have been developed and tested for use as area monitors in underground mines. Test results for the personal and area monitors were satisfactory for underground mine applications.

OP 42–82. Bureau of Mines Studies Forest Appraisal Part of RARE II Program, by Steven A. Fechner and Mark P. Meyer. Alaska Miner, v. 10, No. 5, May 1982, pp. 13, 18. Part of the requirements of RARE II withdrawals for the Chugach National Forest require that a mineral assessment be done of the area. The eastern half of the forest, called the SOUND Study Area, has been examined over the past 3 years. This report presents a review of the work so far in the 4-year program.

OP 43–82. Control of Radiation Hazards in Underground Uranium Mines, by John C. Franklin. Ch. 69 in Radiation Hazards in Mining: Control, Measurement, and Medical Aspects, ed. by M. Gomez. Pub. by Society of Mining Engineers of AIME, New York, 1981, pp. 441–446. Alpha-emitting radon daughter products are a recognized health hazard contributing to the development of lung cancer in persons exposed to excessive concentrations over an extended period. The primary control technique used by the mining industry is dilution with fresh air. Because the uranium is deposited in porous sandstone in most U.S. mines, the control of this hazard with dilution requires excessive volumes of air. As the mines become larger and deeper, the cost for ventilation becomes a major expenditure for the mining industry. Most mines are maintaining levels of radon daughters lower than required by law but to maintain these present levels the mining companies are going to be drilling more vent holes or using other control techniques as the mine expands. These control techniques are being investigated by the Bureau of Mines to determine their effectiveness, cost, and safety for underground use.

OP 44–82. Airborne Radiation Warning System, by John C. Franklin and David M. Shaw. Ch. 148 in Radiation Hazards in Mining: Control, Measurement, and Medical Aspects, ed. by M. Gomez. Pub. by Society of Mining Engineers of AIME, New York, 1981., pp. 980–983. A 32-channel warning system for high working level, fan operation, and airlock-doors has been constructed. The working level monitors have a microcomputer for accumulating the pulses, converting to working level, and triggering an alarm at a variable set point and at one working level. The system can detect changes in air velocity which indicate surface fan failures or changes in the ventilation system. Using this alarm system, the ventilation engineer will be alerted prior to excessive levels of radon daughters being reached so corrective action can be taken.

OP 45–82. Multicomponent Regular Solutions, by N. A. Gokcen. Scripta Metallurgica, v. 16, 1982, pp. 723–727. Statistical thermodynamics of the binary regular solutions is now on a firm basis with a treatment based on the actual enumeration of configurations of molecules in solution. The equations resulting from the first approximation to the binary regular solutions are fairly simple but they become complicated for ternary and multicomponent solutions. Similar equations have not yet been derived for multicomponent solutions. The purpose of this paper is therefore to derive the appropriate equations for multicomponent regular solutions and to discuss briefly their significance.

OP 46–82. A Resin-Loaded Paper X-Ray Fluorescence Method for Determining Uranium in Phosphate Materials, by Benjamin W. Haynes, Jerome Zabronsky, and David L. Neylan. Proc. 30th Ann. Conf. on Applications of X-Ray Analysis, Denver, Colo., Aug. 3–7, 1981, pp. 107–111. An analytical method has been developed at the Bureau of Mines Avondale Research Center for determining uranium in phosphate rock processing and waste materials using a combination of preconcentration and X-ray spectrography. Previous work has shown the usefulness of resin-loaded papers for preconcentration in X-ray analysis on samples of varying matrices. This method allows the determination of other radionuclides in the sample while avoiding the use of alpha spectrometry for determining uranium. A roundrobin analysis of phosphate material samples involving this center and other Bureau of Mines research centers gave results that agreed with values obtained by accepted procedures. Good agreement was also obtained for the certified value of uranium in National Bureau of Standards SRM 120b phosphate rock.

OP 47–82. Factors Affecting Radon Transport and the Concentration of Radon in Mines, by R. F. Holub, P. J. Dallimore, and the Department of Physics and Geosciences, Western Australian Institute of Technology. Ch. 154 in Radiation Hazards in Mining: Control Measurement, and Medical Aspects, ed. by M. Gomez. Pub. by Society of Mining Engineers of AIME, New York, 1981, pp. 1022–1028. Basic to solving the problem of the role of radon transport on radon concentrations in mines is to establish whether it occurs primarily as diffusion in force flow through porous rock or through fissures in the rock. The laboratory experiments performed involved measurements of diffusion and emanation coefficients, porosity, and permeability of representative rock samples. Significant differences have been found when comparing the results of the laboratory permeability determinations to those of the mine determinations. Considerations of underlying principles, however, suggest that the diffusion and emanation coefficients are the same in laboratory and mine. It was also found that moisture content plays a dominant role in radon transport through rock. Using these concepts and findings, some conclusions about the radon concentrations in mines have been drawn.

OP 48–82. Assessment of Toxicity Impacts Associated With Phosphogypsum in Florid¬, by Alexander May and John W. Sweeney. Proc. Environmental Symp. '82, sponsored by the Fertilizer Inst., San Antonio, Tex., Mar. 8–10, 1982, pp. 97–121. A part of the Bureau of Mines Minerals Environmental Technology research program is to assess problems associated with radium in the large tonnages of phosphogypsum in Florida. Another part is to develop a data base so that, through a continuing research effort, potential environmental problems can be identified and mitigated. The Bureau's Tuscaloosa Research Center conducted research to characterize phosphogypsum to determine if it is hazardous or toxic, and if so, to investigate means of mitigating the situation so that the phosphogypsum could be used in a variety of high-volume applications.

OP 49–82. The Role of the Bureau of Mines in Radiation Hazards Research, by George E. Niewiadomski. Ch. 18 in Radiation Hazards in Mining: Control, Measurement, and Medical Aspects, ed. by M. Gomez. Pub. by Society of Mining Engineers of AIME, New York, 1981, pp. 97–104. This paper highlights the current efforts of the Bureau of Mines radiation hazards research program. It is aimed at obtaining a fundamental understanding of the behavior and transport of radon and radon daughters, developing more accurate and reliable instruments and measurement methods, and developing cost-effective control techniques. Also discussed are the most recent accomplishments and the future research plans of the program.

OP 50–82. Comparative Cavability Studies at Three Mines, by Louis A. Panek. Ch. 9 in Design and Operation of Caving and Sublevel Stoping Mines, pub. by Society of Mining Engineers of AIME, New York, 1981, pp. 91–106. This paper explains the rationale of the Bureau of Mines ongoing investigation that has the objective to develop procedures for precalculating the minimum span required for sustained caving and the size distribution of the caved ore fragments, based on rock mass strength tests and measurements of joint spacing and attitude. With the help of such quantitative design procedures the undercut-cave method can be extended to a much wider range of mineral deposit characteristics.

OP 51–82. Ground Movements Near a Caving Stope, by Louis A. Panek. Ch. 24 in Design and Operation of Caving and Sublevel Stoping Mines, pub. by Society of Mining Engineers of AIME, New York, 1981, pp. 329–354. Measurements of ground movements showed that a halo of cracking develops about a caving stope, extending to distances greater than 100 meters, the principal change of deformation being extension directed toward the cave. The development of the fracture zone of expansion has significant implications with respect to the caving, drawing, and ground support operations.

OP 52–82. Geotechnical Factors in Undercut-Cave Mining, by Louis A. Panek. Underground Mining Methods Handbook, pub. by Society of Mining Engineers of AIME, New York, 1982, pp. 1456–1465.

This paper is a state-of-the-art summary that relates the underlying geotechnical factors to the mining processes and presents approaches to generating the measurement data that are needed to resolve the corresponding problems.

OP 53–82. Large-Scale Dewatering Tests of Phosphate Clay Waste: Progress Report, by B. J. Scheiner, Annie G. Smelley, and D. R. Brooks. Proc. Environmental Symp. '82, sponsored by the Fertilizer Inst., San Antonio, Tex., Mar. 8–10, 1982, pp. 57–70. Recently, the Bureau of Mines developed a dewatering technique for phosphatic clay waste. The technique consists of treating the clay waste with a flocculant such as polyethylene oxide and dewatering the resulting flocs on a mechanical device such as a rotary screen. In small-scale continuous tests at the Bureau's Tuscaloosa Research Center, clay waste was consolidated from a nominal 4 pct solids to about 20 pct solids. Based upon these encouraging results, a field test unit was operated at the Estech Corp.'s City Silver Mine, located near Bartow, Fla. The unit is now operating at the Occidental Suwannee River Mine near White Springs, Fla. This report describes the results of field tests conducted to date.

OP 54–82. U.S. Bureau of Mines Develops Portable Crusher for Underground Hardrock Mines, by Robert L. Schmidt. Eng. and Min. J., v. 183, No. 1, January 1982, pp. 72–75. The high cost of materials-handling in most underground hardrock mines prompted the Bureau of Mines to develop a portable, low-headroom crusher. This equipment can be positioned close to the face to allow the operation maximum utilization of low-cost conveyor haulage. The unit was successfully tested in a limestone quarry, and a long-term production test is planned.

OP 55–82. The Bureau of Mines Automated Minerals Information System—AMIS, by Jon P. Stone and L. Michael Kaas. Proc. 17th Internat. Symp. on computer applications in the mineral industry, Golden, Colo., Apr. 19–23, 1982; ch. 67 in Application of Computers and Operations Research in the Mineral Industry, pp. 740–753. The Automated Minerals Information System (AMIS) is an integrated data base system being developed to support the Bureau of Mines minerals information collection and analysis activities. The system facilitates cross-referencing and integration of domestic and foreign information from a variety of sources. The AMIS provides a central source of minerals information that is versatile and responsive to the needs of problem and policy analysts as well as supporting the needs of those involved in data collection and interpretation. As the AMIS becomes fully implemented, it will become an important tool in forecasting and assessing the impact of policy decisions that affect the supply and demand for minerals. This paper describes the AMIS in detail.

OP 56–82. Brushes Lessen Stopping Leaks, by Robert J. Timko, Mervin D. Marshall, and John C. King. Coal Age, v. 87, No. 4, April 1982, pp. 108–114. Most ventilation air that enters a typical coal mine never reaches the mine working sections. Because of poor stopping construction, the air short circuits to the returns instead. With power costs at the present level and expected to rise, mines are becoming aware that ventilation air is a significant cost of operation. The Bureau of Mines concentrated on practical, low-cost improvements in building concrete block stoppings that would be available to any mine operator. It was found that a strong and airtight block stopping could be built by brushing instead of trowelling on mortars. Using a brush, rather than a trowel, has several benefits. The average mine laborer is more proficient with a brush. The final sealant finish is smooth, and any unsealed holes are apparent. Airtightness is improved at the block joints and around the periphery of the stoppings, where leakage is most prevalent. Finally, in the hands of the mine laborer, this method offers a faster application with less waste.

OP 57–82. Resource and Environmental Assessment of Large-Volume Wastes: Cement Kiln Dust, Phosphate Rock Wastes, and Coal Ash, by Benjamin W. Haynes, Gary W. Kramer, Robert C. Gabler, Jr., and Robert L. Stoll. Proc. 14th Mid-Atlantic Industrial Waste Conf., June 27–29, 1982, College Park, Md., pp. 222–231. The Bureau of Mines Avondale Research Center has investigated the resource recovery potential of three large-volume wastes in response to questions raised concerning some of the potential environmental problems that could be caused by these wastes. These wastes—cement kiln dust, phosphate rock wastes, and coal ash—were chosen because of their potential for resource recovery and possible alternative uses. By determining alternative uses and/or valuable accessory minerals present, the wastes could be converted from a potentially hazardous waste to a resource, reducing adverse environmental effects. Details of these studies on large-volume waste are given including methods of analyses, compositions of the wastes, resource recovery potential, and environmental assessment.

OP 58–82. Mining Picks Up Across the State. Gold Was the 1980 Glamour Metal, by Tom Pittman. Alaska Construction & Oil, v. 22, No. 6, June 1981, pp. 28, 30–31, 34. This paper discusses the mining activity of gold and barite in Alaska during 1980. The discussion includes comparisons of production and prices between 1979 and 1980 and gives estimates for the future.

OP 59–82. How the Six Cleanest U.S. Longwalls Stay in Compliance, by Charles D. Taylor and Robert A. Jankowski. Min. Cong. J., v. 68, No. 5, May 1982, pp. 37–40. The objective of a U.S. Bureau of Mines program was to conduct dust surveys at six longwall sections having double-drum shearers, which were regularly in compliance, and to identify the dust control techniques that were the most effective. As each of the mines selected had a record of regular compliance with Federal Dust Standard, all sampling was "short-term" (often less than 30 minutes) and no attempt was made to relate the survey results to dust sampling results obtained by the companies for compliance purposes. The sampling procedures used during this survey were developed jointly by the Bureau of Mines and Foster-Miller Associates, Inc. In addition to monitoring dust levels, measurements were also taken throughout the shift to monitor airflow along the face, and water usage on the shearer. This program was a cooperative effort of the Bureau of Mines and the Mine Safety and Health Administration.

OP 60–82. Subsidence Control by Backfilling, by Alice S. Allen and James Paone. Ch. 4 in Underground Mining Methods Handbook, ed. by W. A. Hustrulid. Pub. by the Society of Mining Engineers of AIME, New York, 1982, pp. 210–226. The consequences of subsidence become more serious as increasing requirements for mineral products conflict with the needs of an expanding population for surface land area. As a means of controlling

subsidence in urban undermined areas, the Bureau of Mines has developed the pumped-slurry process for backfilling underground mine workings that are inaccessible because of flooding, gas accumulation, or caving. In a mixing tank, fill materials are placed in suspension and conveyed in a closed system through a slurry pump, distribution pipeline, and injection borehole into subsurface mine voids. Materials used for fill include crushed waste rock left from mining and processing, fly ash, and sand. In many areas, the local mine pool provides adequate quantities of water. The objective of backfilling mine voids is to mitigate adverse environmental effects of underground mining. The potential for future subsidence is substantially diminished. If waste mine rock is used for fill material, unsightly waste piles are eliminated, restoring land for higher economic use. Removal of waste piles also eliminates bank fires caused by spontaneous combustion, noxious and poisonous gases, particulate matter, and sediment and acid drainage that may enter nearby streams and ponds.

OP 61–82. Bureau of Mines Research To Improve Underground Metal/Nonmetal Mining Technology, by L. L. Davis. Min. Eng., v. 33, No. 3, March 1981, pp. 305–312. Current research by the Bureau of Mines to develop technology for improving efficiency and productivity in metal/nonmetal mines is described. The research program addresses a wide variety of problems associated with each of the major categories of mining: underground mining, surface mining, in situ mining, and premining investigations. An overview of the Bureau's research activities is given with emphasis on underground mining. In particular, two innovative and promising concepts currently under development are described: a unique shaft sinking system that uses an impact hammer for rock fragmentation, and a low-profile portable crusher for underground hard-rock applications.

OP 62–82. Utilization of Domestic Low-Grade Titaniferous Materials for Producing Titanium Tetrachloride, by G. W. Elger, J. E. Tress, and R. R. Jordan. Pres. at AIME Ann. Meeting, Dallas, Tex., Feb. 14–18, 1982; pub. in Light Met., 1982, pp. 1135–1147. The Bureau of Mines is investigating the use of low-grade domestic titaniferous materials to produce titanium-rich slags as substitutes for imported rutile used in titanium tetrachloride production. This investigation is part of the Bureau's program to develop technology for maintaining an adequate supply of minerals to meet national economic and strategic needs.

OP 63–82. Restoration of Groundwater Quality Following Pilot-Scale Acidic In-Situ Uranium Leaching at Nine-Mile Lake Site Near Casper, Wyoming, by William H. Engelmann, P. E. Phillips, Daryl R. Tweeton, Kent W. Loest, and Michael T. Nigbor. Soc. Pet. Eng. J., June 1982, pp. 382–398. The results of the first restoration effort for a pilot-scale acidic leaching of a uranium ore body in the United States are given. The project was performed under an agreement between the Bureau of Mines and a joint venture consisting of Rocky Mountain Energy, Mono Power Co., and Halliburton Co. The leaching phase is described only briefly; it was reported earlier by Tweeton. Leaching was done with H_2SO_4 (pH range of 1.6 to 3.9) and H_2O_2 (80 to 1,000 ppm) over an 11-month period. The restoration phase began in September 1978 and was completed in 11 months. Water samples were taken from observation wells located between injection and production wells while the leaching solution was decreased in strength. Ground water quality in the leaching ore zone was restored by diluting and neutralizing effects of injecting native groundwater and treated water produced from recovered solution. Recovered water was purified by a combination of chemical precipitation and reverse osmosis. In situ measurements of pH, Eh, dissolved oxygen, conductivity, and temperature were made by a downhole probe in one of the wells. Water samples were taken and analyzed for U, V, Na, K, Ca, Mg, SO_4, P, Cl, F, Fe, Mn, Si, Zn, As, and Se.

OP 64–82. Longwall Cuts Dust Build-up, by Robert A. Jankowski and Joseph Hetrick. Coal Age, v. 87, No. 6, June 1982, 4 pp. A longwall at Barnes and Tucker Coal Co.'s Lancashire No. 20 mine, near Barnesboro, Pa., is controlling respirable dust successfully with a bidirectional shearer featuring a small and a large drum and a cutting sequence that keeps face workers in a split of clean air during most of the mining cycle. The longwall unit, which cuts about 800 tons per shift in a 60-in-thick area of the Lower Kittanning seam, has a consistent record of compliance with a 2.0-mg/m^3 Federal respirable-dust standard. According to a survey the Mine Safety and Health Administration conducted in 1978, the average face worker's exposure to respirable dust at the mine ranged from 1.1 to 2.0 mg/m^3. In 1981, dust exposure was 0.6 to 1.5 mg/m^3 for designated occupations. Air along the 400- to 500-ft-wide longwall face flows into the tailgate and out through the headgate. A separate split of air from the belt entry returns into the gob entry as well. The longwall panel is supplied with 18,000 ft^3/min of air that achieves a face velocity of 200 ft/min.

OP 65–82. Recent Advances in Mine Safety Technologies in the United States of America, by Robert L. Marovelli and Chi-shing Wang. Proc. 11th World Min. Cong., Belgrade, Yugoslavia, May 31–June 3, 1982, v. B, pp. 649–674. Over the past 12 years the U.S. Bureau of Mines almost quintupled its annual expenditures on minerals health and safety research. The expanded research and development program is having significant impact on the advancement of mine safety technologies. This paper highlights some innovations that have been validated by industrial applications or by extensive field demontsrations.

OP 66–82. Recovering Accessory Minerals From Lead and Zinc Process Wastes, by V. R. Miller and D. L. Paulson. Pres. at Resource Recovery and Environmental Issues of Industrial Solid Wastes Symp., Gatlinburg, Tenn., Oct. 28–30, 1981. Pub. in Res. and Conserv., Elsevier Scientific Publishing Co., Amsterdam, the Netherlands, v. 9, August 1982, pp. 95–104. This research is part of a continuing effort to reduce environmental conflicts and occupational hazards associated with mineral processing and to recover valuable constituents in wastes. A laboratory process for lead smelter flue dust (sulfation roasting followed by water leaching) extracts over 95 pct of the Cd and Zn. Ninety-nine percent of the Cd is recovered from solution by sponging with zinc dust, and Zn is electrowon from the resulting solution after purification. The Cd and Zn leach residue consists largely of $PbSO_4$, which is converted to $PbCO_3$ and leached with H_2SiF_6 to produce $PbSiF_6$ electrolyte for lead electrolysis. Accessory minerals (such as Co and Ni) are separated into purification residues for subsequent recovery. A copper-cake residue treatment process consists of leaching with

sulfuric acid to extract Cd and Zn, which are recovered as in the flue dust processing. The insoluble residue, containing Cu, As, Co, and Ni, is leached with manganese dioxide and sulfuric acid to solubilize those metals while leaving a residue of $PbSO_4$. The solubilized metals are recovered from the leach solution by caustic purification (As and Fe removal) and sequential sulfide precipitations. The products are copper sulfide and cobalt-nickel sulfide. The manganese is reclaimed from the leach liquor as manganese dioxide for recycle.

OP 67–82. Ceramic Roadway Aggregates, by A. V. Petty, Jr. Proc. ASTM Committee D–4 Symp. on Road and Paving Materials, Orlando, Fla., Dec. 10, 1980; pub. in Extending Aggregate Resources, ASTM STP 774, 1982, pp. 196–212. Through a cooperative program between the Bureau of Mines Tuscaloosa Research Center and the Federal Highway Administration, ceramic aggregates having high wear resistance and polish resistance were developed. Three hundred aggregate compositions, incorporating a variety of low-cost "waste" materials, were evaluated over a 30-month period. Aggregates are produced using conventional ceramic processing techniques and fired at temperatures ranging from 900° to 1,500° C. British Wheel and Los Angeles Abrasion tests were used for initial screening of the aggregates. These data, in addition to raw materials costs, availability, and energy requirements, were used to select nine compositions for circular track tests at Maryland and North Carolina Highway Department facilities. Economic evaluations showed that present production costs, based on a 1,000-ton-per-day operation, ranged from $10 to $120 per ton of material produced. Guyana bauxite was used as a standard, and several of the selected compositions developed surpassed the bauxite in performance and were lower in cost.

OP 68–82. New Mining Technologies Resulting From U.S. Bureau of Mines Research, by Donald G. Rogich. Proc. 11th World Min. Cong., Belgrade, Yugoslavia, May 31–June 3, 1982, v. B, pp. 397–409. The Bureau of Mines conducts a wide variety of research to improve the technology associated with the exploitation of mineral deposits. These studies, which cover all aspects of surface and underground mining, have produced a number of innovative techniques and equipment that have significant potential benefits in minerals extraction. This paper examines a number of recent developments that have been the product of Bureau of Mines research, with emphasis on the problems to be overcome, the research approach, the resulting developments, and potential benefits. Specific items to be addressed include a retractable drill bit for exploration and development drilling; developments in borehole mining techniques for the exploitation of small, near-surface deposits; new low-headroom crusher developments for room-and-pillar mining; and large-scale crusher developments for open pit mines. These developments have application to a wide variety of minerals exploitation including uranium, limestone, copper, lead, and zinc, as well as problems in minerals exploration.

OP 69–82. Measurement of the Thickness of Amphibole Asbestos Fibers With the Scanning Electron Microscope and Transmission Electron Microscope, by A. G. Wylie, K. B. Shedd, and M. E. Taylor. Proc. 17th Ann. Conf. of the Microbeam Analysis Society, Washington, D.C., Aug. 9–13, 1982. Pub. in Microbeam Analysis—1982, ed. by K. F. J. Heinrich. San Francisco Press, Inc., San Francisco, Calif., Aug. 9, 1982, pp. 181–187. Knowledge of the cross-sectional shape of mineral fibers is important for their accurate dimensional characterization. Two techniques for the measurement of width and thickness of fibers are described and compared: one for the scanning electron microscope (SEM) and one for the transmission electron microscope (TEM). The frequency distributions of log thickness and width determined by these techniques are considerably more accurate when the TEM is used. However, the use of either technique results in essentially the identical quantitative descriptions of the relationship between thickness and width for amosite and crocidolite. A general relationship between thickness and width for amphibole asbestos is log thickness = 0.692 log width — 0.493; a rectangle is a reasonable approximation of its cross-sectional shape.

OP 70–82. Extraction of Leachable Metals and Recovery of Alumina From Utility Coal Ash, by R. C. Gabler, Jr., and R. L. Stoll. Pres. at Resource Recovery and Environmental Issues of Industrial Solid Wastes Symp., Gatlinburg, Tenn., Oct. 28–30, 1981; pub. in Res. and Conserv., Elsevier Scientific Publishing Co., Amsterdam, the Netherlands, v. 9, 1982, pp. 131–142. The extraction of metals from coal ash was investigated as part of a Bureau of Mines program to convert waste materials from a disposal problem to potential secondary resources. The objectives of this study were to produce a more environmentally acceptable waste and offset waste disposal costs with recovered metal values. The research was conducted in two steps: determination of parameters affecting extraction of aluminum from coal ash, and development of extraction-recovery procedures.

OP 71–82. Heteronuclear Compounds of Arsenic and Antimony, by James E. Mauser. Met. Trans. v. 13B, No. 3, September 1982, pp. 511–513. During the roasting of copper ores when both arsenic and antimony sulfides are present, the evolution of arsenic is retarded and the volatilization of antimony increased primarily because of the formation of heteronuclear compounds. These heteronuclear compounds exhibit vapor pressure different from those of their individual parent compounds. Because the arsenic and antimony content in copper ores and concentrates is generally 1 percent or less, the anomalous vaporization behavior of mixed arsenic and antimony oxides and sulfides may be of small magnitude. However, because the phenomenon of preferential antimony volatilization was noted in roasting studies of concentrates and because high-arsenic flue dusts and antimony speiss are sometimes roasted together, the formation of heteronuclear compounds of arsenic and antimony is a factor that should be considered.

OP 72–82. Preparing Rare Earth Silicon Iron Alloys, by E. Morrice and M. M. Wong. Proc. 15th Rare Earth Research Conf., Rolla, Mo., June 15–18, 1981; pub. in The Rare Earths in Modern Science and Technology, ed. by G. J. McCarthy, H. B. Silber, and J. J. Rhyne, v. 3, Aug. 30, 1982, pp. 557–560. As part of its mission to assure the maximum recovery and use of the Nation's mineral resources, the Bureau of Mines investigated an improved procedure for producing rare earth-silicon alloys. For example, a charge consisting of 681 grams of mixed rare-earth oxides, 309 grams of ferrosilicon (75 wt-pct Si), and 182 grams of aluminum metal along with a flux consisting of 681 grams of CaO and 45 grams of MgO was reacted at 1,500° C in an induc-

tion furnace. Good slag-metal separation was achieved. The alloy product contained, in weight-percent, 53 rare earth (RE), 28 Si, 11 Fe, and 4 Al with a rare earth recovery of 80 pct. In currently industrial practice, rare earth recoveries are usually about 60 pct in alloy products that contain approximately 30 wt-pct each of rare earths and silicon. Metallurgical evaluations showed that the alloys prepared in this investigation to be as effective in controlling the detrimental effect of sulfur in steel and cast iron as the commercial rare earth-silicon-iron alloys presently used in the steel industry.

OP 73–82. Use of Low-Btu Gas in Iron Ore Pelletizing, by John C. Nigro. Min. Cong. J., v. 68, No. 8, August 1982, pp. 50–58. The iron ore pelletizing industry has a current energy demand approaching the equivalent of about 4 million tons per year of western coal. In the past, a favorable combination of fuel price and supply led to the use of premium natural gas and No. 2 fuel oil as the major heat sources for the pelletizing process. A shift in premium fuel supplies and price relationships in recent years has forced the industry to seek ways to utilize coal as an alternate source of energy either in direct combustion or through conversion to gaseous or liquid fuels. In 1978, a research program to demonstrate the technical feasibility and practicality of using a hot, raw, low-Btu coal gas as a fuel for high-temperature induration of iron ore pellets was initiated by the Bureau of Mines Twin Cities Research Center. Cooperators in the program include the U.S. Department of Energy and 20 U.S. firms with interests in iron ore, coal, gas, and industrial engineering. Coal gas used in the pelletizing program was derived from gasifying bituminous, subbituminous, and lignite coals. This report summarizes the performance characteristics of a 30-day, around-the-clock gasification-pelletizing test conducted in October and November 1980 with North Dakota Indianhead lignite. Gasification was conducted in a commercial-size, 6.5-foot-diameter, Wellman-Galusha single-stage, fixed-bed, atmospheric producer with a rated capacity of about 30 million Btu per hour. Iron oxide pellets made from a commercial hematite concentrate were fired with the low-Btu gas in a 2.8-foot-diameter by 35-foot-long pilot plant rotary kiln at a rate of 900 pounds of pellets per hour. Gassifier operations at fuel rates up to 3 tons of lignite per hour and hematite pellet induration with raw lignite gas of 160 Btu per standard cubic foot are described.

OP 74–82. Infrared Temperature Measurements of Gas and Dust Explosions, by K. L. Cashdollar and M. Hertzberg. Pres. at 6th Symp. on Temperature, Washington, D.C., Mar. 14–18, 1982, Pub. in Temperature. Its Measurement and Control in Science and Industry, ed. by J. F. Schooley. American Institute of Physics, New York, v. 5, 1982, pp. 453–463. This paper presents temperature measurements of gas and dust explosions. Instrumentation used includes a commercial rapid-scan spectrometer and two multiwavelength infrared pyrometers developed at the Bureau of Mines. The rapid-scan spectrometer has a wavelength range of 1.7 to 4.8 μm and a maximum rate of 800 scans per second. One of the pyrometers is a three-wavelength, near-infrared instrument with a time response of about 20 μsec, and it measures continuum radiation from particles in the flame at wavelengths of 0.8, 0.9, and 1.0 μm. The second infrared pyrometer measures continuum radiation from hot particles at four wavelengths (1.6, 2.3, 3.8, and 5.0 μm) and band emission from carbon dioxide gas at 4.4 and 4.6 μm. It has a time response of about 25 μsec. Temperatures for small- and large-scale methane-air explosions were measured with the rapid-scane spectrometer, based on the absolute radiance and on emission-absorption measurements using a blackbody source. Measurements of both gas and dust temperatures for small-scale dust explosions were made with the rapid-scan spectrometer and the two pyrometers. The two pyrometers have also been used to make temperature measurements within full-scale mine coal dust explosions.

OP 75–82. Refractory Dolomite Raw Materials, by T. A. Clancy and D. J. Benson. Proc. Raw Materials for Refractories Conf., University of Alabama, Tuscaloosa, Feb. 8–9, 1982, v. 1, No. 1, pp. 220–253. As one of its goals to reduce the Nation's dependence on imported strategic and critical materials, the U.S. Bureau of Mines is conducting research to encourage the use of plentiful domestic dolomitic resources. Greater use of our dolomite materials in a variety of refractory processes could reduce our dependence on imported chromite and more expensive seawater periclase. A review of the literature on dolomite refractories has indicated that the United States has traditionally used less dolomite refractories than European countries. Characterization studies of 14 domestic dolomite ores, which included chemical and mineralogical analyses, density and hydration determinations, and microstructure and thermal decomposition evaluations, have shown that there were noticeable differences in the hydration, microstructure, and thermal behavior of the various ores.

OP 76–82. Rock Mechanics Instrumentation and Monitoring for Ground Control Around Longwall Panels, by Paul H. Lu. Proc. Internat. Symp. on State-of-the-Art of Ground Control in Longwall Mining and Subsidence, Honolulu, Hawaii, Sept. 4–5, 1982, pp. 159–166. This report by the Bureau of Mines presents several practical and inexpensive types of rock mechanics instrumentation for ground control around longwall panels. Application of these critical parameters, determined by this instrumentation, to the design and modification of rational longwall-mining systems is also discussed. In order to design or select an optimum mine structure or system, realistic and precise values of the design parameters must be determined in operating mines by (1) measuring ground stresses, (2) mining induced load transfer, and (3) strata movements as well as deformation moduli and rock strengths. Based on these parameters, rational and realistic criteria for mine design can be established by conducting case studies. It was found that several basic design parameters can be easily measured or determined in situ with simple, inexpensive, and practical instruments such as hydraulic borehole pressure cells, automatic recording convergence meters, automatic recording multiple-anchor-point extensometers, and hydraulic pressure recorders.

OP 77–82. Recovery of Metals and Minerals From Selected Processing Wastes, by H. V. Makar, D. M. Soboroff, and F. J. Palumbo. Res. and Conserv., Elsevier Scientific Publishing Co., Amsterdam, the Netherlands, v. 9, 1982, pp. 179–190. To improve metal and mineral recycling technology while minimizing undesirable environmental effects, the Bureau of Mines is devising and evaluating recovery methods for scrap materials that cannot now be processed using conventional techniques. Characterization and leaching tests with chromite tailings, tin recovery from detinning sludges, and conversion of flue dusts

generated by the secondary copper and brass industry to zinc oxide are described. Procedures tested include leaching, mineral beneficiation, and roasting. Resource potential and environmental considerations are discussed.

OP 78–82. The Mechanization of Mining, by Robert L. Marovelli and John M. Karhnak. Sci. Am., v. 247, No. 3, September 1982, pp. 90–102. Today more than 80 percent of the mineral needs of the U.S. economy are met by only 1 percent of the labor force. This paper examines the mechanization of mining in terms of its effect on the mining of coal.

OP 79–82. Dewatering High-Clay Content Preparation Plant Tailings, by Bernard J. Scheiner. Min. Cong. J., v. 68, No. 9, September 1982, pp. 233–234. The U.S. Bureau of Mines, as part of its mission to eliminate health and safety hazards at the mine site, is developing alternate treatment and disposal methods for coal-clay waste. In the preparation of coal to produce low-ash material, a waste product containing fine coal and clay is generated. This waste product, generally minus 28 mesh in size, with the major portion being minus 325 mesh, is difficult to handle owing to the low settling of the fine clay particles. The material is usually processed in a thickener to produce a slurry containing about 30 percent (by weight) solids that is generally impounded behind earthen dams. It has been estimated that about 16 million tons of these waste solids are generated annually. Disposition of the slurries behind dams poses a potential health and safety hazard because of possible dam failure and because months and sometimes years are required for the slurry to settle and thicken naturally.

OP 80–82. Recycled Materials for Refractories, by D. E. Wittmer and A. V. Petty, Jr. Proc. Raw Materials for Refractories Conf., the University of Alabama, Tuscaloosa, Feb. 8–9, 1982, v. 1, pp. 309–328. A major goal of the Bureau of Mines is to investigate technology that can reduce the Nation's dependence on strategic and critical imported raw materials. To this end, the Tuscaloosa Research Center has been involved in a program to investigate the potential of utilizing waste materials to produce refractories containing chromite and alumina. Magnesite-chrome brick have been produced by recycling steel plant waste refractories using conventional beneficiation techniques. In addition, preliminary evaluation of a synthetic high-alumina dross appears promising. Currently, some high-alumina refractory waste materials are being used in commercial refractories and demand is increasing for recycled refractories.

OP 81–82. Heat Capacity From 5 to 300 K of α- and β-TiO, Relative Enthalpy to 1200 K, Enthalpy of Transition, and Thermodynamic Properties to 1265 K, by R. P. Beyer, R. R. Brown, K. O. Bennington, and M. J. Ferrante. J. Chem. Thermodyn., v. 14, 1982, pp. 957–965. The heat capacities of TiO(α) and TiO(β) were measured from 5 to 305 K by adiabatic calorimetry. High-temperature enthalpies up to 1,192 K for TiO(α) were determined by copper-block drop calorimetry. The enthalpy of transition for TiO(α) to TiO(β) was determined by hydrofluoric acid solution calorimetry and by differential scanning calorimetry. The values at 298.15 K of C_p°, $[S^\circ(T) - S^\circ(0)]$, and $-[G^\circ(T) - H^\circ(0)]/T$ are 39.89, 34.26, and 13.75 $J \cdot K^{-1} \cdot mol^{-1}$ for TiO(α), 40.40, 35.75, and 14.65 $J \cdot K^{-1} \cdot mol^{-1}$ for TiO(β). These thermodynamic functions are also calculated from 5 to 1,265 K for TiO(α), and from 5 to 300 K for TiO(β). The enthalpy of transition from α to β at 298.15 K is 4.7 $kJ \cdot mol^{-1}$ and at 1,265 K is 5.4 $kj \cdot mol^{-1}$.

OP 82–82. Large Rock Conveying Systems and Their Application in Open-Pit Mines, by T. W. Martin, J. M. Goris, and T. J. Crocker. Min. Eng., v. 34, No. 10, October 1982, pp. 1481–1485. The current technology of large rock conveyors is reviewed. Based on this investigation, two large rock conveyor concepts have been developed and a test facility investigation designed and fabricated. The Bureau of Mines will test these concepts along with loading and transfer points for handling mine run rock material up to 1.5 m (4.9 ft) in size. An evaluation of open pit mining systems using large rock conveyors documents substantial cost savings when compared with truck haulage.

OP 83–82. Electrochemical Determination of the Thermodynamic Properties of Sphalerite, ZnS(β), by S. C. Schaefer and N. A. Gokcen. High Temp. Sci., v. 15, 1982, pp. 225–237. As part of the Bureau of Mines effort to provide thermodynamic data for the advancement of minerals technology, thermodynamic properties of sphalerite ZnS(β) were investigated with a high-temperature galvanic cell employing stabilized zirconia as the electrolyte. In the temperature range 948 to 1,210 K, potential measurements were obtained for the cell.

OP 84–82. Pneumatic Beneficiation of Mica, by G. V. Sullivan and M. H. Stanczyk. Proc. 14th Internat. Miner. Processing Cong. on Worldwide Industrial Application of Mineral Processing Technology, Toronto, Ontario, Canada, Oct. 17–23, 1982, v. 1, No. 1, pp. V6.1–V6.19. The Bureau of Mines has conducted research into the pneumatic recovery of coarse mica pursuant to its objective of devising technology that will help maintain an adequate supply of minerals and metals to meet national economic and strategic needs. The pneumatic beneficiation technique may be advantageous in areas where water resources are limited. Researchers used a Bureau-designed system of crushers, screens, and zigzag air classifiers to concentrate coarse liberated mica particles from mica-bearing materials. A hammer mill, modified by removing 70 of its 80 free-swinging hammers and the crushing screen, proved effective for crushing and delaminating the mica without overgrinding. This pneumatic system was used to concentrate mica ores from Arizona, North Carolina, and South Dakota and waste tailings from Alabama, Georgia, and South Dakota. Using these samples, it was demonstrated that plus 0.21-millimeter-size mica can be effectively recovered by the pneumatic method. Mica concentrates containing more than 90 percent mica were produced with attendant recoveries of up to 78 percent.

OP 85–82. Determination of Sulfonamides in Animal Tissues and Feeds, by Michael H. Thomas and Karen E. Soroka. Ch. 33 in Advances in Thin Layer Chromatography. Clinical and Environmental Applications, ed. by J. C. Touchstone. John Wiley & Sons, Inc., New York, 1982, pp. 425–437. Sulfonamide drugs have proven to be effective antibacterial agents in many food-producing animals. The U.S. Food and Drug Administration has set the tolerance level for the resultant residues in uncooked edible tissues at 0.1 ppm. A rapid screening method to detect these drugs was developed to prevent gas chromatography-mass spectrometry (GC-MS) confirmation analysis of an excessive number of false positive and false negative samples. The method provides the ability to monitor multiple sulfonamides simultaneously at the tolerance level with a

degree of accuracy and precision. The two most significant factors responsible for these characteristics are the internal standard and the preadsorbent spotting zone. For laboratories without access to a GC-MS instrument or a need for confirmatory information, the technique is sufficiently accurate and sensitive to function as the determination procedure. Since 18 to 24 samples can be analyzed completely per day, the procedure offers the added benefit of high sample throughput.

OP 86–82. Gold, by W. C. Butterman and J. M. Lucas. Ch. in On Gold, ed. by H. A. Lipscomb and D. R. Libey. The Waterleaf Press, DeKalb, Ill., 1982, pp. 47–89. This paper was written as part of the approach to gold as an investment in the future, based on the performance of gold in the past. A brief history on gold is presented and the process of investing in gold in a future market is examined in much the same manner as any commodity would be examined in a future market. Only a certain amount of gold is available, and the supply and demand relationships are covered.

OP 87–82. Deep Cutting: Key to Dust-Free Longwalling, by Jonathan Ludlow and Richard J. Wilson. Coal Min. and Proc., v. 19, No. 8, August 1982, pp. 40–43. The correlation between depth of cut and dust generation has been established in laboratory and test fields that have been conducted in the United States and abroad for a number of years. This article describes a recent testing program that has proved the benefits associated with deep and slow cutting on a U.S. longwall face. The tests showed that respirable dust from longwall mining can be significantly reduced without adversely affecting production by simply increasing the depth of cut of the shearer.

OP 88–82. Testing of Fire-Resistant Conveyor Belting, by Frank J. Perzak, Ellsworth R. Spencer, and Michael J. Sapko. Can. Min. Met. Bull., v. 75, No. 884, August 1982, pp. 115–119; reprinted in Fire Prev. in Min. Ind., 1982, pp. 1–5. The fire resistance of several mine conveyor belts is evaluated using a new belt-flammability apparatus developed by the U.S. Bureau of Mines. The test, experimental details, and a calculated flammability index (FI) are described. The FI values are useful for ranking the fire resistance of mine conveyor belts. Values are determined using parameters readily measured with thermocouples, high-temperature flow probes, and a methane-oxygen torch, all of which are components of the Bureau's new test apparatus. The FI varies directly with the flame-spread rate and the rate of heat release during burning and varies inversely with the critical (minimum) ignitor energy output. The fire-resistance ranking of nine different belt types using this moderately scaled apparatus is compared with available full-scale data on belt fires. This comparison shows that the ranking based on the FI is consistent with the full-scale data.

OP 89–82. Vibration and Noise From Blasting, by David E. Siskind. Inter-Noise 82, v. 1, May 17, 1982, pp. 281–284. Adverse environmental effects from blasting continue to be a major problem for the mining industry, the public living near mining operations, and the governmental agencies responsible for setting environmental standards. The Bureau of Mines has established a comprehensive blasting research program dealing with the many technical aspects of generation and propagation of ground vibrations and airblast, structure response and damage, and proper instrumentation. This paper describes the Bureau's programs and lists agencies and industries that are utilizing the results of the Bureau's research.

1983

OP 1–83. Changing Patterns in Industrial Demand for Sulphur, by D. E. Morse and J. E. Shelton. Paper in International Conference Sulphur '82, Proceedings of the Conference, Volume 1: Preprints, ed. by A. I. More (London, Nov. 14–17, 1982). The British Sulphur Corp. Ltd., London, 1982, pp. 9–19. An attempt has been made to project the level of U.S. industrial sulfur demand in 1990, using various macroeconomic indicators, and using the United States as a model for the world as a whole, a further projection of total world industrial sulfur demand has been made. The potential world demand for current industrial uses for sulfur by 1990 is estimated to be 31.6 million metric tons. The most promising new uses for sulfur are believed to be in road paving materials and sulfur concrete. The potential world demand for new uses by 1990 is estimated to be 6.0 million metric tons. Thus, the total demand for industrial uses in 1990 is projected to be 37.6 million metric tons, which represents an annual growth rate of 5.4 pct from 1981 to 1990.

OP 2–83. Overview of Bureau of Mines Coal Mine Research, by John N. Murphy. Paper in Proc. 13th Annu. Inst. on Coal Min. Health, Safety, and Res. (VA Polytech. Inst., Blacksburg, VA, Aug. 24-26, 1982). VA Polytech. Inst., 1982, pp. 70–95. The Bureau of Mines mining research program is divided into two principal problem areas: (1) health and safety and (2) conservation and development. This paper focuses on the Bureau's coal mine health and safety research program and emphasizes recent accomplishments or new developments that will shortly be available for use by the industry.

OP 3–83. Comparison of Methods for Recovering Metal Values From Salton Sea KGRA Brines, by L. E. Schultze and D. J. Bauer. Geothermal Resour. Council Trans., v. 6, Oct. 1982, pp. 111–113. The Bureau of Mines is investigating methods for recovering metal values from geobrines. Two precipitation techniques were evaluated for recovering selected metal values from Salton Sea Known Geothermal Resource Area brines. Lime addition precipitates more than 95 pct of the iron, manganese, lead, and zinc, while sulfide addition precipitates more than 90 pct of the lead and zinc and lesser amounts of iron and manganese. A comparison of these techniques and a discussion of the respective advantages and disadvantages are presented.

OP 4–83. Dewatering and Consolidation of Coal-Clay Tailing From Preparation Plants, by B. J. Scheiner and P. M. Brown. Paper in Proceedings of the Consolidations and Dewatering of Fine Particles Conference (cosponsored and pub. by BuMines, Univ. of AL College of Eng., and AL Min. and Miner. Resour. Inst., University, AL, Aug. 10–12, 1982), 1982, pp. 133–151. The Bureau of Mines is conducting research on a novel method for dewatering coal-clay waste as an alternative to ponding

now being practiced by the industry. The method consists of mixing coal-clay waste with a flocculant, polyethylene oxide (PEO), and dewatering the resulting flocs in a hydrosieve screen. The technique is being tested in a unit operating at 400 gal/min, located at the Jim Walter's No. 7 Mine in Brookwood, AL. In continuous tests, coal-clay waste has been dewatered from a nominal 3 pct solids to products ranging from 50 to 60 pct solids. When placed in a pit, the dewatered material continues to consolidate to 70 pct solids in several days.

OP 5–83. A Progress Report on Large-Scale Dewatering Tests of Northern Florida Phosphate Clay Waste, by Annie G. Smelley, B. J. Scheiner, and D. R. Brooks. Paper in Proceedings of the Consolidation and Dewatering of Fine Particles Conference (cosponsored and pub. by BuMines, Univ. of AL College of Eng., and AL Min. and Miner. Resour. Inst., University, AL, Aug. 10–12, 1982), 1982, pp. 265–284. The Bureau of Mines is testing a dewatering technique for phosphate clay waste that will recover a portion of the water now being lost using conventional waste disposal methods and produce solids suitable for land reclamation. The technique uses a flocculant, polyethylene oxide (PEO), that forms strong, stable flocs that can be dewatered on a static screen followed by further dewatering on a rotary screen. In field tests conducted in northern Florida, clay wastes containing a nominal 2.5 pct solids have been consolidated to greater than 20 pct solids. The rate at which PEO-treated material continues to dewater in a mine cut is also being investigated. Preliminary results indicate that PEO-treated material will dewater to 29 pct solids in 127 days.

OP 6–83. Quantitative Measurement of Polymeric Bonds Using Viscometric Techniques, by D. A. Stanley, S. W. Webb, and B. J. Scheiner. Paper in Proceedings of the Consolidation and Dewatering of Fine Particles Conference (cosponsored and pub. by BuMines, Univ. of AL College of Eng., and AL Min. and Miner. Resour. Inst., University, AL, Aug. 10–12, 1982), 1982, pp. 468–490. The amount of polyethylene oxide (PEO) required to dewater calcium-exchanged montmorillonite is affected by shear stresses, both during mixing of the clay and polymer and during mechanical deformation of the flocculated mass to remove water. The Bureau of Mines measured changes in viscosity with time at a constant rate of shear for shear rates up to 350 per minute for PEO-montmorillonite mixtures. The energy density of the bonds formed by the PEO-montmorillonite complex then was calculated for two different bond systems. These different bond systems are present because the fundamental clay particles form flocs that are bridged to form aggregates of flocs. The implications of these results as they relate to PEO dewatering of phosphatic clay waste are discussed.

OP 7–83. Using Retroreflective Material To Enhance the Conspicuity of Coal Miners, by Barry H. Beith, Mark S. Sanders, and James M. Peay. Human Factors, v. 24, No. 6, Dec. 1982, pp. 727-735. This study investigated the use of retroreflective material to increase conspicuity of miners. A scaled simulation was created using dolls configured as miners. Twelve observers viewed four configurations of retroreflective material on dolls in 3 body postures at 1 of 3 locations in the visual field. In a subsequent experiment, nine observers compared two configurations. The results confirmed the poor conspicuity of the configuration currently required in mines, which features retroreflective tape on the helmet only. All experimental retroreflective configurations significantly improved detectability over this configuration. Overall, the most cost-effective configurations were those in which the belt and/or armbands were covered with retroreflective material.

OP 8–83. Rapid-Sampling System for Dusts and Gases, by R. S. Conti, M. Hertzberg, F. T. Duda, and K. L. Cashdollar. Rev. Sci. Instrum., v. 54, No. 1, Jan. 1983, pp. 104-108. The Bureau of Mines researched a system for the rapid grab sampling of heterogeneous mixtures of gases and dusts during the preignition and postignition stages of dust explosions. The combustion chamber in which the explosion occurs is first fitted with a hypodermic sampling needle with its inlet end at the desired sampling point within the chamber and its sharp, injecting end protruding outside of the chamber. Rapid sampling (approximately 25 to 50 ms) is achieved with a double-acting, air-pressure-actuated cyclinder. The forward stroke of the cylinder thrusts the rubber septum seal of an evaculated glass sampling tube onto the protruding needle, which punctures the septum, filling the tube with gas and dust from the combustion chamber. The return stroke of the cyclinder reseals the sampling tube by returning the mechanism to its original position. The initial time of sampling and the duration of sampling are independently variable and controlled by a microprocessor. Results obtained with a trimodal distribution of coal dust show no significant size discrimination at least up to 70 μm. Data obtained from laboratory-scale coal dust explosion tests are also presented. Such data provide valuable insights into the basic phenomena involved in explosions.

OP 9–83. Assessment of Effectiveness of Janelid Ventilation, by A. Erickson, K. Heller, and E. Thimons. Min. Congr. J., v. 68, No. 10, Oct. 1982, pp. 39–44. The effectiveness of a loader-mounted fan on diesel vehicles combined with natural convection of a dead heading (the patented Janelid system) was investigated experimentally. The results were obtained using CO_2 as a tracer gas in a one-quarter-scale model heading. Bouyant forces were scaled to establish similarity with full scale. For a loader moving in a typical load-haul-dump cycle, the loader-mounted fan reduced the tracer gas concentration by 26 pct compared with a reduction of 32 pct for a jet fan of four times the flow capacity.

OP 10–83. Statistical Thermodynamics of Long-Range Order, by N. A. Gokcen. Scr. Metall., v. 17, No. 1, 1983, pp. 53–58. Statistical thermodynamics of long-range order are part of the Bureau of Mines program to provide a scientific base for use in developing new alloys and alloy phases. Numerous statistical thermodynamic attempts have been made to formulate the behavior of long-range order in alloys after the work of Gorsky, and Bragg and Williams (GBW). The quasichemical method is often erroneously claimed to be an improvement over the GBW method. The permutation of the bonds in the quasichemical method is made to become the permutation of atoms for zero exchange energy, or when the temperature is sufficiently high, through a dubious normalization process. The normalization process of the quasichemical method yields the same equations for the excess Gibbs energy of solution as without normalization, and the actual enumerations of configurations prove that the permutable entities are the atoms, not the bonds. This communication has a twofold purpose: (1) to show that the permutation of atoms yields proper new equations for order-disorder phenomena after

reasonable corrections and (2) to discuss the errors in the previous regular assembly treatments.

OP 11–83. Computer Model Simulates Screening Process Under Variety of Conditions. Semi-Empirical Approach Allows Researchers More Latitude. Part I, by Douglas C. Grant, Kevin Hennings, Thomas Bobick, and Roy Bartholomae. Pit & Quarry, v. 75, No. 5, Nov. 1982, pp. 59–63. A U.S. Bureau of Mines sponsored program was undertaken by the Advanced Technology Center of Allis-Chalmers Corp. to improve performance modeling of vibrating machines. This work was requested to increase public knowledge of screening performance with emphasis on the performance of nonmetallic decks. The program included extensive testing on a special vibrating screen test apparatus, development of a mathematical model of screening behavior, and incorporation of simulation parameters. The test fixtures and mathematical model are described, and the mathematical results are compared with screen test data.

OP 12–83. Computer Model Simulates Scretning Process Under Variety of Conditions. Semi-Empirical Approach Allows Researchers More Latitude. Part II, by Douglas C. Grant, Kevin Hennings, Thomas Bobick, and Roy Bartholomae. Pit & Quarry, v. 75, No. 6, Dec. 1982, pp. 67–68. A U.S. Bureau of Mines sponsored program was undertaken by the Advanced Technology Center of Allis-Chalmers Corp. to improve performance modeling of vibrating machines. This work was requested to increase public knowledge of screening performance with emphasis on the performance of nonmetallic decks. The program included extensive testing on a special vibrating screen test apparatus, development of a mathematical model of screening behavior, and incorporation of simulation parameters. The test fixtures and mathematical model are described, and the mathemtical results are compared with screen test data.

OP 13–83. A Review of the Deposits and Beneficiation of Lower-Grade Chromite, by Ralph H. Nafziger. J. South African Inst. Min. and Metall., v. 82, No. 8, Aug. 1982, pp. 205–226. This paper reviews the major deposits of lower grade chromite in the world and a wide variety of methods used for the recovery of chromium from these deposits. Gangue materials in more coarsely sized ores can be separated by gravity means, whereas flotation techniques are required for finer grained materials. However, unless there is considerable iron in the ores, physical means cannot increase the Cr-Fe ratios. Chemical techniques such as hydrometallurgical methods, chlorination, roasting and leaching, and smelting are required for this purpose. A greater understanding of the physical properties of chromites and the chemical reactions that take place in the recovery operations is required before the recoveries from lower grade chromites can be maximized. More efficient recovery operations can be realized if it can be shown definitively that the reduction of chromites occurs via either a gas-solid or solid-solid mechanism, for example. The effects of specific impurities on the chromite reduction reactions need to be better understood, as do reagent and pH control in the flotation of chromite.

OP 14–83. Alaska Mining in '83: From Gold to Hardrock & Gravel. The Dollars Are Changing Direction, by Tom L. Pittman and John J. Mulligan. Alaska Construction & Oil, v. 24, No. 1, Jan. 1983, pp. 21-23. This article describes the changing mineral industry and mineral-related activities in Alaska. The sand and gravel industry, placer gold production, mineral legislation, U.S. Bureau of Mines activities, and other developments are discussed.

OP 15–83. Are Zeolites Dimensionally Equivalent to Asbestos? By K. B. Shedd, R. L. Virta, and A. G. Wylie. Paper in Process Mineralogy II: Applications to Metallurgy, Ceramics and Geology (Proc. Symp. sponsored by Metall. Soc. AIME, Dallas, TX, Feb. 15-18, 1982). Metall. Soc. AIME, 1983, pp. 395-399. Questions regarding possible health effects from exposure to zeolites arose when the inhabitants of two villages in Turkey were found to have high incidences of mesothelioma, a disease generally identified with exposure to asbestos. No asbestos deposits are known in the area, but some fibrous zeolites have been found. Further investigations have resulted in conflicting opinions as to whether fibrous zeolites are related to the high incidence of mesothelioma in Turkey. The U.S. Bureau of Mines examined the habits of domestic zeolites by scanning and transmission electron microscopy. Only erionite and mordenite particles possessed acicular to fibrous habits. With the exception of a rarely occurring wooly erionite sample, the fibrous zeolites were not dimensionally equivalent to asbestos.

OP 16–83. Effect of Ferrous Scrap Composition Changes on the Quality of Iron and Steel Castings, by W. L. Swager, H. W. Lownie, Jr., C. E. Mobley, and R. H. Nafziger. Am. Foundrymen's Soc. Trans., v. 90, 1982, pp. 811-819. Because the foundry industry has expressed concern over the possible deterioration of ferrous scrap used as charge material for ironmaking and steelmaking, the Bureau of Mines contracted with Battelle's Columbus Laboratories to determine the extent of the problem and what might be done. Data obtained from the literature, scrap processors and brokers, practicing foundry operators, and trade associations indicate no substantial evidence to support the thesis that the quality of purchased ferrous scrap available to foundries is expected to decline significantly during the next decade. Tramp elements already present will continue to be present in purchased scrap, with B, Cr, Pb, and Sb in iron and Sb, P, and S in steel being of most concern. Continuing lot-to-lot variation will make quality control by foundries increasingly important. Foundries and their suppliers of purchased scrap have the potential to control tramp elements within practical limits. Costs will increase in the long term owing to increased demand for premium grades of scrap, necessary upgrading of scrap to maintain low-tramp levels, and increased expenses to control tramp elements.

OP 17–83. Mineralogy and Beneficiation of Phosphate-Bearing Rocks From Northern Michigan, by Lawrence L. Brown, Albert R. Rule, and Charles B. Dallenbach. Pres. at TMS-AIME Annu. Meeting, Dallas, TX, Feb. 14-16, 1982. Paper in Process Mineralogy II: Applications in Metallurgy, Ceramics, and Geology, ed. by R. D. Hagni. Metall. Soc. AIME, Warrendale, PA, pp. 119–133. As part of the Federal effort to help maintain an adequate supply of fertilizer materials, the Bureau of Mines conducted research to characterize complex low-grade Michigan phosphate materials and to devise methods for recovering fertilizer-grade phosphate concentrates. The rock is from middle Precambrian sedimentary formations in the Marquette Range located in the central part of the Upper Peninsula of Michigan. Occurrence of phosphate-bearing sediments in Precambrian rocks is rare. This deposit,

containing 12 to 15 pct P_2O_5, is believed to be the richest Precambrian phosphate deposit in the United States. Petrographic examination showed that the conglomeritic rock contains crystalline apatite both in "black pebbles" and in quartz matrix. Attrition scrubbing and sizing tests showed that there is no tendency for phosphate to concentrate in any of the sized fractions. In beneficiation tests, which included grinding to minus 325 mesh followed by phosphate mineral flotation using a fatty acid-fuel oil collector, a phosphate concentrate was obtained that had a grade of 30 pct P_2O_5 and a P_2O_5 recovery of 72 pct. This concentrate should be suitable for fertilizer manufacture.

OP 18–83. Mathematical Modeling of Spontaneous Combustion of Coal, by John C. Edwards. Pres. at 112th TMS-AIME Annu. Meeting, Atlanta, GA, Mar. 6-10, 1983; TMS Paper Selection A83-21, 16 pp. A mathematical model of spontaneous combustion of coal in a pile was developed. The model simulates under the condition of constant unidirectional flow of air through a bed of uniform coal particles, the temperature rise in the air-and-particle system associated with a first order Arrhenius particle surface reaction. The following transport mechanisms are included: (1) heat conduction into the particle interior, (2) oxygen depletion due to particle surface reaction, (3) diffusion and forced convection of oxygen, and (4) heat conduction and convection in the air. The model is developed as a set of coupled partial differential equations that are solved numerically. A parametric analysis is made of particle size, inlet air temperature, particle packing, and ventilation velocity on the time required for thermal ignition to occur and the depth in the bed at which it occurs.

OP 19–83. Activity Coefficients of Solutes in Binary Solvents, by N. A. Gokcen. High Temp. Sci., v. 15. Mar. 10, 1983, pp. 293-300. The activity coefficients in dilute ternary systems are discussed in detail by using the Margules equations. Analyses of some relevant data at high temperatures show that the sparingly dissolved solutes in binary solvents follow complex behavior even when the binary solvents are very nearly ideal. It is shown that the activity data on the solute or the binary system cannot permit computation of the remaining activities except for the regular solutions. It is also shown that a fourth-order equation is usually adequate in expressing the activity coefficient of a solute in binary solvents at high temperatures. When the activity data for a binary solvent are difficult to obtain in a certain range of composition, the activity data for a sparingly dissolved solute can be used to supplement determination of the binary activities.

OP 20–83. Determination, Estimation, and Correlation of Activities in Hydrometallurgical Ionic Solutions, by N. A. Gokcen. Pres. at 112th AIME Annu. Meeting, Atlanta, GA, Mar. 6-10, 1983; proc. 3d Int. Symp. on Hydrometallurgy, Dec. 15, 1982, pp. 329–340. Methods of rapid determination, estimation, and correlation of aqueous ionic activities are briefly discussed. New data are presented for binary solutions of $AlCl_3$, $Al(NO_3)_3$, $CrCl_3$, $CuSO_4$, NaCl, and $ZnSO_4$. These and other data are used to discuss the limitations of estimation methods.

OP 21–83. U.S. Short-Term Demand Outlook for Soda Ash and Factors Affecting U.S. Soda Ash Availability in the World Market, by Dennis S. Kostick. Chem. and Ind. (London), No. 4, Feb. 21, 1983, pp. 161–165. Soda ash has been used in the United States for nearly 300 years and it is not surprising that most of the end uses have reached maturity and tend to follow the population trend, which for the last several years has been leveling out. The major soda ash markets in the United States are similar to those in other industrially developed countries, namely glass, chemicals, soaps and detergents, pulp and paper, and water treatment. Most of these industries throughout the world have been affected by the general downturn in the world economy, which, in turn, has affected soda ash demand. This paper concentrates on the short-term outlook for soda ash consumption in the United States and some of the factors that will affect the availability of U.S. soda ash for export.

OP 22–83. Reparameterization of the Becker-Kistiakowsky-Wilson Equation of State for Water-Gel Explosives, by V. Krishna Mohan and J. Edmund Hay. Combust. and Flame, v. 50, 1983, pp. 207–218. This paper describes the results of the reparameterization studies on the Becker-Kistiakowsky-Wilson (BKW) equation of state for water-gel explosives. The original set of BKW parameters ($\alpha = 0.5$, $\beta = 0.1$, $K = 11.85$, and $\Theta = 400$) predicts a higher detonation velocity and detonation pressure and a lower detonation temperature compared with the experimental values for these explosives. Among the several combinations of parameters examined, the following set—$\alpha = 0.5$, $\beta = 0.1$, $K = 8.85$, and $\Theta = 1{,}850$—is found to give realistic values for the various detonation properties. Moreover, the predicted and the experimental detonation velocities are seen to be in fair agreement. A comparison of the computed and the experimental (obtained from Crawshaw-Jones measurements) fume characteristics show that (1) inclusion of the wrapper material in the explosive composition increases the concentration of fumes and gives correspondence between the two products such as CO, H_2, NH_3, and CH_4; (2) the measured NO_x concentration is difficult to get in these computations; and (3) calculations of the product compositions for the isentropic expansion of detonation products along the Chapman-Jouguet isentrope give freeze-out temperatures in the range of 1,000 to 1,800 K. These computations were also performed for two ammonium nitrate-fuel oil mixtures and were found to be in good agreement with the experimental data.

OP 23–83. Prereduction and Melting of Domestic Titaniferous Materials, by R. H. Nafziger and R. R. Jordan. Metall. Trans. B, v. 14B, No. 1, Mar. 1983, pp. 55–62. Two domestic ilmenites and one titaniferous magnetite were prereduced by the Bureau of Mines in a batch rotary kiln with coal char to assess the feasibility of this technique in improving melting operations and subsequent electric furnace processing. All three prereduced titaniferous materials were melted satisfactorily in an electric arc furnace to produce iron as a metal suitable for further refining to steel; metallizations ranging from 63 to 83 pct of the iron oxides were achieved. The ilmenites yielded titanium-enriched slags that were amenable to further processing by conventional methods. Prereduction decreased electrode consumption during furnace operation and also conserved expensive electrical energy that otherwise must be used to reduce and melt totally the entire titaniferous materials charge.

OP 24–83. Chelating Crosslinked Starches as Flocculants for Oxide and Hydroxide Mineral Fines, by S. C. Termes and R. L. Wilfong. Pres. at 112th AIME Annu. Meeting, Atlanta, GA, Mar. 6–10, 1983. Soc. Min. Eng. AIME preprint 83–195, 9 pp.; Ch. 18 in

Process Mineralogy III, Applications in Metallurgy, Coal, Concrete, Smelting and Exploration, ed. by W. Petruk (Proc. Symp. sponsored by Process Mineral. Comm., SME-AIME Annu. Meeting, Atlanta, GA, Mar. 6–10, 1983). Soc. Min. Eng. AIME, New York, 1984, pp. 289–305. As part of an effort to provide basic data on the fundamental scientific and engineering principles of minerals beneficiation, the Bureau of Mines is conducting research on the flocculation of mineral fines. This paper presents results of studies using crosslinked starches containing carboxyl, diethanolamine, iminodiacetic acid, and xanthate groups to flocculate hematite, geothite, chromite, manganite, pyrolusite, cuprite, and cassiterite fines. The carboxyl and xanthate derivatives flocculated all minerals except cassiterite; the latter was flocculated by only the diethanolamine derivative. The iminodiacetic acid derivative flocculated hematite, geothite, chromite, cuprite, and pyrolusite fines. Zeta potential measurements were made to help define the reaction mechanism responsible for flocculation. These measurements indicate that electrostatic attraction probably is not involved, except possibly in the case of the diethanolamine derivative. The separation of hematite from quartz by selective flocculation with chelating crosslinked starches under two pH conditions and with two dispersing agents is described. Best recoveries and grades were found when either the carboxyl or xanthate derivative was added at the natural pH of the pulp in the absence of a dispersing agent.

OP 25–83. Control of Diesel Exhaust Emissions in Underground Coal Mines—Single-Cylinder Engine Optimization for Water-in-Fuel Microemulsions, by T. J. Callahan, T. W. Ryan III, G. B. O'Neal, and R. W. Waytulonis. (Proc. SAE Int. Cong. and Exposition on Alternate Fuels for Spark Ignition and Diesel Engines, Detroit, MI, Feb. 28–Mar. 4, 1983.) SAE Tech. Paper Series 830553, 1983, pp. 55–66. The increased use of diesel-powered equipment in underground mines has prompted interest in reducing their exhaust pollutants. Control of particulate emissions without substantial penalties in other emissions or fuel consumption is necessary. This paper describes test results on a prechamber, naturally aspirated, four-cycle diesel engine in which two different concentrations of water-in-fuel emulsions were run. The independent variables comprising the test matrix were fuel, speed, load, injection timing, injection rate, and compression ratio. The dependent variables of the experiment included particulate and gaseous emissions and engine thermal efficiency. Regression analysis was performed on the data to determine how particulate emissions were affected by fuel and engine parameters. Results of this analysis indicated that substantial reductions in particulate emissions could be obtained by utilizing water-in-fuel emulsions.

OP 26–83. Bench-Scale Studies To Recover Alumina From Clay by a Hydrochloric Acid Process, by J. A. Eisele, D. J. Bauer, and D. E. Shanks. Ind. Eng. Chem. Prod. Res. Dev., v. 22, No. 1, 1983, pp. 105–110. As part of its goal of producing cell-grade alumina from clay, the Bureau of Mines conducted bench-scale cyclic tests of the Bureau's proposed clay—HCl leaching—HCl sparging process and investigated in detail the crystallization of aluminum chloride hexahydrate. The composition of recycled leaching liquor was determined for two HCl sparging crystallization conditions: 36% HCl and 26% HCl. Crystallization research showed that cell-grade alumina could not be produced without a recrystallization step.

OP 27–83. Producing Lead Metal From Lead Chloride in a 3,000-Ampere Cell, by C. H. Elges, M. M. Wong, and R. G. Sandberg. Paper in Chloride Electrometall., ed. by P. D. Parker (Symp., TMS-AIME 111th Annu. Meeting, Dallas, TX, Feb. 15–16, 1982). The Metall. Soc., AIME, 1982, pp. 89–100. The Bureau of Mines, under a cost-sharing, cooperative research program with lead producers, is studying a process to eliminate sulfur oxide generation and to minimize lead emissions in the production of lead metal. The new process consists of leaching lead sulfide concentrate with a ferric chloride-brine solution to produce lead chloride, which is then converted to lead metal by fused-salt electrolysis. For 18 months the Bureau operated an integrated process investigation unit, including both leaching and electrolysis sections, which was designed to treat 750 lb of concentrate and to produce 500 lb of lead metal per day. Electrowinning of lead metal is accomplished in a 3,000-amp fused-salt cell at 450° C, utilizing a LiCl-KCL-$PbCl_2$ electrolyte. This paper describes the development, construction, and operation of this 3,000-amp cell.

OP 28–83. Beneficiation of Florida Dolomitic Phosphate Ores, by T. O. Llewellyn, B. E. Davis, and G. V. Sullivan. Pres. at SME-AIME Annu. Meeting, Atlanta, GA, Mar. 6–10, 1983. Soc. Min. Eng. AIME preprint 83–10, 7 pp. The Bureau of Mines conducted studies to recover phosphate from four dolomitic southern Florida deposits not currently mined. The samples contained 5.8 to 10.2 percent P_2O_5 and 1.7 to 4.8 percent MgO. Chemical analyses of sized fractions indicated that no pebble concentrate (plus 1.2 mm) could be produced from these samples. A scheme was developed that consisted of desliming, grinding, scrubbing, and redesliming the ore to produce a flotation feed. Conventional one-step fatty acid-fuel oil batch flotation tests on the samples resulted in concentrates containing 29.0 to 31.3 percent P_2O_5 at flotation recoveries ranging from 72.4 to 96.1 percent of the flotation feed. The MgO content of the concentrates ranged from 0.47 to 1.36 percent. Continuous flotation of the Manatee No. 2 sample indicated that commercial-grade phosphate concentrates analyzing 31.3 percent P_2O_5 and 0.55 percent MgO could be produced with a flotation recovery of 89.9 percent. The MgO content of concentrates obtained from the Manatee No. 1 and Hardee samples was 1.20 to 1.36 percent, respectively. Leaching with aqueous SO_2 reduced the MgO content of these phosphate concentrates to 0.5 and 0.8 percent, but with a concomitant loss in phosphate recovery.

OP 29–83. Fluidized-Bed Decomposition of Aluminum Chloride Hexahydrate, by E. Miller, G. E. Call, P. R. Haskett, and L. J. Nicks. Pres. at 112th TMS-AIME Annu. Meeting, Atlanta, GA, Mar. 6–10, 1982. Paper in Light Metals 1983, ed. by E. M. Adkins, The Metall. Soc., AIME, pp. 253–271. As part of an investigation by the Bureau of Mines of methods for recovering alumina from domestic nonbauxitic resources, aluminum chloride hexahydrate (ACH) crystals are decomposed in two dense fluidized-bed reactors in series. In the first reactor, ACH is fluidized by the gases of decomposition (HCl and H_2O) produced by indirect heating of the bed and by steam. Concentrated hydrochloric acid may be recovered for use in the process. Partially decomposed solids enter a second fluidized-bed reactor for completion of the decomposition to cell-grade alumina by direct heating with combustion gases. Results from the first-stage decomposition step in a 4-in cylindrical glass reactor and in a tubular bundle reactor are reported. Test conditions

included a fluidization face velocity of 0.4 m/sec, space times of 30 min or longer, heating indirectly to temperatures of 190° to 375° C, and gas compositions of 0 to 43 mol-pct HCl and 100 to 57 mol-pct steam. The direct-heated second-stage reactor, a 4-in alloy cylinder, was operated at a fluidization range of 600° to 1,005° C, and with furnace gases containing steam and oxygen of 17.4 to 57.8 total vol-pct. The product is composed of coarser particles than are normally used in an alumina reduction cell, and contains 0.1 pct chloride, which is not present in Bayer alumina.

OP 30–83. Prereduction and Smelting of Domestic (U.S.) Chromites From Montana and California, by R. H. Nafziger, P. E. Sanker, J. E. Tress, and R. A. McCune. Ironmaking and Steelmaking, v. 9, No. 6, 1982, pp. 267–277. Four chromites from mines in Montana and California were prereduced to provide suitable charge material for the production of ferrochromium in an electric arc furnace. A part of the Bureau of Mines program investigating technology for efficient and economic recovery of metals from domestic resources, this study has shown that prereduction of these chromites increases productivity and decreases electrical-energy consumption with respect to cases when unreduced materials were used. About 75% chromium metallization and 75% total metallization were realized when high-iron chromites from Montana were prereduced with coal char and coke breeze in a batch rotary kiln. Chromium and total metallizations near 95% were obtained when a metallurgical-grade chromite was prereduced. Satisfactory ferrochromium for the production of stainless steel was produced in an electric arc furnace from all the prereduced materials.

OP 31–83. Control of Diesel Exhaust Emissions in Underground Coal Mines—Steady-State and Transient Engine Tests With a Five Percent Water-in-Fuel Microemulsion, by Glenn B. O'Neal, H. E. Dietzmann, T. W. Ryan III, and R. W. Waytulonis. (Proc. SAE Int. Cong. and Exposition on Alternate Fuels for Spark Ignition and Diesel Engines, Detroit, MI, Feb. 28–Mar. 4, 1983). SAE Tech. Paper Series 830555, 1983, pp. 77–83. This paper is the fourth in a series describing work sponsored by the Bureau of Mines to reduce diesel particulate and gaseous emissions through fuel modification. A stabilized water microemulsion fuel developed in previous work was tested in a Caterpillar 3304 NA four-cylinder engine with compression ratio and injection timing and rate optimized for this fuel to demonstrate the emissions reductions achieved. It was tested in both standard and optimum configurations with both baseline DF-2 and optimized microemulsion fuels. Gaseous and particulate data are presented from steady-state tests using a computer-operated minidilution tunnel and from transient tests using a total exhaust dilution tunnel. The optimized engine-fuel combination was effective in reducing particulates and oxides of nitrogen in steady-state tests. However, the standard engine-fuel combination provided the lowest particulate and NO_x emissions in transient tests.

OP 32–83. Dewatering of Fine Particle Clay Waste Using a Flocculant, by B. J. Scheiner and Annie G. Smelley. Pres. at SME-AIME Annu. Meeting, Atlanta, GA, Mar. 6–10, 1983. Soc. Min. Eng. AIME preprint 83–2, 10 pp. The Bureau of Mines is conducting research on a dewatering technique for fine particles generated during the mineral beneficiation process that will recover a portion of the water now being lost using conventional waste disposal methods and significantly reduce the time required for land reclamation. The technique utilizes a flocculant, polyethylene oxide (PEO), that forms strong stable flocs that can be dewatered rapidly on static and/or rotary screens. In field tests, phosphate clay waste has been dewatered from a nominal 2.5 percent solids to greater than 20 percent solids. In other field tests, coal-clay waste has been dewatered from a nominal 3 percent solids to greater than 55 percent solids. In addition, small-scale continuous tests have shown that bentonitic clays can be dewatered from 12 percent solids to 40 percent solids.

OP 33–83. A Large-Scale Impact Spalling Test, by R. Blickensderfer and J. H. Tylczak. Wear, Elsevier Sequoia, the Netherlands, v. 84, No. 3, Feb. 1, 1983, pp. 361–373. A unique test apparatus is described that effectively produces spalling on wear-resistant alloys and can be used to study the causes of spalling. The work was conducted by the Bureau of Mines as part of an effort to minimize the consumption of strategic materials used during the mining and processing of minerals. The test utilizes balls 75 mm in diameter made of the test alloys, which are dropped a distance of 3.5 m. Multiple impacts over a range of energy are produced between the balls. The unique design of the test apparatus provides a multiplying effect that results in 30,000 or more total impacts per hour on 20 or so test alloys. The four major types of failure that were observed on 22 commercial and experimental alloys that received up to 300,000 impacts are discussed.

OP 34–83. Arizona's Artillery Peak Manganese Deposits, by Peter G. Chamberlain. Pres. at SME-AIME Fall Meeting and Exhibit, Denver, CO, Nov. 18–20, 1981. Soc. Min. Eng. AIME preprint 81–367, 8 pp. The Bureau of Mines is conducting research to boost domestic production of manganese. Virtually no mining exists in the low-grade and/or small deposits that occur in this country. One large, low-grade manganese deposit located in west-central Arizona—the Artillery Peak district—was extensively studied and sporadically mined during the 1940's and 1950's. Although manganese mining in the district has been long dormant, recent studies indicate that the deposits may be amenable to economical production by heap and/or in situ leaching methods. A conceptual design for an in situ leaching system features undercutting and blasting a block of ore, leaching with SO_2, and extracting the manganese as a sulfate or oxide. Possible applications to other manganese deposits depend upon formation permeability and specific manganese mineralogy.

OP 35–83. Stability Evaluation of Retreating Longwall Chain Pillars With Regressive Integrity Factors, by Paul H. Lu. Proc. 5th Cong. of the Int. Soc. for Rock Mech., Melbourne, Australia, Apr. 10–15, 1983, v. 2, pp. E37–E40. Profiles of mining-induced loading and residual strength across a pillar vary with the position of the longwall face. The residual pillar-strength profile can be constructed on the basis of laboratory-determined triaxial compressive strength, in which the in situ measured horizontal pressure is considered as the constraint. The vertical-loading profile can be established with the measured vertical pressures. Vertical and horizontal pillar pressures can be measured with hydraulic borehole pressure cells. Defined as the ratio of the integrated total strength to the integrated total load under the profiles, the integrity factor is proposed here as a rational parameter for evaluating chain-pillar stability.

OP 36–83. Simplest Formula of Copper Iodide: A Stoichiometry Experiment, by D. J. MacDonald. J. Chem. Educ., v. 60, No. 2, Feb. 1983, p. 147. An experiment suitable for use in teaching principles of stoichiometry and chemical laboratory techniques is described. It is intended for high school or college courses in general chemistry. The experiment involves dissolving a known mass of copper metal and quantitatively precipitating the copper as copper iodide, CuI. A student using the experiment is given as background information the atomic masses of copper and iodine and is expected to determine the empirical formula of copper iodide, that is, to decide from his or her measurement of its I:Cu atom ratio whether copper iodide is CuI or CuI_2. In use by a group of typical students at the University of Nevada at Reno, the experiment gave an average result for the I:Cu ratio equal to 1.02 with a standard deviation of 0.16.

OP 37–83. Electric Arc Furnace Melting of Simulated Transuranic Wastes, by R. H. Nafziger and L. L. Oden. Pres. at 6th Int. Symp. on the Scientific Basis for Nuclear Waste Management, Boston, MA, Nov. 1–4, 1982; Mat. Res. Soc. Symp. Proc., v. 15, 1983. Elsevier Scientific Publishing Co., Amsterdam, the Netherlands, pp. 639–646. As part of an interagency agreement between the Bureau of Mines, U.S. Department of the Interior, and the U.S. Department of Energy through its contractor, EG&G Idaho, Inc., the Bureau conducted six melting tests at its Albany Research Center to assess the feasibility of melting transuranic-containing wastes. The tests were conducted with simulated wastes in a conventional refractory-lined electric arc furnace. Charge materials included concrete, soil, metal, wood, CaO- and Na_2O-containing waste sludges, cement, and polyethylene mixed in various proportions in both unburned and partially incinerated forms. The investigation showed that it is possible to melt these materials in a 1-metric-ton conventional electric arc furnace and separate the slag and metal provided that suitable fluxes are added to condition the siliceous slags. However, the electric arc furnace cannot be considered an efficient incinerator. The molten slags were poured into 210-liter steel drums having a 0.64-cm-thick steel chill plate on the bottom. All slags were tapped from the furnace satisfactorily. The concrete and sludge materials required the most energy for melting. The highest electrode consumption occurred when the sludges were melted. A high alumina-chrome refractory is satisfactory for use as a furnace lining in melting these wastes. Offgases and particulates from all of the tests were sampled and analyzed. The greatest amounts of particulate matter in the offgas streams were obtained from melting sludges and incinerated wastes.

OP 38–83. The Effect of Ion-Implanted Alloy Additions on the Linear Polarization and Corrosion Fatigue Behavior of Steel, by B. D. Sartwell, R. P. Walters, N. S. Wheeler, and C. R. Brown. Paper in Corrosion of Metals Processed by Directed Energy Beams, ed. by C. R. Clayton and C. M. Preece (Proc. TMS-AIME Fall Meeting, cosponsored by The Metall. Soc. of AIME and Mater. Sci. Div. of ASM, Louisville, KY, Oct. 13, 1981). Metall. Soc. AIME, December 1982, pp. 53–73. As part of the research to determine substitute alloying elements, investigations have been conducted by the Bureau of Mines to determine the effects of different alloying elements, introduced into the substrate by ion implantation, on the corrosion and oxidation behavior of steel. This investigation involved using the three-point linear polarization test to determine the effects of lead and titanium implantation on the aqueous corrosion behavior of iron in a dilute sulfuric acid solution. This technique proved to be a quick, accurate corrosion rate test suitable for evaluating the ion-implanted alloys so that an assessment could be made of the effects of the specific alloy additions on corrosion behavior.

OP 39–83. Filtration of Asbestos and Other Solids With Magnesium Oxide, by J. E. Schiller and S. E. Khalafalla. Pres. at SME-AIME Annu. Meeting, Las Vegas, NV, Feb. 24, 1980. Soc. Min. Eng. AIME preprint 80–108, Mar. 1988, pp. 237–242. Owing to its unique surface properties, magnesium oxide (MgO) is an excellent medium to filter asbestos and other suspended solids from water. MgO operates up to twice as long as a sand filter before backwashing is required while flow rate and filtrate clarity are as good or better with MgO .

OP 40–83. Energy Recovery Using Hydraulic Turbines in Deep Underground Mines, by R. N. Torbin and E. D. Thimons. Mech. Eng., v. 105, No. 4, Apr. 1983, pp. 57–61. Mines in the United States are continually descending to greater depths in the search for minable deposits, but the high temperatures and humidities encountered at these depths make a comfortable working environment difficult and expensive to maintain. To help deal with this problem, the Bureau of Mines awarded a contract to investigate and evaluate commercially available means of energy recovery for the deep mining industry. This paper discusses benefits that can be realized using high-pressure water to operate a turbine, the economic considerations, the use of turbine technology in mine applications, and outlines the research program plan for further study.

OP 41–83. Size and Shape Characteristics of Amphibole Asbestos (Amosite) and Amphibole Cleavage Fragments (Actinolite, Cummingtonite) Collected on Occupational Air Monitoring Filters, by Robert L. Virta. Kim B. Shedd, Ann G. Wylie, and Janet G. Snyder. Ch. 47 in Aerosols in the Mining and Industrial Work Environments. Volume 2. Characterization, ed. by V. A. Marple and B. Y. H. Liu. Ann Arbor Sci. Pub., Ann Arbor MI, Mar. 1983, pp. 633–643. The objective of this study by the Bureau of Mines was to determine if particle populations from asbestiform and nonasbestiform mineral sources can be distinguished through least-squares regression analyses using the relationship:

$$\log_{10} \text{width} = F \log_{10} \text{length} + b$$

where F = fibrosity index, the slope of the regression line

b = intercept on the $\log_{10}$ width axis

Amphibole particles on air monitoring filters from three mining and two industrial sites were characterized by scanning electron microscopy and energy-dispersive X-ray spectroscopy analysis. The data are evaluated using particle length and width summary statistics and compared with analyses by linear regression. Conclusions based on comparison of data manipulation using these two techniques follow: The mining site particle populations are morphologically similar, the industrial site particle populations are morphologically similar, and size and shape characteristics of mining site populations are statistically different from those of the industrial sites. Determination of either an asbestos or a nonasbestos source of amphiboles using linear regression techniques on data obtained from examination of air monitoring filters is a potential application of this technique.

OP 42–83. Adhesion and Hardness of Platinum Coatings Electrodeposited From Molten Salts, by R. P.

Walters, M. J. Lynch, and D. R. Flinn. Plat. and Surface Finishing J., v. 70, No. 5, May 1983, pp. 91–95. Utilizing a direct pull solder method, the adhesion of platinum coatings to TZM and Fe10Cr substrates was determined. The average fracture value was 331 MPa (48,000 lb/in), with fracture occurring in the substrate or in some combination of the substrate, coating, and solder, but not at the deposit-substrate interface, indicating that the true adhesion of the coatings is greater than the measured fracture values. Cross-sectional hardness values were dependent on the average grain width, with hardness values ranging from 52 to 120 HK_{25} at 35 and 8 μm, respectively, from the substrate-coating interface.

OP 43–83. Geologic Estimates and Future Costs of Strip Mining Coal, by Emil D. Attanasi and Eric K. Green. Energy Systems and Policy J., v. 6, No. 3, 1982, pp. 193–212. Geologic coal-resource appraisals, which typically describe the location and general characteristics of coalbeds, do not generally provide enough information to estimate the cost of developing the resource or to predict the escalation of costs expected to result from physical depletion. This paper considers the nature of data and methods of appraisal required to provide this cost information to policymakers. Illinois is used as a prototype area for analysis because of its long history of coal mining and its demonstrated coal reserve base of strippable coal that exceeds all but two of the States in the United States. Evidence of gradual depletion of Illinois strippable coal reserves is provided by declining labor productivity, decreasing average mine size, and increasing overburden depth. The procedures used to estimate the costs of mining remaining deposits indicate that the physical characteristics that will affect mining costs most significantly are depth of overburden, thickness of coal seam, and areal extent of coal of the minable reserve blocks. Findings presented here provide guidelines for the collection of economic and geologic data in order to improve coal appraisals, particularly those currently in progress in the Western United States.

OP 44–83. Infrared Temperatures of Coal Dust Explosions, by Kenneth L. Cashdollar and Martin Hertzberg. Combus. and Flame, v. 51, 1983, pp. 23–35. A comprehensive set of temperature measurements is presented for coal dust explosions as a function of dust concentration. Data include the dependence of explosion temperature on particle size, volatility, oxygen content, and added rock dust. The majority of the data are for constant volume explosions in a laboratory-scale vessel, but data from a coal dust burner flame and full-scale mine dust explosions are also included. In all of the measurements, the gas temperature was significantly higher than the dust particle temperature. The measurements were made with a three-wavelength near-infrared pyrometer and a six-wavelength infrared pyrometer (in the 1- to 5-μm-wavelength region). Some thermocouple measurements are shown for comparison.

OP 45–83. Using the U.S. Bureau of Mines Minerals Availability System for Supply-Demand Analysis, by Eric Green and James Grichar. Mater. and Soc., v. 6, No. 4, 1982, pp. 471–482. In recent years numerous attempts have been made to model nonfuel minerals markets and forecast trends in price, demand, supply, import reliance, etc. On the supply side, econometric models based on historical data were constructed with less than satisfactory results. Such models and their estimates of the future primary supply of nonfuel minerals may be more accurate if the physical characteristics of the known deposits are evaluated using standardized engineering-cost methodology. The Minerals Availability System (MAS) of the U.S. Bureau of Mines transforms this type of deposit information into estimates of potential nonfuel minerals production. MAS estimates potential production from domestic and foreign deposits; this will be done for 34 commodities. This paper shows how MAS can be used in partial equilibrium analysis of the copper market. In particular, a domestic primary supply function is developed based on MAS data; this and other models are then used to predict equilibrium price and quantity under various assumptions.

OP 46–83. Domains of Flammability and Thermal Ignitability for Pulverized Coals and Other Dusts: Particle Size Dependences and Microscopic Residue Analyses, by Martin Hertzberg, Kenneth L. Cashdollar, Daniel L. Ng, and Ronald S. Conti. Paper in Nineteenth Symposium (International) on Combustion (Haifa, Israel, Aug. 8–13, 1982). Combustion Inst., Pittsburgh, PA, 1982, pp. 1169–1180. New data presented for the particle size dependence of the domains of flammability and thermal ignitability for two bituminous coal dusts and for polyethylene powder showed that below some threshold or characteristic diameter, the behavior of all the dusts was independent of particle size and approached that of an equivalent premixed gas. Above the characteristic diameter, the lean limit of flammability and the minimum autoignition temperature increased with increasing particle size. For still larger particle sizes, a critical diameter was reached, above which the dusts were nonexplosive at ambient temperature. Both the characteristic diameter at which a size dependence first appears and the critical diameter above which the dust is nonexplosive increase monotonically with increasing volatility of the dust. The characteristic diameter and critical diameter also increase monotonically with increasing ambient temperature and with increasing oxygen content of the dispersing gas.

OP 47–83. Supply Prospects for the U.S. Copper Industry: Alternative Scenarios: Midas II Computer Model, by W. R. Hibbard, Jr., H. D. Sherali, A. L. Soyster, and L. J. Sousa. Mater. and Soc., v. 6, No. 2, 1982, pp. 201–210. The Midas II linear programming model of the U.S. copper industry was revised to reflect conditions resulting from the 1980–81 recession, the high cost of money, and reduced demand. Various scenarios were run to evaluate the impact of tax reductions, high rates of economic growth, severance tax, and changes in pollution control requirements on copper demand, supply, and price. The most stimulating effects resulted from high demand generated by an increased rate of economic growth. The next most stimulating effects resulted from a 20% tax cut together with no pollution control costs. The tax cut alone caused little change from the base case. The most devastating effects resulted from requiring an 18% rate of return combined with an Intergovernmental Council of Copper-Exporting Countries embargo. The 18% rate of return reduced U.S. production that was made up from imports. When the imports were not available, the impact was drastic. The model seemed to perform appropriately under the circumstances prescribed.

OP 48–83. Mining, by Barry W. Klein and Ronald F. Balazik. Ch. 15 in U.S. Ind. Outlook 1982, pp. 147–150. Mining production is expected to increase in 1982, as was the expectation for 1981.

Tax law changes should encourage investment, and a new cabinet-level council is addressing mineral industry issues and problems. Improvement will be gradual, however, because changes in Government policy do not have immediate effects. This paper covers SIC codes 10 and 14, nonfuel metallic and nonmetallic minerals. SIC code 10 includes ores of such metals as iron, copper, lead, zinc, and molybdenum. SIC code 14 includes both nonmetallics, such as stone, sand and gravel, and clays, and chemical minerals such as phosphate rock, potash, and sulfur.

OP 49–83. Mining, by Barry W. Klein, Annette P. Graham, and Anthony Oprychal. Ch. 16 in U.S. Ind. Outlook 1983, pp. 16-1—16-7. Mining production is expected to increase somewhat in 1983 compared with the relatively low levels in 1982. This anticipated improvement reflects the upturn in the economy forecast for 1983. In April 1982, the President submitted to Congress the National Materials and Minerals Program Plan and Report, which recognizes the vital importance of minerals to the economy and national security. This paper covers SIC codes 10 and 14, metallic and nonmetallic mineral industries, excluding fuels. SIC code 10 includes ores of such metals as iron, copper, gold, molybdenum, and lead. SIC code 14 includes nonmetallics, such as stone, sand and gravel, and clays; and chemical minerals such as phosphate rock, sulfur, salt, and potash.

OP 50–83. The Vapor-Liquid Equilibria of the Aluminum Chloride-Ferric Chloride System, by H. C. Ko, A. Landsberg, and Jack L. Henry. Metall. Trans. B, v. 14B, June 1983, pp. 301–304. Work was undertaken at the Bureau of Mines Albany (OR) Research Center to measure the vapor-liquid equilibria in the aluminum chloride-iron chloride system at realistic pressures. The equilibrium diagram constructed from these data can be used to evaluate the possibility of using distillation for separating iron chloride from aluminum chloride. This work is part of a larger effort to study the carbochlorination of domestic clay as a means to produce anhydrous aluminum chloride for reduction in the more energy-efficient chloride cell.

OP 51–83. Iodine, by P. A. Lyday. Min. Eng., v. 35, No. 5. May 1983, p. 495. In 1982, U.S. iodine demand decreased as the economy remained depressed and iodine prices remained high. Demand decreased 9% to about 36 kt (3,950 st) valued at $48 million. Imports from Japan (81%) and Chile (18%) were the major source of U.S. supply. Two U.S. companies produced at 1981 levels and supplied about 25% of domestic demand. Demand is expected to increase during 1983.

OP 52–83. Feasibility of In Situ Leaching of Metallic Ores Other Than Copper and Uranium, by George M. Potter, Clement K. Chase, and Peter G. Chamberlain. Pres. at 2d SME-SPE Int. Symp. on Solution Mining, Denver, CO, Nov. 18–20, 1981, SME preprint 81-363, 6 pp.; pub. in Interfacing Technologies in Solution Mining, ed. by W. J. Schlitt and J. B. Hiskey. Soc. Min. Eng. AIME, Littleton, CO, 1982, pp. 123–130. Under contractual arrangements with the Bureau of Mines, Mountain States Research and Development, Inc., completed a technological investigation to determine the feasibility of in situ mining of metal commodities other than copper and uranium. The study was based upon available literature and experience. The selection of potential candidates for in situ mining was influenced by economic importance, probable amenability to in situ methods, and environmental considerations. Four metals (or metal pairs) were chosen for feasibility studies: aluminum (with a copper byproduct), gold-silver, and manganese were recommended for further study and action; cobalt-nickel was also recommended contingent upon preliminary laboratory leaching and recovery investigations and field geohydrological work. Mining and recovery plans and an economic evaluation are included. Other metals with potential for in situ leaching are lead-zinc, molybdenum, and vanadium.

OP 53–83. Strategic Planning in the Minerals and Materials Industries in an International Era, by Louis J. Sousa. Mater. and Soc., v. 7, No. 1, 1983, pp. 49–50. Strategic planning is a process in which a firm attempts to clearly define what it is trying to achieve and to identify the optimal paths for achieving these objectives. Materials firms recently have come to place more attention on strategic planning. Foreign competition has increased significantly. For most of the major metals, a slow growth future seems to be in the offing. Strategic planning can provide materials firms with a better understanding of the change that is occurring so rapidly. It can enable a firm to better control as it maneuvers towards the most profitable directions.

OP 54–83. Iron Oxide Pigments, by W. I. Spinrad, Jr. Min. Eng., v. 35, No. 5, May 1983, pp. 495–496. U.S. mine production and shipments of crude iron oxide pigments and finished iron oxide shipments and U.S. imports decreased markedly in 1982 compared with 1981 levels. U.S. exports over the same period increased sharply. Decreases in demand for iron oxide pigments have been caused by curtailed consumption and inventory reduction by most domestic consumers of these pigments.

OP 55–83. State Severance Taxes: An Analysis of the Impact of Rate Changes on Copper Recovery Costs, by Phillip N. Yasnowsky and Annette P. Graham. Mater. and Soc., v. 6, No. 2, 1982, pp. 233–246. This paper uses the Bureau of Mines Minerals Availability System to analyze the possible effect of assumed State severance tax rate changes on copper recovery costs. For a comprehensive background study of severance taxes, the reader is referred to the Bureau's Information Circular 8788.

OP 56–83. Strontium, by J. E. Ferrell. Min. Eng., v. 35, No. 5, May 1983, pp. 510–511. The United States continued as the world's largest producer and consumer of strontium compounds, even though there has been no domestic mining of strontium ores since 1959. Imports dropped sharply for strontium minerals (celestite) from 45 kt (49,699 st) in 1981 to 30 kt (33,075 st) in 1982—the lowest annual tonnage since 1975. More than 99% of the celestite came from Mexico. Strontium compound imports also declined from the 1981 level by about 32% to 1.8 kt (1,942 st).

OP 57–83. Quartz Crystal, by W. Johnson. Min. Eng., v. 35, No. 5, May 1983, p. 506. Industrial quartz crystal continues to be of critical importance to the electronics industry. It is used extensively for military and civilian communications networks requiring precise frequency control, oscillator watches, and numerous other timing devices including automobile microprocessors. Only a minute amount of quartz crystal is used for optical purposes.

OP 58–83. Bromine, by P. A. Lyday. Min. Eng., v. 35, No. 5, May 1983, pp. 487–488. The

article is an overview of the bromine industry during 1982. The United States continued to be the largest producer of bromine in the world. Ethylene dibromide, used as a lead scavenger in gasoline, was the largest area of demand. Sections discuss U.S. development, foreign developments, and outlook for the future of the industry.

OP 59–83. An Econometric Model of the Short-Run Demand for Workers and Hours in the U.S. Auto Industry, by Julius C. Chang. J. Econometrics, Elsevier Science Publishers B.V., North-Holland, v. 22, No. 3, August 1982, pp. 301–316. Based on the labor hoarding theory and the Koyck-type adjustment mechanism, a model of the short-run demand for workers and hours in the U.S. auto industry is developed and estimated using Michigan and U.S. data, respectively. Statistical tests of the model structure are then conducted to confirm the theoretical specifications.

OP 60–83. Recovery of Lead From Battery Sludge by Electrowinning, by E. R. Cole, A. Y. Lee, and D. L. Paulson. J. Met., v. 35, No. 8, August 1983, pp. 42–46. Research by the Bureau of Mines has resulted in a combination electrorefining-electrowinning method for recycling the lead from scrap batteries. The lead metal grids and lugs are separated from the sludge by ball milling, washing, and screening and are melted and cast into anodes for electrorefining by the Betts process using waste fluosilicic acid as the electrolyte. The Betts process, established in commercial use for 80 years, has been well described in the literature and needs no further description here. The sulfate-oxide-metal sludge remaining after separation of the lead metal is treated in a two-step leaching operation with ammonium carbonate, waste fluosilicic acid, and Pb powder to solubilize the lead for recovery by electrowinning. Unlike electrorefining, electrowinning is not being practiced commercially now. Prior attempts to electrowin lead have failed because large quantities of insoluble lead dioxide are deposited on the anodes at the expense of lead deposition on the cathodes. This paper describes bench-scale research for recovering lead from battery sludge by electrowinning that prevents PbO_2 formation at the anodes. The bench-scale work has been successfully completed, and electrowinning experiments are presently being conducted in a 20-liter multielectrode cell.

OP 61–83. Survival Kits for the Breath of Life, by Nicholas Kyriazi. Foote Prints, v. 46, No. 1, June 1983, pp. 18–23. This is a brief discussion of some of the equipment being developed by the U.S. Bureau of Mines to improve the odds for the survival of miners exiting an underground coal mine after an emergency and to enhance the safety of rescue team members recovering the mine. At a lay worker's technical level, a new escape breathing apparatus, a low-profile rescue breathing apparatus, a mine rescue team protective ensemble, and a rescue team helmet are presented with appropriate background information describing their need and operation.

OP 62–83. Thermal Degradation of Oil Shale With Molten Nitrates, by Yael Miron. Thermochim. Acta, Elsevier Science Publishers, B.V., Amsterdam, the Netherlands, v. 65, 1983, pp. 213–237. The present study was conducted at the Bureau of Mines to explore the effect of a variety of molten nitrate salts on the thermal decomposition of one oil shale sample from the Green River Formation. Thermal analysis, coupled with effluent gas analysis, was used for all the tests in which the samples were heated at a constant heating rate. Weight losses of heated oil shale in the presence of nitrates were found to be higher than similar losses in the absence of nitrates. Ammonium nitrate degraded the oil shale at a lower temperature than that at which oil shale started to decompose when heated by itself, or in the presence of sodium nitrate or potassium nitrate. From scanning electron microscopy of the heated oil shale samples, it appears that ammonium nitrate attacked both the inorganic and the organic portions of the shale. These results indicate that a more detailed investigation of the effects of ammonium nitrate, and perhaps other nitrates, on fuel recovery from oil shale will be a worthwhile undertaking.

OP 63–83. How To Design Cabs and Canopies. Part I—Measuring the Problems, by William W. Aljoe. Coal Min. & Proc., March 1983, pp. 61–67. This is the first of a series of three articles. The purpose of the series is to describe the results of approximately 3 years of research, sponsored by the Bureau of Mines, to document the application of cabs and canopies in low coal mines. This article describes a procedure to define the minimum and practical working heights at which canopies can be used without roofing and without restricting operator comfort or vision.

OP 64–83. How To Design Cabs and Canopies. Part II—Increasing Comfort and Vision, by William W. Aljoe. Coal Min. & Proc., April 1983, pp. 94–118. This is the second of a series of three articles. The purpose of the series is to describe the results of approximately 3 years of research, sponsored by the Bureau of Mines, to document the application of cabs and canopies in low coal mines. This article examines the problems of operator comfort and vision resulting from the canopies on existing equipment.

OP 65–83. How To Design Cabs and Canopies. Part III—Avoiding and Solving Problems, by William W. Aljoe. Coal Min. & Proc., May 1983, pp. 58–63. This is the third of a series of three articles. The purpose of the series is to describe the results of approximately 3 years of research, sponsored by the Bureau of Mines, to document the application of cabs and canopies in low coal mines. This article discusses how optimum machine selection, changes in mine operating procedures, and improvements in cab and canopy design can help solve canopy-related problems inherent to low coal mines.

OP 66–83. Heat Capacities of Titanium Disulfide From 5.87 to 300.7 K, by Richard P. Beyer. J. Chem. & Eng. Data, July 1983, pp. 347-348. The heat capacity of TiS_2 was determined from 5.87 to 300.7 K by adiabatic calorimetry. The values at 298.5 K for $C_p°$, $S°(T)-S°(0)$, $-[G°(T)-H(0)]/T$, and $H°(T)-H°(0)$ are 67.34, 78.21, 36.89 J mol^{-1} K^{-1}, and 12.38 kJ mol^{-1}, respectively.

OP 67–83. Noise Control of an Underground Mine Personnel Carrier, by Anthony G. Galaitsis and Thomas G. Bobick. Noise Contr. Eng. J., v. 21, No. 1, July-August 1983, pp. 4–9. The interior noise of a mine-operated rail personnel carrier was reduced by replacing some standard components with acoustically treated components. The latter included

a softer suspension, softer motor mounts, damped panels, sound-absorbing motor enclosures, and helical gears. Depending on operating conditions, the modified vehicle was 6 to 7.5 dBA quieter than an unquieted vehicle. The noise level in the vehicle interior was reduced to approximately 85 dBA at an average vehicle speed.

OP 68–83. The Oxygen Cost of an Escape From an Underground Coal Mine, by Eliezer Kamon, Diane Doyle, and John Kovac. Am. Ind. Hyg. Assoc. J., v. 44, No. 7, July 1983, pp. 552–555. Six 27- to 63-year-old coal miners performed an escape maneuver from an underground mine along a passageway that required walking and running erect or stooped, duckwalking, and crawling. The miners traveled at different speeds, for each mode of locomotion. The minute pulmonary ventilation (V_E), uptake (V_{O_2}), and heart rate (HR), recorded continuously on a magnetic tape via lightweight meters carried on the miners' waists, indicated similar average and peak values for all modes of locomotion. The mean V_E, V_{O_2} (L•min^{-1}, STPD), and HR (b•min^{-1}) were, respectively, 49, 1.63, and 143 for the average values, and 52, 1.92, and 161 for the peak values. Compared to the aerobic capacity obtained during graded treadmill test to exhaustion, the average effort of the escape was performed at 64% and the peak effort at 70% of the miners' aerobic capacity for an escape time of 58 minutes.

OP 69–83. Methane in Pennsylvania Coal: An Overview, by Carla A. Kertis, James P. Ulery, and Roger L. King. Ch. 24 in Pennsylvania Coal: Resources, Technology and Utilization, ed. by S. K. Majumdar and E. W. Miller. PA Acad. Sci., 1983, pp. 439–461. The hazards of methane gas have been associated with coal from the inception of underground mining. Methane occurs in the air of most coal mines because when coal was formed from ancient peat swamps, methane was also formed. The common occurrence of methane and its explosibility when mixed with air are directly responsible for numerous mine disasters. Owing to the inherent gassiness of all underground coal mines, various methods of removing methane have been developed. These degasification techniques have improved safety conditions in coal mines while maintaining high production rates and have facilitated the use of a valuable energy resource.

OP 70–83. Interfacing an XRF Spectrometer and Computer System To Aid Data Management, by D. G. Kuehn, D. C. Lundeen, R. L. Brandvig, and R. H. Jefferson. Am. Lab., v. 15, No. 9, September 1983, pp. 16–23. Data management for X-ray fluorescence spectroscopy can be cumbersome and time-consuming, especially when multielement analyses are required for each sample material. To speed and simplify the process while utilizing existing equipment, the Bureau of Mines has interfaced free-standing X-ray fluorescence and computer systems. This report discusses the implementation procedures in terms of both hardware and software requirements.

OP 71–83. Smelting Ferrochromium From a New Guinea Lateritic Chromite, by R. H. Nafziger. Trans. Inst. Min. Metall. (Sec. C: Miner. Process. Extr. Metall.), v. 92, June 1983, pp. C73–C82. The Bureau of Mines cooperated with the NORD Resources Corp. to evaluate the feasibility of smelting a lateritic chromite concentrate from New Guinea to produce ferrochromium by electric arc furnace processing. One series of five tests was conducted in a nominal 100-kg furnace to evaluate slag compositions, carbonaceous reductants, and smelting characteristics of the chromite. A second series of five 1-ton furnace tests was made to obtain such engineering data as energy consumption, melting rates, and bath temperatures. Results showed that a high-carbon ferrochromium can be prepared from the New Guinea lateritic chromite concentrate, although the phosphorus levels were high. Chromium recovery in the ferroalloy with up to 52 wt % chromium averaged nearly 80%. Energy consumption compared favorably with that reported in commercial practice. Submerged arc operations provided the most efficient smelting conditions. On the basis of results obtained in the small-scale batch operations, agglomeration of the charge materials may not be required. Because of the relatively fine size of the chromite concentrate, carbon requirements should include woodchips to improve operation of the furnace. In general, variables for smelting lateritic chromites are similar to those for the production of high-carbon ferrochromium from offgrade chromites.

OP 72–83. Noise Control for Aggregate Plants, by Robert J. Pokora, Terry L. Muldoon, and Thomas G. Bobick. Pit & Quarry, September 1983, pp. 40–44. Barrier materials, operator enclosures, and resilient materials were used in a demonstration program for retrofitting aggregate plants for noise reduction. The techniques employed in the program can provide guidelines for designing, installing, and evaluating retrofit noise control systems in crushing and screening plants. This article discusses the details of a survey of the nonmetallic mining industry, the design and installation of retrofit noise control treatments, and the field evaluation of those controls under actual operating conditions.

OP 73–83. Specimen Preparation and Sizing by Image Analysis of Respirable Quartz Particles Collected on Coal Mine Air-Monitoring Filters, by J. G. Snyder and C. W. Huggins. Proc. 18th Annu. Meeting, Microbeam Anal. Soc. of America, Phoenix, AZ, Aug. 6–12, 1983; pub. in Microbeam Analysis—1983, ed. by R. Gooley, San Francisco Press, Inc., pp. 22–26. Several quartz standards and respirable coal mine dust samples containing significant amounts of quartz were used to develop a method of quartz particle-size determination by image analysis. Data on the quartz particle size are crucial for the accurate determination of quartz in respirable coal mine dusts collected on air-monitoring filters by MSHA. In this study, three pure ground quartz materials were chosen for particle-size distribution measurements: Minusil -5, Minusil -10, and Silver Bond B. Size distributions for the quartz standards were first determined by a Philips EM 100-B transmission electron microscope as a basis for verification of the results from image analysis. Next, a specimen preparation technique was developed for image analysis. Particle-size analysis was done with a Cambridge Mark II scanning electron microscope interfaced with a Tracor Northern 1310 image analyzer and a Tracor Northern 880 energy-dispersive X-ray spectrometer.

OP 74–83. Hot-Crush Technique for Separation of Cast- and Wrought-Aluminum Alloy Scrap, by Fred Ambrose, R. D. Brown, Jr., Dominic Montagna, and H. V. Makar. Proc. 4th Recycling World Cong.,

New Orleans, LA, Apr. 5-7, 1982; pub. in Conserv. & Recycling, v. 6, No. 1/2, 1983, pp. 63-69. A novel technique for the separation of cast and wrought aluminum alloy scrap is described. This technique, developed by the Bureau of Mines, exploits differences in hot ductility between cast and wrought aluminum. Tests are in progress to demonstrate its use for upgrading mixed aluminum scrap into recyclable grades of wrought and cast alloys. This paper describes (1) process development studies using conventional heating, fragmentizing, and screening equipment and (2) process improvements to enhance commercial development.

OP 75–83. New Technique Vacuums Gob Gas. Cross-Measure Boreholes Controlled Longwall Gob Gas at a Bethlehem Mine, by A. A. Campoli, Joseph Cervik, and F. Burns. Coal Min. Process., v. 20, No. 3, March 1983, pp. 48-51. The cross-measure borehole technique is being developed jointly by the Bureau of Mines and Bethlehem Mines Corp. as an alternative to current U.S. longwall methane control techniques. Small-diameter inclined boreholes are drilled from underground locations into roof strata that will be fractured when the longwall panel is removed. Methane contained in the fractured strata is collected in the cross-measure boreholes and drawn through an underground pipeline to a central surface borehole by a vacuum pump.

OP 76–83. Grouting Methane Drainage Holes in Coalbeds, by Joseph Cervik. Proc. ASCE Spec. Conf. on Grouting in Geotechnical Engineering, New Orleans, LA, Feb. 10-12, 1982, pp. 651-664. Horizontal drainage holes drilled into gassy coalbeds are effective in reducing methane flows into mine workings during mining operations. Drainage holes were drilled 415 to 2,126 ft (126 to 648 m) long. Holes were sealed with cement before interception by the mining machine to avoid formation of explosive methane-air mixtures. The cement slurry consisted of cement, fly ash, and fluidifier. Excess water was used in the slurry to avoid plugging problems because of the distance the slurry was pumped. When the hole was filled with slurry, pressure was increased to squeeze excess water into the coalbed fracture system. Examination of intercepted drainage holes showed that in some cases, water had separated from the slurry and had not been squeezed into the fracture system. In no case was cement slurry forced into the fracture system. In a subsequent study, water content of the slurry was reduced to recommended quantities. Where water flow from drainage holes before grouting was less than 0.5 gal/min (1.9 L/min), holes were satisfactorily sealed. Water flow greater than 2 gal/min (7.6 L/min) before grouting diluted the slurry and water stratified in the hole. When the hole was intercepted, gas pressure forced water and then methane from the hole. The resulting methane accumulation caused the machine-mounted methane monitor to indicate the high methane accumulation, thus deenergizing electrical power to the mining machine.

OP 77–83. Control of Methane in Gob and Bleeders by the Cross-Measure Borehole Technique, by Joseph Cervik and Roger L. King. Proc. 14th Annu. Inst. on Coal Mining Health, Safety, and Research, Blacksburg, VA, Aug. 23-25, 1983, pp. 139-148. In Europe and the United Kingdom, small-diameter drainage holes (cross-measure boreholes) are drilled into strata overlying a longwall to control methane in the gob and to prevent it from mixing with the ventilation air. These drainage holes are connected to an underground pipeline that is maintained under a partial vacuum by surface vacuum pumps. Bureau of Mines tests in the Upper Kittanning Coalbed utilizing the cross-measure borehole system demonstrated the capture of 50 pct of the total methane generated by the mining operation. The angle of the hole above horizontal, depth of penetration of the hole into the gob, and location of the pipeline and collar of the hole are important parameters affecting the performance of the cross-measure borehole technique.

OP 78–83. Reverse Performance Characteristics of Main Mine Fans, by M. F. Dunn, F. S. Kendorski, S. Bhattacharya, V. Rajaram, and E. D. Thimons. Min. Sci. & Technol., Elsevier Science Publishers B.V., Amsterdam, the Netherlands, v. 1, No. 1, October 1983, pp. 59–68. During a mine fire or other emergency, it may be desirable to reverse the airflow in order to provide an escapeway or to isolate a fire. Also, in colder areas, the airflow may be reversed to prevent ice buildup. When reversing main mine fans, the mine operator usually does not know what operating characteristics of flow and pressure to expect. Laboratory and field tests of vane axial main mine fans were conducted to establish forward and reverse performance characteristics under controlled conditions and in typical mine installations. All fans tested were between 81 and 96 in (2.1 and 2.4 m) in diameter. The data obtained suggest that reverse performance characteristics are dependent upon the blade angle and the hub-to-tip ratio. There is also evidence that reverse performance can be predicted for a family of blade angles for a given hub-to-tip ratio. Generally fan quantity is 30% to 60% less in reverse than when operating in the normal forward mode, with static pressure equal to the square of the volume percentage change.

OP 79–83. Methane Drainage Experience With Horizontal Boreholes in a Western Coalbed, by Gerald L. Finfinger, John H. Perry, and Roger L. King. Proc. Australas. Inst. Min. and Metall. Symp. on Seam Drainage With Particular Reference to the Working Seam, Wollongong, NSW, Australia, May 11–14, 1982, pp. 102–115. The Bureau of Mines in cooperation with Kaiser Steel Corp. conducted two methane drainage studies in an advancing section of the Sunnyside No. 1 Mine where production was being severely hampered by methane emissions. Six horizontal boreholes were completed during the studies to an average length of 291 m. Total gas production from the boreholes as of December 1981 has exceeded 6,088,800 m^3. Methane emissions into the section were reduced by 40 pct as a result of the first drainage system. The second drainage system is currently producing 11,328 m^3/d from four boreholes. Mining of the section is expected to begin within 2 years.

OP 80–83. Water Removal From Mine Slimes and Sludge Using Direct Current, by D. J. Kelsh and R. H. Sprute. Drying Technol., v. 1, No. 1, April 1983, pp. 57–81. Recent tests by the Bureau of Mines have demonstrated the effectiveness of electrokinetic dewatering to consolidate a variety of coal and mineral slimes. Material properties and application methods that affect performance are briefly reviewed, and some operating and proposed field installations are described. Application of the method to other slimes and sludges can best be determined through laboratory testing, but certain

physical properties can be helpful predictors of responsiveness.

OP 81–83. Methane Drainage: Development of a Large-Scale Field Demonstration Using Vertical Boreholes, by Roger D. King and Michael A. Trevits. Proc. Australas. Inst. and Metall. Symp. on Seam Drainage With Particular Reference to the Working Seam, Wollongong, NSW, Australia, May 11–14, 1982, pp. 81–88. The United States Steel Corp. in cooperation with the U.S. Government is conducting a large-scale methane drainage field demonstration using stimulated vertical boreholes drilled in advance of mining. A grid pattern of 23 boreholes, isolating approximately 1.5 km^2 of coalbed area, was drilled to the lower bench of the Mary Lee Coalbed, Jefferson County, AL. Upon completion of drilling operations, various hydraulic stimulation treatments utilizing nitrogen-generated foam, water, and gelled fluid were performed to enhance the rate of methane gas removal. Production from the grid pattern began in September 1977 and continued as the last borehole was placed on production during October 1980. To date, in excess of 33,800,000 m^3 of methane gas has been drained as a result of this effort. Underground mining operations were approximately 3.2 km from the grid pattern when production began and have currently progressed to within 1.6 km. Underground interception of the grid is expected in 1986.

OP 82–83. Computer-Implemented Coalbed Methane Data Base, by John C. LaScola, David M. Hyman, and William P. Diamond. Ch. 29 in Proc. 1st SME-AIME Conf. on Use of Computers in the Coal Industry, Morgantown, WV, Aug. 1–3, 1983, pp. 251–257. The U.S. Department of the Interior, Bureau of Mines, has established a computer-implemented coalbed methane data base containing data representing over 2,000 coal samples from approximately 250 coalbeds located in 17 States and 1 Canadian Province. Space for approximately 130 sample characteristics is reserved for each sample record and is divided for access efficiency into three separate physical files. A software package was written to provide a user-friendly environment in which the three files can be manipulated simultaneously. These files can be used interactively in DATATRIEVE 11, a commercially available sorting, retrieval, and report-writing software package, or in any FORTRAN-compatible system for statistical analysis. The data base was established for coalbed methane research in response to the health and safety needs of the mining industry. Possible applications of the data base include mine planning related to the occurrence of gas, as well as delineating areas of resource recovery and utilization.

OP 83–83. Program Computes Radius-of-Curvature Coordinates for Straight, Deviated Holes, by David C. Oyler. Oil & Gas J., v. 81, No. 43, Oct. 24, 1983, pp. 100–108. The Bureau of Mines, U.S. Department of the Interior, has developed a program for the Hewlett-Packard HP-41C(V) that determines the change of position of a drill hole between two survey stations, using the radius-of-curvature calculation method. Values required to perform a single calculation are the bearings, inclinations, and measured depth at each station. The program automatically stores the most recent values of bearing, inclination, and measured depth for use in the next survey and automatically updates a set of hole position coordinate values. The program also asks for magnetic declination and project angle values upon initialization so that bearings obtained from magnetic compass data can be automatically corrected for declination and so that a cross section of the hole can be plotted. The program is friendly to the user, prompting for all required data entry and echoing the entered data and all output data with labels. It is also designed to allow correction of data entry mistakes and erasure of surveys calculated from errant data.

OP 84–83. Coal Cutting Research Slashes Dust, by Wallace W. Roepke. Coal Min. Process., v. 20, No. 2, October 1983, pp. 38–44. The Coal-Cutting Technology Group at the Bureau of Mines Twin Cities (MN) Research Center is investigating ways to reduce primary dust generated by coal cutting. The progression of research within the program is from fundamental laboratory research, to fundamental field research, to field concept verification. Then the Bureau recommends warranted changes and/or prototype development to industry. Currently the group has several projects in each phase of research. The Bureau's current fundamental studies of bit characteristics are directed toward determining the effects of conical bit wear on primary respirable dust generation, energy, and cutting forces; establishing best conical bit mount condition to increase life by enhancing bit rotation; and comparing chisel-type cutters to conical-type cutters. Additionally, to establish a suitable homogeneous reference material for cutting experiments, a synthetic coal with a plaster base is being developed.

OP 85–83. Comparison of Magnetic Properties of Natural Mischmetal and Synthetic Mischmetal Alloyed With Cobalt, Copper, and Magnesium, by J. W. Walkiewicz, E. Morrice, and M. M. Wong. Pres. at 21st Intermag Conf., Philadelphia, PA, Apr. 5–8, 1983; pub. in IEEE Trans. on Magnetics, v. MAG-19, No. 5, September 1983, pp. 2053–2055. One of the objectives of the Bureau of Mines is to develop substitutes for scarce materials. Alloys containing mischmetal, lanthanum, praseodymium, neodymium, cobalt, copper, and magnesium were evaluated for use in permanent magnets in lieu of Sm-Co alloys. Magnets were fabricated by powder metallurgy techniques that consisted of arc melting the metals, crushing and grinding the resultant alloy, aligning and compacting the powder, and sintering the green compacts. A cerium-free synthetic mischmetal consisting of La-Pr-Nd was developed that had substantially better magnetic properties than natural mischmetal when alloyed with cobalt, copper, and magnesium.

OP 86–83. Synthetic Construction Aggregate Developed From Phosphate Fertilizer Waste, by Alexander May, John W. Sweeney, and James R. Cobble. Pres. at SME-AIME Fall Meeting and Exhibit, Salt Lake City, UT, Oct. 19–21, 1983, SME preprint 83–300, 15 pp. In its role of providing technology to promote the efficient use of minerals and mineral process waste, the U.S. Bureau of Mines conducted research at its Tuscaloosa (AL) Research Center to identify and develop high-volume uses for phosphogypsum. Mixtures containing a maximum of 5 pct phosphogypsum, 6 to 10 pct lime, and the remainder fly ash had compressive strengths as high as 4,800 psi. The effects of the amounts of phosphogypsum, lime, and fly ash were investigated. Also, the effects of fly ash to lime ratios were studied.

OP 87–83. Compact Unit Collects Mine and Mill Dust, by Jon Sandstedt and Steven Page. Min. Equip. Int., v. 7, No. 10, pp. 40, 41–44. Wet collectors and water spray systems usually provide adequate dust control for underground and surface

applications at low cost. However, there are applications where water usage cannot be tolerated because of availability, disposal, or material handling problems. In trona mines, for example, water mixes with trona dust to form a cement-like material that is difficult to remove. This report describes a dry dust collector, developed under a Bureau of Mines contract, that has the dry fabric filtration advantages of (1) high efficiency, (2) easy material handling, and (3) all temperature operation, while minimizing the usual disadvantages of frequent maintenance and large size.

OP 88–83. Effect of Microorganisms on In Situ Uranium Mining, by Marylynn V. Yates, James A. Brierley, Corale L. Brierley, and Steven Follin. Appl. Environ. Microbiol., v. 46, No. 4, October 1983, pp. 779–784. The extraction of some metal values, e.g., uranium or copper, may be accomplished by using solutions to remove metals from ore bodies without practicing conventional mining. This process is referred to as in situ leaching and has been used industrially to recover uranium. The growth of microbial populations during in situ leaching is believed to be one of the causes of flow path plugging in the ore body, which results in decreased uranium production. Leach solution and solid samples from well casings and submersible pumps were collected from an in situ mining operation experiencing plugging problems. *Bacillus* sp., *Micrococcus* sp., pseudomonads, and xanthomonads were isolated from these samples on concentrations of 10^5 colony-forming units per milliliter. A mixed culture of these organisms was inoculated into a uranium core specimen in the laboratory to assess the role of microbes in the plugging problem. A one-third decrease in permeability was effected in 16 days. Hydrogen peroxide killed the microorganisms in the core and alleviated the plugging problems. Periodically injecting hydrogen peroxide into the ore body through the production wells may reduce microbial plugging problems.

1984

OP 1–84. The Present State of Dust Control in United States Coal Mines, by John A. Breslin. Conf. on Health in Mines, Luxembourg, May 30–31, 1983. Comm. Eur. Communities Rep. 2359, 1983, pp. 13–17. This paper presents the current status of respirable dust control in coal mines in the United States. Federal regulations, average dust concentrations in the mines, current control problems, and dust control research of the Bureau of Mines are discussed.

OP 2–84. Recovery of Platinum-Group Metals and Gold From Electronic Scrap, by H. E. Hilliard and B. W. Dunning, Jr. Paper in The Platinum Group Metals—An In Depth View of the Industry (1983 Int. Precious Met. Seminar, Williamsburg, VA, Apr. 10–13, 1983). Int. Precious Met. Inst., 1983, pp. 129–142. The Bureau of Mines, in cooperation with the National Association of Recycling Industries (NARI) and the Defense Property Disposal Service, studied recycling problems associated with recovering precious metals from electronic scrap. Specific problems encountered by NARI members included the recovery of platinum-group metals (PGM) from electronic reed switches and telephone relays. The Bureau investigated hydrometallurgical techniques as possible alternatives to pyrometallurgical processes for recovering PGM. In addition, both scrap sources (switches and relays) required some mechanical upgrading to produce fine-particle concentrates ideally suited to hydrometallurgical processing.

OP 3–84. A Low-Cost, Low-Maintenance Treatment System for Acid Mine Drainage Using Sphagnum Moss and Limestone, by Robert L. P. Kleinmann, Thomas O. Tiernan, Joseph G. Solch, and Richard L. Harris. Proc. 1983. Symp. on Surface Mining, Hydrology, Sedimentology and Reclamation, Lexington, KY, Nov. 27-Dec. 2, 1983, pp. 241–245. Acid seeps that continue after reclamation obligate mine operators to long-term water treatment. To provide a low-cost, low-maintenance alternative, the Bureau of Mines investigated the feasibility of establishing a sphagnum moss bog as a self-perpetuating treatment system. The moss removes iron by cation exchange, oxidation of Fe^{2+}, and precipitation of iron hydroxides and sulfides. Acidity is then neutralized with limestone that, because of the iron removal step, does not become armored.

OP 4–84. Analysis of Recent Mine Blasting Accidents, by Dennis V. D'Andrea and Larry R. Fletcher. Paper in Proceedings of the Ninth Conference on Explosives and Blasting Technique (Annu. Meeting, Dallas, TX, Jan. 31-Feb. 4, 1983). Soc. Explos. Eng., v. 9, 1983, pp. 105–122. To determine the most frequent causes of accidents in mine blasting, the Bureau of Mines analyzed blasting accident data obtained from the Mine Safety and Health Administration, U.S. Department of Labor. Accident totals from 1971 through 1981 are tabulated for metal-nonmetal and coal mines both surface and underground. In the past 11 yr (1971–81 inclusive) there has been an annual average of 9 fatal and 121 nonfatal blasting accident victims. Underground mining averaged 6 fatal and 93 nonfatal injuries each year. Abstracts from 369 accidents that occurred from 1978 through 1981 were examined to determine accident causes. Most accidents occurred during scheduled blasting, and failure of the blast area security system was the leading cause. Blast area security problems were failure to clear the blast zone, failure of personnel to follow instructions, inadequate guarding, and failure to retreat to a safe location or take adequate cover. Other common causes include premature blasts, excessive flyrock, fumes, and misfires. The blaster was the miner most frequently injured in these accidents. Examples of typical blasting accidents are presented.

OP 5–84. A Study of Misfires in Mining, by Larry R. Fletcher and Dennis V. D'Andrea. Paper in Proceedings of the Ninth Conference on Explosives and Blasting Technique (Annu. Meeting, Dallas, TX, Jan. 31-Feb. 4, 1983). Soc. Explos. Eng., v. 9, 1983, pp. 123–132. A misfire results when explosives fail to detonate as planned during a mine blast. Accidental detonation of misfires is a frequent cause of personal injury, equipment damage, and lost production. In an effort to minimize these problems, the Bureau of Mines investigated the causes of misfires, methods for detecting misfires, and procedures for

their disposal. During this investigation, input was obtained from explosives suppliers, mining companies, blasting contractors, blasting consultants, and governmental agencies. Additional data were obtained through detailed analyses of blasting accidents involving misfires. The greatest number of misfire accidents are caused by drilling into bootlegs in underground metal and nonmetal mines. Improper disposing of misfires is the second most frequent accident category, and some accidents are due to impact initiation of explosives in the muck. Misfires are usually caused by misunderstanding, improper use, or some failure of the initiation system. Other causes are cutoffs, insufficient firing current, inadequate priming, improper explosive storage, and damage to the initiation system. Visual inspection is still the only available method for detecting misfires. Disposal of misfires in underground mines is generally by refiring; at surface mines, they are usually dug out during the mucking operation. Extreme care must be exercised when digging out misfires.

OP 6–84. Mining, by Barry W. Klein, Phillip N. Yasnowsky, and Annette Graham. Ch. 16 in U.S. Industrial Outlook 1984, Dep. Commerce, 24th ed., Jan. 1984, pp. 16-1—16-6. The mineral industry was expected to have begun its recovery by yearend 1983, and mining production is expected to show a moderate gain in 1984. This predicted increase is a result of the strong economy anticipated for 1984. The industries this chapter covers are mine ores of such metals as copper, iron, gold, silver, and zinc (SIC 10) and nonmetallic minerals such as stone, sand and gravel, clays, phosphate rock, salt, sulfur, and potash, but excluding fuels (SIC 14).

OP 7–84. Electrochemical Flotation of Sulfides: Chalcocite-Ethylxanthate Interactions, by P. E. Richardson, J. V. Stout III, C. L. Proctor, and G. W. Walker. Int. J. Miner. Process., Elsevier Science Publishers B.V., Amsterdam, the Netherlands, v. 12, 1984, pp. 73–93. This paper discusses part of a U.S. Bureau of Mines research effort to use electrochemical techniques to control sulfide flotation with the aim of developing new methods to process low-grade, complex domestic ores. The interactions between chalcocite and ethylxanthate (EtX^-) have been studied in an electrochemical-microflotation cell containing a packed bed of the mineral as a working electrode. Spectrophotometric and electrochemical techniques have shown that in the potential range −0.7 to 0 V (SCE) at a pH of 9.2 there are at least four distinct reactions: (1) a reaction of EtX^- to form ethylperxanthate at reducing potentials near −0.5 V; (2) a reaction of EtX^- with soluble Cu(II) at the open circuit potential (—0.028 V); (3) an exchange reaction whereby EtX^- displaces an oxidation product; and (4) a charge transfer oxidation reaction. The exchange and charge transfer oxidation reactions occur over the same potential range (−0.5 to −0.1 V) and are both believed to produce cuprous xanthate and possibly cupric xanthate as an adsorbed hydrophobic species. Xanthate adsorbed as − 0.1 V can be desorbed as the ethylxanthate ion at more negative potentials. The flotation response of chalcocite is also shown to parallel closely the adsorption of EtX^- by reactions 3 and 4 and the reduction of the adsorbed product during cathodic decreases in potential.

OP 8–84. Rapid Identification and Sorting of Scrap Metals, by W. D. Riley, R. E. Brown, and D. M. Soboroff. Pres. at 4th Recycling World Congr., New Orleans, LA, Apr. 6–9, 1982; pub. in Conserv. Recycling, v. 6, No. 4, 1983, pp. 181–192. The Bureau of Mines, U.S. Department of the Interior, is conducting research on methods for the rapid identification and sorting of mixed metal scrap so that domestic scrap resources can be utilized more fully. Initial studies include a technical assessment of available identification methods and of their current or potential use for various scrap sorting problems. Methods investigated were thermoelectric, spectroscopic, and X-ray measurements. A survey of these techniques is presented, with data showing applications to specific scrap identification systems.

OP 9–84. Measuring In-Seam Coal Cutting Forces, by Wallace W. Roepke and James C. Church. Min. Eng., v. 35, No. 9, Sept. 1983, pp. 1281–1286. The U.S. Bureau of Mines developed a portable in-seam tester for direct in situ measurement of coal cutting forces. Since manufacturers and operators currently have no method available for evaluating the cutting characteristics of a coal seam in situ, the device is expected to provide the additional engineering data needed to optimize the equipment-seam match. It may also help develop the next generation of mining machines.

OP 10–84. Reducing Dust Through Deep Cutting, by Robert L. Schmidt. World Min. Equip., v. 7, No. 12, Dec. 1983, pp. 17–18. This paper briefly reviews the history of research on machine parameters for dust reduction in the United Kingdom and the United States over the past 25 years. The most significant variables were found to be cut depth and bit speed. Recent, full-scale research shows dust reduction over 60 pct on drum miners and longwall shearers through parameter control.

OP 11–84. Electrochemical Flotation of Sulfides: Reactions of Chalcocite in Aqueous Solution, by G. W. Walker, J. V. Stout III, and P. E. Richardson. Pres. at 56th Colloid and Surface Symp., Blacksburg, VA, June 13–16, 1982; pub. in Int. J. Miner. Process., Elsevier Science Publishers B.V., Amsterdam, the Netherlands, v. 12, 1984, pp. 55–72. This paper discusses the first phase of a U.S. Bureau of Mines study to use electrochemical techniques to control sulfide flotation with the aim of developing new methods to recover minerals from progressively lower grade, more complex ores. It has been established that (1) under slow potentiodynamic sweeps or potentiostatic conditions, the current-voltage characteristics of chalcocite bed electrodes are essentially the same as those of single electrodes; (2) reactions in the chalcocite-0.5M borate system can be studied quantitatively using a combination of spectrophotometric and electrochemical techniques; and (3) the reactions can be correlated with the collectorless flotation response. A microflotation-electrochemical cell, utilizing a packed bed of conducting sulfide mineral particles as the working electrode, was used to obtain correlations between the electrochemical reactions occurring on the bed and flotation response. Continuous analysis of the electrolyte by fast-scan ultraviolet spectrometry was used to monitor solution chemistry.

OP 12–84. Research by the Bureau of Mines on Underground Support Systems, by D. D. Bolstad. Paper in CNCRM Symp. on Underground Support Systems, Sudbury, Ontario, Canada, Sept. 19-21, 1983, 12 pp. The U.S. Department of the Interior's Bu-

reau of Mines performs research in mining health and safety and productivity as one of its primary functions. Ground support research in these areas ranges from defining geomechanical phenomena to evaluating prototype support systems. This paper provides a limited review of current programs.

OP 13–84. Aluminum Chloride Leaching of Calcined Kaolin Clay, by P. R. Bremner, L. J. Nicks, and D. J. Bauer. Pres. at Metall. Soc. AIME 113th Annu. Meeting, Los Angeles, CA, Feb. 26-Mar. 1, 1984. TMS Paper Selection A84–47, 1984, 11 pp. As part of a program to devise alternative technologies for producing alumina from domestic resources, the Bureau of Mines investigated the leaching of calcined kaolin clay to form basic aluminum chloride solutions. Bench-scale experiments were conducted for single-stage batch leaching with $AlCl_3$ solution and three-stage countercurrent leaching with substoichiometric HCl. Variable conditions of clay calcination and leaching were studied to determine their effects on aluminum extraction and pregnant liquor composition.

OP 14–84. Mercury. Oversupply Weakens Price, by Linda C. Carrico and James B. Hedrick. Eng. and Min. J., v. 185, No. 3, Mar. 1984, pp. 100–101. World mine production was essentially the same in 1983 as in 1982. U.S. mine production and secondary industrial production satisfied about 78% of total U.S. demand. Spain continued to be the leading supplier of foreign mercury to the United States. Mercury prices declined on a world basis in 1983 in response to an oversupply of material.

OP 15–84. How Gassy Noncoal Mines Can Simulate Methane Flow, by A. B. Cecala, R. H. Grau, and E. D. Thimons. Eng. and Min. J., v. 185, No. 2, Feb. 1984, pp. 51–53. The Bureau of Mines has successfully tested a method to simulate methane gas flows from face areas through the returns of noncoal mines. This technique involves releasing a small quantity of tracer gas at a working area and sampling for that gas downstream in the return airways. By measuring the reduction in the tracer gas concentration, a reduction for any face released volume of methane gas can be calculated. This information is useful in selecting locations for methane monitors and in deciding the necessity for permissible equipment in the returns.

OP 16–84. Recovery of Gold and Silver From Ores by Hydrometallurgical Processing, by J. A. Eisele, A. F. Colombo, and G. E. McClelland. Paper in Precious Metals: Mining, Extraction, and Processing, ed. by V. Kydryk, D. A. Corrigan, and W. W. Liang (Proc. AIME-IPMI Int. Symp. on Precious Metals, Los Angeles, CA, Feb. 27–29, 1984). Metall. Soc. AIME, 1984, pp. 387–395. The Bureau of Mines has played an important role in the revival of precious-metal mining underway in the Western United States. During the past 30 yr, many techniques used by industry to recover gold and silver were pioneered and developed by the Bureau. In 1952, technology was developed to strip gold from granular activated carbon and allow the carbon to be reused. In 1969, the heap-leaching concept was applied to low-grade gold and silver ores and mine wastes. Heap leaching in conjunction with carbon adsorption-desorption permits very low value material to be economically processed. In 1970, an oxidation treatment based on hypochlorite was developed to increase the recovery of gold from carbonaceous gold ores by cyanidation. In the early 1950's, attempts were made to employ carbon-in-pulp technology to recover gold from ores, but the fixed price of gold and increasing operational costs made the process unprofitable. The Bureau and Homestake Mining Co. jointly operated a carbon-in-pulp pilot plant, and the technology was used in full-scale production at the Homestake Mine in 1972. In 1973, a pressure-stripping method, which decreased the time needed for the stripping step, was developed to desorb gold and silver from carbon. An alcohol desorption method, developed in 1976, also decreased the carbon stripping time. These stripping methods are in commercial use. In 1979, an agglomeration pretreatment was developed that permitted clayey precious-metal ores to be heap-leached. Agglomeration-heap-leaching technology is being used by at least 30 operations, several of them major gold and silver mines. Almost all precious-metal-mining companies use at least one of the above techniques in production facilities.

OP 17–84. Perspective on Chromium From the U.S. Bureau of Mines, by Ralph C. Kirby and John F. Papp. Chromium Rev., v. 1, No. 1, Apr. 1983, pp. 6–7. The importance of chromium is demonstrated by its inclusion in the Strategic Materials Stockpile maintained by the Federal Government for the protection of national security. The stockpile contains about a 3-yr supply of chromium-containing materials at current consumption rates and is to be used to fill national security needs in the event of a supply shortage. The Bureau of Mines, among others, is researching ways that might allow the United States to become less dependent upon chromium. The research is aimed at the development of processes that would permit the use of low-grade domestic ore, the recycling of chromium-containing materials, the production of more chromium-efficient materials, and the identification of alternatives to chromium-containing materials.

OP 18–84. Recycling and Metal Recovery Technology for Stainless Steel Pickling Liquors, by J. B. Stephenson, J. C. Hogan, and R. S. Kaplan. Pres. at AIChE Meeting, Denver, CO, Aug. 28–31, 1983; pub. in Environ. Prog., v. 3, No. 1, Feb. 1984, pp. 50–53. Most stainless steels require a final treatment in nitric and/or hydrofluoric acid pickling baths for the removal of oxide scales formed during processing to final gauge and shape. These pickling baths become ineffective as their metal content increases. The baths appear to be particularly sensitive to the concentration of iron. Conventional operating procedures call for the replacement and disposal of the spent acids. The high cost of waste acid disposal and the loss of the valuable nickel and chromium they contain are important considerations. This review covers recovery and recycling processes for spent nitric and hydrofluoric acid pickle liquors generated during the production of stainless steels.

OP 19–84. Applications for Turbomachinery in the Deep Mining Industry, by Robert Torbin and Edward Thimons. Turbomachinery Int., v. 24, No. 9, Nov.–Dec. 1983, pp. 23–26. As mines descend to greater depths in search of minerals, higher temperatures and humidities are encountered associated with the heat released from off the surrounding rock. These conditions make a comfortable working environment difficult and expensive to maintain. To overcome this condition, large quantities of water must be carried down long vertical pipelines to be used for refrigeration and personnel cooling. The cost associated with providing this cooling is rising, and creates financial hardships on the mining opera-

tion, especially in times of unstable mineral prices. To help deal with this problem, the U.S. Bureau of Mines has awarded a contract to Foster-Miller, Inc., of Waltham, MA, to investigate and evaluate commercially available means of energy recovery for the deep mining industry.

OP 20–84. A Multistep Shear Test for Bond Strength of Claddings, by Robert Blickensderfer and J. Michael Burrus. J. Test. and Eval., v. 12, No. 1, Jan. 1984, pp. 3–12. A test for determining the bonding shear strength of a clad metal and the fixture for performing the test are described. The test specimen, which is relatively easy to machine, has approximately nine shear steps ranging in depth from shallower than the cladding to deeper than the cladding. Thus, at least one of the shear lips gives the shear strength very near the interface between the cladding and the base metal. Test results on a variety of bimetals are presented. Results are compared with ASTM Specification for Corrosion-Resisting Chromium Steel Clad Plate, Sheet, and Strip (A 264) criteria. This work was conducted by the Bureau of Mines, U.S. Department of the Interior, as a part of its effort to develop vacuum-rolled claddings to conserve strategic materials.

OP 21–84. Recovery of Cobalt and Nickel From Lead Smelter Matte, by Robert M. Doerr, R. B. Prater, Jr., and E. R. Cole. Pres. at Metall. Soc. AIME 113th Annu. Meeting, Los Angeles, CA, Feb. 26–Mar. 1, 1984. Metall. Soc. AIME paper selection A84–59, 1984, 19 pp. Research to find basic technology for Co and Ni recovery is part of an overall effort by the Bureau of Mines to help reduce import vulnerability by enhancing the Nation's ability to produce critical and strategic minerals from domestic resources. The Missouri lead ores mined annually contain sufficient Co to provide about 25 pct of current national demand, if all of it could be recovered. About 5 pct of that Co reports to the Pb-smelter mattes, along with quantities of As, Ni, Pb, Ag, and Cu. Not only is this a loss of Co, but it makes the matte unsuitable for environmentally acceptable Cu recovery techniques. This paper describes the basis for selective oxidative (MnO_2-H_2SO_4) leaching of the matte, followed by selective recovery of salable or usable products of Cu, Co, Ni, and Mn from the resulting leach liquor.

OP 22–84. Preparation of Tungsten Carbide by Gas Sparging Tungstate Melts, by J. M. Gomes, A. E. Raddatz, and T. G. Carnahan. Pres. at Metall. Soc. AIME 113th Annu. Meeting, Los Angeles, CA, Feb. 26–Mar. 1, 1984. Metall. Soc. AIME paper selection A84–48, 1984, 12 pp. The Bureau of Mines is investigating a novel method for the separation of tungsten carbide from concentrates. The method eliminates several steps in the conventional method. Wolframite or scheelite is decomposed in a two-phase chloride-silicate melt. Tungsten is concentrated in the chloride phase as sodium tungstate, and the iron, manganese, or calcium oxides are retained in the silicate phase. After separating the phases, the molten chloride-tungstate phase is sparged with hydrocarbon gas and yields tungsten monocarbide. The paper discusses bench-scale research that delineates operating variables.

OP 23–84. Continuous Miner Dust Collector Proves Worth at Eastover, by G. J. Hundman, P. Disney, and E. F. Divers. Coal Min. and Process., v. 20, No. 2, Feb. 1983, pp. 46–48. An improved dust collector system, mounted in a continuous miner boom, has improved face ventilation and dust removal from both blowing and exhaust face ventilation air. The scrubber system is designed for low coal seams, compatibility with a 10-ft line curtain, high reliability, and low maintenance. It consists of two (twin) scrubbers, each mounted in the forward inby end of the boom. The twin-scrubber system delivers a total of 5,000 cfm, with one scrubber mounted on each side of the continuous miner's auger support frame. Each scrubber consists of a 2,500-cfm centrifugal fan, direct-driven at 4,000 rpm by a hydraulic motor; a flooded stainless steel wire mesh scrubber panel, 14- by 16- by ¼-in thick; water sprays (two on each scrubber at 2.5 gpm at 150 psig); a water-droplet eliminator; and associated ductwork. Air intakes are located within 6 ft of the coal face and are designed to reduce clogging during the mining cycle. All components except the exhaust duct are fabricated from heavy-gauge steel.

OP 24–84. Control and Distribution of Face Air by Water Sprays on Mining Machines, by F. N. Kissell and T. Muldoon. Proc. Australas. Inst. Min. and Metall.-Illawarra Branch Symp. on Ventilation of Coal Mines, Wollongong, NSW, Australia, May 10–13, 1983, pp. 18–1—18–10. It has been recognized for some time that a water spray in a tube can act to move air through that tube. However, it is a more recent notion that a series of spray nozzles arranged in a logical fashion can be used to modify the airflow pattern on a mining machine to achieve a desired ventilation effect. The first development in this regard, the spray fan, was successful in quickly controlling airflow. This success led to other applications. The intent of this paper is to provide an update on those items that are familiar and to discuss, in some detail, the results that have recently been obtained.

OP 25–84. How U.S. Longwalls are Achieving the 2.0 mg Standard—Past Trends and Future Technology, by Fred Kissell, Robert Nesbit, and Jonathan Kelly. Proc. Symp. on Dust Suppression in Mines, Luxembourg, May 30–31, 1983. Comm. Eur. Communities Doc. No. 2363/83, May 1983, pp. 75–87. In July-August 1982, the average respirable dust "designated occupation" sample from U.S. double-drum shearer longwall faces was 1.7 mg/m^3, and the trend has been more faces coming into compliance with the 2.0-mg/m^3 standard. A key reason for lower measured dust levels in U.S. mines is occupational sampling, and this has also permitted both researchers and mine operators to test and utilize a wider variety of approaches in lowering the dust breathed by mine workers. An important element of the Bureau's research program is to forecast prospective reductions in dust levels due to the various "dust avoidance" techniques permitted by occupational sampling. Reductions in dust have been forecasted for the following specific items, both alone and in reasonable combination: (1) unidirectional cutting, (2) homotropal ventilation, (3) use of one drum only for a portion of the mining cycle, (4) shearer equipped with asymmetrical drums or proportioned waterflow to drums, and (5) shearer remote control by radio or umbilical cord.

OP 26–84. Longwall Lighting, by W. H. Lewis, J. Peay, J. C. Yingling, and George R. Bockosh. J. Mine Vent. Soc. S. Afr., v. 37, No. 1, Jan. 1984, pp. 1–8. The introduction of lighting systems into underground coal mines in the United States has been a controversial issue. Longwall lighting, however, has received widespread management and

miner acceptance with tangible benefits being realized in both safety and production. Based on the experience that longwall operators have had with their lighting systems, the following general conclusions seem appropriate: (1) A wide selection of lighting equipment and suppliers exists. (2) Intrinsically safe fluorescent systems are more widely used. (3) The majority of operators reported that maintenance requirements are low or moderate with only a few experiencing major maintenance problems. (4) The biggest maintenance problem has been damage to the system power cables. This paper describes the present state of the art and status of longwall lighting in the United States. Specific subtopics discussed are as follows: review of MSHA lighting regulations and requirements for longwalls, overview of available lighting hardware, installation procedures and costs, and analysis of installations to date.

OP 27–84. Corrosion Properties of Amorphous Iron-Zirconium Films in 1*N* Sulfuric Acid, by L. D. McCormick, N. S. Wheeler, C. R. Molock, and C. L. Chien. J. Electrochem. Soc., v. 131, No. 3, Mar. 1984, pp. 530–534. Amorphous iron-zirconium alloys, ranging in composition from $Fe_{90}Zr_{10}$ to $Fe_{33}Zr_{67}$, have been studied by anodic polarization and passivation decay in 1*N* sulfuric acid. The results showed a compositional enhancement of corrosion resistance with increasing zirconium concentration. Auger electron spectroscopy indicated that exposure to the sulfuric acid solution enhances the surface zirconium concentration with respect to the bulk of the exposed alloy and also with respect to the as-deposited surface composition. X-ray photoemission spectroscopy shows that the passive film is a mixture of zirconium oxides and hydroxides and iron oxides and hydroxides.

OP 28–84. Continuous Ferric Chloride Leaching of Galena, by J. E. Murphy, B. R. Eichbaum, and J. A. Eisele. Pres. at Soc. Min. Eng.-AIME Annu. Meeting, Los Angeles, CA, Feb. 26–Mar. 1, 1984. Soc. Min. Eng. AIME preprint 84–124, 1984, 5 pp. The Bureau of Mines demonstrated ferric chloride leaching of galena concentrate on a continuous bench-scale basis. Leaching was performed at 95° C and with a contact time of 15 min. The ferric chloride leaching solution was continuously fed to a leaching tank at a constant rate for periods up to 45 h. In each test a constant redox potential was maintained in the slurry exiting the leaching tank by controlling the concentrate feed rate. In the 45-h test, lead extraction exceeded 99.5 pct, and the lead chloride produced was 99.97 pct pure.

OP 29–84. Ten Ways To Reduce Longwall Dust, by George E. Niewiadomski, Robert A. Jankowski, and Fred N. Kissell. Min. Cong. J., v. 8, No. 8, Aug. 1982, pp. 10–14. The need to improve productivity and to meet the growing demand for coal has prompted the coal industry to shift to greater utilization of longwall mining. Although longwall mining offers many advantages, there is a severe problem in the control of respirable dust and in the ability to comply with the 2-mg/m^3 Federal dust standard. The Bureau of Mines has been aggressively seeking solutions to the problem for several years and has successfully demonstrated cost-effective engineering controls that are available for immediate application. In cooperation with MSHA and the mining industry, the Bureau continues to assist the industry in implementing currently available techniques to reduce the dust exposure of all longwall face workers. Although substantial progress has been achieved, because of the complex and interactive factors involved, not all of these improved techniques are applicable on every longwall installation. Physical characteristics on each panel directly impact the dust control requirements to be implemented. In addition, many new procedures have been developed but not evaluated under the diverse conditions encountered throughout the industry. In response, the Bureau has undertaken a major joint effort with industry to identify and document technology that may eliminate the longwall dust problem. This will be accomplished through the most extensive systematic in-mine evaluation of the effectiveness of available and promising longwall dust control techniques ever attempted.

OP 30–84. Tafel Constants and Changes in Hydrogen Coverage During Corrosion of Fe18Cr, by Murray Rosen and Jonathan G. Harris. J. Electrochem. Soc., v. 130, No. 12, Dec. 1983, pp. 2329–2334. Cathodic tafel constants associated with the hydrogen reaction at Fe18Cr in H_2-saturated 1*N*H_2SO_4 were determined by computer analysis of the potential decay following current interruption at fixed starting potentials positive to the corrosion potential. The values of $b = -2.3\ RT/\alpha F$ were evaluated from the general current-interruptive equation, $E = E_i + b \log [1 + t/\tau]$, from its linear log form, and from a modification of the general equation that was derived to analyze multiple tafel regions. For starting potentials of 0, —0.05, —0.075, and —0.2V (RHE), the number of tafel regions was 3, 3, 2, and 1, respectively. The amount of hydrogen associated with the electrode at the fixed potentials and during decay was determined from anodic charging pulses. Results indicated that the bonding strength between metal sites and hydrogen varies with decay and starting potential. The first tafel region from 0, —0.05, and —0.075V was under combination control, $2H \rightarrow H_2$. The decay from —0.2V was controlled by the electrochemical-desorption step, $H^+ + e + H \rightarrow H_2$.

OP 31–84. Face Ventilation Analysis by Probability Plotting of Transformed Methane Concentration Data, by W. E. Schroeder and Fred N. Kissell. J. Mine Vent. Soc. S. Afr., v. 36, No. 11, Nov. 1983, pp. 109–117, and No. 12, Dec. 1983, pp. 126–130. Analysis of environmental data is never straightforward, and methane emission data from underground coal mines are no exception. In the United States, considerable effort has been expended by the U.S. Department of the Interior, Bureau of Mines, to develop ventilation devices that dilute methane at coal mine working faces. Careful analysis is required to measure the effectiveness of those devices. The most prevalent underground coal mining method in the United States is by continuous mining machine. Research showed that methane emissions during operation of this machine occur as a series of peaks and that concentration peak values will fit a normal or log-normal distribution. It appeared that normal distributions were obtained when the emitted methane was vigorously mixed into the incoming fresh air stream and log-normal distributions were obtained when mixing was less vigorous. The purpose of this paper is to explore that finding in greater detail, as well as to assess the benefits gained by transforming concentration data; that is, correcting measured raw values for the effects of variables that could not be controlled during testing.

OP 32–84. Parachute-Type Stoppings—USBM Develops Different Designs for Day-to-Day and Emergency Ventilation Control, by Edward D. Thimons and Fred N. Kissell. Eng. and Min. J., Feb. 1979, pp. 91–94. A parachute-type stopping intended for changing the course of mine ventilation air during mine emergencies has been designed and tested. Some production uses are also visualized for metal mines. Preliminary tests in the laboratory and underground indicate that the parachute stopping is a workable concept, but further developmental research is required.

OP 33–84. USBM Develops Damage-Resistant Brattice, by Edward D. Thimons and Fred N. Kissell. Eng. and Min. J., Sept. 1978, pp. 204–208. The Bureau of Mines has developed a damage-resistant brattice, intended for use as a stopping in locations where blast damage to stoppings is a problem, the roof is relatively flat, and the differential pressure across the stopping is not high. Damage-resistant brattices consist of a series of vertically hung brattice panels joined to each other by Velcro connections that improve the airtightness of the brattice. When the brattice is subjected to strong blast forces, the Velcro connections peel apart, allowing the panels to open without incurring damage. The Velcro connections can then be resealed in a matter of minutes. A preliminary test in the Bureau's Safety Research Mine and subsequent long-term testing at the White Pine copper mine in Michigan and the Retsof salt mine in New York show that damage-resistant brattices withstand blasting better than conventional stoppings, while still performing as efficient air barriers when the Velcro connections are sealed.

OP 34–84. Using Sulphur Hexafluoride Tracer Gas for Mine Ventilation Analysis, by E. D. Thimons and F. N. Kissell. Paper in Proc. Int. Mine Ventilation Cong., Johannesburg, Republic of South Africa, Sept. 15–19, 1975. J. Mine Vent. Soc. S. Afr., Marshalltown, Repub. S. Afr., 1975, pp. 97–102. Mine ventilation systems are generally very complex, and many aspects of a mine ventilation network can be studied by conventional anemometer and smoke-cloud techniques. However, problems such as recirculation of return into intake air, leakage from adjacent mines, lost intake air, and unknown transit flow times through stoped areas call for new ways of analyzing airflow underground. Use of sulfur hexafluoride as a tracer gas can be an effective means of analyzing these ventilation problems. The Bureau of Mines is concerned with finding solutions to these problems in conjunction with its ventilation programs. Studies have been conducted by the Bureau in several mines in order to show the value of the sulfur hexafluoride tracer gas.

OP 35–84. Current Status of R&D on Alumina From Domestic Nonbauxitic Resources, by James A. Barclay. Ch. 9 in Proceedings of the 1984 Bauxite Symposium (Los Angeles, CA, Feb. 26-Mar. 1, 1984, ed. by L. Jacob, Jr.) Soc. Min. Eng. AIME, New York, Mar. 1984, pp. 165-199. Results of investigations over approximately 10 yr by the Bureau of Mines and others on technology for recovering cell-grade alumina from domestic nonbauxitic resources such as clay, anorthosite, alunite, dawsonitic oil shale, coal ash, and coal shale are reviewed. It is concluded that, although many innovative techniques have evolved from this effort and have been shown to be technically feasible, energy and economic considerations will prevent any of the processes from competing with the Bayer process under normal conditions. Based on the Bureau's experience, some variation of clay-HCl leaching, HCl gas sparging crystallization has the greatest potential as an alternative to the Bayer-bauxite process.

OP 36–84. Mid-Continent Has Early Success With the Longest Longwall Face Ever Operated in the US, by Bradley J. Bourquin and Jasinder S. Jaspal. Min. Eng., Jan. 1984, pp. 48–52. Operation of the first longwall panel to be mined under a cooperative agreement between the U.S. Bureau of Mines and Mid-Continent Resources at the Dutch Creek No. 1 Mine is underway. The 800-ft-wide longwall face, which is part of a multilift longwall demonstration, is extracting a 10-ft-high top lift from a 28-ft-thick coal horizon in an area of the property where the Coal Basin A and Coal Basin B beds have come together to form one seam. This face, the longest ever operated in the United States, is being worked on an advancing longwall system. From the first month of operation the performance of the longwall face has yielded high productivity and safety, which should be of interest to coal producers in the United States.

OP 37–84. Electromagnetic Detection of Trapped Miners, by J. Durkin. IEEE Commun. Mag., v. 22, No. 2, Feb. 1984, pp. 37–46. The Bureau of Mines conducted field studies in coal mines throughout the United States to determine the effectiveness of electromagnetic techniques in locating miners trapped underground following a mine accident. Data from these tests were used to generate models of expected signal and noise distributions as found above these mines. These distributions have aided in placing the expected performance of a through-the-earth electromagnetic communications technique into a probabilistic framework. Results show that at a 10% false-alarm rate, the expected probability of detecting a miner's signal from a depth of 1,000 ft is 54%; at 500 ft it is 95%. These depths exceed the actual depths of 90% and 50%, respectively, of U.S. coal mines. Sensitivity studies showed that at a depth of 1,000 ft, the probability of detection will improve approximately 2% for each decibel of increase in signal-to-noise ratio.

OP 38–84. Hydrolysis of Inorganic Iron(III) Salts, by Charles M. Flynn, Jr. Chem. Rev., v. 84, No. 1, 1984, pp. 31–41. The scope of this review includes studies on the hydrolysis and precipitation of Fe(III) from aqueous solutions of its inorganic salts, chiefly the nitrate, perchlorate, chloride, and sulfate. After a survey of structural and thermodynamic properties of the relevant Fe(III) species, this review examines the reactions of hydrolysis and precipitation in aqueous Fe(III) solutions. These reactions, most of which occur slowly, include the formation, aging, and agglomeration of a red cationic hydrolytic polymer. The constitution of the slowly precipitated hydrous oxide products is also examined. For comparison, the constitution and aging of rapidly precipitated hydrous iron(III) oxides is briefly surveyed. Techniques employed in the study of Fe(III) hydrolysis and precipitation include pH measurement, visible and infrared spectroscopy, ultracentrifugation, electron microscopy, and X-ray diffraction. Electrokinetic properties and thermal dehydration of precipitated iron oxides are not considered. Iron(III) oxides, hydrous oxides, or related compounds formed via oxidation of elemental iron or iron(II) compounds, or via other redox reactions, are not considered.

OP 39–84. Recovery and Recycling of Chromium-Bearing Solutions, by L. C. George, N. L. Rogers, and Glenn L. Horter. Paper in Proc. of the 29th Natl. Soc. for the Advancement of Mater. and Process Eng. (SAMPE) Symp. (Reno, NV, Apr. 3–5, 1984). V. 29, Apr. 1984, pp. 853–858. Bell Helicopter Textron, Inc., under a cooperative agreement with the Bureau of Mines, evaluated technology for the regeneration of waste chromic acid devised by the Bureau. Laboratory and pilot studies were performed to determine the applicability of electrolytic membrane cell technology to Bell's process stream for the surface preparation of aluminum alloy components. The study revealed that the technology reduced chemical cost by regenerating chromic acid for reuse, reduced waste treatment costs, and reduced hazardous waste disposal costs. Bell has installed a regeneration unit based on the Bureau-developed technology in its Hurst, TX, plant.

OP 40–84. America's Dependence on Strategic Minerals, by V. Anthony Cammarota, Jr. Pres. at Conf. on Strategic Minerals and International Economic Assistance, Wilmington, DE, Dec. 8–10, 1982. Ch. 22 in American Strategic Minerals, Crane, Russak & Co., Inc., New York, 1984, pp. 29–57. This paper illustrates the degree of U.S. dependence on domestically produced and imported strategic materials, the source of imports on a geographical basis, and the trends that may be foreseen for the remainder of this decade in terms of the future supply of these materials. Strategic materials were defined and 20 were selected for an examination of recent trends in import dependence and the outlook for a reversal in the trend. For the minerals and metals for which the United States is over 75 pct dependent, the major source countries are oftentimes the Republic of South Africa, the U.S.S.R., and the developing countries of Africa, Asia, and South America. Based on reserves and resource estimates, it appears that these countries will continue to be major suppliers of strategic materials for the foreseeable future.

OP 41–84. Separation and Recovery of Cobalt From Copper Leach Solutions, by T. H. Jeffers. Pres. at Metall. Soc. AIME 113th Annu. Meeting, Los Angeles, CA, Feb. 26–Mar. 2, 1984. Metall. Soc. AIME paper selection A84–21, 1984, 8 pp. The Bureau of Mines developed a procedure using a chelating ion-exchange resin to successfully extract cobalt from a pH copper-processing solution containing only 30 mg/L cobalt. Cyclic tests with the commercial resin XFS-4195 in 4-ft-high by 1-in-diam columns gave an average cobalt extraction of 95 pct when 65 bed volumes of solution were processed at a flow rate of 4 gpm/ft^2. Elution of the cobalt using a 50-g/L sulfuric acid solution yielded an eluate containing 0.5 g/L cobalt. Nickel, copper, iron, zinc, and aluminum were coextracted with the cobalt and also appeared in the eluate. Selective elution of the loaded resin and solvent extraction procedures using di-2-ethylhexyl phosphoric acid and Cyanex 272 removed the impurities and produced a cobalt sulfate solution containing 25 g/L cobalt.

OP 42–84. Gaseous Corrosion of Metals in a 60% H_2O, 40% HCl Environment, by J. P. Carter, B. S. Covino, Jr., T. J. Driscoll, W. D. Riley, and M. Rosen. Corrosion, v. 40, No. 5, May 1984, pp. 205–214. Laboratory tests were conducted on iron, nickel, titanium, and cobalt base alloys and zirconium 702, primarily at temperatures of 95° to 400° C for exposure periods of 15 days in a 60 vol % H_2O, 40 vol % HCl gaseous mixture. The alloys were also exposed for a period of 66 days. Field tests were conducted in a rotary calciner and a fluidized bed decomposer using the more corrosion-resistant alloys from the laboratory tests. For the laboratory tests, titanium and cobalt base alloys showed the lowest corrosion rates at 140° to 380° C, and the Ti-0.2Pd alloy exhibited the lowest corrosion rates at 95° to 140° C. The conditions for field tests were found to be less severe than for the laboratory tests, resulting in lower corrosion rates. Element profiles obtained with auger electron spectroscopy indicated that the most prevalent corrosion-resistance process for most nickel base alloys was gaseous oxidation involving O_2. The major process opposing this was HCl attack, which resulted in thinning of the oxide portion of the film and the formation of nickel chloride. Titanium buildup at the film-metal interface of Rene 41 samples helped give Rene 41 an extremely low rate of corrosion.

OP 43–84. Magnesium Oxide for Improved Heavy Metals Removal, by J. E. Schiller and S. E. Khalafalla. Min. Eng., Feb. 1984, pp. 171–173. To improve technology for treating process water, U.S. Bureau of Mines research has shown that magnesium oxide (MgO) has many advantages over lime or caustic soda for precipitating heavy metals. Sludge produced by MgO occupies only 0.2 to 0.3 times as much volume as the precipitate made using a soluble base. While a settled, lime-formed precipitate is easily resuspended, the MgO-metal hydroxide sludge becomes cemented together on standing. Settling of the metal hydroxides from a dilute suspension is more complete than precipitates formed with other bases. Virtually any metal that can be precipitated by raising the pH can be treated using MgO. A threefold to fourfold stoichiometric excess of solid reagent is added. The mixture is reacted for 5 to 10 min. Polymer is added, and settling or filtration completes the process. Because of the greater cost of MgO compared with lime, large-scale practice of this technology will probably be limited to water containing 50 mg/L or less of dissolved metals. For such dilute solutions, chemicals are not a large fraction of total treatment costs, so more desirable sludge properties might justify higher chemical expenses. While the MgO process is technically suitable for widespread application, the extent to which it is adopted will probably be determined by a trade-off between the greater cost of MgO compared with lime and the superior properties of the precipitates and their corresponding ultimate disposal costs.

OP 44–84. An Approach to Air Quality Control for Diesel Mucking in Underground Mines, by George H. Schnakenberg, Jr. Pres. at Annu. Am. Conf. Ind. Hyg., Philadelphia, PA, May 22–27, 1983. Am. Ind. Hyg. Assoc., v. 8, 1984, pp. 107–117. The Bureau of Mines, in its pursuit of methods to improve the quality of the underground workplace, has funded studies on the behavior of diesel exhaust components in deadened drifts. Real-time and time-integrated measurements of CO_2, CO, NO, and NO_2 and gravimetric measurements of particulates analyzed for hydrogen, carbon, and the nitrogen fraction were performed in several mines and under controlled conditions in a test drift. The relationship among the contaminants was examined in light of the fact that the CO_2 concentrations found are only the result of the amount of fuel burned and the exhaust dilution of background CO_2 is subtracted out. Although the engine operates over several modes for

a given production activity, the ratio of each of the other exhaust-contaminant concentrations to the CO_2 concentration was found to be relatively constant for a given engine in a given activity. The fact that the relationship is constant can be exploited in that CO_2 levels alone can be used to give a measure of the level of diesel exhaust air quality. Furthermore, time-weighted averages of the other contaminants (CO, NO, NO_2, particulate) and CO_2, or direct tailpipe measurements with the engine suitably loaded, can be made and the ratios compared with previous data. Changes in the ratio indicate changes in engine and/or exhaust control systems, and maintenance may be indicated; changes in the ambient CO_2 level reflect changes in ventilation. The measurement technology and a graphical approach for this method are presented as well.

OP 45–84. Application of Cross-Measure Borehole Technology to Retreat Longwalls in the United States, by J. Cervik, F. E. McCall, and A. A. Campoli. Paper in Proc. 20th Int. Conf. on Safety in Mines Research Institutes, Sheffield, United Kingdom, Oct. 3–7, 1983, 13 pp. Prior to 1970, ventilation was the primary method of controlling methane in gobs. Mining regulations require that the methane concentration in the entries adjacent to the gob be 2 vol pct or less. As mining depth increased, gassier coalbeds and surrounding strata were encountered, and acceptable methane levels in the entries adjacent to the gob could not be maintained by ventilation alone. Consequently, surface gob boreholes were introduced as an auxiliary gob gas control method. Surface gob boreholes cannot always be drilled because mining may be under populated areas, topography may be too severe, or access to private property may be denied. The cross-measure borehole technique, which is used in the United Kingdom and Europe, appears to be an alternative method of controlling gob gas. This paper describes joint efforts by the Bureau of Mines and the mining industry to adapt cross-measure borehole technology to multiple-entry retreat longwall mining in the United States.

OP 46–84. Chlorate Oxidation—An Alternative Anode Reaction in Electrowinning, by G. R. Smith and W. R. Thompson. Paper in Anodes for Electrowinning, ed. by D. J. Robinson and S. E. James (Metall. Soc. AIME Annu. Meeting, Los Angeles, CA, Feb. 26–Mar. 2, 1984). Metall Soc. AIME reprint, 1984, 12 pp. Electrolysis studies by the Bureau of Mines have demonstrated that zinc or copper electrowinning can be combined with the electrochemical production of sodium perchlorate to achieve a significant decrease in the use of electrolysis energy. Current efficiencies exceeding 90 pct were obtained for each half-cell reaction, using current densities and temperatures in the ranges typically employed for the respective electrowinning and electrochemical reactions. The cationic permselective membrane separating the two half-cells exhibited a high efficiency, allowing less than 4 pct of the anolyte and catholyte to interdiffuse during electrolysis.

OP 47–84. Mercury Removal From Gold Cyanide Leach Solution, by W. L. Staker, W. W. Simpson, and R. G. Sandberg. Miner. and Metall. Process., May 1984, pp. 56–61. The Bureau of Mines investigated selective extraction of Au and Ag from a low-grade Au ore containing Hg. Gold and silver were extracted from the ore in cyanide slurries, and Hg extraction was suppressed with sodium or calcium sulfide. Maximum Au extraction and minimum Hg extraction were obtained using solutions containing 0.34 lb NaCN/ton of solution. Increasing the cyanide concentration increased Hg extraction without increasing Au extraction. Mercury extraction from the ore was suppressed with 0.5 to 2.9 lb CaS/lb Hg in the ore. Gold-to-mercury ratios of 100:1 to 400:1 were obtained in the leach solution and on the activated carbon in a carbon-in-pulp circuit.

OP 48–84. Bureau of Mines Respirable Dust Measurement and Monitoring Program, by K. L. Williams and G. H. Schnakenberg, Jr. Ch. 9 in Aerosols in the Mining and Industrial Work Environment. Ann Arbor Sci., Ann Arbor, MI, v. 1, 1984, pp. 99–107. This chapter reviews current projects and discusses the future direction of the Bureau of Mines respirable dust measurement and monitoring program. Projects presently underway include the development of a mining machine-mounted respirable dust monitor based on light scattering; the development of direct-indicating personal dust exposure monitors, one using light scattering and the other using a tapered element oscillating microbalance technique; a feasibility study of a light reflectance technique for measuring the mass of dust deposited on a filter; an in-house evaluation of various existing dust monitors; and two projects related to the determination of the quartz content of dust samples. The technical aspects of the various developments are not discussed in detail; rather, the philosophy and rationale behind the development or investigation are explained. Also, the chapter points out the need for and nature of a planned respirable coal mine dust monitoring strategy study.

OP 49–84. Evaluation of Surface Deformation Characteristics Over Longwall Panels in the Northern Appalachian Coalfield, by Vladimir Adamek and Paul W. Jeran. Paper in Proc. Soc. Min. Eng. AIME 1st Int. Conf. on State-of-the-Art of Ground Control in Longwall Mining and Mining Subsidence, Honolulu, HI, Sept. 5–9, 1982, pp. 183–198. Characteristics of surface deformations—i.e., subsidence, inclination, curvature, and horizontal strains—are evaluated, based on information obtained by direct field measurements over three longwall panels in the northern Appalachian coalfield. Surface deformations were precomputed using Bals' and Knothe's theories. The results were compared with Bureau of Mines field data to evaluate the applicability of the two theories to U.S. mining conditions. Measured horizontal movements and the resulting horizontal strains differ as much as 300 pct from precomputed values. Topography has no detectable effect on vertical movements but appears to have substantial effect on the development of horizontal strains. The horizontal deformations computed from field measurements generally exceed the limits used in other countries to protect surface structures.

OP 50–84. Evaluation of Existing Predictive Methods for Mine Subsidence in the U.S., by Vladimir Adamek and Paul W. Jeran. Paper in Workshop on Surface Subsidence Due to Underground Mining (sponsored by West Virginia University, Morgantown, WV, Nov. 30–Dec. 2, 1981). West Virginia University, Morgantown, WV, Mar. 1982, pp. 88–98. Two existing predictive methods were chosen for evaluation; an influence function (Bals' theory) and a profile function (hyperbolic). These were applied to several field-measured subsidence profiles over U.S. coal mines. The effect of homogeneous

versus nonhomogeneous overburden on surface subsidence is demonstrated and the utilization of Bals' theory as a subsidence predictive method for both types of overburden is examined. The major factor affecting subsidence profile characteristics is the migration of the inflection point toward the centerline of the longwall panel. A computer program was written to aid in the analysis.

OP 51–84. An Investigation Into the Effects of a Retreating Longwall on a Three-Entry Gateroad System, by Richard A. Allwes, Jeffrey M. Listak, and Gregory J. Chekan. Paper in Proc. Soc. Min. Eng. AIME 112th Annu. Meeting, Atlanta, GA, Mar. 6–10, 1983, pp. 95–112. This paper presents the final results of an in-mine study conducted by the Bureau of Mines on a three-entry gateroad system utilizing the stiff-yield pillar design concept. The analyses of roof-to-floor convergence and roof-bolt loading of headgate systems and tailgate chain pillar stresses are presented in detail as the longwall panels were mined. Stress distribution within pillars, relative stress changes between yield and abutment pillars, and the histories of pillar stress, roof-to-floor convergence, and roof-bolt loading as a function of longwall movement are discussed.

OP 52–84. In-Mine Assessment of a Longwall Entry System, by D. R. Babich, R. A. Allwes, and L. V. Wade. Paper in Proc. Soc. Min. Eng. AIME 1st Int. Conf. on State-of-the-Art of Ground Control in Longwall Mining and Mining Subsidence, Honolulu, HI, Sept. 5–9, 1982, pp. 97–105. The design of a longwall entry system is discussed in this Bureau of Mines paper. This is done primarily through the results of an in-mine case study made of two sets of longwall entries utilizing the stiff-yield pillar design concept. The rock mechanics instrumentation plan used in the case study is shown, including a description of the instrumentation layout and the types of instruments used. The analysis of the stress changes in the abutment and yield pillars is presented in detail as the longwall panels were mined. Conclusions concerning when the pillar first started to experience significant stress, pillar stress history as the longwall face approached and moved past the pillars, stress distribution within the pillars, and relative stress changes between yield and abutment pillars are discussed. The paper concludes with a discussion of the redistribution of stress in the vicinity of the longwall panel.

OP 53–84. The Minerals Availability Program of the U.S. Bureau of Mines—Purpose, Progress and Methodology, by Harold J. Bennett and Robert L. Davidoff. Pres. at Soc. Min. Eng. AIME 113th Annu. Meeting, Los Angeles, CA, Feb. 26–Mar. 2, 1984, Soc. Min. Eng. AIME preprint 84–112, 11 pp. The Minerals Availability Program is a Bureau of Mines program to systematically measure and classify identified worldwide nonfuel mineral resources according to their respective extraction technology, economics, and commercial availability. The program is designed to identify, collect, compile, and evaluate information on worldwide active mines as well as on developed and explored mineral deposits, and on mineral processing plants. Objectives are to classify domestic and foreign resources, to identify by cost evaluations resources that are reserves, and to prepare analyses of the availability of these resources for 34 commodities and secondary minerals. Availability analyses consider such factors as geographic location, the type of producible material, the technology and time required to produce a marketable product, and the productive capacity and unit cost for each deposit. These factors, reflected in the aggregated tabular and graphical data in the study for each commodity, are developed for consideration in the formulation of both domestic and foreign mineral policy. To date, the data have been collected for the 34 commodities; expected first cycle completion date for all 34 is early 1986. Raw and aggregated data are available to the public in the form of computer-generated listings, tapes, and maps as well as in published reports. Also, systems developed to assist in performing the engineering and economic analyses are available.

OP 54–84. Tungsten—Can the Market Economy Countries Hold Their Own? by Donald I. Bleiwas, Ronald J. Hurdlebrink, and Terry F. Anstett. Pres. at Soc. Min. Eng. AIME 113th Annu. Meeting, Los Angeles, CA, Feb 26–Mar. 2, 1984, Soc. Min. Eng. AIME preprint 84–111, 15 pp. The U.S. Bureau of Mines evaluated the potential availability of tungsten from 57 tungsten mines and deposits in 19 market economy countries. The 38 properties that were producing at the time the study was performed contained approximately 375,000 tons of WO_3 (tungsten trioxide). The total estimated recoverable resource from all properties studied, both producers and nonproducers, was 1.2 million tons of WO_3 (demonstrated level). Approximately 143,000 tons of WO_3 is recoverable from producing properties with costs at or below January 1983 market price. The study indicates that by 1990 production from currently operating mines in market economy countries will decrease as their demonstrated resources become exhausted. Some of this potential decline may be offset by lower than anticipated levels of market demand, discoveries of additional resources at producing mines, development of other known deposits, and/or discoveries of new deposits. Development of new tungsten resources will likely result in costs higher than exist at currently producing properties. China has been steadily increasing production and export of tungsten in various forms and currently supplies about 25 pct of U.S. imports. China's tungsten mines are large, high-grade operations capable of producing at relatively low cost. These factors, coupled with China's apparent need for foreign exchange, could lead to further expansions of production and exports from China, with a consequent increased dependence by market economy countries on China for tungsten requirements and a threat to the survival of the market economy countries' tungsten industries.

OP 55–84. U.S. Bureau of Mines Rock Bolting Research, by D. D. Bolstad, J. R. M. Hill, and J. M. Karhnak. Paper in Rock Bolting, Theory and Application in Mining and Underground Construction, ed. by O. Stephansson (Proc. Int. Symp. on Rock Bolting, Abisko, Sweden, Aug. 28–Sept. 2, 1983). A. A. Balkema Publ., Rotterdam, Netherlands, 1983, pp. 313–320. U.S. Bureau of Mines research is developing technology that can lead to reduced accidents from roof falls in underground mining operations. Research efforts have focused on the development of systems to install rock reinforcements remotely, and on studies to define the interaction mechanics between rock mass and support systems. Remote manual roof bolters, a fiberglass epoxy-resin pumpable roof-bolting system, and automated bolter modules, all of which utilize flexible shaft drills and bolt benders-inserters, are

being developed. These systems provide remote longer-than-seam-height drilling and bolting capabilities. Systems are also being developed to grout rock bolts remotely in mine roof through application of a slurry injection system using low-cost, fast-setting gypsum cement. A device to evaluate the bond quality of full-column grouted bolts nondestructively is also under development. A full-scale geotechnical model of a coal mine entry, in correlation with finite-element analysis, is being used by the Bureau for research in the area of roof-bolt support interaction mechanics.

OP 56–84. Induction Time Studies of Fe18Cr and 430 SS Under Open Circuit Conditions in Chloride-Containing Sulfuric Acid, by B. S. Covino, Jr., and M. Rosen. Corrosion, v. 40, No. 4, Apr. 1984, pp. 140–146. In order to promote the effective and efficient application of corrosion-resistant metals and alloys in mineral-processing environments, the Bureau of Mines has characterized the effect of aggressive ions on the corrosion and passive behavior of two stainless steels, Fe18Cr and AISI 430 SS. Samples prepassivated in oxygen saturated 1*N* H_2SO_4 at 0.6 V normal hydrogen electrode and then released to open circuit and aged for times ranging from 10 to 80,000 min (55 days) were subsequently exposed to chloride ion concentrations ranging from 5 to 44 parts per thousand. Susceptibility to chloride ion attack was determined as a function of time in solution, chloride ion concentration, and open circuit potentials at the time chloride was added by measuring the amount of time required for a sample to begin corroding after adding the chloride ion.

OP 57–84. Effect of Atmospheric Moisture on the Deterioration of Coal Mine Roof Shales, by R. A. Cummings, M. M. Singh, and N. N. Moebs. Min. Eng., v. 35, No. 3, Mar. 1983, pp. 243–245. Disintegration of the immediate shale roof in coal mines interferes with ventilation, production, and safety. The effect is seasonal and correlates with high levels of moisture in the intake ventilation air. Disintegration, although not completely understood, is caused by shale dilation and weakening upon exposure to atmospheric moisture. Fluctuating moisture conditions are particularly deleterious, but may be at least partially controlled by tempering the air before it is brought to the working place. This paper discusses a 2-year program that was conducted on behalf of the Bureau of Mines to study the deterioration problem in mines.

OP 58–84. A Computer-Implemented Data Base for Coalbed Methane Resource Characterization and Research, by William Patrick Diamond, David Michael Hyman, and John Charles LaScola. J. Petrol. Technol., v. 36, No. 5, May 1984, pp. 846–848. The Bureau of Mines has obtained gas content data on more than 1,500 coal samples from approximately 250 coalbeds in 17 States. A computer-implemented coalbed methane data base was established to respond more efficiently to health, safety, and mine-planning related data requests from the coal industry and to the resource characterization needs of those interested in using coalbed methane. The system also will be used for coalbed methane research, including multivariate statistical analysis of the physical, chemical, and geologic province factors influencing the methane generation and storage capacity of coal, with the ultimate goal of developing an indirect method of estimating the gas content of coalbeds.

OP 59–84. The Impact of Diminishing Rutile Resources on Titanium Production and Costs, by Richard J. Fantel, David A. Buckingham, and Daniel E. Sullivan. Pres. at Soc. Min. Eng. AIME 113th Annu. Meeting, Los Angeles, CA, Feb. 26–Mar. 2, 1984, Soc. Min. Eng. AIME preprint 84–109, 11 pp. This paper addresses the impact of declining world rutile resources upon the production of titanium products and their associated costs. Titanium is used primarily for the production of pigments; in its metal form it is considered a strategic and critical material to the U.S. defense and aerospace industries. There are two major mineral sources for titanium: ilmenite and rutile. Both these mineral types can be used to produce titanium pigments. Only high-grade titanium concentrates, such as rutile, high-grade ilmenite, and synthetic rutile (which is produced through further processing of ilmenite), can be used in the production of titanium metal. This paper draws upon the data and analyses of a recent Bureau of Mines Minerals Availability Program appraisal that evaluated the international availability of titanium from market economy countries. The paper will show that production from economic rutile mines will decline sometime after the turn of the century and that rutile shortages could be alleviated by production from other high-grade titanium resources such as higher cost rutile deposits and anatase deposits, or through an increase in world synthetic rutile capacity.

OP 60–84. Quartz Crystal, by J. E. Ferrell. Min. Eng., v. 36, No. 5, May 1984, pp. 528–529. The industrial quartz crystal industry rebounded sharply during the second half of 1983. Estimated domestic mine production of lasca, the mineral feedstock material used for growing cultured quartz crystal, increased fourfold during the year. The recovery in the cultured quartz industry was due to a turnaround in the automotive industry, which uses quartz crystal in its microprocessors, and increased quartz sales for microprocessors in computer hardware, videocassette recorders, and cordless telephones. In 1983, cultured quartz crystal was produced by seven companies in five States. About 32 companies in 11 States consumed quartz crystal to produce crystal units for various electronic and optical products.

OP 61–84. Strontium, by J. E. Ferrell. Min. Eng., v. 36, No. 5, May 1984, p. 531. The U.S. strontium industry experienced a major shakeup during 1983 when the leading domestic producer of strontium chemicals announced plans to close its plants. Changes also occurred in the world marketplace as Japan surpassed the United States as the leading consumer of strontium compounds. Neither the United States or Japan mine celestite, the commercial strontium mineral form. Mexico supplies most of the U.S. celestite demand, while Spain satisfies most of the Japanese demand. Primary strontium compounds were used primarily in glass manufacture for television picture tubes, and to a lesser extent in pyrotechnics and signals, ferrite permanent magnets, pigments and fillers, and electrolytic production of zinc.

OP 62–84. Longwall Dust Control, a Perspective View of How U.S. Mine Operators Are Coping With the Problem, by Robert A. Jankowski and John A. Organiscak. Paper in Proc. Eur. Econ. Communities Conf. on Longwall Dust Control, Luxembourg, May 30–31, 1983, Doc. No. 2365/83, pp. 103–124. The

Bureau of Mines recently completed a survey of six U.S. longwall operations that show a consistent record of compliance with Federal dust standards and six operations experiencing the greatest difficulty maintaining compliance levels. The selection of the six "cleanest" longwall double-drum shearers was based on mine operator and MSHA compliance records. A list of 10 longwall double-drum shearers experiencing the most difficulty with compliance was also obtained from MSHA. During the surveys, 4 of the 10 operations implemented improved dust controls that substantially lowered dust levels; thus the results discussed in this report are from the six U.S. longwall faces still having the greatest difficulty complying with the Federal dust standards. The objective of the surveys was to (1) identify the dust control techniques that were most effective, (2) determine whether existing technology was capable of controlling dust from the major longwall dust sources, and (3) identify the areas where existing technology was not adequate. This information would permit mine operators to select the most appropriate techniques to control longwall dust levels and provide additional direction to research efforts designed to develop control technology for specific problem areas.

OP 63–84. Improved Face Ventilation Lowers Longwall Dust Levels, by Robert A. Jankowski and Fred N. Kissell. Paper in Proc. Soc. Min. Eng. AIME 112th Annu. Meeting, Atlanta, GA, Mar. 6–10, 1983. Soc. Min. Eng. AIME preprint 83–171, 7 pp.; paper in Trans. Soc. Min. Eng. AIME, v. 274, 1984, pp. 2024–2028. The Bureau of Mines, in close cooperation with the mining industry, has recently established several improved face ventilation techniques for longwall mining systems. These include coursing the primary face intake from tailgate to headgate, installing curtains at the intake end of the longwall face, and identifying improved techniques for measuring face ventilation parameters on longwall sections. Application of these techniques throughout the mining industry should reduce the health hazard associated with excessive exposure to respirable dust.

OP 64–84. Soda Ash by D. S. Kostick. Min. Eng., v. 36, No. 5, May 1984, pp. 530–531. Domestic production of natural and synthetic soda ash increased because of the 48% rise in exports, mainly to Asia and South America. Several proposed international soda ash projects were announced that could influence the size of the future U.S. export market. Domestic apparent consumption of soda ash increased slightly as demand improved for soda ash in soap and detergents, pulp and paper, and chemicals. The growing market displacement of glass containers, the largest end use of soda ash, by polyethylene terephthalate bottles continued to severely affect domestic soda ash sales.

OP 65–84. The Competitive Position of Nickel-Cobalt and Copper-Cobalt Deposits in Canada, Zambia, Zaire, and the Pacific Islands, by James F. Lemons, Jr. Pres. at Soc. Min. Eng. AIME 113th Annu. Meeting, Los Angeles, CA, Feb. 26–Mar. 2, 1984, Soc. Min. Eng. AIME preprint 84–107, 13 pp. The potential production of cobalt from nickel sulfide deposits in Canada, from nickel laterite deposits in the Pacific Islands, and from the copper deposits in Zaire and Zambia will be a function of the cost of recovery of the primary nickel and copper products. This cost of production varies significantly for these deposits and is related to the differences in the cost of labor, energy, and supplies; to production technology; and to the grade and recovery of nickel, copper, and cobalt. This Bureau of Mines paper investigates these cost and technology differences as they relate to the cost competitiveness of the deposits in Canada, Zambia, Zaire, and the Pacific Islands.

OP 66–84. Use Lower Shearer Drum Speeds To Achieve Deeper Coal Cutting, by Jonathan Ludlow and Robert A. Jankowski. Min. Eng., v. 36, No. 3, Mar. 1984, pp. 251–255. A longwall operator can make few changes to increase output, significantly reduce respirable dust, and decrease power consumption. Reducing drum speed, and thereby cutting with increased pick penetration, is one. This article defines the benefits of deep cutting in terms of reduced dust production and power consumption. It also identifies the practical aspects of high pick penetration in terms of shearer performance and coal loading.

OP 67–84. Bromine, by P. A. Lyday. Min. Eng., v. 36, No. 5, May 1984, pp. 508–509. A 1983 review of changes in the bromine industry during the year. The review included changes in Government environmental and trade programs that affected the industry. The domestic and overseas industry was included in the review, which also contained an outlook section projecting future changes.

OP 68–84. Iodine, by P. A. Lyday. Min. Eng., v. 36, No. 5, May 1984, pp. 518–519. A 1983 review of changes in the iodine industry during the year. The review included changes in Government stockpiles, imports, and the domestic and foreign industry. The development of new capacity in the United States and existing capacity in Japan was included. An outlook section projected future changes.

OP 69–84. Hazardous Roof Structures in Appalachian Coal Mines, by Noel N. Moebs and John L. Ellenberger. Ch. 2 in Ground Control in Room-and-Pillar Mining, ed. by Y. P. Chugh (Proc. Polish-American Conf. on Ground Control in Room-and-Pillar Mining, Soc. Min. Eng. AIME, Carbondale, IL, Aug. 6–8, 1980). Soc. Min. Eng. AIME, 1982, pp. 9–16. Geologic structures in mine roof rock contribute to many roof falls in Appalachian coal mines. These structures include paleochannels, scours, pinch-outs, slickensides, clay veins, and cravasse splays consisting of thinly interlaminated sandstone and shale. These structures often can be identified during, and sometimes before, development and mine projections can be revised to reduce the adverse effects of discontinuities in roof structure. Large areas of roof consisting of laminated sandstones or incompetent strata generally can be delineated from exploratory drill-hole data and the need for supplementary support can be anticipated. Because an accurate description of roof geology also provides some indication of optimum length and type of roof bolts that should be installed, this Bureau of Mines paper describes the hazardous roof structures most commonly encountered in the Appalachian coal region.

OP 70–84. Are Charge Materials Affecting Casting Quality? by R. H. Nafziger, R. F. Farrell, and J. E. Brynildson. Mod. Cast., v. 74, No. 5, May 1984, pp. 23–26. The foundry industry has expressed concern regarding the quality of scrap used

to prepare iron castings owing to the growth of alloy steel production and its influence on tramp element levels when recycled. Reliable and current information is unavailable on the amount of tramp elements contained in iron castings produced over a significant period of time. Accordingly, the Bureau of Mines is analyzing over 50 cast iron samples from participating foundries throughout the United States on a quarterly basis under a Memorandum of Agreement between the Bureau and the American Foundrymen's Society. A direct-reading spectrograph and atomic absorption techniques provide the determination of 28 elements on each sample. The objective is to determine if the level of tramp elements in charge materials is changing over a period of time. Results to date indicate that the type of furnace used and the geographic location and size of the foundry did not significantly affect casting compositions. Owing to the variability of charge materials used, correlation of the analyses with charge compositions was unsuccessful. The data obtained thus far represent insufficient time to justify a statistical evaluation of possible trends.

OP 71–84. Longwall Dust Control Research, by George E. Niewiadomski and Robert A. Jankowski. Paper in Proc. 12th Annu. Inst. on Coal Mining Health, Safety and Research, Blacksburg, VA, Aug. 24–26, 1981, pp. 79–92. The Bureau of Mines has been active in respirable dust research since passage of the Federal Coal Mine Health and Safety Act of 1969. Until several years ago, the main thrust of the research program was on the development and new and improved dust control technologies to reduce the miners' exposure to respirable dust in mines employing conventional and continuous mining methods. As a result of the efforts of the Bureau, the Mine Safety and Health Administration (MSHA), and the coal mining industry, significant progress has been achieved in lowering the dust levels in these mines from over 5 mg/m³ in 1969 to less than 2 mg/m³ today. This is reflected in the number of citations issued by MSHA in recent years. Based on inspection data, at least 95 pct of all conventional and continuous mining sections are currently in compliance at any given time.

OP 72–84. Taking the Dust Out of Longwalls, by George E. Niewiadomski, Robert A. Jankowski, and Fred N. Kissell. Min. Equip. Int., v. 6, No. 12, Dec. 1982, pp. 25–28. Longwall mining offers many advantages, but controlling respirable dust can be difficult especially at mines using double-drum shearers. However, the Bureau of Mines, in cooperation with the mining industry, has developed and tested cost-effective solutions—including improved ventilation, better uses of water, and improved machine design—that are currently in use. This paper discusses those solutions and some cases where the solutions do not apply.

OP 73–84. Unconventional Uses of Geotechnical Tools for Impoundment Seepage Investigations, by Steven E. Follin, George L. Chedsey, and Andrew Mac G. Robertson. Paper in Sixth Symposium on Uranium Mill Tailings Management, Fort Collins, CO, Feb. 1–3, 1984, pp. 615–626. Proper design of dewatering or seepage control systems for existing waste impoundments requires reliable estimates of soil parameters, knowledge of pore pressure distribution, and good information about the layering present. As part of a program to improve the effectiveness of dewatering systems used in the mining industry, the Bureau of Mines sponsored field tests of two recently developed instruments, the piezocone penetrometer and the Delft 66-mm continuous sampler. These tools, developed for other applications in which soft soils are encountered, were used to obtain soil and hydrologic information at an active uranium tailings impoundment. This paper describes the equipment, its operation, the fieldwork performed, and the results obtained.

OP 74–84. Direct Flotation of Potash From Insoluble Slime-Bearing Sylvinite and Carnallite Ores, by D. G. Foot, Jr., and J. L. Huiatt. Trans. Soc. Min. Eng. AIME, v. 272, May 1983, pp. 1974–1978. The Bureau of Mines devised a direct flotation method for treating low-grade carnallite ($KCl \cdot MgCl_2 \cdot 6H_2O$) and sylvinite (a mixture of KCl and NaCl) ores characterized by a high content of water-insoluble impurities. The procedure consists of flocculation-depression of the insoluble slimes; decomposition leach (carnallite only); potash rougher, cleaner, and recleaner flotation; and final product leaching. The technique eliminates the necessity of removing the water-insoluble slimes by mechanical or flotation desliming. Laboratory results demonstrated that the direct flotation procedure, when compared with conventional techniques, yielded equivalent or improved flotation results with equal or less reagent consumptions. The direct flotation method recovered 81.6% of the solid phase KCl from carnallite ore and 79.7% of the KCl from sylvinite ore in final products containing 60.5% and 60.9% K_2O, respectively. A flowsheet incorporating the described flotation procedure is presented.

OP 75–84. Black Sand Survey Along the Pacific Coast, by John Gomes. Paper in Fifth Annual Conference on Alaskan Placer Mining (sponsored by the Univ. of AK, Fairbanks, AK, Mar. 30–31, 1983), comp. and ed. by B. W. Campbell, J. Madonna, and M. S. Husted. Miner. Ind. Res. Lab. Rep. No. 68, 1983, pp. 49–52. The Bureau of Mines investigated the occurrence and recovery of byproduct gold and heavy minerals from west coast sand and gravel operations. Heavy mineral (black sand) concentrates were prepared from sand samples from 150 locations. Magnetite, ilmenite, zircon, chromite, rutile, radioactive minerals, platinum-group minerals, and gold were identified in many of the concentrates. Individual magnetite, ilmenite, zircon, chromite, rutile, thoria, platinum-group minerals, and gold products were prepared from selected concentrates. Low- and high-intensity magnetic, electrostatic, flotation, and amalgamation techniques were used to beneficiate the black sands.

OP 76–84. Heap Leaching of Gold Ores, by John Gomes. Paper in Fifth Annual Conference on Alaskan Placer Mining (sponsored by the Univ. of AK, Fairbanks, AK, Mar. 30–31, 1983), comp. and ed. by B. W. Campbell, J. Madonna, and M. S. Husted. Miner. Ind. Res. Lab. Rep. No. 68, 1983, pp. 80–83. During the 1970's, the Bureau of Mines investigated a particle agglomeration technique for improving the flow of leaching solution through heaps of clayey or crushed, low-grade gold-silver ores, wastes, and tailings. This technology has been adopted on a broad scale by the precious-metals-processing industry. This report presents information on five commercial operations that have benefited from agglomeration technology and that represent a cross section of current heap leaching practice. The technology is cost effective because of decreased leach times and improved precious metal recoveries.

OP 77–84. Cast-On Surfacing of Polystyrene Pattern Castings, by J. S. Hansen. Paper in Am. Foundrymen's Soc. 87th Annu. Meeting, Des Plaines, IL, Apr. 10–15, 1983. AFS Trans., v. 91, 1983, pp. 65–70. In support of its objective to decrease the use of critical materials through conservation and wear reduction, the Bureau of Mines investigated a hardsurfacing technique for use in mining and metallurgical processing equipment that confines alloy additions to wear-prone surfaces only and improves wear resistance. In the technique, powdered, wear-resistant material is pasted on a polystyrene pattern and transferred to a casting surface at the time of pouring. Vacuum is applied to a special casting flask to eliminate gas, maintain shape, and promote intimate contact between the powder and liquid metal. Three examples are cited in which high-carbon ferrochrome was applied as a surfacing material to AISI 1030 steel castings. Ferrochrome paste with less than 0.5% polyvinyl acetate or cellulose binder resulted in hardsurfaces with few inclusions, few shrinkage voids, and no gas porosity. The hardsurfaces, containing $M_{23}C_6$ carbides, were fused and metallurgically bonded to the castings. A heat-treated ferrochrome-surfaced casting performed 27% better than water-quenched (Rc 62) AISI 1060 steel in a test for low-stress abrasive wear. Work is continuing to improve process variables and to evaluate alternate hardsurfacing materials.

OP 78–84. Anticipating Facies-Related Coal Mining Problems in Hartshorne Formation, Arkoma Basin, by David W. Houseknecht and Anthony T. Iannacchione. Am. Assoc. Petrol. Geol. Bull., v. 66, No. 7, July 1982, pp. 923–930. The close relationship observed between sedimentary facies and potential coal mining problems within the Hartshorne Formation of the Arkoma Basin provides the basis for anticipating where mining problems may jeopardize safe and economical coal production in undeveloped parts of the basin. Deltaic facies within the Hartshorne include distributary-channel sandstones and interdistributary-bay shales, siltstones, and sandstones. A thick, linear, distributary-channel sandstone is closely related to several potential mining problems: (1) both underlying and overlying coalbeds are locally thin and discontinuous along the trend of the sandstone, (2) coal quality decreases significantly adjacent to the sandstone (decrease in free swelling index and increase in sulfur), (3) the sandstone is a natural gas reservoir that may emit gas into adjacent coal mines, and (4) geologic factors favoring unstable roof conditions and coalbed rolls are locally associated with the sandstone. In contrast, interdistributary-bay deposits, because of relative homogeneity and lateral persistence, do not present potential facies-related problems. Basinwide availability of geophysical logs from gas wells makes facies mapping and delineation of potential problem areas a straightforward procedure that must be integrated into formulation of exploration strategy, evaluation of reserves, and mine planning if Hartshorne coal resources are to be safely and economically exploited.

OP 79–84. Roundrobin Investigation of Respirable Quartz Dust, by Charles Huggins. Paper in Proceedings of the Symposium on Control of Respirable Coal Mine Dust (cosponsored by MSHA and labor and management of the coal industry), ed. by J. A. Barrett, M. Jacobson, W. H. Sutherland, G. R. Tinney, and P. M. Turcie, Beckley, WV, Oct. 4–6, 1983, pp. 287–296. Five interagency roundrobin investigations were run by five laboratories in order to examine the analysis of quartz in coal dust by infrared spectroscopy and X-ray diffraction. The objective was to obtain consistent results from all laboratories. Three reference quartz standards were used during the investigations, and minus 5-μm Minusil was chosen as the preferred standard by four of the five laboratories. Quartz particle size distribution measurements were made by scanning electron and transmission electron microscopy on the reference standards. The results of the final roundrobin show that consistent values can be obtained from different laboratories using the same standard and similar techniques.

OP 80–84. Modify Spray Heads To Reduce the Dust Rollback on Miners, by Natesa I. Jayaraman, Fred N. Kissell, and W. E. Schroeder. Coal Age, v. 89, No. 6, June 1984, pp. 56–57. The Bureau of Mines recently developed a water spray system that reduces dust levels at the continuous miner operator position, particularly in mines where respirable dust standards are more stringent because of silica in the coal. The purpose is to reduce dust rollback caused by the dense dust at the cutter head spreading back over the operator's cab. This article describes the three factors that promote dust rollback and the features in the new design of the spray system that improve the dust conditions. The design features include (1) a moderate spray pressure of 100 psi at the nozzles, (2) arrangement of top and side sprays for low reach, and (3) use of underboom sprays for increasing the dust knockdown efficiency. The degree of improvement effected by the new system depends on the degree of present exposure of the operator. In recent trials, the new system reduced dust levels by 40 pct.

OP 81–84. Dust Control Systems, by Fred N. Kissell. Paper in Proceedings of the Eleventh Annual Institute on Coal Mining Health, Safety and Research (cosponsored by VA Polytech. Inst. & State Univ., MSHA, and BuMines), ed. by M. Karmis, J. A. Lamonica, J. L. Patrick, and J. R. Lucas, Blacksburg, VA, Aug. 26–28, 1981, pp. 62–83. An overview of the Bureau of Mines Respirable Dust Control Program is presented. Completed and ongoing developments in the areas of dust generation, ventilation, scrubbers, personal protection, and instrumentation are discussed. The program is implemented through in-house and contract projects that are conducted at the Bureau's Pittsburgh Research Center and the Twin Cities Research Center.

OP 82–84. Mining-Induced Stress Measurement With Hydraulic Borehole Pressure Cells, by Paul H. Lu. Paper in Proceedings of the 25th U.S. Symposium on Rock Mechanics, Evanston, IL, June 25–27, 1984. Soc. Min. Eng. AIME, ch. 22, 1984, pp. 204–211. This paper proposes an unconventional, simple, and practical method of measuring mining-induced ground stresses with hydraulic borehole pressure cells. The method is a direct ground stress measuring technique. It does not require the value of deformation modulus for back-calculation of stresses; instead, it directly measures the ground stress in situ. The applicability and practicality of the technique are shown by two case studies. The technique may be applied to monitoring a stress buildup that may lead to mine roof failure or to rock and coal outbursts.

OP 83–84. Reducing Longwall Tailgate Workers' Dust Exposure Utilizing Water-Powered Scrubbers, by

John A. Organiscak, Jon C. Volkwein, and Robert A. Jankowski. Paper in Proc. Soc. Min. Eng. AIME Fall Meeting, Salt Lake City, UT, Oct. 19–21, 1983, pp. 113–118. The Bureau of Mines evaluated a new dust control technique for longwall personnel required to work at the tailgate end of the face. This technique utilizes a water-powered scrubber to clean a portion of the face air, which is discharged behind a brattice partition at the working area. Laboratory simulation of this system in a wind tunnel resulted in average efficiencies greater than 70 pct with system efficiency directly related to scrubber quantity. Underground evaluations indicated a similar direct relationship between scrubber quantity and system efficiency. Gravimetric measurements of respirable dust made during these underground evaluations resulted in average protection efficiencies ranging from 30.7 to 42.5 pct with increasing scrubber air quantity.

OP 84–84. Improving Dust Control on Longwall Shearers, by R. A. Pimentel, R. F. J. Adam, and R. A. Jankowski. Paper in Proc. Soc. Min. Eng. AIME 113th Annu. Meeting, Los Angeles, CA, Feb. 26–Mar. 2, 1984, pp. 63–82. Many longwall operators experience difficulty complying with the Federal regulation limiting average dust exposure. Others are currently in compliance, but the dust exposure limit keeps them from increasing their production. Spray water is a major means of dust control. Excess water can cause problems in the transportation system and the cleaning plant, and reduces the British thermal unit value of the run-of-mine coal. Thus, the dust exposure per unit of water sprayed must be maximized. This paper discusses underground tests recently completed as part of a Bureau of Mines research program to determine the effects of variations in spray water flow rate, pressure, proportioning, and spray orientation on longwall shearers.

OP 85–84. Clay Dikes in the Lower Kittanning Seam in Northern West Virginia, by John T. Popp and Anthony T. Iannacchione. Pres. at 96th Annu. Meeting, Geol. Soc. Am., Indianapolis, IN, Oct. 31–Nov. 3, 1983. Abstr. With Programs, v. 15, No. 6, Sept. 1983, p. 662. Clay dikes have been mapped in the Lower Kittanning Seam and the strata immediately surrounding the seam in an underground mine in northern West Virginia. Individual clay dikes, ranging in size from a thin film to intrusions several feet wide, have been traced as far as 900 ft laterally within the seam and surrounding strata. The vertical extent of the clay dikes is unknown.

OP 86–84. Fundamental Approaches to Longwall Dust Control, by Steven K. Ruggieri and Robert A. Jankowski. Paper in Soc. Min. Eng. AIME 112th Annu. Meeting, Atlanta, GA, Mar. 6–10, 1983, pp. 3–8; Paper in Proc. Symp. on Control of Respirable Dust, Beckley, WV, Oct. 4–8, 1983, pp. 1–5. The Bureau of Mines is currently assessing the effectiveness of longwall dust control techniques in use today and those proposed for the future. The objective is being achieved through laboratory and field evaluations of dust control practices, using innovative sampling procedures, and state-of-the-art respirable dust monitors and support instrumentation. This makes it possible to quantify the effectiveness or lack of effectiveness of specific techniques. The results will provide the coal industry with the information necessary for proper application of dust control techniques.

OP 87–84. Interpretation of Piezometer Cone Testing of Tailings, by Eben Rust, Dirk van Zyl, and Steven Follin. Paper in Sixth Symposium on Uranium Mill Tailings Management, Fort Collins, CO, Feb. 1–3, 1984, pp. 627–638. The piezocone penetrometer is an in situ testing tool that is particularly useful for the investigation of tailings impoundments. This equipment is ideally suited for testing of tailings since a lightweight pushing frame can be used for advancing the probe. A field testing program was completed at a uranium tailings impoundment in Uravan, CO. This paper describes how the results of piezocone tests are interpreted and demonstrates these methods using the data obtained.

OP 88–84. Bureau of Mines Technology for Dewatering of Phosphatic Clays, by B. J. Scheiner. Paper in Phosphatic Clay Workshop, ed. by S. W. Clark (sponsored by Florida Institute of Phosphate Research and Central Florida Regional Planning Council, Bartow, FL, Apr. 16, 1982). FL Inst. Phosphate Res., No. 02–020–012, 1982, pp. 55–64. The Bureau of Mines has developed a dewatering technique for phosphatic clay waste. The technique consists of treating the clay waste with a flocculant such as polyethylene oxide and dewatering the resulting flocs on a mechanical device such as a rotary screen. In small-scale continuous tests at the Bureau's Tuscaloosa Research Center, clay waste was consolidated from a nominal 4 wt % solids to about 20 wt % solids. Based upon these results, a field test unit was operated at the Estech Corp. Silver City Mine, located near Bartow, FL. The unit is now operating at the Occidental Suwannee River Mine located near White Springs, FL. This report describes the results of field tests conducted to date.

OP 89–84. Mineral Processing Water Treatment Using Magnesium Oxide, by Joseph E. Schiller, Daniel N. Tallman, and Sanaa E. Khalafalla. Environ. Prog., v. 3, No. 2, May 1984, pp. 136–141. This paper describes two applications where magnesium oxide (MgO) can be used to purify process water in two ways: (1) to filter out suspended solids and (2) to precipitate dissolved heavy metals. Granular MgO (periclase mineral) out-performs sand in deep bed filters, since an MgO filter system operates with cycles up to twice as long and gives a cleaner filtrate than a comparable sand filter. To precipitate heavy metals, powdered MgO (magnesia chemical) is used instead of lime or caustic soda. The MgO-formed sludge cements into a solid mass on standing and occupies only about 20 to 30 pct of the volume as the precipitates produced by more soluble bases.

OP 90–84. Use of CO_2 Measurements in Monitoring Air Quality in Dead-End Drifts, by George H. Schnakenberg, Jr., Paul Schaefer, and John H. Johnson. Paper in Mine Ventilation, Third International Congress, Harrogate, England, June 6–13, 1984, pp. 383–389. The U.S. Bureau of Mines, in its pursuit of methods to improve the quality of the underground workplace, has funded studies on the behavior of diesel exhaust components in dead-end drifts. Real-time and time-integrated measurements of CO_2, CO, NO, and NO_2 and gravimetric measurements of particulates analyzed for hydrogen, carbon, and the nitrogen fraction were performed in several mines and under controlled conditions in a test drift. The relationship among the contaminants was examined on the basis that the CO_2 concentrations are only the result of the amount of fuel

burned and the exhaust dilution if background CO_2 is subtracted. Although the engine operates over several modes for a given production activity, the ratio of each of the other exhaust-contaminant concentrations to the CO_2 concentration was found to be relatively constant for a given engine in a given activity. The fact that the relationship is constant can be exploited in that CO_2 levels alone can be used to give a measure of the level of diesel exhaust air quality. Furthermore, time-weighted averages of the other contaminants (CO, NO, NO_2, and particulate) and CO_2, or direct tailpipe measurements with the engine suitably loaded, can be made and the ratios can be compared with previous data. Changes in the ratio indicate changes in engine and/or exhaust control systems, and maintenance may be indicated; changes in the ambient CO_2 level reflect changes in ventilation. The measurement technology and a graphical approach for this method is presented.

OP 91–84. Use of Instantaneous Samplers To Evaluate the Effectiveness of Respirable Dust Control Methods in Underground Mines, by C. D. Taylor, R. A. Jankowski, S. K. Ruggieri, and T. L. Muldoon. Ch. 32 in Aerosols in the Mining and Industrial Work Environments. Volume 2. Characterization, ed. by V. A. Marple and B. Y. H. Liu (Proc. Int. Symp. on Aerosols in the Mining and Industrial Work Environment, Minneapolis, MN, Nov. 1–6, 1981). Ann Arbor Sci., Ann Arbor, MI, 1981, pp. 433–440. Sampling strategies, which can be used in coal mines with GCA RAM (respirable aerosol monitor) instantaneous dust sampling instruments, have been developed to provide information that cannot be obtained with full-shift gravimetric sampling. As part of a Bureau of Mines dust control research contract, GCA RAM instruments were used on one longwall face to determine dust levels when using two different water spray systems. Sampling on the longwall face was conducted adjacent to and upwind of the shearer to estimate the shearer operator's exposure. A stationary face location was also sampled to profile dust levels near the shearer. Results of the sampling were compared to determine the relative dust control effectiveness of each water spray system.

OP 92–84. Issues Affecting U.S. Ferrochromium Import Dependency, by Paul R. Thomas. Pres. at Soc. Min. Eng. AIME 113th Annu. Meeting, Los Angeles, CA, Feb. 26–Mar. 2, 1984. Soc. Min. Eng. AIME preprint 84–108, 15 pp. This paper addresses two issues affecting the international ferrochromium market as they pertain to the changing pattern of U.S. chromium import dependency. These issues are (1) the long-term ferrochromium production cost differential between the United States and the Republic of South Africa, and (2) the ability of Zimbabwe to expand ferrochromium production and exportation. This paper draws upon the data and analyses of a recent Bureau of Mines Minerals Availability Program appraisal that evaluated the international availability of chromium in the form of chromite and ferrochromium from 10 market economy countries. South African ferrochromium producers are shown to have a long-term production cost advantage over U.S. producers of $0.03 to $0.04 per pound of contained chromium in 1981 dollars. Zimbabwean ferrochromium production and exportation are expected to increase in the future. Major expansions of production capacity will be dependent upon alleviating potentially serious constraints in electric power, rail, and port facilities. In the long term, ferrochromium production costs in Zimbabwe are expected to increase faster than the rate of inflation because as chromite mining from the podiform resources in Zimbabwe increases, production from the Great Dyke resources will increase.

OP 93–84. South African Gold Production: How Much, for How Long and at What Cost, by Paul R. Thomas and Edward H. Boyle, Jr. Pres. at Soc. Min. Eng. AIME 113th Annu. Meeting, Los Angeles, CA, Feb. 26–Mar. 2, 1984. Soc. Min. Eng. AIME preprint 84–110, 11 pp. This paper addresses the long-term cost and availability of primary gold production from the Republic of South Africa. Forty-four major producing or developing operations were evaluated. The analyses present estimates concerning (1) total refined gold potentially available from demonstrated resources, (2) annual production potential into the next century, (3) long-term weighted average total costs for underground mine production and surface waste reprocessing, (4) the expected annual decrease in gold production, and (5) the ability of other market economy countries to compensate for the anticipated decline in South African gold output. This paper draws upon the data and analyses of a recent Bureau of Mines Minerals Availability Program appraisal that evaluated the worldwide availability of gold and silver from primary precious metal operations and as a byproduct of base metal production.

OP 94–84. Controlled Burnout at an Abandoned Coal Mine Fire, by Robert F. Chaiken. Paper in Proceedings of the Eighth Underground Coal Conversion Symposium (sponsored by U.S. Dep. Energy, Keystone, CO, Aug. 15–19, 1982), pp. 511–514. This paper presents a new Bureau of Mines technique called "burnout control" that shows promise for controlling fires in abandoned coal mines and waste banks and also for extracting the thermal energy represented by such "wasted" coals. The technique involves complete combustion of the coal in place while maintaining total control of the resulting heat and fumes. The thermal energy produced and brought to the surface as high-temperature gas can be as much as 20 times the equivalent thermal energy required to operate the burnout control system.

OP 95–84. Economic Benefits From Burnout of Abandoned Coal Mine Fires, by Robert F. Chaiken. Paper in Proceedings of the Ninth Annual Underground Coal Gasification Symposium, ed. by P. R. Wieber, J. W. Martin, and C. W. Byrer (sponsored by U.S. Dep. Energy, Bloomingdale, IL, Aug. 7–10, 1982). U.S. Dep. Energy, Morgantown Energy Technol. Center, Morgantown, WV, DOE/METC/84–7, Dec. 1983, pp. 523–532. Burnout control of abandoned coal mine fires was investigated by the Bureau of Mines to determine the feasibility of completely burning out the coal in situ while maintaining control of the heat and fumes produced. The control process would also enable the thermal energy developed underground to be brought to the surface as high-temperature flue gas suitable for powering an on-site, waste heat, boiler-steam turbine electrical generation plant. Since accelerated coal burning will lead to earlier self-extinguishment of the mine fire after the fuel is totally consumed, burnout control offers a means for eliminating a serious environmental problem while at the same time converting a coal waste to a coal resource. Unlike most conventional methods of extinguishing abandoned coal mine fires (such as excavation and quenching), burnout control through the production and sale of electricity can

lead to net revenues that would make the process economically viable. This paper documents some of the cost factors involved in determining the net revenues from burnout control. Net cash flow analyses indicate the possibility of sufficient rates of return from relatively low capital investment to attract the interest of private investors.

OP 96–84. Burnout Control of Fires in Abandoned Coal Mines and Waste Banks by In Situ Combustion, by R. F. Chaiken, L. E. Dalverny, M. C. Irani, and I. A. Zlochower. Paper in Proceedings of Seventh Underground Coal Conversion Symposium (sponsored by U.S. Dep. Energy, Fallen Leaf Lake, CA, Sept. 8–11, 1982), pp. 380–392. The Bureau of Mines investigated a novel approach to eliminating environmental and public safety hazards that are associated with fires in abandoned coal mines and waste banks which involves the use of in situ combustion technology to accelerate the burning of the wasted coals in place. This technology would be used under exhaust ventilation control conditions that would allow for total management of the hot gases produced. Combustion stoichiometries would be optimized to minimize unburnt combustibles and to maximize the heat content of the gas products, which will be exhausted at one or more fan locations. When necessary, scrubber systems would be employed to remove air pollutants, such as sulfur dioxide; heat utilization systems (process heat, steam, and electricity) would also be employed to offset operational costs. Ultimately, complete burnout would solve the fire and acid water formation problems of the abandoned coal mine or waste bank. Pertinent technical data from the burning of tonnage quantities of coal and coal refuse under simulated in situ conditions are discussed in this paper in terms of burnout control.

OP 97–84. Safeguarding of Blast-Affected Areas, by Dennis V. D'Andrea and Jerry Bennett. Paper in Proc. Soc. Explos. Eng. 10th Annu. Conf. on Explosives and Blasting Techniques, Lake Buena Vista, FL, Jan. 29–Feb. 2, 1984, pp. 100–119. A recent Bureau of Mines analysis has shown that failure of blast area security systems is the major cause of mine blasting accidents. Accidents occur during scheduled blasting because of failure to clear the blast zone, inadequate guarding and failure of personnel to follow instructions, retreat to a safe location, and/or failure to take adequate cover. The high incidence of blast-site security-related accidents could be considerably reduced by increased attention to improving minesite blast-guarding practices. Mining and Marketing Associates, Inc., conducted research under contract to the Bureau of Mines to determine the state-of-the-art of blast area guarding and to recommend safe procedures and areas deserving of future research. This paper is a summary of that research. Case studies of current blast area guarding practices at two surface and three underground mines are presented; practices at these five mines are considered to be much safer than those generally found in the industry. The essential elements of an effective blast-guarding system are outlined, along with recommendations for improving procedures. Although the survey of military and industrial surveillance and detection technology did not reveal any security systems immediately available for transfer to the mining industry, areas with a potential for adaptation were identified.

OP 98–84. Bureau of Mines Recycling Research, by Roger DeCesare. J. Met., July 1984, pp. 44, 143. Three areas of current Bureau of Mines recycling research are summarized in this review article: critical metals recovery from superalloy scrap, utilizing zinc wastes in electrogalvanizing processes, and rapid scrap identification technology. Metals such as cobalt, chromium, and nickel can be recovered from dissolved superalloy scrap if it is made readily leachable by first forming intermetallic compounds with either aluminum or zinc. Zinc-containing furnace dust, currently considered a potetial environmental disposal problem, can be used as a replacement for virgin zinc in electrogalvanizing processes. More scrap metal can be effectively recycled if low-cost identification and sorting methods are developed for scrap processors to use. These projects typify the broad spectrum of recycling research undertaken by the Bureau in its efforts to increase mineral recovery from wastes generated throughout the minerals industry.

OP 99–84. Maintain Filters To Control Roof Dust, by Edward Divers and John McClelland. Coal Age, v. 89, No. 8, Aug. 1984, pp. 141–142. Although the roof strata of many underground coal mines contains well over 50% silica, the exposure of roof bolter operators to excessive levels of respirable silica can be controlled readily and inexpensively by taking a few simple maintenance procedures. The primary areas for concern are dust in the blower exhaust and dust escaping the collar of the drill hole. Mine operators can provide adequate protection from dust during roof drilling by using good-quality filter cartridges and replacing them as they become clogged or damaged, flushing the collector system, and checking periodically for system leaks and overloaded filters. This paper discusses the areas for concern and some methods that can be utilized to alleviate the problems.

OP 100–84. Reducing Oxidation of Pyrite Through Selective Reclamation Practices, by Patricia M. Erickson, Robert L. P. Kleinmann, and Peter S. A. Campion. Paper in 1982 Symposium on Surface Mining Hydolrogy, Sedimentology and Reclamation, Lexington, KY, Dec. 5–10, 1982, pp. 97–102. Reclamation efforts concentrating on establishing vegetation frequently fail to control discharge of acid mine water from surface mines and coal refuse areas. A proposed method of combining control of acid drainage and establishment of vegetation is to use the plant-soil zone to produce a low-oxygen environment in the underlying pyritic material. Oxygen consumption by plant roots, soil biota and organic material decay, and oxygen diffusion barriers formed by fine-grained material provide potential means of limiting the oxygen available for pyrite oxidation. Detailed studies of field relationships among pyrite oxidation, reclamation treatments, and subsurface oxygen profiles were conducted at an experimental refuse area and an abandoned surface mine. Preliminary results from unreclaimed refuse areas indicated that significant oxygen concentrations were limited to the uppermost meter of material. A shallow, near-surface oxygenated zone was also found at the experimental refuse area in plots subjected to various reclamation treatments. Soil moisture sample pH values from the plots were generally consistent with pyrite oxidation being limited to the oxygenated zone. The effects of 13 reclamation treatments on subsurface oxygen and water quality profiles were investigated.

OP 101–84. Hydrogeochemistry of a Large Mine Pool, by Patricia M. Erickson, Robert L. P. Kleinmann, Emanuel T. Posluszny, and Patricia J. Leonard-Mayer. Paper in Proc. 1st Int. Mine Water Congr., Budapest, Hungary, Apr. 19–23, 1982, pp. 27–42. Flooded mine workings underlie approximately 17,500 ha of the northern anthracite field in northeastern Pennsylvania. The U.S. Bureau of Mines is examining the hydrology and geochemistry of this large mine pool complex in order to identify flow patterns, sources of acid mine drainage, and chemical stratification. Fluid resistivity, temperature, pH, and oxidation reduction potential are being measured with down-hole instruments in 12 mine shafts open to depths down to 460 m. Samples collected at various depths are being analyzed for concentrations of total and ferrous iron, sulfate, manganese, aluminum, pH, alkalinity or acidity, and fecal coliform bacteria. Water flowing from the mine pool remains heavily contaminated by acid mine drainage more than 30 yr after the pool started to form. One goal of this study is to determine if pyrite oxidation is still adding to the pollutant load or if previously oxidized products are being flushed from the pool. A preliminary survey of water quality at depth suggests that changes in chemical parameters within the pool are closely related to the mined-out coal seams. Generally, water quality was found to decrease gradually with depth and to change sharply at the elevation of mined-out beds. The results of this study will provide better understanding of flow and geochemical processes in the mine pool. Consequently, the effects of rehabilitation plans, such as changing the mine pool elevation or reducing surface infiltration, can be evaluated more objectively.

OP 102–84. Dust Control in Longwall Shearer Faces Through Air Movement by Water Sprays, by Natesa I. Jayaraman and Fred N. Kissell. Ch. 14 in Longwall-Shortwall Mining, State of the Art, ed. by R. V. Ramani. Soc. Min. Eng. AIME, New York, 1981, pp. 115–120. This paper describes a Bureau of Mines research project that resulted in a simple procedure for reducing the dust exposure of longwall shearer operators. The project involved researching and testing a water spray and passive shield system to hold dust against the face and away from the shearer operators. The system is known as the Shearer-Clearer.

OP 103–84. Recent Experience With the Spray Fan, by Fred N. Kissell, William Schroeder, Steven Ruggieri, and Stanley Hoover. Paper in Proc. Soc. Min. Eng. AIME, Int. Mine Ventilation Congr., Reno, NV, Nov. 4–8, 1979, pp. 685–690. Methods were developed under a Bureau of Mines contract to increase the amount of fresh air that reaches the front of a continuous-mining machine, with emphasis on removing methane buildups that occur at the cutterhead. Using a full-scale plywood mockup of a coal mine working face area, the study showed that in many instances only about 20 pct of the fresh air heading towards an exhaust brattice or tubing actually gets to within 1 ft (0.3 m) of the face. Enhancing and moving forward the natural airflow pattern will provide more air at the face, which can be accomplished by taking advantage of the air-moving abilities of the conventional water spray. It was discovered that if all the water sprays on the machine were realigned, then ventilation efficiencies of 70 pct or more were achieved regularly. This meant that if 9,000 cfm (4.2 m^3/s) was entering the brattice, at least 6,300 cfm (3.0 m^3/s) of this was reaching to within 1 ft (0.3 m) of the face. The water spray realignment consists of placing a few nozzles on the side of the machine opposite the curtain and tilting the front sprays slightly toward the curtain side. Two underground tests and two independent laboratory tests of the water "spray fan" have been completed. In general, they have confirmed the performance of the spray fan system, but they also have provided useful information as to its difficulties and limitations.

OP 104–84. Bactericidal Control of Acid Problems in Surface Mines and Coal Refuse, by Robert L. P. Kleinmann. Paper in Symposium on Surface Mining Hydrology, Sedimentology and Reclamation, Lexington, KP, Dec. 1–5, 1980, pp. 333–337. A bacterium *Thiobacillus ferroxidans,* accelerates acidification of pyritic material and significantly increases the eventual level of acid production by catalyzing pyrite oxidation in the zone of aeration. Bactericides can be effective in reducing acid formation if added to infiltrating precipitation. However, the bactericidal treatment must be repeated frequently to prevent repopulation. To accomplish this at low cost, the Bureau of Mines developed a controlled release technique involving diffusion and dissolution of anionic detergents from pellets of an elastomeric matrix. Release is expected to continue for approximately 5 yr after application of the pellets. The technique was tested in the laboratory, on small coal refuse piles in central Pennsylvania, and on hydrologically isolated sections of an abandoned surface mine in northern West Virginia. Detergent concentrations of approximately 25 ppm in the pyritic material delayed or prevented acidification of coal refuse and reduced acidity of drainage from acid-producing material by 50% to 95%.

OP 105–84. Control of Acid Mine Drainage Using Anionic Surfactants, by Robert L. P. Kleinmann and Patricia M. Erickson. Paper in Proc. 1st Int. Mine Water Congr., Budapest, Hungary, Apr. 19–23, 1982, pp. 51–63. Acid drainage from abandoned coal mines pollutes thousands of kilometers of streams in the Eastern United States and causes the coal mining industry of the area to spend millions of dollars annually to prevent further degradation of local waterways. To control the formation of acid drainage at its source, the U.S. Bureau of Mines investigated the role of iron-oxidizing bacteria in the oxidation of pyrite. It was determined that inexpensive bactericides can be used to control the rate of pyrite oxidation and thereby reduce the acidity of drainage. At concentrations of 25 mg/L or greater, certain biodegradable anionic surfactants, such as sodium lauryl sulfate, kill the acidophilic iron-oxidizing bacteria in the pyritic material. To prevent repopulation, the surfactant was incorporated into rubber pellets, from which the surfactant is gradually released over time. After an initial application of surfactant solution, these pellets were placed so as to intercept and treat infiltrating rainwater on a surface mine or refuse pile. The rubber formulation can be adjusted to modify the duration of release; results of laboratory studies were used to optimize both phases of the treatment process. The technique was tested in small-scale laboratory and field experiments. Treatment resulted in titratable acidities that were 75 pct lower than those of controls in laboratory simulations, 67 pct lower when one of two 25-metric-ton coal refuse piles was treated, and 95 pct lower when a test was

conducted on isolated sections of an acid-producing surface mine. Large-scale field tests were conducted at surface mines and coal refuse piles in Ohio, West Virginia, and Pennsylvania to provide information on adsorption of the surfactant by fine-grained particles and to determine if downstream concentrations of surfactant pose a potential environmental problem. Preliminary results indicated surfactant concentrations of the effluent of 0.1 mg/L or less, well within the World Health Organization's suggested stream concentrations of less than 1.0 mg/L.

OP 106–84. Field Evaluation of a Bactericidal Treatment To Control Acid Drainage, by Robert L. P. Kleinmann and Patricia M. Erickson. Paper in Symposium on Surface Mining Hydrology, Sedimentology and Reclamation, Lexington, KY, Dec. 7-11, 1981, pp. 325–330. The U.S. Bureau of Mines has demonstrated that inhibition of an iron-oxidizing bacterium, *Thiobacillus ferrooxidans*, slows the rate of pyrite oxidation and thereby reduces acidity in mine drainage from surface mines and coal refuse piles. Long-term inhibition is accomplished at low cost by controlled release of sodium lauryl sulfate (SLS), an anionic surfactant, from rubber pellets. In addition, surfactant solution is applied so as to treat each acre-foot of pyritic material with the equivalent of 7 lb of dry surfactant, excess surfactant must be provided to saturate the adsorption capacity of the material. The surfactant solution reduces subsequent adsorption of the slowly released SLS and provides a rapid reduction in the population of *T. ferrooxidans*. Results of laboratory studies were utilized to optimize both phases of the treatment procedure. Field tests were conducted at inactive, acid-producing surface mines and coal refuse piles at sites in Ohio, Pennsylvania, and West Virginia. It was noted that the effectiveness of the technique required good infiltration of rainfall. Percolation tests at a partially reclaimed site in West Virginia indicated that overburden that had been impacted may be too impermeable for the surfactant to infiltrate to the pyritic material. In contract, 50- to 95-pct reductions in acidity were observed in previous small-scale tests at more permeable sites.

OP 107–84. Full-Scale Field Trials of a Bactericidal Treatment To Control Acid Mine Drainage, by Robert L. P. Kleinmann and Patricia M. Erickson. Pres. at Annu. Meeting, Geol. Soc. Am., New Orleans, LA, Oct. 18–21, 1982. Abstr. With Programs, v. 14, No. 7, pp. 531–532; paper in 1982 Symposium on Surface Mining Hydrology, Sedimentology and Reclamation, Lexington, KY, Dec. 8–10, 1982, pp. 617–622. Sodium lauryl sulfate (SLS) is one of several anionic detergents known to be effective in inhibiting the iron-oxidizing bacterium, *Thiobacillus ferrooxidans*. Since *T. ferrooxidans* plays a critical role in determining the rate of pyrite oxidation, the Bureau of Mines investigated the use of SLS as a method to control the formation of acid mine drainage. In previously reported pilot-scale tests, the detergent successfully controlled *T. ferrooxidans* and thereby reduced acid production 60 to 90 pct. During 1982, the Bureau conducted five full-scale field trials at active and abandoned surface mines and coal refuse piles. The first of these tests was at a 10-acre inactive refuse pile near Beckley, WV. After a 3-month lag period, average acidity decreased from 900 mg/L to 350 mg/L and iron decreased from over 100 mg/L to 2 mg/L. An 8-acre active section of a large refuse pile was treated similarly; acidity and sulfate decreased from over 4,000 mg/L to less than 100 mg/L and iron decreased from 1,000 mg/L to 2 mg/L or less. At both sites, a single application was effective for about 4 months. Other field tests have been conducted at active and abandoned surface mines in Ohio and West Virginia.

OP 108–84. Reclamation and the Control of Acid Mine Drainage, by Robert L. P. Kleinmann and Patricia M. Erickson. Ch. 18 in Papers Presented Before the Abandoned Mine Reclamation Symposium, ed. by N. Smeck and P. Sutton (sponsored by All Ohio Chap., Soil Conserv. Soc. Am., St. Clairsville, OH, Nov. 3–5, 1982). OH State Univ., St. Clairsville, OH, 1982, pp. 18–1—18–12. The Bureau of Mines is currently evaluating reclamation practices in terms of their effect on acid production. Site-related factors, identified prior to reclamation, appear to be critical in abatement of acid production. Recent developments in acid mine drainage control, such as the use of soluble alkaline materials and the application of anionic surfactants to inhibit iron-oxidizing bacteria, are currently in use at active mining operations and are potentially applicable to abandoned mine lands. In addition, the possibility of using vegetation, mulches, and soil amendments to limit the oxygen diffusion into pyritic material is currently being investigated for potential long-term control of acid mine drainage.

OP 109–84. Delineation of Zones of Acid Mine Drainage Using Surface Geophysics, by Kenneth J. Ladwig. Paper in 1982 Symposium on Surface Mining Hydrology, Sedimentology and Reclamation, Lexington, KY, Dec. 5–10, 1982, pp. 279–287. Electromagnetic (EM) induction terrain conductivity surveys were conducted at three reclaimed surface mines in Pennsylvania to evaluate potential applications of the technique in acid mine drainage (AMD) control. At a 6-ha (15-acre) reclaimed strip mine with a perennial acidic seep issuing from the base of the spoil backfill, 2 days of EM surveying defined the locations of two pockets of acid-producing preparation plant refuse buried in the spoil and yielded information on the probable flow of ground water from the acid source to the seep. At an 8-ha (20-acre) reclaimed surface mine with acid discharges from subdrains and an intermittent seep, less than 2 days of EM surveying established the approximate positions of the buried high and low walls, defined probable flow paths to the drain outlets, and located a potential zone of ground water storage within the spoil contributing to the acidic seep. At a 15-ha (37-acre) reclaimed mountaintop removal mine with two large areas of perennial acidic seeps, 3 days of EM surveying located zones of stored water within the spoil and probable flow to the seepage areas. The results of these studies indicate that the high conductivity associated with AMD and AMD sources is a good target for electrical detection. The ease of field operations and clearly defined electrical anomalies associated with AMD and AMD sources distinguish EM as a potentially valuable tool in preliminary site characterization at acid-producing reclaimed surface mines.

OP 110–84. Electromagnetic Induction Methods for Monitoring Acid Mine Drainage, by Kenneth J. Ladwig. Ground Water Monit. Rev., v. 3, No. 1, 1983, pp. 46–51. In the past 15 yr, surface geophysical methods have found an increasing number of applications in ground water contamination monitoring. More recently, electromagnetic (EM) induction methods, long used for mineral exploration, have

been added to the suite of geophysical tools readily adaptable to ground water studies. EM surveys are used to measure terrain conductivity, or inverse resistivity. Field operations with EM methods are fast and simple, providing a rapid means of obtaining good qualitative data on shallow subsurface conductivity distributions. Successful applications of EM surveying have recently been reported for defining landfill leachate plumes and fresh and salt water interfaces. This paper discusses the use of EM methods in reclaimed mining site monitoring for three specific field examples.

OP 111–84. Influence of Passageway Fires on Ventilation Flows, by C. K. Lee, C. C. Hwang, J. M. Singer, and R. F. Chaiken. Ch. 50 in 2nd Mine Ventilation Congress, Reno, NV, Nov. 4–8, 1979. Soc. Min. Eng. AIME, New York, 1980, pp. 448–454. The influence of passageway fires on ventilation flows was investigated in three horizontal fire tunnels: (1) a laboratory-scale fire tunnel network, (2) a small-scale fire-plume tunnel, and (3) a laboratory-scale simulated mine gallery. Wood was used in the first and third tunnels and gas burners were used in the second tunnel to generate passageway fires. Experimental measurements included gas mass flow rate, velocity, temperature, and pressure on the passageways and exhaust fans. The effects of the fires were investigated by comparing the measurements obtained before and during the fires. Results show that a passageway fire essentially increases the flow resistances of the passageways of a tunnel flow network by virtue of volatile fuel mass injection and high combustion temperatures. The ventilation airflow rate is consequently throttled to lower values than that before the fire. At severe throttling, reverse flow occurs. Conditions for reverse flow are characterized by two Froude numbers based on gas velocity and density upstream of the fire and height of the passageway. The Froude numbers and the characteristics of the passageway fire are necessary to analyze mine ventilation-fire interaction and to predict mine ventilation patterns during fires.

OP 112–84. Mine Sealing by Pneumatic Stowing in Ohio, by Slavoljub D. Maksimovic. Ch. 10 in Papers Presented Before the Abandoned Mine Reclamation Symposium, ed. by N. Smeck and P. Sutton (sponsored by All Ohio Chap., Soil Conserv. Soc. Am., St. Clairsville, OH, Nov. 3–5, 1982). OH State Univ., St. Clairsville, OH, 1982, pp. 10-1—10-14. The Bureau of Mines tested a method of constructing mine seals using pneumatic stowing to backfill six abandoned mine openings in Ohio. During the stowing, well-graded aggregate with sufficient fines was ejected from a nozzle at high velocity, creating a high-compaction fill upon impact. The method is safer and faster than conventional methods, it is cost competitive, and it eliminates or reduces the exposure of workers to possible hazards, since they can be kept outside the openings. The technique may be used for sealing abandoned and active mine openings, even in remote locations and during severe weather conditions.

OP 113–84. Ferrous Iron Oxidation by *Thiobacillus Ferrooxidans*: Inhibition With Benzoic Acid, Sorbic Acid, and Sodium Lauryl Sulfate, by Steven J. Onysko, Robert L. P. Kleinmann, and Patricia M. Erickson. Appl. Environ. Microbiol., v. 48, No. 1, July 1984, pp. 229–231. Acid mine drainage is formed by the weathering or oxidation of pyritic material exposed during the mining of coal deposits and is a major water pollution problem in the Appalachian region of the United States. The rate of pyritic material oxidation can be greatly accelerated by certain acidophilic bacteria such as *Thiobacillus ferrooxidans*. These bacteria promote indirect oxidation of pyrite through the catalysis of the oxidation of ferrous iron to ferric iron. These bacteria also may catalyze direct oxidation of pyrite to oxygen. A number of organic compounds, under laboratory conditions, can apparently inhibit both the oxidation of ferrous iron to ferric iron by *T. ferrooxidans*, and the weathering of pyritic material by mixed cultures of acid mine drainage microorganisms. Sodium lauryl sulfate (SLS), an anionic surfactant, has proved effective in this regard. Benzoic acid, sorbic acid, and SLS at low concentrations, each effectively inhibited bacterial oxidation of ferrous iron in batch cultures of *T. ferrooxidans*. The rate of chemical oxidation of ferrous iron in low-pH, sterile batch reactors was not substantially affected at the tested concentrations of any of the compounds.

OP 114–84. General Methods of Primary Dust Control During Cutting, by W. W. Roepke. Min. Eng., v. 36, No. 6, June 1984, pp. 636–644. One phase of Bureau of Mines research deals with reduction of primary respirable dust generated by bit cutting action at a coal seam face. This paper presents a summary of coal cutting technology addressing this problem. All aspects of the cutting system affecting miner health and safety are discussed. Cutting design concepts are considered that minimize dust generation, energy used, and ignitions, while maintaining production. With present equipment, an operator can maintain production and minimize dust energy and ignitions by cutting at maximum depth (maximum sumping or advance rate) at all times, at minimum revolutions per minute with fewest possible bits, and with lowest possible included bit tip angle, i.e., minimum bit wear.

OP 115–84. Insoluble Cross-Linked Starch Xanthate as a Selective Flocculant for Sulfide Minerals, by S. C. Termes, R. L. Wilfong, and P. E. Richardson. Pres. at Soc. Min. Eng. AIME Annu. Meeting, Dallas, TX, Feb. 14–18, 1982. Soc. Min. Eng. AIME Trans., v. 274, 1984, pp. 1971–1977. This paper discusses recent Bureau of Mines research on the selective flocculation of various minerals with insoluble cross-linked starch xanthate (ISX). ISX is insoluble, has a shelf life of more than a year when kept cold, and has a higher molecular weight due to cross-linking than the soluble, noncross-linked starch xanthate used in previous flocculation studies on nonsulfide minerals. ISX readily flocculates a number of sulfide mineral fines, but no siliceous gangue. Floc formation, floc size, and settling rate are dependent on pH. The pH dependence, however, differs for each mineral. Bornite has been selectively flocculated from bornite-quartz mixtures, and the bornite-containing flocs were separated from the unflocculated quartz using decantation and washing procedures.

OP 116–84. Methane Encountered at the Bureau of Mines Oil Shale Shaft, by Robert P. Vinson, Kenneth C. Cox, and Fred N. Kissell. Paper in Proc. 12th Oil Shale Symp., Denver, CO, Apr. 17–20, 1979, pp. 339–842. In studies published in 1975 and 1977, the Bureau of Mines called attention to the possibility that deep oil shale mines would be gassy. The presence of methane gas in mines creates an addi-

tional hazard as well as impacting the economics of mining. In November 1978, a methane ignition occurred in the Bureau of Mines oil shale research shaft in Colorado, which was subsequently classified as gassy by the Mine Safety and Health Administration. In December 1978, a second ignition was followed by a fire that necessitated flooding of the shaft. The present paper briefly reviews the circumstances surrounding those incidents and their implication for methane gas hazards in other oil shale deposits.

OP 117–84. Alloy Plating Using a Particle Occlusion Method, by J. E. Allison, Jr., and G. R. Smith. Paper in 71st Annual Technical Conference, American Electroplaters' Society, SUR/FIN '84, Session K—Alloy Plating I (New York, July 16–19, 1984). Am. Electroplat. Soc., Winter Park, FL, 1984, pp. 1–14. As part of a broad research program on conservation of critical metals, the Bureau of Mines studied a modified aqueous electrodeposition method for preparing stainless steel type alloy coatings. Chromium powder ($\simeq$2 μm) was suspended in an Fe-Ni alloy electroplating bath and occluded in the alloy electrodeposit matrix. The occlusion process was significantly affected by the composition of the electrolyte and the structure and composition of the electrodeposited matrix. A maximum quantity was occluded when the electrodeposited matrix consisted of a crystallographic dual-phase γ(Ni,Fe)-α(Fe,Ni) structure. Up to 21 wt pct Cr was occluded from Cr powder suspensions of 20 vol pct. Heat treatment at 800° to 1,100° C served to homogenize the composite coatings. An interdiffusion region of $\simeq$80 μm was observed at the AISI 1020 substrate–alloy coating interface after heat treatment of a 125-μm-thick composite coating. Martensitic type stainless steel coatings have been produced.

OP 118–84. Oxygen Solubility in Brines, by Stephen D. Cramer. Ind. and Eng. Chem., Process Des. and Dev., v. 23, No. 3, July 1984, pp. 618–620. The solubility of oxygen in water and brines, expressed as the Henry's law constant, is reported for temperatures from 0 to 300° C. A smoothing and interpolation formula based upon a widely used heat capacity equation fit the solubility data well over this temperature range and may be extrapolated to somewhat higher temperatures. The solubility of oxygen in water and brines exposed to air saturated with water vapor is given for temperatures from 0° C to the normal boiling point.

OP 119–84. Solubility of Methane in Brines From 0 to 300° C, by Stephen D. Cramer. Ind. and Eng. Chem., Process Des. and Dev., v. 23, No. 3, July 1984, pp. 533–538. The solubility of methane was measured in brines at temperatures from 0 to 300° C by the technique of gas extraction. Results, expressed in terms of the Henry's law constant, were fit to a smoothing and interpolation formula for subsequent interpretation and analysis. The results can be extrapolated to temperatures above 300° C. The Henry's law constant exhibits maximums in the temperature range 80° to 100° C. Methane is salted out with increased concentration of dissolved salts. The salting-out coefficient is strongly dependent upon temperature. The effect of temperature on solubility in a hypersaline geothermal brine is different from that for the simpler sodium chloride brines owing to the more complex chemistry of the geothermal brine.

OP 120–84. Staged Heap Leaching—Direct Electrowinning, by J. A. Eisele, C. H. Elges, M. D. Wroblewski, and G. E. McClelland. Paper in First International Symposium on Recovery of Precious Metals (sponsored by Int. Symposia on Mining, Reno, NV, June 10–14, 1984). Miller Freeman Publ., San Francisco, CA, 1984, pp. 21–29. The Federal Bureau of Mines, Reno Research Center, is conducting research to develop a staged agglomeration-heap leaching system and to electrowin the dissolved precious metals from the pregnant leaching solution. For direct electrowinning to be successful, the pregnant solutions generated during the initial stages of leaching must be higher grade than obtained by conventional heap leaching. The precious metal concentration of the pregnant solution can be increased by agglomeration pretreatment with cyanide solution that starts the leaching process during the curing period, by leaching with small volumes of solution, and by cycling the leaching solution through more than one heap in a staged manner. The resulting pregnant solution is passed directly through an electrowinning circuit. The barren solution from electrowinning is recycled to the leaching circuit. Bench-scale research on the development of the staged leaching system and on the development of an efficient electrowinning cell is described.

OP 121–84. Improved Sprayfans Provide Ventilation Solutions, by Steven K. Ruggieri, Diane M. Doyle, and John C. Volkwein. Coal Min., v. 21, No. 4, Apr. 1984, pp. 94–96, 98. The Bureau of Mines has refined the original spray-fan system (water sprays that move and direct air) into a simpler and more effective improved spray fan. The system has concentrated sprays at the mine hinge point and increased front spray power and angle to improve the face ventilation of a full-scale laboratory model. Tracer gas testing in the model showed a 40-pct improvement in face ventilation over the original spray-fan system.

OP 122–84. Techniques for Recovering Metal Values From Postflash Geothermal Brines, by L. E. Schultze. Paper in Geothermal Energy: Bet On It!, ed. by R. Wright and R. G. Richards (Geotherm. Resour. Council Annu. Meeting, Reno, NV, Aug. 26–29, 1984). Trans. Geotherm. Resour. Council, Davis, CA, v. 8, Aug. 1984, pp. 159–162. The U.S. Department of the Interior, Bureau of Mines, devised methods for recovering metal values from postflash geothermal brines. A ZnS-PbS concentrate was obtained by treating brine with H_2S and lime. Subsequently iron and manganese were removed by using a lime slurry to adjust the pH of the brine to 8.5. Lithium was precipitated by treating brine with a solution of $AlCl_3$ and adjusting the pH to 7.5 with a lime slurry. The mixed Al-Li precipitate was dissolved with HCl, and the resulting solution was treated with gaseous HCl to separate Li from Al and recover $AlCl_3$ for recycle. The LiCl solution was distilled to recover HCl, and the distillation residue was purified to remove $CaCl_2$. The LiCl product was 99.9 pct pure. The treated brine was acidified to pH 5.5 and returned to the injection well.

OP 123–84. Small Hydropower Development for Mining Industry, by Robert N. Torbin, Steven D. Lautenschlaeger, and Edward D. Thimons. Paper in Water For Resource Development (Am. Soc. Civ. Eng., Hydraulics Div., Conf., Coeur d'Alene, ID, Aug. 14–17, 1984. Am. Soc. Civ. Eng., 1984, pp.

684–688. The high temperatures and humidities encountered in deep mines make a comfortable and healthy work environment difficult and expensive to maintain. Therefore, large refrigeration systems are employed to condition the working air to help control temperature and humidity. The refrigeration systems can be located on the surface or underground on the working levels of the mine. Regardless of location, large quantities of water are required to be brought into the mine to operate these refrigeration systems. The large values of head and flow offer an excellent opportunity for energy recovery due to the large amount of available potential energy. This paper describes a program the Bureau of Mines has undertaken to study the feasibility of recovering this energy.

OP 124–84. Evaluation of Instruments for Monitoring the Effectiveness of Dust Control Techniques, by Kenneth L. Williams. Paper in Proceedings of the Symposium on Control of Respirable Coal Mine Dust (cosponsored by Mine Safety and Health Administration, U.S. Dep. Labor, and labor and management of the coal industry), ed. by J. A. Barrett, M. Jacobson, W. H. Sutherland, G. R. Tinney, and P. M. Turcic, Beckley, WV, Oct. 4–6, 1983, pp. 217–237. The Bureau of Mines is evaluating three dust measuring instruments that could be used to monitor the effectiveness of dust control techniques. The real-time aerosol monitor, a commercially available nephelometer, has been extensively tested and widely used by Bureau research personnel. Another commercially available nephelometer called the MINI-RAM is currently undergoing evaluation by the National Institute for Occupational Safety and Health and the University of Minnesota. The tapered element oscillating microbalance is an experimental prototype that relates the frequency of oscillation of a special tapered element-filter combination to the mass of dust collected on the filter. This presentation includes a description of each instrument, most recent test results, and a brief discussion of potential applications.

OP 125–84. Mineral Industries of China, by E. Chin. Paper in Mining Annual Review, M. West (ed.). The Min. J. Ltd., London, England, reprint, 1984, 4 pp. This paper presents data on the minerals industry of China covering foreign investments; basic tax changes; exploration; and the coal, oil and gas, and iron and steel industries.

OP 126–84. Mineral Industries in the U.S.S.R., by Richard M. Levine. Paper in Mining Annual Review, M. West (ed.). The Min. J. Ltd., London, England, reprint, 1984, 13 pp. This paper presents data on the minerals industry of the U.S.S.R. covering issues and events, mineral industry technology, secondary production, production plans, and foreign trade and assistance.

OP 127–84. In-Line Aeration and Treatment of Acid Mine Drainage, by Terry E. Ackman, Robert L. P. Kleinmann, and Steven J. Onysko. Paper 29 in Symposium on the Reclamation, Treatment and Utilisation of Coal Mining Wastes (Durham, England, Sept. 10–14, 1984). National Coal Board, United Kingdom, Sept. 1984, pp. 29.1–29.12. This report describes a Bureau of Mines designed treatment system, currently in full-scale operation, that has proved to have economic and environmental advantages over conventional treatment. The in-line aeration and treatment system functions in existing acid mine drainage pipelines using the energy of existing mine water discharge pumps. The system offers reduced maintenance, operating, and capital costs as well as improved iron oxidation reaction time.

OP 128–84. Evaluating and Improving Materials for Mineral Processing, by R. Blickensderfer, J. H. Tylczak, B. W. Madsen, and J. S. Hansen. Paper in Int. Conf. on Tribology in Mineral Extraction War on Wear, London, England, Sept. 17–19, 1984. Mech. Eng. Publ. Ltd., London, England, v. 11, No. C347/84, 1984, pp. 15–21. The Bureau of Mines, U.S. Department of the Interior, is actively engaged in the war on wear. The emphasis of its research is on improving the wear resistance of materials that contain strategic and critical metals by applying metallurgical processes such as heat treatment and microstructural control. Another approach is to reduce the amounts of strategic and critical metals in certain alloys while maintaining adequate wear resistance by substituting other metals or by using alternative metallurgical processes. Because the greatest wear losses occur during comminution of ore, materials used in crushing and grinding mills have received much attention. This paper presents research on spalling and abrasion of commercial grinding balls and white cast irons, abrasion resistance of low-alloy steels, cast-on hardsurfacing, slurry wear of materials, and ball mill erosion-corrosion.

OP 129–84. Substitutes for Chromium in Stainless Steels, by John S. Dunning, Max L. Glenn, and Howard W. Leavenworth, Jr. Met. Prog., v. 126, No. 5, Oct. 1984, pp. 19–24. The United States is completely dependent upon foreign sources for chromium, with major reserves concentrated in the Republic of South Africa and Zimbabwe. Although supplies of chromium are said to be sufficient for 600 years, the economic and strategic consequences of a disruption in this supply for a lengthy period could be quite serious. Concern for U.S. dependence on foreign sources for chromium has prompted research by the Bureau of Mines and others that has begun to clarify some options for potential substitution. The focus of this article is on elements that can replace all or part of the chromium in stainless steels.

OP 130–84. A Spray Fan To Deliver More Air to the Coal Face, by Fred Kissell. Paper in Proc. 1978 National Safety Congress, Chicago, IL, Oct. 12–15, 1978, p. 14. The conventional water spray of the sort found on mining machinery is known to move a moderate quantity of air. This research showed that if all of the water sprays on a continuous miner were arranged to act in concert, then a substantial amount of air could be moved to the working face during cutting. The result is a lowering of methane concentrations and greatly reduced probability of face ignitions.

OP 131–84. New Developments in Mine Ventilation, by Fred N. Kissell. Ch. 6 in Underground Mining Methods Handbook, ed. by W. A. Hustrulid. Soc. Min. Eng. AIME, 1982, pp. 1674–1679. Recent developments in mine ventilation are reviewed. For hard-rock mines, the list includes new types of stoppings and a method to easily measure stopping leakage. A tracer gas technique for measuring mine ventilation airflow is also discussed. For coal, items

include improvements in face ventilation, drainage of methane, and forecasting methane emissions.

OP 132–84. Measuring the Methane Content of Coalbeds for Resource Evaluation, by Charles M. McCulloch, Jeffrey R. Levine, Fred N. Kissell, and Maurice Deul. Pres. at Geol. Soc. Am. Annu. Meeting, Salt Lake City, UT, Oct. 20–22, 1975. Abstr. With Programs, 1975, pp. 1194–1195. The methane content of coalbeds can be measured prior to mining by using a simple Bureau of Mines technique called the "direct method." Coal cores from exploration drilling are enclosed in an airtight canister when the core barrel is brought to the surface. Methane emitted into the canister from the coal core is used to calculate coalbed gas content.

OP 133–84. Overview of Bureau of Mines Coal Mine Research, by John N. Murphy. Min. Technol., v. 66, No. 766, Aug. 1984, pp. 259–272. The Bureau of Mines mining research program is divided into two principal problem areas: health and safety and conservation and development; both programs address coal as well as metal and nonmetal problems, but this paper is limited to coal mining activities. The health and safety program addresses problems in underground and surface mines and in surface facilities associated with those mines. The conservation and development program focuses on problems relative to reducing the environmental impact of productivity and resource recovery. The emphasis of this paper is directed toward recent accomplishments that will be available to industry in the near future.

OP 134–84. Chemical and Electrochemical Reactions in the Chalcocite-Xanthate System, by C. S. O'Dell, R. K. Dooley, G. W. Walker, and P. E. Richardson. Paper in Proceedings of the International Symposium on Electrochemistry in Mineral and Metal Processing, ed. by P. E. Richardson, S. Srinivasan, and R. Woods (165th Meeting sponsored by Electrochem. Soc., Cincinnati, OH, May 6–11, 1984). Electrochem. Soc., Inc., Pennington, NJ, v. 84–10, 1984, pp. 81–95. The interactions between chalcocite and ethylxanthate were examined by the Bureau of Mines in an electrochemical-microflotation cell containing a particle bed working electrode. Cyclic voltammetry showed the formation of a chemisorbed product commencing at −0.5 V (saturated calomel electrode) with bulk oxidation products, possibly cuprous xanthate, forming above −0.23 V. Relating the charge passed on a potentiostated mineral bed after addition of xanthate to spectrophotometric changes in xanthate suggests the presence of a fast chemical reaction and a charge transfer reaction. The strong correlation between flotation response and potential indicates that chemisorption of the ethylxanthate produces a hydrophobic layer sufficient for chalcocite flotation.

OP 135–84. Keystone Achieves Positive Dust Control During Dry Drilling, by Steven J. Page and Mark Folk. Eng. and Min. J., v. 185, No. 9, Sept. 1984, pp. 84–85. In conventional room-and-pillar mining, the drilling of mining faces is frequently a severe source of airborne dust. Without the use of effective dust control, instantaneous total dust concentrations occasionally reach or exceed 200 mg/m^3, and the time-weighted average often exceeds the 10-mg/m^3 total dust standard. The control of dust produced by face drilling includes dry collection systems or the following three wet dust suppression systems: external water sprays, water injection through the drill, or foam injection through the drill.

OP 136–84. Correlations Between Measurements With RAM-1 and Gravimetric Samplers on Longwall Shearer Faces, by Steven J. Page and Robert A. Jankowski. Am. Ind. Hyg. Assoc. J., v. 45, No. 9, 1984, pp. 610–616. Simultaneous RAM-1 and gravimetric personal sampler respirable dust measurements were made by the Bureau of Mines at two locations adjacent to a moving shearer on longwall faces. These locations were (1) 4.6 to 6.1 m (15 to 20 ft) on the ventilation intake side of the shearer headgate drum and (2) at the shearer midpoint, between the two operators. Despite the fact that the RAM-1 monitors were laboratory-calibrated to five equivalent readings, underground readings were often lower, particularly at the intake side of the shearer. The RAM-gravimetric ratio of all readings was 0.53 at the intake position and 0.75 at the midpoint position for all data. When only head-to-tail cut passes were analyzed, the RAM-gravimetric ratios were 0.58 at the intake position and 1.00 at the midpoint position. The difference between RAM and gravimetric dust readings is attributed to a combination of factors such as ambient air velocity and cyclone orientation.

OP 137–84. Semiconducting Characteristics of Galena Electrodes, by P. E. Richardson and C. S. O'Dell. Paper in Proceedings of the International Symposium on Electrochemistry in Mineral and Metal Processing, ed. by P. E. Richardson, S. Srinivasan, and R. Woods (165th Meeting sponsored by Electrochem. Soc., Cincinnati, OH, May 6–11, 1984). Electrochem. Soc., Inc., Pennington, NJ, v. 84–10, 1984, pp. 132–151. Electrochemical, interfacial capacitance, and surface photovoltage measurements were used by the Bureau of Mines in a study of oxygen reduction and xanthate chemisorption on in situ cleaved natural and synthetic lead sulfide crystals. Electrodes cleaved in nitrogen sparged 0.1*M* sodium tetraborate assume the flatband potential, V_{fbp}, at the instant of cleavage, and thus the cleavage potential decreases with increasing bulk electron concentration. Highly n-type electrodes have a cleavage potential (V_{fbp}) of $\simeq$ −0.6 V (SCE [saturated calomel electrode]), and highly p-type electrodes have a value of $\simeq$ −0.2 V (SCE). The space charge is readily varied by applied potentials in the range −0.2 to −0.6 V. The effect of the variable space charge layer on oxygen reduction and xanthate chemisorption is discussed.

OP 138–84. Ventilation Monitoring Instrumentation, by George H. Schnakenberg, Jr., and Fred N. Kissell. Ch. 5 in Underground Mining Methods Handbook, ed. by W. A. Hustrulid. Soc. Min. Eng. AIME, 1982, pp. 1669–1678. Currently available ventilation monitoring instrumentation is reviewed. Price and availability are discussed. Guidelines for proper use of the most common air velocity instruments are given, and their performance limitations reviewed. MSHA-approved gas detectors are listed.

OP 139–84. Zinc and Copper Electrowinning Combined With Sodium Perchlorate Production, by G. R. Smith. Paper in Proceedings of the International Symposium on Electrochemistry in Mineral and Metal Processing, ed. by P. E. Richardson, S. Srinivasan, and R. Woods (165th Meeting sponsored by Electrochem. Soc., Cincinnati, OH, May 6–11, 1984). Electrochem. Soc., Inc., Pennington, NJ, v. 84–10, 1984,

pp. 548–561. Electrolysis studies by the Bureau of Mines have demonstrated that zinc and copper electrowinning can be combined with the electrochemical production of sodium perchlorate in a cationic membrane cell to achieve a significant decrease in the use of electrolysis energy. Current efficiencies exceeding 88 and 80 pct were obtained for electrowinning and electrochemical production, respectively, using typical current densities, electrolyte compositions, and electrolysis periods. The cationic membrane effectively separated the two half-cells, allowing as low as 1.5 pct (0.9 g) of the Zn^{2+}, 0.02 pct (0.01 g) of the Cu^{2+}, 0.9 pct (0.25 g) of the ClO_4^-, and 1.0 pct (2.9 g) of the SO_4^{2-}, to interdiffuse during electrolysis.

OP 140–84. Upgrading High-Iron Chromite Concentrates by Carbonyl Processing, by A. Visnapuu and W. M. Dressel. Ch. 16 in Process Mineralogy III. Applications in Metallurgy, Coal, Concrete, Smelting and Exploration, ed. by W. Petruk (Proc. Symp. sponsored by Process Mineral. Comm., SME-AIME Annu. Meeting, Atlanta, GA, Mar. 6–10, 1983). Soc. Min. Eng. AIME, New York, 1984, pp. 259–274. The Bureau of Mines, U.S. Department of the Interior, has upgraded high-iron domestic chromite concentrate to high-chromium concentrate by a laboratory carbonyl process. The chromite concentrate product has a chromium-to-iron ratio in excess of 3:1 compared with the starting concentrate ratio of 1.6:1. The high-iron chromite was first reduced to convert the iron oxides to the metal, and then treated with carbon monoxide at elevated pressures and low temperatures to convert the metallic iron fraction to iron pentacarbonyl. Carbonylation was accelerated by the addition of hydrogen sulfide in small quantities. A constant flow of carbon monoxide swept the iron pentacarbonyl formed in the reactor out through a pressure-reducing valve. The mixture of carbon monoxide and iron pentacarbonyl at atmospheric pressure was then passed through a heated section to decompose the iron pentacarbonyl to carbon monoxide and iron, whereupon the latter plated out on the heated surface. Carbon monoxide pressure, temperature, and promoter trends for enhanced carbonylation are presented.

OP 141–84. Correlation of the Electrosorption of Sulfur and Thiol Collectors With Contact Angle and Flotation, by G. W. Walker, C. P. Walters, and P. E. Richardson. Paper in Proceedings of the International Symposium on Electrochemistry in Mineral and Metal Processing, ed. by P. E. Richardson, S. Srinivasan, and R. Woods (165th Meeting sponsored by Electrochem. Soc., Cincinnati, OH, May 6–11, 1984). Electrochem. Soc., Inc., Pennington, NJ, v. 84–10, 1984, pp. 202–218. The hydrophobic character of a variety of base-metal sulfides was examined in the presence of sodium hydrosulfide and potassium ethylxanthate. The magnitudes of hydrophobicity induced by electrodeposition of sulfur and by electrochemical reaction between the minerals and ethylxanthate were determined by contact angle measurements on polished surfaces and by flotation of mineral particles. During flotation, mineral-reagent interactions were followed by monitoring the solution composition spectrophotometrically. The results show that on gold and chalcopyrite the oxidation of hydrosulfide to sulfur and the oxidation of ethylxanthate to dixanthogen produced hydrophobic surfaces, while on pyrite, sulfur deposition was more effective than dixanthogen in producing a hydrophobic surface. Chalcocite, in contrast to gold, chalcopyrite, and pyrite, was found to react directly with ethylxanthate and hydrosulfide, but only the metal xanthate product was hydrophobic. Covellite, which is a possible product of the reaction between hydrosulfide and chalcocite, did not react with hydrosulfide but behaved more like a catalytic surface for the deposition of sulfur.

OP 142–84. Agglomeration Heap Leaching of Precious Metals, by J. A. Eisele and D. L. Pool. Paper in Leaching. Unit Operations and Processes (14th Annu. Hydrometall. Meeting, Timmins, Ontario, Canada, Oct. 14–17, 1984). CIM Metall. Soc., Timmins, Ontario, Canada, No. 11, 1984, pp. 1–15. The Bureau of Mines developed a particle agglomeration technique to improve the flow of leaching solution through heaps of low-grade gold and silver ores that contain clays. Bench-scale experiments and industrial practice show that the percolation rate of cyanide leaching solution is greatly enhanced by mixing the ore with Portland cement as a binder, moistening the mixture, mechanically tumbling to form agglomerates, and aging before heap building and leaching. A slight modification of the technique allows its application to precious-metal-bearing tailings, which cannot normally be treated by heap leaching because they are too fine.

OP 143–84. Cutting Trials With a Water-Jet-Assisted In-Seam Tester, by Robert J. Evans, Howard J. Handewith, and Michael Hood. Ch. 78 in Rock Mechanics in Productivity, Protection (25th Symp. on Rock Mechanics, Chicago, IL, June 25–27, 1984), pp. 767–773. An in-seam tester, a hydraulically activated single-pick instrument to measure and record pick cutting forces, was designed and fabricated to establish criteria necessary for the design and development of a water-jet-assisted rotary drum cutting system using moderate-pressure jets (3,000 to 10,000 psi). Data are presented for cutting trials in a simulated coal block and underground in the Pittsburgh coal seam for water-jet assist and dry cutting. Data analyses indicate that water-jet assist significantly reduces pick forces.

OP 144–84. Assessment of Environmental Impacts Associated With Phosphogypsum in Florida, by Alexander May and John W. Sweeney. Paper in The Chemistry and Technology of Gypsum, ed. by R. A. Kuntze (Symp. sponsored by ASTM Committee C-11 on Gypsum and Related Building Materials and Systems, Atlanta, GA, Apr. 14–15, 1983). ASTM Spec. Tech. Publ. 861, Oct. 1984, pp. 116–139. In its role to provide technology to prevent or limit adverse environmental impacts associated with mining or minerals processing, the U.S. Bureau of Mines has conducted research at its Tuscaloosa Research Center to assess the environmental impacts of phosphogypsum produced by the Florida phosphate industry. Over the years, stockpiles containing 304 million metric tons of phosphogypsum have accumulated, and the industry continues to generate an additional 30 million metric tons per year. Samples from approximately 300 m of drill core, obtained from 9 stockpiles, were characterized using chemical, X-ray diffraction, emission spectrographic, radiological, and physical means. The data developed indicated that phosphogypsum is not a corrosive or toxic hazardous waste as defined by the Environmental Protective Agency criteria. Radium analyses averaged 21 pCi/g and its content was inversely related to particle sizes. Thirty-nine elements were detected in phosphogypsum; concentrations of these elements did not vary with depth within the stockpiles.

OP 145–84. Evaluation of Radium and Toxic Element Leaching Characteristics of Florida Phosphogypsum Stockpiles, by Alexander May and John W. Sweeney. Paper in The Chemistry and Technology of Gypsum, ed. by R. A. Kuntze (Symp. sponsored by ASTM Committee C-11 on Gypsum and Related Building Materials and Systems, Atlanta, GA, Apr. 14–15, 1983). ASTM Spec. Tech. Publ. 861, Oct. 1984, pp. 140–159. The U.S. Bureau of Mines conducted studies to determine if phosphogypsum, a waste material from the processing of phosphate rock, contains hazardous toxic materials as defined by the Environmental Protection Agency (EPA) and whether leaching of these toxic materials and radium may occur. Samples of the phosphogypsum stockpiled material were evaluated using the EPA extraction procedure, atomic absorption, neutron activation, X-ray diffraction, and chemical and physical means. Radiological tests performed used both the germanium-lithium and emanation methods. The data show that the phosphogypsum stockpiles are not hazardous toxic waste as defined by EPA criteria. Trace elements and radium are not leached from the phosphogypsum stockpiles. Absorption of trace elements and radium by phosphogypsum is the major reason for their not being leached. The standard error of measurement of radium concentrations was 4.7 pCi/g.

OP 146–84. CSM-USBM Rotary Cutting Machine: Research Capabilities and Trials for Improving the Performance of Tunnel, Shaft and Raise Boring Machines, by Levent Ozdemir, Robert J. Evans, Russell J. Miller, and William Sharp. Ch. 7 in 1983 RETC Proceedings, Volume 1 (6th Rapid Excavation and Tunneling Conf., Chicago, IL, June 12–16, 1983). CO School of Mines, Golden, CO, 1983, pp. 106–130. This paper describes the specifications and capabilities of a 6-ft (1.83-m) diameter laboratory rotary cutting machine that was designed and fabricated under a Bureau of Mines contract awarded to the Colorado School of Mines. The machine will be used to carry out research and development programs aimed toward improving the design and operation of mechanical tunnel, shaft, and raise boring equipment.

OP 147–84. Development of a Water Jet Assisted Drag Bit Cutting Head for Coal Measure Rock, by Levent Ozdemir and Robert J. Evans. Ch. 41 in 1983 RETC Proceedings, Volume 2 (6th Rapid Excavation and Tunneling Conf., Chicago, IL, June 12–16, 1983). CO School of Mines, Golden, CO, 1983, pp. 701–718. An ongoing research program at the Colorado School of Mines is investigating the application of low-to-moderate pressure water jets to assist the cutting performance of drag-type cutter bits commonly used on coal mine cutting machinery. The results to date indicate that a water jet directed to impinge the rock in the immediate vicinity of cutter tip can provide significant benefits in terms of reduced cutting forces, prolonged bit life, and less airborne dust, as well as reduced tendency of sparking during cutting. This paper describes the findings of this research effort designed to fully evaluate and optimize the parameters affecting the performance of a combined water-jet-assisted, drag-bit cutting system for coal mine applications.

OP 148–84. Water Jet Coal Cutting: The Resurgence of an Old Technology, by William E. Souder and R. J. Evans. Ch. 42 in 1983 RETC Proceedings, Volume 2 (6th Rapid Excavation and Tunneling Conf., Chicago, IL, June 12–16, 1983). CO School of Mines, Golden, CO, 1983, pp. 719–739. From time to time, major technological innovations arise that alter the time-honored ways of doing things. Such innovations can dramatically benefit society in terms of new products, increased outputs, reduced costs, and general modernizations. However, the advent of these types of technologies is likely to be resisted because of their uncertain potentials, and because they disrupt established routines and industry patterns. This paper reviews the case history of water jet coal cutting, and assesses its potential to become a major innovation within the next decade.

OP 149–84. Some Patterns of Technology Transfer and Utilization in Water Jet Cutting, by William E. Souder and R. J. Evans. Paper in The Second U.S. Water Jet Symposium, ed. by D. A. Summers and F. F. Haston (sponsored by School of Mines & Metallurgy, Univ. MO—Rolla, MO, May 24–26, 1983). Univ. MO—Rolla, MO, 1983, pp. 225–234. From time to time, major technological innovations arise that alter the time-honored ways of doing things. Such innovations can dramatically benefit society in terms of new products, increased outputs, reduced costs, and general modernizations. However, the advent of these types of technologies is likely to be resisted because of their uncertain potentials, and because they disrupt established routines and industry patterns. This paper reviews the case history of water jet coal cutting and assesses its potential to become a major innovation within the next decade.

OP 150–84. Chlorination-Grade Feedstock From Domestic Ilmenite, by John B. Wright, Gerald W. Elger, Jack E. Tress, and Harry E. Bell. Pres. at Soc. Min. Eng. AIME Fall Meeting, Denver, CO, Oct. 24–26, 1984. Soc. Min. Eng. AIME preprint 84–379, 1984, 13 pp. This paper describes laboratory techniques and subsequent results of Bureau of Mines research to produce chlorination-grade feedstock from an abundant, low-grade, domestic, rock ilmenite ore. The research is part of the Bureau effort to devise technology that may help decrease U.S. dependence on imported raw materials. A rock ilmenite containing about 46 wt pct TiO_2 was smelted in an electric arc furnace with coke, woodchips, and Na_2CO_3 to separate most of the iron as pig iron and to form a low-iron, titanium-enriched slag. The slag was ground, pelletized, oxidized, and then sulfated with mixtures of SO_2 and air in a continuous 4.5- to 9.1-kg/h apparatus at 1,023 to 1,223 K. The sulfated slag, containing 60 to 65 pct TiO_2, was reground and leached in water at ambient temperature to decrease the combined levels of the troublesome Ca, Mg, and Mn impurities from 7.0 to 1.7 wt pct. At levels of more than 3 wt pct, these impurities contribute to operating and disposal problems. The final product was upgraded to about 84 wt pct TiO_2. This material potentially is suitable for chlorination in a fluidized-bed reactor. The most favorable results were achieved with leached slag sulfated at a feedrate of 4.5 kg/h and at temperatures of 1,073 to 1,123 K.

OP 151–84. Strategy in Reducing Dust in the Coal Mines of the United States, by John A. Breslin. Paper in VIth International Pneumoconiosis Conference, Bochum, Federal Republic of Germany, Sept. 20–23, 1983. ILO, Washington, DC, v. 3, 1984, pp. 1724–1729. This paper describes the strategy and the technical measures used in the United States to control respirable dust in coal mines. Federal law limits the average respirable dust concentration to

which each coal miner may be exposed to no more than 2.0 mg/m³. The allowable dust limit is reduced if the quartz content of the dust exceeds 5 pct. Dust measurements are made in the mines using personal gravimetric dust samplers worn by the miners. The average dust concentration for continuous mining machine operators was reduced from about 6.5 mg/m³ in 1968 to 1.3 mg/m³ in 1980. This success was due primarily to improvements in face ventilation. In some mines significant dust reductions have been achieved by use of dust collectors mounted on the mining machines. Control of dust is much more difficult for longwall operations, and the Bureau of Mines has conducted extensive research since 1979 to alleviate this problem. Some new techniques have been developed that enable mine operators to comply with the 2.0 mg/m³ dust standard for longwalls. One new technique uses the air entrained by water sprays to divert dust away from the shearer operators and reduces dust exposure by as much as 50 pct. Dust reductions have also been achieved by improvements in longwall face ventilation, more efficient use of water, and modifications in the methods of coal cutting.

OP 152–84. Direct Electrowinning of Gold, by C. H. Elges III, M. D. Wroblewski, and J. A. Eisele. Paper in Proceedings of the International Symposium on Electrochemistry in Mineral and Metal Processing, ed. by P. E. Richardson, S. Srinivasan, and R. Woods. Electrochem. Soc., Pennington, NJ, v. 84–10, 1984, pp. 501–512. Electrowinning gold and silver from cyanide leaching solutions has been utilized by industry for many years. Steel wool cathodes are loaded to high levels with precious metals and fire-refined to produce dore bullion. If the leaching solutions are dilute, the gold and silver are concentrated by adsorption on activated carbon, followed by desorption in order to produce a strong enough solution for electrowinning. The electrowinning cells are operated at about 80° C, which is the solution temperature coming from stripping. The Bureau of Mines is developing an electrowinning cell having improved mass transfer (IMT) characteristics. The gold and silver are deposited onto steel wool cathodes directly from dilute leaching solutions, and the carbon adsorption-desorption step is avoided. An additional benefit is that electrolysis can be done at ambient temperatures and does not require heating large quantities of solution. By fortifying the dilute leaching solution with NaOH and recirculating the electrolyte rapidly within the cathode compartment, better current efficiency and deposition rates were obtained at ambient temperature with the IMT cell than with the conventional Zadra cell.

OP 153–84. Improved Face Ventilation by Spray Jet Systems, by Fred N. Kissell. Paper in Proceedings of the Second Annual Mining Institute 1979 (cosponsored by MSHA and AL Miner. Resour. Inst.), Tuscaloosa, AL, Apr. 11–13, 1979, pp. 1–12. Under a Bureau of Mines contract, methods were developed to increase significantly the amount of fresh air that reaches the front of a continuous mining machine. The emphasis was on removing methane buildups that occur at the cutterhead. Using a full-scale plywood mockup of a coal mine working face area, the study showed that in many instances only about 20 pct of the fresh air heading toward an exhaust brattice or tubing actually gets to within 1 ft of the face. To provide more air at the face, the natural airflow pattern should be enhanced and moved forward. The change in the natural airflow pattern can be accomplished by taking advantage of the air-moving abilities of a conventional water spray. It was discovered that by realigning a few nozzles on the side of the machine opposite the curtain and tilting the front sprays slightly toward the curtain side, the ventilation efficiencies of 70 pct or more were achieved regularly. This meant that if 9,000 cfm of air was entering the brattice, at least 6,300 cfm of the air was reaching to within 1 ft of the face.

OP 154–84. The Advantages of Inhole Motor Drilling, by Stephen J. Kravits, Albert Sainato, and Gerald L. Finfinger. Coal Min., v. 21, No. 11, Nov. 12, 1984, pp. 44–46. The Bureau of Mines pioneered the rotary drilling technology of horizontal boreholes into coal as an effective method of removing methane from coalbeds. To date, more than 10 billion cu ft of methane has been removed, consistently reducing methane emissions at active faces by at least 50%. Although horizontal boreholes have been drilled to depths greater than 2,500 ft, inherent problems have prevented universal acceptance of this technique. This paper presents a discussion on the advantages of inhole motor drilling compared with rotary drilling.

OP 155–84. Leaching Sulfide Minerals by Oxidative Electrolysis in Membrane Cells, by K. P. V. Lei and T. G. Carnahan. Paper in Proceedings of the International Symposium on Electrochemistry in Mineral and Metal Processing, ed. by P. E. Richardson, S. Srinivasan, and R. Woods. Electrochem. Soc., Pennington, NJ, v. 84–10, 1984, pp. 374–390. Sulfide minerals present a significant resource for strategic, precious, and base metals. The Federal Bureau of Mines is investigating an oxidative-electrolysis procedure for leaching sulfide minerals. Leaching of sulfide minerals was performed by electrolysis of sodium chloride solution in cells equipped with ion-selective membranes to separate the anodic and cathodic reactions. The metal sulfide minerals were oxidized by chlorine produced at the anode and converted to soluble metal ions, sulfate ions, and elemental sulfur. Sodium hydroxide was simultaneously generated at the cathode. The objectives of this paper are to discuss the important requirements for developing a membrane electrolysis cell, to review past and current results on the oxidative-electrolysis leaching of sulfide minerals or materials, and to demonstrate the feasibility of incorporating the leaching technique into a viable hydrometallurgical process.

cell-grade, 25-ton-per-day pilot plant, preliminary design .....OFR 122(1)—(6)–80
domestic availability, Minerals Availability Program appraisal ..... IC 8861
extraction, from dawsonite-bearing oil shale .. RI 8796
from aluminum chloride hexahydrate, thermal decomposition, patent ..... P 18–83
from aluminum nitrate solutions, patent ..... P 15–81
from anorthosite, hydrochloric acid-fluoride-gas sparging process ..... RI 8806
from anthracite culm, with energy recovery OFR 121–83
from clay, aluminum chloride hexahydrate crystallization by hydrogen chloride sparging ..... RI 8590
aluminum chloride leach liquor, iron removal from RI 8560
aluminum chloride solutions, organic contaminant removal ..... RI 8619
aluminum nitrate nonahydrate calcination . RI 8705
basic chloride method ..... RI 8866
chlorination rates of aluminous resources .. IC 8952
clay chlorination chemical equilibria ..... RI 8696
corrosion resistance of materials used in recovery RI 8565
direct calcination of aluminum chloride . OFR 62–81
effects of feed preparation on hydrochloric acid leaching ..... RI 8618

Alumina, from clay, hydrochloric acid leaching using hydrogen chloride for crystallization, environmental impact ..... OFR 165(1)–81
hydrochloric acid process, bench-scale study RI 8476; OP 26–83
clay feed factors ..... RI 8772
leaching rates ..... RI 8744
miniplant material balance ..... RI 8759
pilot plant site environmental evaluation OFR 165(2)–81
treatment of ferric chloride stripping liquor RI 8725
hydrogen chloride sparging crystallization of aluminum chloride hexahydrate ..... RI 8593
hydrolysis of aluminum hydroxy sulfate from aluminum sulfate solution ..... RI 8550
metallurgical processes, environmental factors OFR 70–81
miniplant solids-liquid separation tests .... RI 8805
nitric acid leaching ..... RI 8834
environmental impact ..... OFR 165(1)–81
offgas use for crystallization ..... OFR 62–81
sulfurous acid-caustic purification process .. IC 8959
sulfurous acid leaching ..... RI 8533
from coal waste, waste composition and availability IC 8940
from coal wastes ..... OFR 139–84
from kaolin, aluminum chloride leaching .. OP 13–84
from nonbauxitic resources, miniplant project OP 53–81
from U.S. nonbauxitic resources ..... OP 35–84
miniplant operation, aluminum chloride liquor from leach residue ..... RI 8831
misted raw kaolin feed, production ..... RI 8712
reactor design effect on kaolin attrition .... RI 8877
miniplant tailings, sand bed dewatering ..... RI 8677
production, cell feed material preparation .. OP 43–81
recovery, from anorthosite lime sinter processing RI 8714
from powerplant coal ash ..... RI 8721; OP 70–82
recycled, refractory use ..... OP 80–82
Alumina carbochlorination, reaction kinetics OFR 101–83
Alumina miniplant, aluminum nitrate nonahydrate crystallization ..... RI 8830
aluminum oxide from alunite pellets ..... RI 8821
clay-hydrochloric acid leaching, material balance RI 8759
iron solvent extraction, aluminum nitrate liquor OFR 64–83
kaolin calcination, in direct-fired rotary kiln .. RI 8736
solids-liquid separation tests ..... RI 8805
Alumina pilot plant, 25-ton-per-day capacity, estimated costs ..... OFR 122(1)—(6)–80
preliminary design ..... OFR 122(1)—(6)–80
Alumina refractories, high-temperature corrosion resistance, to lignite ash slags ..... RI 8430
Alumina refractory brick, thermal properties, oxide and salt solution effect ..... RI 8845
Alumina refractory concretes, coal gasification effect on OP 39–81
Aluminosilicate materials, sulfuric acid reactions OFR 37–83
Aluminum, annual data ..... MY 1983 (v. 1)
availability, market economy countries ..... IC 8917
chloride solutions, in alumina from clay, organic contaminant removal ..... RI 8619
chromium partial replacement in stainless steels RI 8918
extraction, from anorthosite, using hydrochloric acid and fluoride ..... RI 8694
facts and problems ..... B 671
from clay, chloride process ..... IC 8923
patent ..... P 10–83
from Georgia kaolin, characterization .... OFR 172–84
Aluminum, from kaolinite, role and structure of hydrogen ions ..... OFR 66–84
general information ..... MCP
in stainless steel, sulfidation and oxidation resistance RI 8856
in superalloy scrap recycling, leaching rate increase RI 8833
interference, during CO reduction of laterite ores OFR 29–80
recovery, from aluminum salt slags, experimental process ..... RI 8446
from Pacific sea nodules, using sulfur dioxide OP 51–81
separation, from shredded auto scrap ..... RI 8771
separation of wrought and cast, hot-crush technique OP 74–83
patent ..... P 5–82
soft-soldering system ..... RI 8747
thermodynamic data ..... B 672
U.S. consumption by end use, statistical projection method ..... IC 8825
Aluminum alloy, impacting on rusted steel, incendivity measurement ..... RI 8684
Aluminum chloride, alumina from clay, offgas use for crystallization ..... OFR 62–81
vapor complex formation with aluminum raw material impurity elements ..... OFR 63–81
Aluminum chloride-ferric chloride system, vapor-liquid equilibria ..... OP 50–83
Aluminum chloride hexahydrate, decomposition in hydrogen gas, patent ..... P 14–81
fluidized-bed decomposition ..... OP 29–83
from kaolinitic clay, strong acid-weak acid method RI 8908
hydrogen chloride sparging crystallization ... RI 8590
from aluminum chloride liquor ..... RI 8593
thermal decomposition, patent ..... P 18–83
Aluminum chloride leach liquor, iron removal from, solvent extraction ..... RI 8560
separation from leach liquor residue, horizontal belt filtration ..... RI 8831
Aluminum chloride leach liquors, separation of undissolved siliceous residue from, by vacuum belt filtration ..... IC 8873
Aluminum chloride solutions, boehmite from, hydrothermal precipitation ..... OFR 121–80
Aluminum dross, recycling, as refractory-grade bauxite substitute ..... OP 80–82
Aluminum hydroxy sulfate, from aluminum sulfate solution, by high-temperature hydrolysis RI 8550
Aluminum industry, market instability ..... OFR 97–81
Aluminum nitrate leach liquors, iron extraction from RI 8634
Aluminum nitrate liquor, iron solvent extraction OFR 64–83
Aluminum nitrate nonahydrate, calcination, in a fluidized bed ..... RI 8705
crystallization, alumina miniplant ..... RI 8830
Aluminum nitrate solutions, alumina from, patent P 15–81
Aluminum oxide, from alunite pellets, reduction-oxidation roasting ..... RI 8821
from anorthosite lime sintering, leach liquor desilication ..... RI 8713
Aluminum raw materials, vapor complex formation between aluminum chloride and impurity elements ..... OFR 63–81
Aluminum salt slags, aluminum recovery from, experimental process ..... RI 8446
Aluminum smelter potlining, as fluorspar substitute in basic oxygen steelmaking ..... RI 8699, 8775
as fluorspar substitute in cupola ironmelting RI 8530, 8775
Aluminum sulfate solution, aluminum hydroxy sulfate from, high-temperature hydrolysis ..... RI 8550

Aluminum sulfate solution, high-temperature hydrolysis, patent ..... P 15–83
Aluminum sulfide, high-temperature enthalpy and X-ray powder diffraction data ..... RI 8526
thermodynamic data ..... OP 48–81
Alunite pellets, reduction-oxidation roasting ... RI 8821
American Samoa, mineral industry, annual review MY 1983 (v. 2)
Americium, thermodynamic data ..... B 672
Amine flotation, chromite ores, from Stillwater Complex RI 8502
chromium recovery from chromite ores, patent P 1–82
Ammonia, facts and problems ..... B 671
Ammoniacal-ammonium sulfate leach, cobalt recovery from, lignite use ..... RI 8870
nickel-copper-cobalt recovery from, patent .... P 12–81
Ammonium leaching, iron-cobalt alloys, cobalt behavior OFR 64–84
Ammonium nitrate, molten, thermal degradation effect on oil shale ..... OP 62–83
Ammonium nitrate-fuel oil, reactivity with pyrite, inhibitor evaluation ..... RI 8727
Ammonium nitrate-fuel oil haulers and loaders, improved automatic fire protection system OFR 46–83
Ammonium phosphate, as flame retardant in foam OFR 109–83
Amosite, chemical and physical characterization RI 8452
identification and quantification, methods ....OP 1–80
on occupational air monitoring filters, characterization OP 41–83
Ampacities, mine face equipment cables, requirements standardization .....OFR 135–81
Amphibole fibers, thickness measurement .... OP 69–82
Amphibole minerals, fiber and fragment surface charge measurements ..... RI 8483
Amphibole particles, surface charge heterogeneity OP 56–80
Amphiboles, Soapstone Ridge, GA, petrographic examination ..... RI 8627

Cast irons, damping properties, influence of graphite morphology on ..... OP 43–80
Castables, zirconia, calcia, stabilized ..... OFR 65–81
Casting, induction melting reactive metals ..... B 673
molybdenum, in zirconium oxide investment molds RI 8624
titanium, bentonite-bonded olivine molds .... RI 8587
bentonite-bonded zircon molds ..... RI 8587
in olivine, garnet, chromite, or zircon molds RI 8443
Castings, iron and steel, effect of ferrous scrap composition changes on ..... OP 16–83
Castle Crags RARE II area, CA, mineral investigation MLA 8–83
Castle Peaks Wilderness Study Area, CA, mineral investigation ..... MLA 9–84
Catalyst, for methanol synthesis, patent ..... P 3–80
thorium oxide-containing, preparation, patent P 35–81
Catalysts, from thorium-copper intermetallics, for methanol synthesis ..... OP 22–81
high-surface-area transition metal, preparation, patent ..... P 8–81, 29–81
hydrogenation, from intermetallic compounds RI 8631
Raney nickel, methanation activity, additive effect on RI 8487
waste, in critical metals, assessment ..... OFR 197–82
Catalytic coal gasification, equipment material development ..... OP 53–80
Cationic flotation, hematitic oxidized taconite .. RI 8505

Cationic flotation, western Mesabi Range oxidized taconites, comparison with anionic flotation RI 8552
Cavability, comparative studies at three mines OP 50–82
Caving mining, drift linings, field study ..... RI 8811
Caving stope, ground movement measurements OP 51–82
Caving stopes, ground movement near, monitoring RI 8585
Cavitation, fluid, rock crushing and fragmenting OFR 33–83
Cavities, underground, surveying instrument, patent P 7–82
Cement, annual data .....MY 1983 (v. 1)
facts and problems ..... B 671
rapid-set, as molding sand binder for small ferrous castings ..... RI 8417
Cement kiln dust, acid mine drainage inhibition, evaluation ..... OFR 49–80
characterization ..... IC 8885
Eastern U.S., characterization .....OP 8–81
resource and environmental assessment .... OP 57–82
U.S., anion characterization by ion chromatography RI 8661
Cementation, zinc dust, from sulfide concentrate chlorine-oxygen leach liquors ..... RI 8707
Cementation strength, natural, retorted oil shale OFR 54–80
Cements, inorganic, in mine roof bolting ..... RI 8494
modified-sulfur, patent .....P 2–82, 12–83
use in concretes, flexible pavings, coatings, and grouts ..... RI 8545
Central African Republic, mineral industry, annual review .....MY 1983 (v. 3)
Central lubrication system, for underground mining equipment ..... OFR 23–80
Central Mining Institute, Poland, inert gas mine fire extinguishing system .....OFR 212–83
Centralia mine fire, PA, control problems ..... RI 8799
Centrifugal casting, glass-ceramic pipe, from mining and processing wastes ..... RI 8910
Centrifugal model, coal waste embankments, stability analysis ..... OFR 43–81
Centrifugation, coal waste dewatering .....OFR 114–81
Ceramic aggregates, roadway use ..... OP 67–82
Ceramic materials, as die inserts in ferrous diecasting, evaluation ..... RI 8557
chemically bonded, review ..... IC 8878
comminution, attrition grinding process ..... B 670
corrosion resistance, to hydrochloric acid RI 8650, 8807
to nitric acid ..... RI 8851
high-temperature corrosion resistance, literature review ..... IC 8843
Ceramic powders, high-purity ultrafine nonoxide, turbomill production ..... RI 8854
Ceramics, manganese dioxide use in, literature review and analysis ..... OFR 68–80
powders from solutions and suspensions, rapid solidification process ..... OFR 66–81
silicon nitride-alumina compositions, additive effect on sintering ..... RI 8466
zirconia castables, calcia stabilized ..... OFR 65–81
Cerium, annual data .....MY 1983 (v. 1)
thermodynamic data ..... B 672
Cerium-nickel catalysts, for hydrogenation reactions RI 8631
Certification, blasters, State regulations .... OFR 59–81
Certification tests, human subject, of self-rescuers, evaluation ..... OFR 48–84
Cesium, annual data .....MY 1983 (v. 1)
facts and problems ..... B 671
thermodynamic data ..... B 672
Chad, mineral industry, annual review .MY 1983 (v. 3)
Chain conveyors, noise control study .....OFR 133–80
Chainless haulage system, link-loc, for longwall mining, patent ..... P 5–81
Chalcocite, aqueous solution reaction, electrochemical flotation of sulfides ..... OP 11–84
formation enthalpies, bromine calorimetric determination ..... RI 8710
selective flotation .....OFR 141–83
Chalcocite-ethylxanthate interactions, electrochemical flotation of sulfides ..... OP 7–84, 134–84
Chalcopyrite, flotation, effect of potassium ethylxanthate degradation ..... RI 8787
selective flotation .....OFR 141–83
Chalcopyrite ores, column leaching, using thermophilic bacteria .....OFR 113–80
copper leaching .....OFR 180–83
in situ leaching, effect of sodium chloride leach solution additive ..... RI 8626
temperature effects ..... RI 8642
percolation leaching, thermophilic bacteria use RI 8827
Chama River Canyon Wilderness and Contiguous RARE II Further Planning Area, NM, mineral investigation ..... MLA 108–82
Chambers Ferry RARE II Further Planning Area, TX, mineral investigation .....MLA 76–82
Chanchelulla RARE II area, CA, mineral investigation MLA 24–83
Channeling, flame, noise and dust reduction OFR 90–81
noise control .....OFR 65–82
Characterization, asbestos fibers, on air monitoring filters ..... OP 41–83
respirable coal dust, by scanning electron microscope OFR 56–80
Charley River area, Alaska, tungsten investigation OFR 29–81
Charts, factor of safety, tailings pond embankments, stability estimation ..... RI 8564
Chattahoochee River RARE II Further Planning Area, GA, mineral investigation ..... MLA 140–82
Cheat Mountain Further Planning Area, WV, mineral investigation ..... MLA 113–82
Chemehuevi Mountains Wilderness Study Area, CA, mineral investigation .....MLA 42–83
Chemical analysis, metal and mineral samples, microwave system for acid dissolution .TPR 120
metal and mineral solution sample preparation, in plastic pressure vessels ..... RI 8480
Chemical industry, critical metals in waste catalysts, assessment .....OFR 197–82
Chemical processes, cost estimates, computer program OFR 95–81
Chemical vapor deposition, group IVB, VB, and VIB elements with nonmetals, literature review IC 8928
valve coatings in coal gasification plants ... OP 57–81
Chenega Island, AK, manganese on ..... MLA 124–82
Chi phase, strengthening of low-chromium ferritic alloys RI 8860
Chichagof Island, AK, parts adjacent to Yakobi Island, mineral investigation .....MLA 97–82
western portion, mineral investigation ..OFR 89–81
Chile, economic indices, development .....OFR 156–84
mineral industry, annual review .....MY 1983 (v. 3)
summary .....MP
China, mineral industries, 1983 ..... OP 125–84
mineral industry, annual review .....MY 1983 (v. 3)
Chiolite, high-temperature enthalpies ..... RI 8442
low-temperature heat capacities ..... RI 8442
Chips Creek RARE II area, CA, mineral investigation MLA 55–83
Chlorate oxidation, electrowinning ..... OP 46–84
Chloride brines, potash recovery from, solar evaporation and flotation ..... RI 8911
Chloride leach solutions, silver recovery from, iodide precipitation ..... RI 8428
Chloride process, aluminum from clay ..... IC 8923

Chloride process solutions, bismuth recovery from, patent P 27–81
Chloride-sulfate strip liquor, zirconium-bearing, zirconium oxide from ... RI 8850
Chlorination, of aluminous resources, rates .... IC 8952
selective, lithium recovery from clay ..... RI 8523
Chlorine, thermodynamic data ..... B 672
Chord tension, Birmingham roof trusses, evaluation OFR 35–84
Christmas Island, mineral industry, annual review MY 1983 (v. 3)
Chrome-magnesite refractories, corrosion resistance to coal and lignite ash slags ..... RI 8633
Chrome refractory wastes, from steelmaking furnaces, recycling ..... RI 8489
Chromic acid etching solutions, recycling demonstration OP 22–82
regeneration and recycling, industrial-scale unit OP 28–81
Chromic acid-sulfuric acid etchants, regeneration, economic evaluation ..... IC 8931
Chromite, Alaska, Kaiyuh Hills deposits ... OFR 178–84
byproduct, sand and gravel operations, California RI 8471
Oregon and Washington ..... RI 8563
Caribou Mountain area, AK, beneficiation ... IC 8916
reconnaissance ..... IC 8915
domestic, high-carbon ferrochromium from . OP 33–80
high-iron, carbonyl processing ..... OP 140–84
imported, dolomite refractories as substitutes IC 8913
in Alaska, study of mineral potential ..... IC 8869
Kanuti River area, AK, beneficiation ..... IC 8916
reconnaissance ..... IC 8915
low-grade, review of deposits and beneficiation methods ..... OP 13–83
New Guinea lateritic, smelting ferrochromium from OP 71–83
ore flotation fundamentals ..... OFR 45–82
recovery, Western U.S. laterites ..... OFR 68–82
U.S., prereduction and melting ..... OP 37–81
Chromite ores, amine flotation, patent ..... P 1–82
low-grade, California, beneficiation ..... RI 8592
Stillwater Complex, amine flotation ..... RI 8502
Chromite sands, in shape-casting titanium ..... RI 8443
Chromite tailings, characterization and leaching tests OP 77–82
Chromites, from Montana and California, prereduction and smelting ..... OP 30–83
Chromium, annual data ..... MY 1983 (v. 1)
availability, from cast heat- and corrosion-resistant alloys ..... IC 8821; OFR 8(1)–80
from stainless steel scrap ... IC 8822; OFR 8(2)–80
from superalloy scrap ..... IC 8821; OFR 8(1)–80
from wrought heat-resistant alloys ..... IC 8822; OFR 8(2)–80
in market economy countries ..... IC 8977
conservation, in tanning industry ..... OP 24–82
electroreduction, using coke electrodes, patent . P 6–81
extraction, low-grade ores ..... OFR 151–82
facts and problems ..... B 671
from high-iron chromite, carbonyl processing OP 140–84
from stainless steel pickling liquors ..... OP 18–84
general information ..... MCP
in stainless steel, partial aluminum substitution RI 8856
partial replacement ..... RI 8900
silicon and aluminum partial replacement . RI 8918
substitutes ..... OP 129–84
in stainless steels, iron-aluminum-molybdenum alloy substitute ..... RI 8654
substitution ..... OFR 110–81
in steelmaking wastes, in-plant recycling .... RI 8724
in waste catalysts, assessment ..... OFR 197–82
in waste slags, leaching prevention ..... RI 8878
Japan's specialty steel industry requirements IC 8946
Chromium, Mount Hurst ultramafics, AK, economic potential ..... OFR 22–84
overview ..... OP 17–84
recovery, amine flotation, patent ..... P 1–82
from low-grade chromite, review of methods OP 13–83
from nickel-cobalt laterites and leach residue RI 8676
from plating rinse waters ..... OFR 109–82
from scrap metals, pyrometallurgical method RI 8571; OFR 75–80
from superalloy scrap, chlorine leaching, patent P 3–83
patent ..... P 13–81
process ..... RI 8570; OFR 69–80
from surface-finishing wastes ..... RI 8760
from tannery sludge ..... OFR 91–80
from tanning wastes ..... OFR 82–84
from waste solutions, patent ..... P 10–82
thermodynamic data ..... B 672
U.S. availability, Minerals Availability System appraisal ..... IC 8895
Chromium-bearing solutions, recycling ..... OP 39–84
Chromium carbide, chemical vapor deposition, literature review ..... IC 8928
Chromium electroreduction, using coke electrodes RI 8472
Chromium-iron alloys, heat-resisting, strengthening RI 8860
preparation, vacuum reduction and simple melting of reduced products ..... RI 8514
Chromium solutions, waste metallurgical, regeneration, patent ..... P 8–82
Chronopotentiometry, ferric ion diffusion and activity coefficient determination ..... RI 8617
Chrysocolla, selective flotation ..... OFR 141–83
Chrysotile, chemical and physical characterization RI 8452
identification and quantification, methods .... OP 1–80
in insulation samples, thermal gravimetric analysis and gas chromatographic analysis ... OP 52–81
Chugach National Forest, AK, copper and gold mining, feasibility ..... OFR 125–84
critical and strategic mineral potential OFR 215–84
mineral investigation ..... MLA 5–84
mineral sampling sites and results ..... OFR 83–81
SOUND Study Area, mineral appraisal .. OP 42–82
placer sampling and related BuMines activities MLA 62–82
Chukchi Imuruk National Reserve (proposed), AK, mineral investigation ..... OFR 28–81
Chute Mountain Wilderness Study Area, MT, mineral investigation ..... MLA 12–84
Circuit breaker, mine power systems, reliability OFR 6(2)–81
mine trolley lines, portable remote control system OFR 142–81
Circuit breaker system, discriminating, patent .. P 32–81
Circuit breakers, direct current, portable calibrator, patent ..... P 16–80
mine face equipment cables, requirements standardization ..... OFR 135–81
Circuit protector, mine power systems, direct current limiting device ..... OFR 176–82
Citico Creek Wilderness Study Area, TN, mineral investigation ..... GS 2–84
Citrate process, demonstration plant, construction and testing ..... OP 12–80
desulfurization solution renewal, hydrogen sulfide generation for ..... RI 8539
flue gas desulfurization, analytical chemistry.. IC 8819
demonstration plant ..... OFR 67–84
sulfur chemical reactions ..... RI 8540
modified, description and economic evaluation RI 8638
pressurized steam stripping of sulfur dioxide solutions RI 8734

Citrate process, sulfur dioxide scrubbing of flue gases, demonstration ..... OP 13–80
Cladding, metals, continuous strip rolling in vacuum ..... RI 8495
Cladosporium cladosporioides, clay removal, from industrial waste waters ..... OP 19–82
phosphate and potash slime flocculation ..OFR 195–82
Clarion River RARE II Further Planning Area, PA, mineral investigation .....MLA 85–82
Clay, alumina from, aluminum chloride leaching ..... OP 13–84
basic chloride method ..... RI 8866
chlorination rates of aluminous resources .. IC 8952
hydrochloric acid process, bench-scale study ..... RI 8476; OP 26–83
clay feed factors ..... RI 8772
effects of feed preparation ..... RI 8618
leaching rates ..... RI 8744
miniplant material balance ..... RI 8759
miniplant reactor design effect ..... RI 8877
nitric acid leaching ..... RI 8834
sulfurous acid-caustic purification process .. IC 8959
aluminum from, chloride process ..... IC 8923
patent ..... P 10–83
chlorination, chemical equilibria ..... RI 8696
kaolinitic, aluminum chloride hexahydrate from, strong acid-weak acid method ..... RI 8908
lithium recovery from, selective chlorination .. RI 8523

machine illumination systems, demonstration OFR 107–82
machine-mounted respirable dust monitor, design and cost study ..... OFR 18–81
medium-frequency radio wave propagation, theoretical model ..... OFR 83–80
methane drainage, horizontal drilling technology, review ..... IC 8829
microseismic roof fall warning system, development OFR 163(1)—(2)–81
mine acid formation factors ..... OFR 128–83
mine closure methods, evaluation ..... OFR 153–81
mobile equipment, population characterization OFR 40(1)—(2)–81
rollover protective structure status OFR 40(1)—(2)–81
northern Appalachian Coal Basin, geologic features, guide ..... IC 8918
Northern Appalachian Coalfield, subsidence data assessment ..... RI 8630
pillar stability, effect of weak floor on ..... OFR 12–81
power systems, electrical safety, evaluation OFR 160–81
power systems grounding ..... OFR 52–82
rail haulage, track switch point position, positive indicator ..... OFR 35–80
resin-grouted bolts, stress distribution around RI 8440
roof behavior, analytical modeling ..... OFR 41–81
roof-bolt interaction with rocks, selected loading conditions, study ..... OFR 51–80
roof bolter low protective canopy, development OFR 17–81
roof hazards, premining identification .... OFR 167–81
roof stability, effect of time lapse between exposure and support ..... TPR 110
roof stabilization, chemical injections ..... OFR 48–80
sealed, fire diagnostics ..... RI 8625
self-drilling roof bolts, development and testing OFR 102–82
shuttle car low protective canopy, development OFR 17–81
single-entry longwall, rock mechanics, finite element analysis ..... OFR 47(1)—(2)–80
Coal mines, small, high fatality rates ..... OFR 124–83
squeeze monitoring, dial-gauge tube extensometer TPR 113
surface, cross-pit overburden and waste handling system ..... OFR 17–80
dewatering systems ..... OFR 32–80
highwall stability improvement, delayed blasting RI 8916
mobile machine operators, noise exposure .. IC 8841
strip mined land reclamation, irrigation OFR 12–82
thin seam, low glare illumination ..... OFR 169–83
trolley wire power distribution systems ... OFR 49–82
tunnel design ..... OFR 85–83
underground, computer simulation, stress analysis OFR 66–82
diesel equipment deployment, effect on air quality OFR 128–81
diesel exhaust emissions ..... OFR 105–82
electrical accident analysis ..... OFR 91–82
electrical power systems ..... IC 8893
fire hazard criteria for noise control products OFR 175–83
methane monitors, intrinsic safety evaluation OFR 88–81
noise control products, flammability .... OFR 92–80
overburden dewatering ..... OFR 103(1)—(2)–82
remote monitoring systems, fire and explosive atmosphere ..... IC 8875
power system faults ..... IC 8944
subsidence prevention using cemented backfill OFR 92–82
supply handling system ..... OFR 99–84
trolley pole remote control ..... OFR 9–81
visual methane indicator ..... OFR 126–82
water diversion ..... OFR 103(1)—(2)–82
U.S., fires, 1950-77, statistical analysis ..... IC 8830
methane emissions in 1980 ..... IC 8987
underground waste disposal requirements OFR 6–80
U.S. longwall, dust standard compliance difficulties IC 8957
untensioned full-column resin bolts, reinforcement mechanisms ..... RI 8439
waste leaching, ground water contamination OFR 73–81
water treatment, scale inhibitors and flocculant polymers ..... RI 8899
working face respirable dust, study ..... OFR 98–81
workings detection, resistivity techniques . OFR 55–81
Coal mining, acid mine drainage reduction, water handling procedures ..... OFR 156–81
ANFO haulers and loaders, improved automatic fire protection system ..... OFR 46–83
Appalachian, roof geologic structures ..... RI 8620
area terrace pit, engineering and economic feasibility OFR 15(1)—(2)–82
auger, aerostatic roof support ..... OFR 14–83
benefit-cost analysis of health and safety research OFR 78–82
bits with worn carbide tips, ignition potential . TPR 121
chemical self-rescuers, 1-hour, safety evaluation OFR 123–80
classroom health and safety training, study OFR 99–83
continuous, electrical energy requirements . OP 29–80
continuous methane monitors ..... OFR 93–82
continuous miner, deep-cutting production tests OFR 61–80
illumination system ..... OFR 90–80
continuous shaft lining system ... OFR 186(1)—(3)–83
drag bits with diamond inserts, cutting characteristics RI 8802
dust control ..... OP 1–84
comparison of six medium-energy use scrubbers RI 8449
continuous miner twin scrubber ..... TPR 112
cutter bit, patent ..... P 3–81

Coal mining, dust control, surfactants effect on wettability ..... OFR 127–81
dust control by deep mining ..... OP 10–84
encountering discontinuities during borehole drilling, probability ..... RI 8665
facies-related problems ..... OP 78–84
float dust generation, field survey ..... OFR 17–82
4M miniminer system, surface evaluation .... RI 8818
frictional ignitions, prevention ..... OP 2–81
Hartshorne Coalbeds, western Arkoma Basin, problems ..... RI 8795
in-mine preparation facility, feasibility ... OFR 20–84
Kloswall longwall system, evaluation .... OFR 102–80
Lancashire No. 20 Mine, PA, longwall dust reduction OP 64–82
longwall ..... OP 36–84
advancing tailgate, flexible liner use ..... OFR 6–82
dust compliance case studies ..... OP 59–82
dust control, deep cutting ..... OP 87–82
deep cutting double arm shearer, field tests OFR 118–81
gateroad roof support ..... RI 8628
hydrologic impact, premining data collection OFR 187–83
massive roof control ..... OFR 115–80
methane control, European and U.S. practices OP 1–82
microseismic monitoring ..... OFR 30(1)—(3)–80
new sonic logging technique ..... TPR 117
Northern Appalachian region, subsidence data OFR 124(1)—(2)–81, 145–81
subsidence preliminary data analysis .... OP 9–81
oscillating full face cutting and transporting system OFR 132–82
shearer air diversion and dust control system, patent ..... P 13–82
slurry transport systems, development and analysis OFR 58–84
support walls, health and safety analysis OFR 121(1)–82
tailgate workers' dust exposure, reduction .. RI 8780
triangular-shaped cutting head, patent .... P 39–81
underground gob gas drainage ..... RI 8644
longwall shearer, confining dust to face ..... TPR 111
longwall subsidence, Deer Creek Mine, UT ... IC 8896
low ..... OFR 162(1)—(3)–83
anthropometry ..... OFR 162(2)–83
biomechanics and work physiology . OFR 162(1)–83
clothing design ..... OFR 162(3)–83
materials handling vehicle, development .. OFR 59–80
mechanization ..... OP 78–82
methane drainage, cableless electronic survey system OFR 14–82
geologic considerations ..... IC 8898
methane ignition, bit impact of drum cutting head RI 8755
mined land reclamation ..OFR 166(1)—(2)–82, 173–82
Midwestern U.S. ..... OFR 174–82
Montana ..... OFR 167–82
mining machine vibration data ..... OFR 97(2)–80
modified cutter bits, reduced energy, dust, and incendivity ..... RI 8801
monitoring and modeling ground water systems, Powder River Basin, MT-WY ..... OFR 25(1)—(2)–83
multiseam, ground control mechanisms .... OFR 7–84
multiseam contour haulback systems, improvements OFR 5–80
pillar stability on steeply pitching seam, finite element analysis ..... RI 8579
pitching, undercut and fill system ..... OFR 57–82
Pocahontas No. 3 seam, roof falls, study .. OFR 36–80
premining hazard prediction, borehole geophysical technique ..... OFR 77–80
projected industry employment and training demands, model ..... OFR 92–81
Coal mining, radial gauge cutter bits, forces and primary dust generation ..... RI 8800
raise drilling, methane control by shaft ventilation IC 8847
reduced dust generation ..... OFR 148–83
remote telemetry methane monitoring system OFR 9–82
roof behavior and support systems, bibliography OFR 60(2)–80
roof bolter, controls standardization ..... OFR 170–82
remote controlled, for high roof areas .. OFR 113–82
remote operator, using existing technology OFR 39–80
roof bolter controls standardization OFR 107–80, 170–82
roof bolts, fully resin-grouted nontensioned, system criteria ..... OFR 46(1)—(5)–80
optimum tension, determining .. OFR 60(1)—(2)–80
shank tension, investigation ..... OFR 82–80
roof pin setting by oscillation ..... OFR 7–82
roof-problem prediction, Pocahontas No. 3 Coalbed, WV ..... IC 8864
roof rock reinforcement ..... OFR 72–82
roof supports, lightweight substitutes ..... OFR 67–80
room-and-pillar, surface subsidence over four sections RI 8645
room-and-pillar retreat mining, manual ..... IC 8849
safety, comparison of U.S. performance with that of other countries ..... OP 47–81
sediment pond electrokinetic densification, feasibility RI 8666
shaft construction personnel, training program OFR 106–81
shale roof deterioration control .... OFR 41(1)—(2)–82
shortwall, illumination system ..... OFR 114–80
shuttle cars, cable reel systems, study .... OFR 98–80
small fires, training program for fighting ..... OFR 179–82
small surface coal operator, impact of government regulations ..... OFR 190–82
solid-state equipment, control and protection circuit evaluation ..... OFR 126–81
steel supports, European design criteria OFR 121(2)–82
subsidence control, backfilling ..... OP 60–82
surface, Appalachian, highwall stability ..OFR 54–82
blasting vibration and airblast noise ..... OP 10–81
Eastern and Central U.S., spoils slaking, environmental effect ..... OFR 146–80

equipment noise, effect of environment and loading conditions ..... OFR 97(1)–80
ground control, geologic and engineering data acquisition ..... OFR 89–80
mine rescue team's protective ensemble OFR 1(1)—(2)–83
near body of surface water, hazard determination criteria ..... OFR 45–81
oil and/or gas well blocks, design criteria OFR 147–81

Coal mining, underground, oxygen self-rescuers, recommended guidelines .... OFR 86(1)—(2)–81
personal equipment evaluation .. OFR 39(1)—(7)–82
portal bus noise control ..... OFR 62–82
underground equipment, electronic instrumentation, vibration qualification ..... IC 8883
underground waste disposal ..... OFR 48–82
waste dewatering systems ..... OFR 114–81
water infusion packer system, patent ..... P 34–81
wood products use ..... OFR 177–82
work force and training needs, study ..... OFR 14–80
Coal panel, room-and-pillar, subsidence over, West Virginia ..... OFR 133–84
Coal pillars, stability, effect of weak floor on OFR 12–81
Coal preparation, in-mine, feasibility ..... OFR 20–84
Coal preparation plants, design, noise control techniques OFR 42–84
noise control ..... OFR 143–83
Coal refuse piles, controlled burnout ..... RI 8478
Coal resources, western Warrior Coalfield, Pottsville Formation, evaluation ..... OFR 193–82
Coal seams, steeply pitching, surface mining, environmental factors ..... OFR 39(1)—(2)–81
thin, mining systems, technology assessment OFR 102–81
Coal slurry, coarse, pipeline injector ..... OFR 190–94
Coal spoils, regraded, hydrologic and erosional characteristics ..... OFR 81–83
Coal storage silos, methane hazard assessment . RI 8525
Coal tunnel fires, smoke characteristics ..... OP 40–81
Coal wants, Westland Mine, southwestern Pennsylvania, geologic character ..... RI 8555
Coal waste, alumina from, waste composition and availability ..... IC 8940
anthracite, physical property data ..... RI 8782
anthracite culm, alumina and energy recovery OFR 121–83
as aggregate in portland cement concrete, mechanical properties ..... RI 8773
cemented, subsidence prevention in underground coal mines ..... OFR 92–82
coarse and fine combined, engineering properties RI 8623
Colorado Plateau, disposal survey ..... OFR 97–84
embankment compaction criteria ..... OFR 98–82
embankment stability, centrifugal model analysis OFR 43–81
graded, slurry transport properties ..... RI 8825
underground mine disposal, evaluation ... OFR 15–80
Coal waste embankments, aerial photos in improving inspections ..... OFR 54–81
Appalachian, inventory ..... OFR 100(1)—(3)–82
controlled burnout, patent ..... P 9–83
filter cloths for seepage control, properties ... RI 8871
Coal waste impoundments, remote monitoring OFR 79–83
Coal wastes, alumina from ..... OFR 139–84
dewatering systems ..... OFR 114–81
geochemical properties ..... OFR 65–84
toxicological effects on aquatic life ..... OFR 65–84
Coalbed degasification, fracture stimulation techniques OFR 135–85
Coalbed discontinuities, encountering during borehole drilling, probability ..... RI 8665
Coalbed gas drainage, geologic considerations .. IC 8898
Coalbed methane, computerized data base .... OP 58–85
Coalbed methane data base, computer-implemented OP 82–83
Coalbeds, characteristics and geology, influence on methane drainage ..... OP 38–80
degasification, horizontal drainage system from directional surface borehole ..... RI 8640
methane content, evaluation ..... OP 15–80
methane in, measuring ..... OP 132–84
premining degasification, directional drilling OP 16–80, 37–80
Coalbeds, U.S., degasification, horizontal drilling technology review ..... IC 8829
Coals, high sulfur-high ash, composition and thickness evaluation model ..... OFR 95–84
low-rank, in iron oxide reduction roasting, study RI 8746
U.S., spontaneous combustion hazard ..... RI 8474
wasted, in abandoned mines, controlled burnout RI 8478
western, flotation and selective agglomeration OFR 125–82
Coating, elongated tubes and strips, sputtering process, patent ..... P 30–81
long tubes or strips, adapting sputtering equipment OP 60–80
Coatings, coal gasification valves, chemical vapor deposition ..... OP 57–81
modified-sulfur cement use in ..... RI 8545
platinum, electrodeposited from molten salts, adhesion and hardness ..... OP 42–83
platinum-group metal, electrochemical studies RI 8656
titanium diboride, electrodeposited, wear properties RI 8537
vapor-aluminum-diffused, stainless steels, analysis RI 8629
wear-resistant, for coal conversion systems . OP 11–80
on polystyrene pattern castings ..... OP 77–84
Cobalt, Alaska, mineral terrane related .... OFR 175–84
western Crazy Mountains ..... OFR 213–84
annual data ..... MY 1983 (v. 1)
behavior, in ammonium leaching of iron-cobalt alloys OFR 64–84
electrowinning, from domestic laterite processing RI 8604
extraction from nickel leach solutions, liquid ion-exchange membrane use ..... OFR 79–82
facts and problems ..... B 671

coal mine illumination evaluation, modifications OFR 101–81
Computer tape, mining excavation and construction sequences ..... CT 1–83
Computerized monitoring systems, underground coal mine, power system faults ..... IC 8944
Computerized training device, development OFR 130–80
Computers, Bureau of Mines multipurpose research network, description ..... OP 1–81
mine-monitoring systems, reliability ..... IC 8882
Concentration, pneumatic, of mica ..... RI 8457
Concrete, asphaltic, recycling using sulfur, patent P 26–80
sulfur-extended, use overview ..... OP 18–81
plasticized sulfur, highway pavement use . OFR 13–83
sulfur-cyclopentadiene oligomer-dicyclopentadiene formation, patent ..... P 12–82
Concrete block stoppings, construction techniques HB 1–83
Concrete cribbing, mine roof support, design and field testing ..... RI 8804
Concrete-lined mine tunnel, deformation and cracking under changing strain ..... OP 38–81
Concrete mine supports, polymer-modified portland cement ..... OFR 93–81
steel-fiber-reinforced, testing and analysis .... RI 8412
Concrete stoppings, leakage reduction ..... IC 8949
Concretes, alumina refractory, coal gasification effect on ..... OP 39–81
modified-sulfur, technology ..... OP 55–81
modified-sulfur cement use in ..... RI 8545
portland cement, with coal aggregates, mechanical properties ..... RI 8773
pozzolan, made with fly ash, laboratory analysis RI 8584
sulfur, corrosion-resistant ..... RI 8758
in corrosive environments, industrial evaluation RI 8786
sulfuric acid corrosive environment use .. OP 20–82
Condrey Mountain RARE II area, CA, mineral investigation ..... MLA 36–83
Conductivity, coal mine earth, electromagnetic transmission tests ..... RI 8869
Congo, mineral industry, annual review MY 1983 (v. 3)
Connecticut, mineral industry, annual review MY 1983 (v. 2)

Conservation and development research, in-house and contract, fiscal year 1984 ..... IC 8982
Conspicuity, increased, coal miners, using retroreflective material ..... OP 7–83
Construction materials, asbestos identification and quantification ..... OP 33–82
modified-sulfur cement use in ..... RI 8545
Consumption, U.S. mineral, by end use, statistical projection method ..... IC 8825
Containment ponds, state-of-the-art technology OFR 94–80
Contaminants, airborne, from welding exhaust, reduction IC 8868
mine inspection data analysis system ..... IC 8859
Continuous miner, coal cutting and loading, electrical energy requirments ..... OP 29–80
deep cutting, production tests ..... OFR 61–80
integrated illumination system ..... OFR 90–80
methane monitoring system, remote telemetry OFR 9–82
training system ..... OFR 140(1)—(2)–83
Continuous miner cutter bit, dust control, patent P 3–81
Continuous miners, chain conveyor noise control, study OFR 133–80
coal cutting fracture mechanics, study .... OFR 60–81
conical bits, ignition tests ..... RI 8820
drag bits with diamond inserts, cutting characteristics RI 8802
drum head, automatic control feasibility ... OFR 8–81
dust control, high-pressure shrouded water sprays RI 8536
twin scrubber installation ..... TPR 112
dust control research ..... OP 84–83
4M miniminer system, surface evaluation .... RI 8818
hard-rock cutting, bit force determination .... RI 8748
hydraulic fluids, improved fire resistance .. OFR 19–81
mechanics and noise generation ..... RI 8743
methane ignition, bit impact of drum cutting head RI 8755
modified bits, reduced energy, dust, and incendivity RI 8801
noise, study ..... OFR 60–81
noise control ..... OFR 171–83
noise measurement ..... IC 8922
radial gauge bits, forces and primary dust generation RI 8800
trona mining, illumination system, design and evaluation ..... OFR 31–81
vibration data ..... OFR 97(2)–80
Contouring, mined land, cost reduction OFR 65(1)—(2)–83
Controls, roof bolters, standardization ..... OFR 107–80
Convergence, coal mine, dial-gauge tube extensometer measurements ..... TPR 113
mine roof and floor, ultrasonic measurements RI 8893
Convergence meter, mine roof movement measurement, study ..... OFR 106–80
Conveyor, high-angle, surface mining systems and cost study ..... OFR 29(1)—(2)–83
steep angle, surface coal mine materials handling system ..... OFR 17–80
Conveyor belt, service machine, development OFR 78–84
Conveyor belts, fire resistance, test method .... RI 8521
testing ..... OP 88–82
haulageway fire detection systems ..... RI 8632
mine, improved fire resistance test method . OP 54–81
Conveyor system, cross-pit overburden handling OFR 3(1)—(2)–80
pullcord lockout device ..... P 8–84
Conveyors, belt cleaning systems, safety evaluation ..... OFR 174–83
chain, noise control study ..... OFR 133–80
continuous multiple unit ..... OFR 101–84
large rock, open pit applications ..... OP 82–82
Cooler, in-line water spray, for mine environment, development ..... OP 15–82
water spray, mine heat exchanger, update .. TPR 114
Cooler, water spray, underground mine, patent . P 14–83
Cooper-Eaton equation, application to compaction of phosphatic clay waste and attapulgite . RI 8739
Copper, annual data ..... MY 1983 (v. 1)
Billings Glacier, AK, mineral investigation OFR 141–81
chromium partial replacement in stainless steels RI 8900
electroreduction, using coke electrodes ..... RI 8472
patent ..... P 6–81
electrowinning, insoluble anodes ..... RI 8531
with sodium perchlorate production ..... OP 139–84
facts and problems ..... B 671
from chalcopyrite ores, leaching ..... OFR 180–83
from leach solutions, coupled transport using hollow fiber membranes ..... OFR 67–81
general information ..... MCP
in situ leaching, effect of sodium chloride leach solution additive ..... RI 8626
technology ..... OFR 181–82
temperature effects ..... RI 8642
U.S. case histories ..... IC 8961
in waste catalysts, assessment ..... OFR 197–82
Klukwan complex, AK, mineral sample results OFR 21–84
market economy country availability, Minerals Availability Program appraisal ..... IC 8930
mining in Chugach National Forest, AK, feasibility OFR 125–84
mining water management plan ..... OFR 145–84

premine planning and environmental requirements, Wisconsin ..... OFR 208–83
pyrometallurgical production, environmental considerations ..... EPA 1–82
Ramparts Diorites, AK, mineral investigation OFR 143–81
recovery, coal-fired reverberatory flue dust OFR 86–83
electrowinning, improved anode ..... OFR 36–83
from ammoniacal-ammonium sulfate leach liquor, patent ..... P 12–81
from chalcopyrite ores, thermophilic bacteria use RI 8827
from copper smelting furnace slags, carbothermic reduction ..... RI 8697
from copper smelting furnace wastes ..... RI 8589
from dump leach liquors, alternative methods RI 8520
from electrolytic zinc plant copper filter cake OP 66–82
from electrolytic zinc waste ..... RI 8582
from electronic scrap ..... RI 8561
from laterite-ammoniacal leach liquors .... RI 8605
from lead smelter matte ..... RI 8615
from Pacific sea nodules, using sulfur dioxide OP 51–81
from primary smelter dusts ..... RI 8554
Western U.S. laterites ..... OFR 68–82
recovery costs, State severance tax impact IC 8879; OP 55–83
smelting, arsenic behavior in static bed roast . RI 8493
thermodynamic data ..... B 672
U.S. availability, depletion allowance impact . IC 8874
U.S. supply-demand analysis, using Minerals Availability Program ..... OP 45–83
vapor phase transport studies ..... OFR 119–80
world supply model, 1980-2000 ..... OFR 105–83
Copper filter cake, electrolytic zinc plant, recovering minerals from ..... OP 66–82
Copper industry, market instability ..... OFR 97–81
productivity trends analysis ..... OFR 192–82
technology forecasting ..... OFR 125(1)—(3)–83
U.S.S.R., summary ..... MI
U.S., market analysis ..... OFR 97–81
problems, issues, and outlook ..... MI
supply prospects, computer model ..... OP 47–83

Copper iodide, stoichiometry experiment ..... OP 36–83
Copper-iron mattes, and iron silicate slags, copper losses and impurity distribution between ..... RI 8655
Copper leach solutions, cobalt from ..... OP 41–84
ferric ion diffusion and activity coefficients, determination ..... RI 8617
Copper-manganese alloys, silverless brazing systems RI 8783
Copper matte, from converter slags, sulfur addition RI 8687
minor-element interactions in smelting ..... RI 8874
Copper mine waters, corrosion of friction rock stabilizers RI 8904
Copper mining, Arizona, ground water monitoring OFR 185–84
in situ, environmental impact ..... OFR 101–80
U.S., financial health ..... IC 8836
Wisconsin, preplanning, cost and time analysis OFR 25–80
Copper-nickel-cobalt mattes, separation from Duluth Complex concentrates ..... RI 8752
Copper-nickel deposits, northern Minnesota, geotechnical mine parameters ..... OFR 10–80
Copper-nickel mattes, Duluth Complex, low-pressure leaching ..... RI 8522
separation from Duluth Complex concentrates RI 8646
Copper-nickel mills, tailings basin reclamation, Minnesota ..... OFR 214–83
Copper-nickel mining, Minnesota, hypothetical mine models ..... OP 13–81
input-output requirements ..... OP 13–81
Copper-nickel ores, Duluth Complex, flotation responses RI 8509
Duluth gabbro, byproduct recovery from flotation tailings ..... OFR 143–82
grinding, heat-quench treatment ..... OFR 122–82
Copper ore, electronic ore sorting tests ..... RI 8490
Copper ores, native, chalcopyrite leaching, using thermophilic bacteria ..... OFR 113–80
Copper oxide ores, leaching, mathematical model OFR 52–80
Copper slag, conversion to glass products .. OFR 123–82
Copper slags, analysis, by flame atomic absorption spectroscopy ..... RI 8484
reverberatory, EPA Extraction Procedure toxicity test results ..... RI 8648
Copper smelters, primary, copper recovery from smelter dust ..... RI 8554
sulfur dioxide emission controls, impact .. OFR 133–82
Copper smelting, arsenic and antimony heteronuclear compound formation ..... OP 71–82
Copper smelting furnace slags, iron and copper recovery from, carbothermic reduction ..... RI 8697
Copper smelting furnaces, magnesite-chrome refractory wastes from, recycling ..... RI 8589
recycling refractories from ..... OP 80–82
Copper sulfide, froth flotation ..... OFR 149–83
Copper sulfide flotation concentrates, molybdenite recovery from, patent ..... P 21–80
Copper sulfide ores, mixed kinetics dump leaching model RI 8647
Copper tailings, porphyry, rutile recovery from . RI 8462
rutile recovery from, patent ..... P 15–82
stabilizing by revegetation ..... OP 32–80
western, rutile occurrence in and recovery from OP 11–82
Cordova Quadrangle, AK, mineral sampling sites and results ..... OFR 83–81
Core drilling, retractable bit system OFR 119–81; OP 13–82
Cornplanter RARE II Further Planning Area, PA, mineral investigation ..... MLA 39–82
Corrosion, alloys, Salton Sea geobrines, tests ...OP 7–81
columbium, in hydrochloric acid solutions .. OP 17–81
East Mesa geothermal brines, field studies ... RI 8504

radiative losses and selective diffusional demixing RI 8607
thermal quenching ..... RI 8469
Flint Mill Gap RARE II Further Planning Area, TN, mineral investigation ..... MLA 99–82
Flocculation, barite, recovery of ultrafine particles from mill wastes ..... RI 8668
chemical, sediment pond solids removal . . OFR 165–82
coal-clay wastes, using polyethylene oxide . OP 31–81
coal plant blackwater ..... OFR 107–83
cross-linked starch xanthate ..... OP 115–84
industrial clay wastes, using polyethylene oxide RI 8498; OP 51–80, 61–80, 32–81
method for clarifying slimes, patent ..... P 31–81
microbial, of phosphate and potash slimes OFR 195–82
mine water treatment, slow release polymers . RI 8899
oxide and hydroxide mineral fines, using cross-linked starches ..... OP 24–83
phosphatic clay wastes, using polyethylene oxide OP 21–81, 33–81
effect of ion exchange ..... OP 33–81
synergism ..... RI 8436
using polyethylene oxide and drum mixer OFR 194–82
potash-clay waste slurries, using polyethylene oxide RI 8741
selective, of collophane ..... OFR 8–83
oxidized taconites ..... RI 8867
slimes dewatering, patent ..... P 40–81
sulfide minerals, insoluble cross-linked starch xanthate RI 8819; OP 16–82
talc slurry dewatering ..... RI 8803
Floor conditions, coal mine, effect on pillar stability OFR 12–81
Florida, central, phosphate mining, LANDSAT monitoring ..... OFR 37–84
Hawthorn Formation, geology ..... FBG 1–81, 1–83
phosphate characterization, evaluation, and beneficiation ..... FBG 1–81
phosphate characterization and beneficiation FBG 1–83
industry input-output tables, 1977 ..... OFR 147–82
Live Oak, mined land reclamation ..... OFR 75–82
mineral industry, annual review ..... MY 1983 (v. 2)
mineral investigation, Buck Lake RARE II Further Planning Area ..... MLA 46–82
Clear Lake RARE II Further Planning Area MLA 80–83
Farles Prairie RARE II Further Planning Area MLA 46–82
Natural Area RARE II Further Planning Area MLA 30–81
Savannah RARE II Further Planning Area MLA 86–82
phosphate, high-magnesium, beneficiation ... RI 8609
phosphate industry, economic significance, input-output analysis ..... IC 8850
environmental impact ..... OP 144–84, 145–84
technological and environmental problems . IC 8914
Florida, phosphate operations slimes, phosphate recovery from ..... RI 8731
phosphate ore beneficiation ..... OFR 8–83
phosphate rock industry, economic impact . OFR 21–80
phosphatic clay wastes, dewatering research overview IC 8980
dewatering with moving screens ..... RI 8529
large-scale dewatering ..... RI 8611
phosphogypsum, environmental impact ..... RI 8639
toxicity assessment ..... OP 48–82
surface water treatment, for phosphate beneficiation use ..... RI 8535
Flotation, chromite ore, fundamentals ..... OFR 45–82
column design and operation ..... OFR 23–83
continuous, dolomitic phosphate ore beneficiation RI 8903
slimes removal from potash ore ..... RI 8516
electrochemical, of sulfides ..... OP 141–84
chalcocite reaction in aqueous solutions .OP 11–84
chalcocite-ethylxanthate interactions OP 7–84, 134–84
froth, copper sulfide ..... OFR 149–83
Missouri coal characteristics ..... OFR 34–83
potash recovery, from carnallite ..... RI 8678
selective, slightly soluble minerals ..... OFR 108–83
very fine minerals ..... OFR 141–83
sulfide, mineral-reagent interactions, symposium proceedings ..... IC 8818
western coals, beneficiation ..... OFR 125–82
western Mesabi Range oxidized taconites, comparison of anionic and cationic flotation systems RI 8552
Western U.S. phosphate ores, carbonate-silica removal RI 8728
Flotation method, hydrocarbonaceous material, patent P 37–81
Flotation responses, Duluth Complex copper-nickel ores RI 8509
Flow analyses, tailings embankments, field application OFR 53–84
Flow problems, combustion, multidimensional, algorithm OP 50–81
Flue dust, coal-fired copper reverberatory, characterization ..... OFR 86–83
Flue dusts, arsenic recovery from, patent ..... P 16–83
copper and brass industry, conversion to zinc oxide OP 77–82
lead smelter, cadmium-zinc-lead recovery from RI 8659
hydrometallurgical treatment of arsenic ... RI 8679
smelter, antimony in, atomic absorption spectrometry determination ..... RI 8510
Flue gas desulfurization, citrate process, analytical chemistry ..... IC 8819
demonstration ..... OP 13–80
demonstration plant ..... OFR 67–84
construction and testing ..... OP 12–80
sulfur chemical reactions ..... RI 8540
electric utility production of sulfur ..... OFR 94(2)–81
modified citrate process, description and economic evaluation ..... RI 8638
pressurized steam stripping of sulfur dioxide solutions RI 8734
Fluid cavitation, rock crushing and fragmenting OFR 33–83
Fluid dynamics, uranium in situ leaching, computer model ..... RI 8479
Fluoborate electrolyte, detinning municipal solid waste RI 8887
Fluorescent lighting systems, coal mine, evaluation OFR 112–80
Fluorescent lights, coal mines, operated from trolley wires, converter ..... OFR 10–81
Fluorine, facts and problems ..... B 671
in phosphate rock processing and waste materials, chemical analysis ..... RI 8576
thermodynamic data ..... B 672

Fluorite, from phosphate slag, solution mining OFR 182–83
selective flotation ..... OFR 108–83
Fluorspar, aluminum smelter potlining as substitute for, in basic oxygen steelmaking .... RI 8699, 8775
in cupola ironmelting ..... RI 8530, 8775
annual data ..... MY 1983 (v. 1)
foreign properties, engineering and cost data OFR 170–84
general information ..... MCP
synthetic, in basic oxygen furnace slags, evaluation RI 8558
in cupola ironmaking, volatility and evaluation RI 8789
Fluosilicic acid solution, phosphorus-containing, lead from, patent ..... P 21–81
Fly ash, acid mine drainage inhibition, evaluation OFR 49–80
in pozzolan concrete, laboratory analysis ..... RI 8584
powerplant, alumina recovery from ..... RI 8721
leachable metals removal from ..... RI 8721
use in controlling tailings pond leachate contamination of ground and surface water ..... OFR 57–83
use in synthetic construction aggregate .... OP 86–83
Fly ash disposal, Missouri, overview ..... OFR 82–83
Fly ash pelletization ..... OFR 89–83
Flynn Lake Wilderness Study Area, WI, mineral investigation ..... MLA 32–82; GS 9–81
Flyrock, blast shield for automated excavation system, testing ..... OFR 111–80
range, surface mine blasting, model for determining OFR 77–81
reduction, by efficient stemming in blasting OFR 8–84
surface mine blasting, procedure evaluation OFR 18–80
Foam, face drill and crusher dust control, evaluation RI 8595
face drill dust control, through-the-drill technique, evaluation ..... RI 8596
high-expansion, flame retardant addition OFR 109–83
mineral processing plant dust control ..... RI 8808
polyimide, development ..... OFR 150–82
Forecasting, mineral demand, using input-output framework ..... OFR 117–82
Forecasts, mineral demand, Bureau of Mines system OP 14–80
Forest lands, U.S., wilderness mineral potential, 1964–84 study ..... GS 4–84
Forging, ductile cast iron, experiments ..... RI 8448
Formaldehyde, in diesel exhaust, reactive contaminants, in-mine measurement ..... OFR 198–82
Formations, jointed, hydrology, surface resistivity measurement ..... RI 8901
Formic acid, in diesel exhaust, reactive contaminants, in-mine measurement ..... OFR 198–82
Fort Piute Wilderness Study Area, CA, mineral investigation ..... MLA 108–83
Fort Union Formation, MT, metal organic and inorganic affinities in coal ..... OFR 207(1)—(2)–83
Fort Union-Powder River region, surface mined land, fish and wildlife enhancement ..... OFR 197–84
Fortymile placer district, Alaska, resource inventory OFR 42–80
Fossil Ridge Wilderness Study Area, CO, mineral investigation ..... MLA 66–83
Foundations, block walls, fatigue assessment using models ..... OFR 144–80
Foundry coke, in cupola operation, partial replacement of RI 8488
Foundry sand, rapid-set cement binder, for small iron castings ..... RI 8417
Foundry sands, titanium casting, substitutes for critical metals ..... RI 8443
Four Notch RARE II Further Planning Area, TX, mineral investigation ..... MLA 77–82
Fox Mountain RARE II area, CA, mineral investigation MLA 128–82
Fracture dominated flow, dewatering, acid mine drainage abatement ..... OFR 109(1)—(2)–84
Fracture mechanics, coal cutting, study ..... OFR 60–81
Pennsylvanian age shales, during mining . OFR 24–83
Fragmentation systems, drill-split, application to underground mining ..... OFR 86–80
France, mineral industry, annual review MY 1983 (v. 3)
Frasch sulfur, industry analysis ..... OFR 94(1)–81
U.S. output, impact of Canadian recovered sulfur on OFR 94(1)–81
Frasch sulfur production, Texas and Louisiana, impact of decreased output ..... OFR 94(4)–81
Free-fall tests, mine cage, single-tooth safety dogs on wood guides ..... OFR 133(1)–81
Freel Peak RARE II area, CA, mineral investigation MLA 44–82
French Guiana, mineral industry, annual review MY 1983 (v. 3)
summary ..... MP
French Springs-Happy Canyon Wilderness Study Area, UT, mineral investigation ..... MLA 25–84
Fresnel lens, haulage vehicle improved visibility OFR 127–82
mine equipment blind area viewer ..... IC 8950
large underground vehicle demonstration OFR 111–84
Frictional ignitions, coal mines, prevention .... OP 2–81
Frictional resistance, polymeric solutions, concentration determination by ..... RI 8559
Front-end loader, automatic fire protection system OFR 73–82
hopper-crusher-conveyor systems for, user manual OFR 212–84
operator training ..... OFR 147–84
tree transplant attachment, mined land reclamation OFR 15–83
user's manual ..... OFR 169–82
Front-end loaders, rubber-tired, in surface mining, noise control ..... OFR 43–84
Front-end wheel loader, fire protection systems, economic analysis ..... RI 8698
Froth flotation, column, mineral fines processing OFR 113–84
copper tailings, rutile recovery from, patent .. P 14–82
molybdenite recovery, from copper sulfide flotation concentrates, patent ..... P 21–80
scheelite ore, using lanolin, patent ..... P 12–80
Stillwater Complex ore, platinum-palladium concentrate preparation ..... RI 8500
sylvinite ores, slime removal by, patent ..... P 6–80
Fuel, refuse-derived, analytical reference material development ..... RI 8426
Fuel systems, hydrogen, for underground mine equipment, development ..... OFR 79–84
Fueling areas, underground, improved automatic fire protection system ..... OFR 160–82
Fuels, mineral, State severance taxes, summary IC 8879
Fuller's earth, annual data ..... MY 1983 (v. 1)
Fumes, mine fire, concentration distribution, real-time simulation ..... OFR 22–82
mine inspection data analysis system ..... IC 8859
treated mine material fire, simulation ..... OFR 4–82
welding, generation, collection, and analysis . RI 8793
Funeral Mountains Wilderness Study Area, CA, mineral investigation ..... MLA 36–84
Furnace linings, chrome-containing, brick from, properties ..... RI 8685
Fuse, safety, elimination from mines, impact OFR 61–81
Fused-salt electrolysis, zinc from zinc chloride, monopolar and bipolar cells ..... RI 8524
Fuses, dc, criteria ..... OFR 116–84

dust explosion temperature determination . OP 16–81
gas and dust explosions ..... OP 74–82
Infrared viewer, visual methane indicator .. OFR 126–82
Inhalation contaminants, in aboveground mining and processing areas, survey handbook OFR 9(1)–80
survey teaching guide, for company safety officers OFR 9(3)–80
for MSHA inspectors ..... OFR 9(2)–80
Injuries, back, mine industry, seminar proceedings IC 8948
salt mine personnel, effect of positive reinforcement on OFR 44–80
Input-output analysis, Florida phosphate industry, economic significance ..... IC 8850
in mineral demand forecasting ..... OFR 117–82
selected U.S. industries, materials changes impact OFR 45–83
Input-output models, U.S. mining industries, disaggregation and updating ..... OFR 19–80
Input-output requirements, Minnesota copper-nickel mining ..... OP 13–81
Input-output structure, mineral industries, 1958 and 1963 ..... OFR 20–80
1967–1972–1977 ..... OFR 72–81
Input-output structures, U.S. mineral industries, 1972 OFR 148–82
Input-output tables, industry, Arizona and Florida, 1977 OFR 147–82
Leontief-type, computer programs ..... OFR 199–82
Inspection, periodic, mine power system insulation OFR 6(5)–81
preshift, of surface mining equipment, training materials development ..... OFR 139(1)—(3)–82
Inspection guidelines, tires, large mobile mine equipment OFR 44–81
Inspection procedures, mine hoist and shaft systems OFR 196(1)—(2)–82
Inspections, coal waste embankments, aerial photogrammetry ..... OFR 54–81
Instrumentation, electronic, underground coal mining equipment, vibration qualification ..... IC 8883
environmental monitoring, mine air and water OFR 33–82
mine, acceptability, environmental criteria . OFR 1–82
mine fire control project, monitoring and data recording ..... RI 8862
Insulation, chrysotile in, thermal gravimetric analysis and gas chromatographic analysis ... OP 52–81
mine power systems, periodic inspection .OFR 6(5)–81
Insulation materials, asbestos identification and quantification ..... OP 33–82
Interburden, surface mining multiple coal seams, handling techniques ..... OFR 80(1)—(2)–81
Intercom system, selective, patent ..... P 4–83
Interior coal province, surface mine spoil stability, evaluation ..... OFR 78(1)—(2)–80
Interior province, U.S., surface coal mine dewatering systems ..... OFR 32–80
Intermetallic compounds, in hydrogenation catalysts RI 8631
Internal combustion engines, underground use, State regulations ..... IC 8845
International Tin Agreement, background study IC 8860
International trade, Tokyo Round of Multilateral Trade Negotiations, impact on minerals ..... IC 8854
Intrinsic safety, hot wire ignition test requirements for instruments, supporting research .... OFR 7–81
methane monitors, evaluation ..... OFR 88–81
power supply circuit ..... P 4–84
Inverter, lighting, with constant power ballast, patent P 18–80
Investment, metal industries, effect of market instability on ..... OFR 97–81
Investment molds, for titanium castings, production RI 8541
zirconium oxide, for molybdenum castings ... RI 8624
Iodide precipitation, silver, from chloride leach solutions RI 8428
Iodine, annual data ..... MY 1983 (v. 1)
facts and problems ..... B 671
1983 overview ..... OP 68–84
synopsis and outlook ..... OP 51–83
thermodynamic data ..... B 672
Ion chromatography, anion characterization, of phosphate rock materials ..... RI 8661
of U.S. cement kiln dust ..... RI 8661
Ion exchange, bound liquid membranes, chromium recovery from plating rinse waters OFR 109–82
effect, in phosphatic clay waste dewatering, using polyethylene oxide ..... OP 33–81
inorganic materials, application to metallurgy RI 8816
montmorillonite clays, rheology ..... RI 8895
multicompartment column, orifice plate design studies RI 8616
tungsten recovery, from Searles Lake brines OP 49–80, 34–82
tungsten sorption from alkaline solution, patent P 28–80
uranium in situ leaching, low-grade acidic solutions RI 8492
Ion-exchange membranes, cobalt extraction from nickel leach solutions ..... OFR 79–82
Ion implantation, alloys formed by, characterization RI 8434
electrochemical corrosion ..... RI 8431
alloys on steel, corrosion fatigue behavior effect OP 38–83
linear polarization effect ..... OP 38–83
film and surface characterization, by proton-induced X-ray emission ..... RI 8455
integral Gaussian profiles, evaluating ..... IC 8811
Ionic solutions, hydrometallurgical, activity determination-estimation-correlation .OP 20–83
Ions, heavy metal, adsorption by xanthated sawdust RI 8427
Iowa, demonstration coal mine and mined reclamation project, progress report, 1980 ..... OFR 185–83
1982 ..... OFR 190–83
mineral industry, anual review ..... MY 1983 (v. 2)

Pacific manganese nodules, mining systems and costs IC 8933
regulations, technical basis for development OFR 87–80
technology transfer to Enterprise, alternatives OFR 84–80
Ocean resources, manganese nodules, Sea Scope expedition, data .....OFR 144–81
OFFCAT system, longwall and pillar reclaiming OFR 132–82
Oh-Be-Joyful Wilderness Study Area, CO, mineral investigation .....MLA 81–83
Ohio, abandoned mines, study for improved closing guidelines ..... OFR 138(3)–84
Coshocton County, water quality, after surface mining OFR 39–84
Jefferson County, surface mined watersheds, hydrology .....OFR 209–84
Ohio, mined land reclamation, pneumatic stowing OP 112–84
mineral industry, annual review .....MY 1983 (v. 2)
Ohio limestone, coal emissions control suitability OFR 38–83
Oil, enhanced recovery, rock-fluid reactions role OFR 61–84
heavy and heavy crude, sulfur recovery from OFR 94(2)–81
Oil mining, open surface flotation method, patent P 17–83
surface, technical and environmental assessment, Kern River Oilfield, CA ..... OFR 6–83
P. R. Springs deposit, UT ..... OFR 6–83
U.S., feasibility ..... OP 44–80
Oil recovery, chemical flooding methods, xanthan gum and hydrolyzed polyacrylamide rheology OFR 22–83
surfactants use .....OFR 157–83
Oil sands, borehole mining, environmentally compatible method .....OFR 50–81
Oil shale, Bureau of Mines environmental research program, overview .....OFR 58–80
creep behavior, elevated temperatures ...OFR 184–84
dawsonite-bearing, alumina extraction from .. RI 8796
soda extraction from ..... RI 8796
fire and explosion properties ..... RI 8726
Horse Draw Shaft, CO, mining and rock mechanics research ..... OFR 24(1)—(7)–84
in situ mining, slurry filling system .....OFR 114–83
in situ retorting, effect on pillars .....OFR 120–80
stress distribution and pillar design ..... RI 8597
methane in mines ..... OP 116–84
Naval Oil Shale Reserve, CO, mechanical properties and overlying strata ..... RI 8608
retorted, natural cementation strength ....OFR 54–80
Paraho and Tosco processes, geotechnical properties OFR 47–81
Paraho process, underground disposal ....OFR 1–80
spent, conversion to glass wool .....OFR 123–82
thermal degradation with molten nitrates .. OP 62–83
waste disposal systems, design parameters ... RI 8544
Oil shale data bank .....OFR 153(1)—(4)–82
bibliography .....OFR 153(1)—(2)–82
patents ..... OFR 153(3)–82
research projects ..... OFR 153(4)–82
Oil shale installation, environmental assessment OP 48–80
Oil shale mining, electrical systems, proposed guidelines and regulatory changes .....OFR 29–84
environmental effects .....OFR 168–82
environmental research program plan, high funding level .....OFR 3(1)–81
low funding level .....OFR 3(3)–81
mid funding level .....OFR 3(2)–81
geophysical techniques .....OFR 57–80
in situ retorting effects on shale pillars ...OFR 76–82
technology .....OFR 168–82
Oil shale pillars, in situ retorting effects ....OFR 76–82
Oil shale shaft and research facility, Bureau of Mines OP 47–80
Oil wells, underground coal mining near, barrier pillars, design criteria .....OFR 147–81
Oklahoma, east-central, Hartshorne Formation, coal mining sedimentary facies analysis ....OP 4–82
Hartshorne Coalbeds, coal mining and gas production problems ..... RI 8795
methane production potential .....OP 5–82
Hartshorne Formation, facies-related problems OP 78–84
mined land hazards, study .....OFR 76–83
mineral industry, annual review .....MY 1983 (v. 2)
Olallie RARE II area, OR, mineral investigation MLA 23–83
Old Crow batholith, Canada, rare-metal occurrences, geologic mapping ..... OP 28–82

Olivine molds, bentonite-bonded, for titanium casting RI 8587
titanium and zirconium castings ..... OP 40–82
Olivine sands, in shape-casting titanium ..... RI 8443
Oman, mineral industry, annual review MY 1983 (v. 3)
Omar copper prospect, AK, cobalt content in samples from ..... MLA 109–82
Open pit mines, rock slopes, risk analysis OFR 46(1)—(8)–81
Open pit mining, coal, area terrace, engineering and economic feasibility ..... OFR 15(1)—(2)–82
fugitive dust study ..... OFR 24–82
in-pit movable crusher ..... OFR 35–82
movable crushers, concepts and applications OFR 75–84
Open pits, mine waste retaining structures for backfilling, conceptual designs ..... OFR 96–81
ore pass design guidelines ..... OFR 179(1)—(2)–84
Openings, abandoned coal mine, Appalachian inventory OFR 100(1)—(3)–82
underground mine, block caving effect on . OFR 74–81
Operator training, underground coal mine equipment, improvement ..... OFR 68–84
Optical materials, manganese dioxide use in, literature review ..... OFR 68–80
Optical membrane filter count technique, correlation with fibrous aerosol monitor ..... RI 8467
Optical probe, improved, for dust explosion monitoring OP 12–82
Optical probes, Bureau of Mines, for dust measurement RI 8542
Optical spectrometer, incendivity measurement, light alloys impacting on rusted steel ..... RI 8684
Optics, fiber, underground mine communications use OFR 77–82
Ore deposits, fluid inclusion gas analysis, exploration tool ..... OFR 69–84
Ore passes, open pit, design guidelines OFR 179(1)—(2)–84
Ore reserves, estimation, geostatistics ..... OFR 168–84
Ore sorting, electronic, tests on native copper ore RI 8490
Oregon, mineral industry, annual review MY 1983 (v. 2)
mineral investigation, Deschutes Canyon RARE II area ..... MLA 6–83
Diamond Peak Wilderness and proposed addition MLA 23–82
Gearhart Mountain Wilderness and RARE II area MLA 33–82
Hells Canyon study area ..... MLA 41–82
Homestead RARE II area ..... MLA 76–83

window and lens design, explosion-proof enclosures IC 8880

Safety, mine cage overwind, shaft bottom buffer OFR 133(2)–81
mine electrical grounding systems, evaluation tests and criteria, development ..... OFR 103–81
mine electrical systems, ground fault and overcurrent protection criteria ..... OFR 158–81
mine fire detection ..... OFR 117–84
mine fire fume concentration, real-time simulation OFR 22–82
mine modular and control system, design and testing OFR 103–80
mine monitor and control system, methodology development ..... OFR 76–84
mine shaft construction, personnel training program OFR 106–81
mine waste dewatering, practices ..... OFR 34–80
mined land hazards, study, Kansas ..... OFR 75–83
Missouri ..... OFR 97–83
Oklahoma ..... OFR 76–83
mineral processing plants, mercury vapor source determination ..... IC 8921
minerals industry, hazard symbols use .... OFR 44–84
mining, ergonomics-human factors in mining, seminar proceedings ..... IC 8866
oil shale mine, electrical systems, proposed guidelines and regulatory changes ..... OFR 29–84
old mine and mill power systems and practices, technical and economic study ..... OFR 24–81
1-hour chemical self-rescuers, evaluation . OFR 123–80
operator training, underground coal mine equipment, improvement ..... OFR 68–84
powerline proximity warning device for cranes, evaluation ..... OFR 22–80
powerline proximity warning techniques for cranes, alternatives ..... OFR 175–82
program model ..... OFR 203–84
radon dosimeter development ..... OFR 85–84
remote control roof bolter ..... OFR 180–84
roof bolt, anchorage quality indicator .... OFR 148–84
roof fall alarm systems, field tests ..... OFR 50–80
surface mine blasting, bibliography ..... OFR 127–84
effects on adjacent underground mines . OFR 126–84
flyrock range, model for determining ... OFR 77–81
surface mine truck, seminar proceedings ..... IC 8828
surface mining equipment, automatic fire protection systems ..... IC 8832
battery handbook ..... HB 2–84
improved seatbelt systems ..... OFR 28–83
steering systems, survey ..... OFR 132–80
underground, supply handling system .... OFR 99–84
underground blasting, evaluation ..... OFR 86–84
underground coal mines, equipment instrumentation, vibration qualification ..... IC 8883
remote monitoring systems, fire and explosive atmosphere ..... IC 8875
underground diesel engine emissions control OFR 110(1)—(2)–84
underground mine, human factors analysis OFR 16–84
management training effectiveness .... OFR 191–84
underground mines, upgraded stench fire warning system ..... OFR 136–81
wire rope terminations, assembly, training and inspection manual ..... OFR 2(3)–81
efficiency and service life ..... OFR 2(1)–81
selection and inspection guide ..... OFR 2(2)–81
wood mine timbers, fire and rot retardant treatments, further studies ..... OFR 27–83
Safety analysis, longwall mining, support walls OFR 121(1)—(2)–82
Safety and health, classroom training, study OFR 99–83
radon reduction by mine ventilation pressure cycling OFR 17–83
underground waste disposal hazards ..... OFR 131–83
Safety dogs, single-tooth, on wood guides, cage free-fall tests ..... OFR 133(1)–81
Safety equipment, oxygen self-rescuers, recommended guidelines ..... OFR 86(1)—(2)–81
Safety fuse, elimination from mines, impact . OFR 61–81
Safety manual, blind shaft borer ..... OFR 32(4)–83
impactor shaft sinking system ..... OFR 112(2)–82
Safety practices, salt mine personnel, effect of applied behavioral analysis and techniques . OFR 44–80
Safety research, Bureau of Mines, status report IC 8812
contract ..... IC 8816, 8839
in-house ..... IC 8817, 8840
summary, fiscal year 1982 ..... IC 8872, 8908, 8956
Safety training, mine, seminar proceedings .... IC 8858
St. Louis Peak Roadless Area, CO, mineral investigation MLA 67–83
Saline Valley Wilderness Study Area, CA, mineral investigation ..... MLA 16–84
Salmon-Trinity Alps Primitive Area, CA, proposed additions, mineral investigation ..... GS 3–82
Salt, annual data ..... MY 1983 (v. 1)
facts and problems ..... B 671
solution mining, state of the art ..... OFR 142–82
technology ..... OFR 181–82
Salt dome, gulf coast, anomalous zone methane hazard assessment ..... RI 8861
methane content of salt ..... RI 8889
Salt domes, occluded gas contents, determination RI 8700
Salt mine, Belle Isle Mine, LA, methane emissions RI 8723
Salt mines, dust, humidity effect on ..... RI 8519
dust reduction, effectiveness of wet cutter bars RI 8512
personnel safety practices, effect of applied behavioral analysis and techniques ..... OFR 44–80
Salton Sea geobrines, alloy corrosion tests ..... OP 7–81
geothermal systems scaling ..... OFR 144–83
iron and nickel base alloys, field stress corrosion tests ..... OP 5–81
metal recovery from, comparison of methods OP 3–83
mineral recovery unit, operation ..... RI 8680
Samarium, annual data ..... MY 1983 (v. 1)
thermodynamic data ..... B 672
Sampler, airborne droplets, impact ..... OP 23–81
patent ..... P 16–81
personal, nitric oxide, development ..... OFR 105–81
nitrogen dioxide, development ..... OFR 105–81
personal dust monitor, tapered element oscillating microbalance ..... OFR 56–84
portable, for in-mine air monitoring, development OFR 108–81
Samples, metal and mineral, microwave system for acid dissolution ..... TPR 120
Sampling, coal mine dust, determination of accuracy OFR 45–80
personal sampler precision ..... RI 8740
diesel exhaust, state of the art ..... OFR 63–80
geobrines, variables ..... RI 8465
radon, rapid response monitor, development OFR 62–80
rapid, dust explosion dust and gases ..... OP 8–83
two gases simultaneously, electrochemical apparatus, patent ..... P 3–82
Sampling data, mine inspections, analysis system IC 8859
Sampling manual, coal mine dust, standard procedures OFR 136(2)–82
Sampling pump, personal, for coal mine dust, laboratory evaluation ..... RI 8637
Sampling tubes, gas, clog prevention ..... OFR 48–83
San Joaquin RARE II area, CA, mineral investigation MLA 79–82
San Juan Basin, NM, clay-mineral assemblages OFR 63–84
Sand, annual data ..... MY 1983 (v. 1)
dust control during bagging, water sprays .... RI 8614

Sand and gravel, facts and problems ..... B 671
Sand and gravel mining, improved ground control safety OFR 60–83
Sand and gravel operations, California, byproduct heavy minerals from .....RI 8471; OP 20–80, 21–80
recovery of platinum-group metals from .. OP 27–81
Oregon, recovery of heavy minerals from ..... RI 8563
preshift equipment inspection, training OFR 139(3)–82
recovery of gold and heavy minerals from ....OP 2–82
small, reclamation and pollution control, planning OFR 35–81

Sao Tome e Principe, mineral industry, annual review MY 1983 (v. 3)
Sapphires RARE II area, MT, mineral investigation MLA 74–83
Saprolites, in east-central Alabama, evaluation of gibbsite in .....OFR 27–84
gibbsite in .....OFR 118–82
potential as refractory-grade bauxite substitute RI 8881; OP 18–82
Satellite data, application to South Carolina surface mine monitoring .....OFR 11–80
Saudi Arabia, mineral industry, annual review MY 1983 (v. 3)
Savage Run Wilderness, WY, mineral investigation MLA 75–82
Savannah RARE II Further Planning Area, FL, mineral investigation .....MLA 86–82
Sawdust, xanthated, heavy metal ion adsorption by RI 8427
Sawmill-Badlands RARE II area, CA, mineral investigation .....MLA 51–82
Sawtooth Mountains B Wilderness Study Area, CA, mineral investigation .....MLA 30–84
Scale inhibitors, mine water treatment ..... RI 8899
Scaling, East Mesa geothermal brines, field studies RI 8504
geothermal systems, Salton Sea brines ...OFR 144–83
mechanical scaling bar development .....OFR 152–82
Scandium, facts and problems ..... B 671
thermodynamic data ..... B 672
Scheelite, recovery, from Western U.S. tactite ores RI 8716
selective flotation .....OFR 108–83
Scheelite ore, froth flotation using lanolin, patent P 12–80
Scodies RARE II area, CA, mineral investigation MLA 47–83
Scoops, low seam battery-powered, illumination OFR 53–82
Scotchman Peak Wilderness Study Area, ID-MT, mineral resources .....GS 1–81
Scrap, aluminum alloys, separation of wrought and cast OP 74–83
Scrap, auto, nonmagnetic metal recovery, water elutriator system ..... RI 8771
electronic, copper and precious metal recovery from RI 8561
platinum-group metals and gold recovery ..OP 2–84
precious metals recovery ..... RI 8757
ferrous, tramp elements, effects on iron casting OP 70–84
iron and steel, annual data .....MY 1983 (v. 1)
summary ....SP 1–82
purchased, effect of contaminants on iron and steel castings .....OFR 37–82; OP 16–83
stainless steel and superalloy, rapid identification RI 8858
superalloy, leaching rate increase, melting with aluminum ..... RI 8833
metal recovery from .....RI 8570; OFR 69–80
Scrap batteries, lead recovery from, electrolytic method RI 8602
nickel-cadmium, pyrometallurgical method ... RI 8574
Scrap metal, Japanese automobile, material content and recovery ..... RI 8855
rapid identification and sorting .....OP 8–84
Sixth Mineral Waste Utilization Symposium, overview IC 8826
Seventh Mineral Waste Utilization Symposium, summary ..... IC 8884
Scrap metals, chromium in, availability . IC 8821, 8822; OFR 8(1)—(2)–80
chromium recovery from, pyrometallurgical method RI 8571; OFR 75–80
ferrous, steel from ..... RI 8622
from shredded autos and urban refuse, use in cupola gray iron ..... RI 8454
identification, methods review ..... IC 8902
urban refuse, corrosion resistance of steels made from RI 8447
Scrap utilization, aluminum smelter potlining, as fluorspar substitute in cupola ironmelting RI 8530
Screen decks, resiliently clad, noise control .. OFR 67–82
test program .....OFR 20–83
Screening, nonmetallic minerals, processing plant noise control .....OFR 50–83
Screening equipment, nonmetallic mining industry, retrofit noise control manual ..... IC 8975
Screens, aggregate plant, noise control ..... OP 72–83
moving, Florida phosphatic clay waste dewatering method ..... RI 8529
vibrating, noise abatement using nonmetallic decks and other treatments .....OFR 120–82
performance prediction, computer model OP 21–82, 11–83, 12–83
performance prediction model .....OFR 137–83
Scrubber, rotating bed, dust control, patent ....P 17–81
Scrubbers, coal dust, improved .....OFR 91–83
coal mine dust control, comparison of six medium-energy scrubbers ..... RI 8449
twin, continuous miner dust control ..... TPR 112
water-powered, longwall tailgate workers' dust exposure control ..... RI 8780
Sculpture, mined land reclamation .....OFR 25–82
Sea deposits, manganese nodules, method for evaluation OFR 64–80
Sea nodules, Atlantic, metal recovery from, patent P 15–80
Pacific, metal recovery from, selective extraction with sulfur dioxide ..... OP 51–81
Sea Scope expedition, manganese nodule resource data OFR 144–81
Seafloor sulfides, Juan de Fuca Ridge, chlorine-oxygen leaching ..... TPR 122
Seafoam mining district, ID, mineral investigation MLA 87–83
Sealants, coal mine, face weathering protection OFR 71–81

Sealants, coal mine, self-cleaning spray nozzle for, patent ..... P 9–80
explosion-proof enclosures, acceptance testing criteria OFR 129–80
wall, radon emanation control ..... OFR 172–82
Seals, mine closure, by pneumatic stowing RI 8729, 8730
mine closure methods, technical and economic evaluation ..... OFR 153–81
Searles Lake brines, tungsten recovery from, ion exchange ..... OP 49–80, 34–82
Seatbelts, improved, surface mining equipment OFR 28–83
Sediment control, surface mining ..... OFR 103–83
Sediment pond, coal mine, electrokinetic densification, feasibility ..... RI 8666
Sedimentation, surface mine water pollution, control OFR 161(1)—(2)–81
Sedimentologic analysis, selected southeastern Montana coals ..... OFR 116–82
Seepage, coal waste embankments, control with filter cloths ..... RI 8871
uranium tailings pond, through partially saturated soils beneath ..... OP 14–81
Seismic communications, trapped miner location system, evaluation ..... RI 8567
Seismic detection, trapped miner ..... OFR 124–84
Seismic detectors, for high-resolution applications, selection guidelines ..... RI 8599
Seismic velocity, longwall coal mine, determination OFR 30(2)–80
Seismographs, evaluation ..... RI 8506
Seismometers, evaluation ..... RI 8506
for high-resolution applications, selection guidelines RI 8599
Selenium, annual data ..... MY 1983 (v. 1)
facts and problems ..... B 671
in uranium waste waters, removal by biological agents OFR 128–82
thermodynamic data ..... B 672
Self-rescuers, compressed oxygen, reliability testing RI 8839
compressed oxygen 1-hour ..... OFR 178–83
destructive testing ..... RI 8890
human subject certification tests, evaluation OFR 48–84
1-hour, ruggedness and reliability evaluation RI 8657
safety evaluation ..... OFR 123–80
oxygen, coal mine escape time studies .... OFR 49–84
performance comparison ..... RI 8876
seminar proceedings ..... IC 8907
underground coal mines, recommended guidelines OFR 86(1)—(2)–81
underground noncoal mines, recommended guidelines ..... OFR 41–84
self-contained, seminar proceedings ..... IC 8907
Selkirks RARE II areas, ID, mineral investigation MLA 22–83
Selway-Bitterroot Wilderness, ID-MT, mineral investigation ..... MLA 102–82
Semiconductor devices, manganese dioxide use in, literature review ..... OFR 68–80
Seminar, technology exchange, mining information systems ..... OFR 119–82
Senegal, mineral industry, annual review MY 1983 (v. 3)
Sensor, metal hydride, thermally activated, patent P 2–83
Separator, continuous dielectric, for mineral beneficiation RI 8437
Serpentine quarry dust, identification and quantification, methods ..... OP 1–80
Service Creek roadless area, CO, mineral investigation MLA 123–82
Sespe Frazier RARE II area, CA, mineral investigation MLA 78–83
Severance taxes, State, rate change impact on copper recovery costs ..... OP 55–83
Seward Quadrangle, AK, mineral sampling sites and results ..... OFR 83–81
Seychelles, mineral industry, annual review MY 1983 (v. 3)
Shaft, circular, excavating equipment ..... OFR 20–82
Shaft design, Coeur d'Alene mining district, results of rock mechanics measurements ..... RI 8435
Shaft lining, continuous system .... OFR 186(1)—(3)–83
Shaft rock mechanics, displacement and support pressure, field measurement ..... RI 8909
Shaft sinking, impactor system, safety analysis OFR 112(1)–82
safety manual ..... OFR 112(2)–82
personnel training program ..... OFR 106–81
development ..... OFR 6–84
Shaft ventilation, coal mine, methane control during raise drilling ..... IC 8847
Shafts, mine cage overwind, bottom buffer energy absorption characteristics ..... OFR 133(2)–81
Shale, in situ oil mining, slurry filling system OFR 114–83
oil, creep behavior, elevated temperatures OFR 184–84
data bank ..... OFR 153(1)—(4)–82
bibliography ..... OFR 153(1)—(2)–82
patents ..... OFR 153(3)–82
research projects ..... OFR 153(4)–82
environmental effects of mining ..... OFR 168–82
technology ..... OFR 168–82
Shale roof, coal mine, effects of moisture ..... OP 57–84
deterioration control ..... OFR 41(1)—(2)–82
Shales, North Carolina Piedmont region ....NCGS 1–82
Pennsylvanian age, fracture mechanics ... OFR 24–83
Torreon Wash-Star Lake areas, NM, clay-mineral assemblages in ..... OFR 63–84
Shank tension, mine roof bolts, investigation OFR 82–80
Shear strength, clad metals, testing ..... OP 20–84
Shear tester, borehole, equipment and technique IC 8867
Shearer, deep cutting double arm, longwall coal mining, field tests ..... OFR 118–81
longwall, coal mine dust collector system . OFR 57–81
coal mine dust control system, patent ..... P 13–82
Shearer-clearer, longwall coal mining, dust control TPR 111
Shearers, longwall coal mine, dust compliance case studies ..... OP 59–82
Sheep Divide RARE II area, OR, mineral investigation MLA 15–83
Sheep Hole-Cadiz Wilderness Study Area, CA, mineral investigation ..... MLA 110–82
Sheep Mountain mining district, ID, mineral investigation ..... MLA 89–83
Sheep Mountain Wilderness Study Area, CA, mineral investigation ..... GS 2–82
Sheet metal, magnesium alloy, superplastic compositions RI 8662
Shell molding, titanium, using zircon, chromite, or olivine molds ..... RI 8443
Shielded cables, defects, detector evaluation . OFR 33–81
Shielded trailing cables, low-voltage, safety benefits and operating costs ..... OFR 81–80
Shinbone Creek RARE II Further Planning Area, AL, mineral investigation ..... MLA 43–82
Shining Rock Wilderness, NC, mineral investigation MLA 13–81
Short-circuit analysis, mine power systems .OFR 6(3)–81
Shortwall mining, illumination system .... OFR 114–80
surface, environmental assessment ..... OFR 126–80
Shotcrete, in mine ventilation bulkhead construction RI 8491
underground mining use, analysis ..... IC 8984
Shovels, electric, improved crowd limit switches and greenhorn ..... OP 14–84
Shuttle car trailing cables, splice testing, figure-S machine ..... OFR 80–80

Shuttle cars, cable reel systems, study ..... OFR 98–80
in low coal, protective canopy, development OFR 17–81
Sialon, from metastable precursor powder, patent P 4–80
sintering, additive effect on ..... RI 8466
Sialon compositions, sintering, effects of additives on RI 8546
Sierra Leone, mineral industry, annual review MY 1983 (v. 3)
Signaling, mine, hoist monitor and display system OFR 42–82
Signs, surface mine haulroads, design and demonstration OFR 189–82
Silica, bagging machine exhaust hoods, sulfur hexafluoride ventilation tests ..... RI 8527
in oxidized taconite process slurries, thermal neutron-gamma ray analysis ..... RI 8460
removal from Western U.S. phosphate ores, flotation techniques ..... RI 8728
Silicate mixtures, metal extraction from, patent P 42–81
Silicates, vanadiferous, Wyoming, vanadium-uranium extraction ..... RI 8822
Siliceous adsorbent, for heavy metal ions, patent P 7–81
Silicon, annual data .....MY 1983 (v. 1)
chromium partial replacement in stainless steels RI 8918
facts and problems ..... B 671
interference, during CO reduction of laterite ores OFR 29–80
summary .....SP 1–82
thermodynamic data ..... B 672
Silicon-aluminum-oxynitride compositions, sintering, effects of additives on ..... RI 8546
Silicon carbide, high-purity ultrafine powder, turbomill production ..... RI 8854
Silicon chloride, vapor complex formation with aluminum chloride .....OFR 63–81
Silicon nitride-alumina compositions, sintering, additive effect on ..... RI 8466
Sill Hill RARE II area, CA, mineral investigation MLA 10–83
Sillimanite, annual data .....MY 1983 (v. 1)
facts and problems ..... B 671
Silos, coal storage, methane hazard assessment . RI 8525
Silver, agglomeration-heap leaching operations . IC 8945
annual data .....MY 1983 (v. 1)
exploration, Fe-Mn oxide-rich fracture coatings OFR 96–84
extraction, Southwest mine dump material heap leaching .....OFR 109–81
facts and problems ..... B 671
from foreign properties, engineering and cost data OFR 140–84
from silver-brazed stainless steel honeycomb scrap, electrolytic stripping cell, patent ..... P 29–80
general information ..... MCP
heap leaching ..... OP 142–84
in electronic scrap, distribution and analyses . RI 8788
recovery, by hydrometallurgical processes .. OP 16–84
from aircraft scrap ..... RI 8477
from chloride leach solutions, iodide precipitation RI 8428
from cyanide tailings, acidic ferrous chloride-sodium chloride leachant ..... RI 8649
from electronic scrap ..... RI 8561
from electronic scrap concentrates ..... RI 8757
from low-grade resources, improved heap leaching RI 8612
secondary, price responsiveness .....OFR 74–82
thermodynamic data ..... B 672
U.S. leaching practices ..... IC 8969
vapor phase transport studies .....OFR 119–80
Silver ores, agglomeration and percolation leaching, patent .....P 9–81, 10–81
Silver Shaft, rock displacement and support pressure, field measurement ..... RI 8909
Singapore, mineral industry, annual review MY 1983 (v. 3)
Single-entry longwall mining, Sunnyside Mines study, 1971–80 .....OFR 25–84
Sintering, sialon compositions, effects of additives on RI 8546
silicon nitride-alumina compositions, additive effect on RI 8466
Sipsey Wilderness and RARE II areas, AL, mineral investigation .....MLA 19–81
Size distributions, particles, adjusting, computer program OP 26–81
Slag erosion, resistance of selected refractories . RI 8823
Slags, basic oxygen furnace, synthetic fluorspar use, evaluation ..... RI 8558
chromium-bearing, acid precipitation leach prevention RI 8878
coal and lignite, corrosion resistance of basic refractories ..... RI 8633
copper, analysis by flame atomic absorption spectroscopy ..... RI 8484
copper converter, sulfur addition to produce matte RI 8687
copper smelting furnace, iron and copper recovery from, carbothermic reduction ..... RI 8697
high-salt aluminum-bearing, aluminum recovery from, experimental process ..... RI 8446
iron and steel, annual data .....MY 1983 (v. 1)
iron silicate, and copper-iron matte, copper losses and impurity distribution between ..... RI 8655
lead blast furnace, effect of composition ..... RI 8753
molten, refractory resistance to, laboratory test RI 8468
titanium, purifying by sulfation, patent ..... P 14–82
Slaking, coal mine wastes, environmental effects OFR 13–82
surface coal mine spoils, Eastern and Central United States, environmental effect .....OFR 146–80
Slate, Vermont, and limestone, glasses from, asbestos substitute .....OFR 124–82
waste, conversion to glass and glass-ceramic products OFR 123–82
Slate mining industry, Vermont and New York, study OFR 125–80
Slate Range Wilderness Study Area, CA, mineral investigation ..... MLA 104–83
Slideboard device, mine face ventilation, patent P 23–81
Slimes, clarifying, patent ..... P 31–81
Florida phosphate operations, phosphate recovery from RI 8731
insoluble, sylvinite and carnallite ores, direct flotation of potash from ..... OP 24–81
mine, dewatering using direct current ..... OP 80–83
molybdenum mine, dewatering ..... RI 8441
phosphate and potash, microbial flocculation OFR 195–82
potash ore, continuous flotation removal process RI 8516
sylvinite ore, removal by froth flotation, patent P 6–80
Slope construction, personnel training program, development .....OFR 6–84
underground mine illumination .....OFR 61–82
Slope failure detection, remote video monitoring OFR 70–83
Slope instability, detection through microseismic techniques .....OP 6–80
Slope stability, coal waste embankments, centrifugal model analysis .....OFR 43–81
rock slopes, open pit mines, risk analysis OFR 46(1)—(8)–81
surface mine, microseismic monitoring system RI 8641
surface mine spoils, Interior coal province OFR 78(1)—(2)–80
tailings embankments, probability density function IC 8941

Slope stability, tailings pond embankments, factor of safety charts ..... RI 8564
Slopes, mine, rock stability-deformation analysis OFR 183–83
Sludge, from acid mine drainage treatment, disposal RI 8672
mine, dewatering using direct current ..... OP 80–83
waste water treatment, zinc recovery from . OP 56–81
Slurries, coal-clay waste, dewatering RI 8636; OP 79–82
mineral particle points of zero charge, determination by titration ..... RI 8635
oxidized taconite beneficiation, process stream analysis RI 8461
tailings, dewatering methods and equipment review IC 8972
Slurry, coal, hydraulic borehole mining ....OFR 117–81
coal-refuse, dewatering ..... RI 8581
coal waste, transport properties ..... RI 8825
coarse coal, pipeline injector .....OFR 190–84
Slurry transport, longwall coal mine, system development and analysis .....OFR 58–84
underground noncoal minerals, feasibility OFR 108–82
Smelter dusts, copper recovery from ..... RI 8554
Smelter flue dusts, antimony in, atomic absorption spectrometry determination ..... RI 8510
Smelter potlining, aluminum, as fluorspar substitute in cupola ironmelting ..... RI 8530
Smelters, nonferrous, sulfur dioxide emission controls, impact .....OFR 133–82
sulfuric acid, byproduct production .....OFR 94(3)–81
Smelting, copper matte, minor-element interactions RI 8874
Smoke, from coal-lined tunnel fires, characteristics OP 40–81
Smoke particles, coal mine fires, submicrometer particle monitoring in sealed areas ..... RI 8586
Smoke protection system, for mine shafts, development OP 3–80
Snap Point Wilderness Study Area, AZ, mineral investigation .....MLA 8–84
Snow Mountain Wilderness Area, CA, mineral resources GS 5–81
Snowbird RARE II Further Planning Area, NC, mineral investigation .....MLA 42–82
Soapstone Ridge, GA, amphiboles, petrographic examination ..... RI 8627
Sociology, consequences of surface mine blasting OFR 144–82
Soda, extraction, from dawsonite-bearing oil shale RI 8796
Soda ash, annual data .....MY 1983 (v. 1)
facts and problems ..... B 671
1983 overview ..... OP 64–84
solution mining, state of the art .....OFR 142–82
U.S., availability in world market, factors .. OP 21–83
short-term demand, outlook ..... OP 21–83
Sodium, thermodynamic data ..... B 672
Sodium aluminate solution, from anorthosite lime sintering, desilication ..... RI 8713
Sodium bicarbonate, facts and problems ..... B 671
Sodium carbonate, annual data .....MY 1983 (v. 1)
Sodium chloride solution, zirconium-hafnium separation, sodium sulfate removal from, patent ... P 30–80
Sodium compounds, annual data .....MY 1983 (v. 1)
Sodium nitrate, molten, thermal degradation effect on oil shale ..... OP 62–83
Sodium perchlorate, production, zinc and copper electrowinning ..... OP 139–84
Sodium silicate gel grout, in horizontal degasification borehole plugging ..... RI 8843
Sodium sulfate, annual data .....MY 1983 (v. 1)
facts and problems ..... B 671
in nickel electrolyte, compatibility with solvent extraction system ..... RI 8754
Sodium sulfate, removal from zirconium-hafnium separation solution, patent..... P 30–80
Sodium sulfide leach, of lead concentrate leach residue, for sulfur and metals recovery ..... RI 8733
Software techniques, microseismic data acquisition RI 8691
Soil, Western U.S., optimum thickness in mined land revegetation .....OFR 70–84
Soil compaction, effects of surface mining in Midwestern U.S. .....OFR 174–82
Soil depth, Northern Great Plains, surface mine reclamation .....OFR 202–82
Soil loosening equipment, mined land reclamation, appraisal .....OFR 33–84
Soil properties, reclaimed surface mined land OFR 187(1)–84
Solar evaporation, process and waste brines, potash recovery ..... RI 8911
Soldering, aluminum, soft-soldering system .... RI 8747
Solid-state equipment, coal mining use, control and protection circuit .....OFR 126–81
Solid waste, municipal, fuel from, analytical reference material development ..... RI 8426
Solid wastes, coal mine, ground water contamination by OFR 73–81
shale and slate, conversion to glass and glass-ceramic products .....OFR 123–82
titanium plant, titanium and coke recovery .. RI 8737
Solids, suspended, removal from water, patent ... P 6–83
Solomon Islands, mineral industry, annual review MY 1983 (v. 3)
Solubility, gases, in geobrines ..... RI 8706
Solutes, in binary solvents, activity coefficients OP 19–83
Solution chemistry, sample preparation, in plastic pressure vessels ..... RI 8480
Solution concentrations, polymeric, determination by drag reduction ..... RI 8559
Solution mining, branched single well for input and output, patent ..... P 20–80
clayey ore, permeability effect of clay stabilizers RI 8902
copper, temperature effects ..... RI 8642
U.S. case histories ..... IC 8961
copper from chalcopyrite ores .....OFR 180–83
environmental impact .....OFR 101–80
in situ, evaporites .....OFR 181–82
in situ uranium leaching, cost analysis..... OFR 97–82
environmentally attractive leachants ..OFR 133–83
research overview, seminar proceedings ..... IC 8852
state of the art, potash .....OFR 142–82
salt .....OFR 142–82
soda ash .....OFR 142–82
uranium, lixiviant excursion detection ..... OFR 5–81
pilot-scale experiment case history ..... RI 8652
uranium ores, lixiviant selection ..... IC 8851
Solutions, hydrometallurgical ionic, activity determination-estimation-correlation .OP 20–83
multicomponent, statistical thermodynamics OP 45–82
Solvent extraction, cobalt, from laterite-ammoniacal leach liquors ..... RI 8419
copper, from laterite-ammoniacal leach liquors RI 8605
iron, from aluminum chloride leach liquor ... RI 8560
from aluminum nitrate leach liquors ..... RI 8634
nickel, from laterite-ammoniacal leach liquors RI 8605
zirconium-hafnium separation, patent ..... P 24–80
zirconyl sulfate purification ..... RI 8849
Solvent extraction emulsions, organic and aqueous phase recovery, patent ..... P 22–80
Solvent extraction kinetics, preliminary investigation OFR 202–84
Solvents, binary, activity coefficients of solutes in OP 19–83
used in mining, thermal degradation products RI 8517

Somalia, mineral industry, annual review MY 1983 (v. 3)
Somerset County, PA, Upper Kittanning Coalbed, roof rock stability prediction ..... RI 8575
Sonar, in powerline proximity warning devices, study OFR 175–82
Sonic agglomeration, maintaining high resonance, patent P 43–81
Sonic logging, new technique ..... TPR 117
Sorbents, efficiency determination, diffusion-type gas samplers ..... OFR 136–83
SOUND Study Area, placer sampling and related BuMines activities, Chugach National Forest, AK ..... MLA 62–82
South Africa, Republic of, economic indices, development OFR 164–84
gold production, overview ..... OP 93–84
mineral industry, annual review ...MY 1983 (v. 3)
South Carolina, mineral industry, annual review MY 1983 (v. 2)
mineral investigation, Ellicott Rock Wilderness Area and additions ..... MLA 29–81
Hell Hole Bay Wilderness Area ..... MLA 122–82
Little Wambaw Swamp Wilderness Area MLA 122–82
Wambaw Creek Wilderness Area ..... MLA 122–82
Wambaw Swamp Wilderness Area .... MLA 122–82
surface mine monitoring, application of satellite data OFR 11–80
South Dakota, Black Hills National Forest, hazardous openings to abandoned mines OFR 74(1)—(3)–80
mineral industry, annual review .....MY 1983 (v. 2)
mineral investigation, Black Elk Wilderness MLA 14–84
Powder River-Fort Union region, surface mined land, fish and wildlife enhancement ..... OFR 197–84
South Piney Creek Wilderness Study Area, CO, mineral investigation ..... MLA 24–84
South Providence Wilderness Study Area, CA, mineral investigation ..... MLA 32–84
Southern Anthracite Field, PA, surface mining steeply pitching coal seams ..... OFR 39(2)–81
Southern Massanutten RARE II Further Planning Area, VA, mineral investigation ..... MLA 73–82
Soviet Union, mineral industries, 1983 ..... OP 126–84
Spain, mineral industry, annual review .MY 1983 (v. 3)
Spalling, impact, iron alloys, ball-on-block wear test RI 8794
large-scale test ..... OP 33–83
Spanish Peaks Roadless Area, CO, mineral investigation MLA 58–83
SPASID, underground mining ground movement prediction, computer program user manual OFR 59–84
Specimen holder, for diffractometer ..... OP 45–80
Spectrometer, X-ray fluorescence, computer interface OP 70–83
portable prototype, testing ..... IC 8888
Spectrophotometric analysis, uranium, using dibenzoylmethane ..... RI 8433
Spectroscopic data, calculating thermodynamic properties from, computer program ..... IC 8871
Sphagnum moss, use in acid mine drainage treatment system ..... OP 3–84
Sphalerite, recovery, from Western U.S. tactite ores RI 8716
thermodynamic properties, electrochemical determination ..... OP 83–82
Sphalerite concentrates, zinc and sulfur recovery from, reaction with sulfuric acid ..... RI 8690
Spillways, mine waste embankment drainage, hydraulic model tests ..... OFR 132–81
Splices, coal mine trailing cables, explosion-proof connector ..... OFR 149–81
Splices, portable trailing cable design and installation OFR 11–83
trailing cable, testing, figure-S machine ... OFR 80–80
Splicing, mine power system cables, errors .... HB 1–81
mines cables, handbook ..... HB 1–84
Split Set mine roof bolts, corrosion resistance, to uranium and copper mine waters ..... RI 8904
Spodumene, stability relationship with petalite, in lithium pegmatites ..... RI 8719
Spoil, coal mine, underground disposal, evaluation OFR 15–80
surface coal mine, burial of toxic material OFR 182–82
Spoils, coal, regraded, hydrologic and erosional characteristics ..... OFR 81–83
coal mine, ground water contamination by OFR 73–81
surface coal mine, Eastern and Central United States, environmental effects of slaking ...OFR 146–80
surface mine, stability evaluation, Interior coal province ..... OFR 78(1)—(2)–80
surface mine stability, Eastern coal province, evaluation and bibliography .....OFR 52(1)–84
field data ..... OFR 52(2)–84
manual of practice ..... OFR 52(3)–84
Spontaneous combustion, coal, effect of moisture transfer OFR 113–81
mathematical model ..... OP 18–83
in U.S. coals, susceptibility ..... RI 8474
underground metal mines, improved protection OFR 79–80
Spoor Canyon RARE II area, CA, mineral investigation MLA 17–83
Spray nozzle, self-cleaning, for coal mine sealants, patent P 9–80
Sprays, water, dust control ..... OFR 98–83
Sputtering, coating elongated tubes and strips, patent P 30–81
Sputtering equipment, adapting for coating long tubes and strips ..... OP 60–80
Square Butte Instant Wilderness Study Area, MT, mineral investigation ..... MLA 45–82
Squeeze monitoring, coal mine, dial-gauge tube extensometer ..... TPR 113
Sri Lanka, mineral industry, annual review MY 1983 (v. 3)
Stability, tailings pond embankments, factor of safety charts ..... RI 8564
Stainless steel, aluminum-containing, sulfidation and oxidation resistance ..... RI 8856
chromium in, substitutes ..... OP 129–84
corrosion ..... OP 56–84
Stainless steel dust, chemical dissolution or leaching tests ..... OP 26–82
physical separation ..... OP 27–82
Stainless steel scrap, chromium availability from IC 8822; OFR 8(2)–80
chromium recovery from, pyrometallurgical method RI 8571; OFR 75–80
rapid identification ..... RI 8858
Stainless steel slags, waste, chromium leaching prevention ..... RI 8878
Stainless steel wastes, in-plant recycling ..... RI 8724
Stainless steels, chromium-free, iron-aluminum-molybdenum alloy substitute ..... RI 8654
chromium partial replacement ..... RI 8900
chromium substitution ..... OFR 110–81
international market analysis ..... OFR 18–83
pickling, literature review ..... IC 8985
reduced-chromium, silicon and aluminum additions RI 8918
substitutes, iron alloys strengthened by Laves phases RI 8470
vapor-aluminum-diffused, analysis ..... RI 8629
Stainless steels pickling liquors, nickel and chromium from ..... OP 18–84

Standard Industrial Classification, minerals data collection system based on ..... OFR 36–82
Stanley Mountain RARE II area, CA, mineral investigation ..... MLA 57–83
Stannic oxide, thermodynamic data ..... RI 8906
Stansbury Roadless Area, UT, mineral investigation MLA 70–83
Starch xanthate, cross-linked, flocculation ... OP 115–84
Starches, cross-linked, in oxide and hydroxide mineral fine flocculation ..... OP 24–83
Starvation Point Wilderness Study Area, UT, mineral investigation ..... MLA 27–84
State regulations, internal combustion engines, underground use ..... IC 8845
Statistical analysis, underground mine disaster fatalities OFR 13–81
Staurolite, annual data ..... MY 1983 (v. 1)
Steam stripping, sulfur dioxide, from citrate process solutions ..... RI 8734
Steel, annual data ..... MY 1983 (v. 1)
facts and problems ..... B 671
ferrous scrap metal use in ..... RI 8622
ion-implanted alloys on, corrosion fatigue behavior effect ..... OP 38–83
linear polarization effect ..... OP 38–83
Japan's specialty steel industry, selected raw material requirements ..... IC 8946
rusted, impacting with light alloys, incendivity measurement ..... RI 8684
stainless, pickling liquors, nickel and chromium from OP 18–84
Steel castings, contaminants effect, purchased scrap OFR 37–82; OP 16–83
Steel industry, market instability ..... OFR 97–81
Steel scrap, annual data ..... MY 1983 (v. 1)
Steel sets, mine roof support, use analysis ..... IC 8992
Steel slag, annual data ..... MY 1983 (v. 1)
Steel supports, underground coal mine, European design criteria ..... OFR 121(2)–82
Steelmaking, basic oxygen furnace, synthetic fluorspar use, evaluation ..... RI 8558
chrome-containing furnace linings, brick from, properties ..... RI 8685
chrome refractory wastes, recycling ..... RI 8489
waste magnesite-chrome refractories, recycling OP 23–80
Steelmaking dusts, carbon steel, chemical dissolution or leaching tests ..... OP 26–82
physical separation ..... OP 27–82
electric arc furnace, bulk sample characterization OP 25–82
characterization ..... RI 8750
stainless steel, chemical dissolution or leaching tests OP 26–82
physical separation ..... OP 27–82
Steelmaking furnaces, recycling refractories from OP 80–82
Steelmaking wastes, stainless and specialty, in-plant recycling ..... RI 8724
Steels, alloy, chromium-free ..... OFR 147–83
low-alloy nitrided, corrosion resistance ..... RI 8894
made from urban refuse magnetic fraction, corrosion resistance ..... RI 8447
stainless, international market analysis .. OFR 18–83
pickling, literature review ..... IC 8985
Steering systems, surface mining equipment, survey OFR 132–80
Stemming, airblast and ground vibration control by OFR 8–84
blasthole, height measuring systems ..... OFR 4–84
Stench fire warning system, upgraded, underground mines ..... OFR 136–81
Stench gas, canister mine fire warning system, concept OP 23–82
fire warning system, in-mine remote actuation RI 8872
Stillwater Complex, anorthositic platinum-palladium ore, beneficiation ..... RI 8763
chromite ores, amine flotation ..... RI 8502
chromium extraction from low-grade ores OFR 151–82
matte smelting and leaching, platinum-group metal recovery ..... RI 8717
platinum-palladium flotation concentrate, preparation from ore ..... RI 8500
platinum-palladium ore, pilot mill flotation .. RI 8885
Stirling engines, underground mining applications OFR 129–83
Stone, crushed, annual data ..... MY 1983 (v. 1)
dimension, annual data ..... MY 1983 (v. 1)
facts and problems ..... B 671
Stone mining, improved ground control safety OFR 60–83
Stope preconditioning, rock burst control .... OFR 51–81
Stopping leaks, reduction, brushing on sealants OP 56–82
Stoppings, concrete, leakage reduction ..... IC 8949
concrete block, construction techniques ..... HB 1–83
damage-resistant ..... OP 33–84
new designs, update ..... OP 42–81
parachute-type ..... OP 32–84
Storage batteries, lead-acid, explosion prevention IC 8842
lead recovery from, electrolytic method, scale-up study RI 8857
recycling, lead recovery from, electrolytic method RI 8602
Stormwater runoff, mined land, finite element simulation OFR 9(2)–84
unit hydrograph models ..... OFR 9(1)–84
Stowing, coal mines, underground waste disposal OFR 48–82
Strategic metals, U.S. dependency, issues, ferrochromium OP 92–84
Strategic minerals, in Alaska, study ..... IC 8869
Strawberry Mountain Wilderness, OR, mineral resources GS 6–81
Streamflow estimation, northern Alaska, surface mining OFR 11–84
Stress, distribution around resin-grouted bolts .. RI 8440
in situ horizontal, Beckley coal mining district, field tests and computer model ..... OFR 143–80
Stress analysis, coal mine roof behavior, analytical modeling ..... OFR 41–81
Sunnyside Mine No. 1, single- and double-entry portions ..... OFR 16(3)–80
three-dimensional, double-entry coal mine OFR 16(1)–80
underground coal mine design, computer simulation OFR 66–82
wire hoist ropes ..... OFR 50–84
Stress determination, in viscoelastic rock mass, hydraulic borehole pressure cells ..... OP 46–81
Stress distribution, oil shale, in situ retorting, finite element analysis ..... RI 8597
Stress reduction, rock burst control, preconditioned zone, mining beyond ..... OFR 52–81
stope block, rock burst control ..... OFR 51–81
Stresses, horizontal, in vertical boreholes, least squares calculation ..... RI 8414
Strontium, annual data ..... MY 1983 (v. 1)
battery electrodes, electrochemical characterization OFR 75–81
facts and problems ..... B 671
1983 overview ..... OP 61–84
synopsis of 1982 activity ..... OP 56–83
thermodynamic data ..... B 672
Structural analysis, longwall panel entries .. OFR 50–82
nonlinear, mines, computer program ..... OFR 19–82
Structural damage, from surface mine blasting ground vibrations, study ..... OFR 105–80
residential, by surface mine blasting ..... OP 12–81
subsidence, ground surface conditions survey OP 12–84

Structural damage, surface mine blasting, study. RI 8507
wood-frame house, from surface mine blasting RI 8896
Structures, damage to, by surface mining airblast RI 8485
Sturgeon River Wilderness Study Area, MI, mineral resources ..... GS 3–80
Submicrometer particles, in coal mine fire sealed areas, monitoring ..... RI 8586
Subsidence, coal mine, economic effect on Illinois, agricultural land ..... OFR 186–84
over four room-and-pillar sections ..... RI 8645
coal mine rock discontinuities influence ... OFR 30–84
coal mine workings detection, resistivity techniques OFR 55–81
coal mining beneath surface water, hazard determination criteria ..... OFR 45–81
ground movement near caving stopes, monitoring RI 8585
longwall, effects on overlying aquifers, Pennsylvania OFR 142–84
longwall coal mine, microseismic monitoring OFR 30(3)–80
longwall coal mining, Northern Appalachian region, data ..... OFR 124(1)—(2)–81, 145–81
preliminary data analysis ..... OP 9–81
Rocky Mountain coal province panels .... OFR 3–84
longwall panel characterization ..... OFR 192–83
mine, predictive methods, evaluation ..... OP 50–84
new sonic logging technique ..... TPR 117
Northern Appalachian Coalfield, data assessment for prediction ..... RI 8630
over room-and-pillar panels, West Virginia OFR 133–84
prediction, consideration of overburden lithology OP 31–82
prevention, cemented backfill use in underground coal mines ..... OFR 92–82
improved guidelines ..... OFR 138(1)—(4)–84
reclaimed surface-mined land, Northern Great Plains, study ..... OFR 145–80
room-and-pillar mines, factors ..... OFR 68–83
structural response, ground surface conditions survey OP 12–84
surface, over longwall panels, Deer Creek Mine, UT IC 8896
thick coal seam, effect on hydrology ..... OFR 93–80
Subsidence control, abandoned coal mine workings, Rock Springs, WY ..... IC 8846
auger mining, aerostatic roof support ..... OFR 14–83
backfilling ..... OP 60–82
Subsidence prediction, computer model .... OFR 102–83
Substations, mine electrical, grounding and bonding guide ..... IC 8835
Sudan, mineral industry, annual review MY 1983 (v. 3)
Sugarloaf RARE II area, CA, mineral investigation MLA 9–83
NV, mineral investigation ..... MLA 96–83
Sulfapave materials, physical and chemical properties RI 8905
Sulfate-chloride brines, potash recovery from, solar evaporation and flotation ..... RI 8911
Sulfates, diesel exhaust, determination ..... RI 8683
sampling state of the art ..... OFR 63–80
Sulfide concentrates, chlorine-oxygen leach liquors, purification by zinc cementation ..... RI 8707
Duluth Complex, copper-nickel-cobalt matte from RI 8752
Sulfide deposits, Mount Henry Clay area, AK OFR 118–84
Sulfide flotation, mineral-reagent interactions, symposium proceedings ..... IC 8818
Sulfide leaching residue, base-metal, weathering RI 8667
Sulfide matte, lead smelter, metal recovery from, chlorine-oxygen leaching ..... RI 8615
Sulfide minerals, selective flocculation, insoluble cross-linked starch xanthate RI 8819; OP 16–82
Sulfide ores, comminution ..... OFR 146–83
complex, metal recovery from, patent ..... P 23–83
Sulfide precipitation, heavy metals, from high-salinity geobrines ..... OFR 91–81
Sulfide tailings, disposal systems, general information OFR 146–81
thickened discharge method ..... OFR 146–81
Sulfides, electrochemical flotation ..... OP 141–84
chalcocite-ethylxanthate interactions OP 7–84, 134–84
chalcocite reaction in aqueous solutions... OP 11–84
oxidative-electrolysis leaching ..... OP 155–84
semiconducting, point defects, hydrometallurgical processes ..... OFR 145–83
Sulfolobus acidocaldarius, use in chalcopyrite leaching RI 8827; OFR 113–80
Sulfonamides, in animal tissues and feed, determination OP 85–82
Sulfur, addition to copper converter slags, to produce matte ..... RI 8687
annual data ..... MY 1983 (v. 1)
as asphalt extender, overview ..... OP 18–81
Canadian recovered, impact on U.S. Frasch sulfur output ..... OFR 94(1)–81
citrate process flue gas desulfurization, chemical reactions ..... RI 8540
electric utility production, from flue gas desulfurization ..... OFR 94(2)–81
facts and problems ..... B 671
foreign properties, engineering and cost data OFR 188–84
Frasch, industry analysis ..... OFR 94(1)–81
in coal ..... OFR 189–83
industrial demand, changing patterns ..... OP 1–83
modified, cements, patent ..... P 2–82
use in concretes, technology ..... OP 55–81
modified citrate process flue gas desulfurization, description and economic evaluation ... RI 8638
non-U.S. production, impact on domestic production OFR 94(3)–81
recovered, overview ..... OFR 94(1)–81
recovery, from leach process residue ..... RI 8733
from petroleum refining and natural gas processing OFR 94(2)–81
from sphalerite concentrates, using sulfuric acid RI 8690
from synfuels, in situ coal gasification, heavy oil, and heavy crude oil ..... OFR 94(2)–81
removal, fluidized bed coal combustion emissions, Ohio limestone suitability ..... OFR 38–83
removal from flue gases, citrate process analytical chemistry ..... IC 8819
Texas and Louisiana, Frasch production, impact of decreased output ..... OFR 94(4)–81
thermodynamic data ..... B 672
U.S. industry, disposal problem ... OFR 94(1)—(4)–81
summary ..... OFR 94(1)–81
use, in recycling asphaltic concrete, patent ... P 26–80
Sulfur cements, modified, patent ..... P 2–82, 12–83
use in construction materials ..... RI 8545
Sulfur concrete, plasticized, highway pavement use OFR 13–83
Sulfur concretes, corrosion-resistant ..... RI 8758
cyclopentadiene oligomer-dicyclopentadiene formulation, patent ..... P 12–82
densifiable, for corrosive environments ..... RI 8905
in corrosive environments, industrial evaluation RI 8786
sulfuric acid corrosive environment use .... OP 20–82
Sulfur dioxide, in citrate process solutions, pressurized steam stripping ..... RI 8734
in diesel exhaust, reactive contaminants, in-mine measurement ..... OFR 198–82
in metal extraction from Pacific sea nodules .. RI 8518
nonferrous metal smelter emission controls, impact on mining and acid market ..... OFR 133–82
personal sampler, development ..... OFR 137–81

Sulfur dioxide, removal from flue gases, citrate process demonstration ..... OP 13–80
Sulfur-extended asphalt pavement, guideline manual OP 29–81
physical and mechanical properties ..... OP 30–81
Sulfur hexafluoride, as mine ventilation research tool, field applications ..... RI 8735
in bagging machine hood enclosure ventilation tests RI 8527
in coal mine face ventilation measurement ... RI 8473
Sulfur hexafluoride gas, tracing mine ventilation OP 34–84
Sulfuric acid, aluminosilicate materials reactions OFR 37–83
from smelter gases, effect of emission controls on market ..... OFR 133–82
iron-zirconium films, corrosion resistance in .OP 27–84
production, acid plants and smelters ....OFR 94(3)–81
sulfur concrete corrosion resistance to ..... OP 20–82
Sulfurous acid, leaching, alumina extraction from clay RI 8533
use in metal recovery from Atlantic sea nodules, patent ..... P 15–80
Sunnyside Mine No. 1, methane drainage by horizontal boreholes ..... OP 79–83
single- and double-entry portions, stress analysis OFR 16(3)–80
Sunnyside Mines, UT, single-entry study, 1971–80 OFR 25–84
Sunshine Mine, ID, telephone system .....OFR 51–83
Superalloy, iron-base, consolidation by powder metallurgy techniques ..... RI 8556
Superalloy scrap, chromium recovery from, chlorine leaching, patent ..... P 3–83
patent ..... P 13–81
process .....RI 8570; OFR 69–80
leaching rate increase, melting with aluminum RI 8833
rapid identification ..... RI 8858
Superalloys, chromium recovery from, pyrometallurgical method .....RI 8571; OFR 75–80
scrap, chromium availability from IC 8821; OFR 8(1)–80
Superplasticity, magnesium alloy sheet, commercial and experimental compositions ..... RI 8662
Superstition Wilderness and contiguous RARE II Further Planning Areas, AZ, mineral investigation MLA 136–82
Supplies, underground coal mine, handling system OFR 99–84
Supply Analysis Model, Minerals Availability System IC 8820
Support walls, longwall coal mining, health and safety analysis ..... OFR 121(1)—(2)–82
steel, underground coal mine, European design criteria OFR 121(2)–82

mining machine, effect on face air ..... OP 24–84, 80–84, 130–84, 153–84
Water treatment sludge, zinc recovery from .. OP 56–81
Water usage costs, U.S. mineral industry, effect on international competitiveness ..... OFR 85–80
Water use planning, northern Alaska, surface mining OFR 11–84
Water vapor, effect on real-time aerosol monitor . RI 8898
in helium, meter calibration ..... RI 8548
Watersheds, surface mined, hydrology and water quality OFR 208–84, 209–84, 210–84
surface mining, premining hydrology and water quality ..... OFR 31–80, 88–80
Wear properties, titanium diboride electrodeposited coatings ..... RI 8537
Wear-resistant coatings, cast-on, from polystyrene patterns ..... OP 77–84
for coal conversion components ..... OP 11–80
Weathering, coal mine face, sealant ..... OFR 71–81
Weaver Bally RARE II area, CA, mineral investigation MLA 93–83
Welcome Creek Wilderness, MT, mineral investigation MLA 17–82
Welding, fume generation, collection and analysis RI 8793
Welding exhaust, surface mine, airborne contaminant reduction ..... IC 8868
Well barrier pillars, underground mine, oil and/or gas leak prevention, design criteria ... OFR 147–81
Well design, in situ uranium leaching, well design OFR 61–83
Wells, for geobrine evaluation, engineering variables RI 8465
fracture sited, mine dewatering ..OFR 109(1)—(2)–84
in situ leaching, water jet perforation ..... RI 8569
Wenaha-Tucannon Wilderness Study Area, WA, mineral investigation ..... MLA 20–83
West Elliotts Creek RARE II Further Planning Area, Al, mineral investigation ..... MLA 50–82
West Face Sacramento Mountains Roadless Area, NM, mineral investigation ..... MLA 27–83
West Needle Wilderness Study Area and contiguous area, CO, mineral investigation ....MLA 35–83
West Pioneer RARE II area, MT, mineral investigation MLA 4–81
West Slope Tetons RARE II Further Planning Area, WY, mineral investigation ..... MLA 111–82
West Virginia, Beckley district, in situ horizontal rock stress, field tests and computer model OFR 143–80
coal waste embankments, inventory OFR 100(1)—(3)–82
Dunkard Basin, coal mine roof hazards, delineation using LANDSAT images ..... OFR 166–81
Federal No. 2 Mine, overlying strata, effect on methane emissions ..... RI 8879
Lower Kittanning Seam, clay dikes ..... OP 85–84
mineral industry, annual review .....MY 1983 (v. 2)
mineral investigation, Cheat Mountain Further Planning Area ..... MLA 113–82
Cranberry Wilderness Study Area .....GS 4–81
Dolly Sods Wilderness Area .....GS 4–80
Mill Creek Wilderness Study Area .....GS 3–83
Mountain Lake Wilderness Study Area ....GS 3–83
Peters Mountain Wilderness Study Area ...GS 3–83
Pocahontas No. 3 Coalbed, geology and mine roof conditions ..... IC 8864
Pocahontas No. 3 seam, roof falls, study ..OFR 36–80
Pottsville lithic arenite and quartz arenite, comparison OP 3–82
Randolph County, mine seals, evaluation of 1967 construction ..... RI 8852
subsidence over room-and-pillar panel ...OFR 133–84
West Virginia University, fourth conference on coal mine electrotechnology, proceedings .....OFR 107–81
fifth conference on coal mine electrotechnology, proceedings ..... OFR 82–81
sixth conference on coal mine electrotechnology, proceedings ..... OFR 163–83
West Yuba RARE II area, CA, mineral investigation MLA 71–83
Westcliffe, CO, closed mines, study ..... OFR 138(2)–84
Westland Mine, PA, coal washouts, geologic character RI 8555
Wet Beaver Creek RARE II Further Planning Area, AZ, mineral investigation ..... MLA 134–82
Wet high-intensity magnetic separation, iron recovery from tailings, patent ..... P 7–80
Wetting agents, coal mine dust control, effectiveness OFR 127–81
laboratory tests ..... RI 8815
Wheel slip monitor, pan scraper application . OFR 32–84
Wheeler Peak Roadless Area, NV, mineral investigation MLA 56–83
Wheeler Peak Wilderness, NM, mineral investigation MLA 127–82
Wheeler Ridge RARE II area, CA, mineral investigation MLA 3–83
Whetstone roadless area, AZ, mineral investigation MLA 129–82
Whipple Mountains Wilderness Study Area, CA, mineral investigation ..... MLA 29–82
White Cloud-Boulder RARE II area, ID, mineral investigation ..... MLA 59–83
White Mountain Wilderness addition, NM, mineral investigation ..... MLA 33–83
White Mountains RARE II area, CA-NV, mineral investigation ..... MLA 94–83
White Pine Mine, roof fall alarm systems, field tests OFR 50–80
roof falls, resistivity warning system ..... OFR 53–80
tiltmeter roof fall warning system, evaluation OFR 66–80

Wild Cattle Mountain RARE II area, CA, mineral investigation ..... MLA 30–83
Wild River RARE II Further Planning Area, NH, mineral investigation ..... MLA 98–82
Wilderness Contiguous RARE II area, CA, mineral investigation ..... MLA 3–81
Wilderness mineral potential, U.S. Forest lands, 1964-84 study ..... GS 4–84
Wildrose Canyon Wilderness Study Area, CA, mineral investigation ..... MLA 37–83
Wilkeson, WA, hydraulic coal mine, feasibility ..... OFR 89–84
Williams Fork Roadless Area, CO, mineral investigation ..... MLA 67–83
Williston Basin, mining resource bibliography ..... OFR 191–83
Windigo Theilson RARE II area, OR, mineral investigation ..... MLA 11–81
Window design, explosion-proof enclosures ..... IC 8880
Wire, dedicated, mine trolley carrier phone system ..... OFR 89–82, 203–82
vibrating, anchoring into a hollow gauge body, patent ..... P 10–80
Wire rope terminations, assembly, training and inspection manual ..... OFR 2(3)–81
efficiency and service life ..... OFR 2(1)–81
removal, safer procedures ..... RI 8859
selection and inspection guide ..... OFR 2(2)–81
Wire ropes, mine hoist, lubrication criteria ..... OFR 65–80
6×19 classification, analysis ..... RI 8817
statistical analysis ..... OFR 54–84
stress analysis ..... OFR 50–84
Wisconsin, copper mining, premine planning and environmental requirements ..... OFR 208–83
mineral industry, annual review ..... MY 1983 (v. 2)
mineral investigation, Flynn Lake Wilderness Study Area ..... MLA 32–82; GS 9–81
Rainbow Lake Wilderness Area ..... MLA 32–82; GS 9–81
Round Lake Wilderness Study Area ..... GS 10–81
Northern Highland, copper mining, premine planning, cost and time analysis ..... OFR 25–80
taxation and mineral operation profitability, hypothetical study ..... MI
Withington Wilderness Area, NM, mineral investigation ..... MLA 72–83
Wollastonite, annual data ..... MY 1983 (v. 1)
Wonder Mountain RARE II area, WA, mineral investigation ..... MLA 105–82
Wood, untreated, in mine fire under forced ventilation experimental study ..... RI 8450
Wood mine timbers, fire and rot retardant treatments ..... OFR 20–81, 115–81
Wood products, coal mining use ..... OFR 177–82
Wood wastes, in iron oxide reduction roasting, study ..... RI 8746
Woodpecker RARE II area, CA, mineral investigation ..... MLA 10–81
Work force, coal mining industry needs, study ..... OFR 14–80
Work locations, mine, analysis to establish illumination needs ..... OFR 111(1)—(2)–81
Working face, coal mine dust concentrations, study ..... OFR 98–81
Working level, radon daughter alpha-energy nondiscrimination, error in working-level calculations ..... OP 45–81
Working level exposure, radon, continuous determination method, patent ..... P 5–80
Working level monitor, mine radiation warning system ..... OP 44–82
World economy, minerals in, annual review ..... MY 1983 (v. 3)
Wyoming, Bear Creek, hydraulic borehole mining, environmental monitoring program demonstration ..... OFR 21–82
Wyoming, Green River, two-bed trona mining, rock mechanics investigation ..... RI 8598
Green River-Hams Fork region, surface mined land, fish and wildlife enhancement ..... OFR 196–84
Hanna Basin, surface mining steeply pitching coal seams ..... OFR 39(2)–81
mineral industry, annual review ..... MY 1983 (v. 2)
mineral investigation, Bridger Wilderness ..... MLA 125–82
Cloud Peak Contiguous roadless area ..... MLA 131–82
Green-Sweetwater RARE II Wilderness Recommendation Area ..... MLA 125–82
Huston Park RARE II Further Planning Area ..... MLA 72–82
Little Goose roadless area ..... MLA 131–82
Palisades RARE II area ..... MLA 46–83
Raymond Mountains Wilderness Study Area ..... MLA 97–83
Rock Creek roadless area ..... MLA 131–82
Savage Run Wilderness ..... MLA 75–82
West Slope Tetons RARE II Further Planning Area ..... MLA 111–82
Nine-Mile Lake site, ground-water quality restoration, after uranium in situ leaching ..... OP 63–82
North Absaroka Wilderness and vicinity, geology and mineral resources ..... GS 1–80
Overthrust Belt, Federal land status ..... SP 2–81
Powder River Basin, monitoring and modeling ground water systems ..... OFR 25(1)—(2)–83
Powder River-Fort Union region, surface mined land, fish and wildlife enhancement ..... OFR 197–84
Rock Springs, abandoned coal mine workings, pumped-slurry backfilling ..... IC 8846
vanadiferous silicates, vanadium-uranium extraction ..... RI 8822

X

X-ray emission, proton-induced, in characterization of thin films and solid surfaces ..... RI 8455
X-ray fluorescence spectrometer, computer interface ..... OP 70–83
portable prototype, testing ..... IC 8888
Xanthan gum, rheology of, oil recovery by chemical flooding methods ..... OFR 22–83
Xanthate, insoluble cross-linked starch, for selective sulfide mineral flocculation RI 8819; OP 16–82
Xanthine, as inhibitor in ANFO reactivity with pyrite, evaluation ..... RI 8727
Xanthomonads, effect on in situ uranium leaching ..... OFR 90–83; OP 88–83
Xenon, thermodynamic data ..... B 672

Y

Yakobi Island and adjacent parts of Chichagof Island, AK, mineral investigation ..... MLA 97–82
Yemen, People's Democratic Republic of, mineral industry, annual review ..... MY 1983 (v. 3)
Yemen Arab Republic, mineral industry, annual review ..... MY 1983 (v. 3)
Yolly Bolly-Middle Eel Wilderness, CA, mineral investigation ..... MLA 103–82
Yolla Bolly-Middle Eel Wilderness proposed additions, CA, mineral investigation ..... MLA 3–81
Ytterbium, annual data ..... MY 1983 (v. 1)
thermodynamic data ..... B 672
Yttrium, annual data ..... MY 1983 (v. 1)
facts and problems ..... B 671
fused-salt electrowinning and electrorefining ..... OP 4–80
thermodynamic data ..... B 672

Yttrium alloys, electrodeposition ..... OP 4–80
Yugoslavia, mineral industry, annual review MY 1983 (v. 3)
Yukon Flats, AK, coal and uranium investigation OFR 140–81
Yukon Flats Basin, AK, trona occurrences ... OFR 69–81

Z

Zaire, cobalt production economics ..... OP 65–84
mineral industry, annual review .....MY 1983 (v. 3)
Zambia, cobalt production economics ..... OP 65–84
economic indices, development .....OFR 121–84
mineral industry, annual review .....MY 1983 (v. 3)
Zapata Creek Wilderness Study Area, CO, mineral investigation .....MLA 24–84
Zeolites, annual data .....MY 1983 (v. 1)
fibrous, comparison with asbestos ..... OP 15–83
size and shape characterization ..... RI 8674
Zeta potential, mineral particle points of zero charge, determination by titration ..... RI 8635
Zimbabwe, mineral industry, annual review MY 1983 (v. 3)
summary .....MP
Zinc, annual data .....MY 1983 (v. 1)
electrolytic waste, recovery of principal metal values from ..... RI 8582
electrowinning, insoluble anodes ..... RI 8531
with sodium perchlorate production ..... OP 139–84
facts and problems ..... B 671
from zinc chloride, electrolysis, monopolar and bipolar fused-salt cells ..... RI 8524
general information ..... MCP
in and near National Petroleum Reserve, AK MLA 121–82
in Salton Sea geobrines, mineral recovery unit, operation ..... RI 8680
in waste catalysts, assessment .....OFR 197–82
Mount Schwatka region, AK, mineral potential OFR 70–80
pollution-free retorting .....OFR 71–83
production and uses ..... OP 18–80
recovery, from brass smelter flue dusts ..... OP 77–82
from electrolytic zinc plant copper filter cake OP 66–82
from electrolytic zinc waste ..... RI 8582
from lead flue dusts ..... RI 8659
from smelter flue dust ..... OP 66–82
from sphalerite concentrates, using sulfuric acid RI 8690
from waste water treatment sludge ..... OP 56–81
separation, from shredded auto scrap ..... RI 8771
thermodynamic data ..... B 672
U.S. availability, Minerals Availability Program appraisal ..... IC 8962
vapor phase transport studies .....OFR 119–80
Zinc chloride, zinc from, electrolysis, monopolar and bipolar fused-salt cells ..... RI 8524
Zinc concentrates, roasting, behavior of cadmium during RI 8543
Zinc oxide, as inhibitor in ANFO reactivity with pyrite, evaluation ..... RI 8727
Zinc oxysulfate, enthalpy of formation ..... RI 8688
Zinc sulfide concentrates, chlorine-oxygen leach liquors, purification by zinc cementation ..... RI 8707
Juan de Fuca Ridge, chlorine-oxygen leaching TPR 122
Zircon, byproduct, recovery from Oregon and Washington sand and gravel operations ..... RI 8563
Zircon molds, bentonite-bonded, for titanium casting RI 8587
titanium alloys, hot isostatic pressing effect .. RI 8897
titanium and zirconium castings ..... OP 40–82
Zircon sand, zirconyl sulfate solution from, method RI 8718
Zircon sands, in shape-casting titanium ..... RI 8443
Zirconia castables, calcia stabilized .....OFR 65–81
Zirconium, annual data .....MY 1983 (v. 1)
corrosion resistance, effect of ferric ion on .... RI 8610
facts and problems ..... B 671
separation from uranium, in aqueous solutions, patent P 6–82
patent ..... P 5–83
solvent extraction separation from hafnium, patent P 24–80
thermodynamic data ..... B 672
Zirconium alloys, corrosion resistance, in alumina recovery from clay ..... RI 8565
Zirconium boride, chemical vapor deposition, literature review ..... IC 8928
Zirconium carbide, chemical vapor deposition, literature review ..... IC 8928
strengthener for iron-aluminum-molybdenum alloys, as chromium substitute in stainless steel . RI 8654
Zirconium castings, olivine and zircon sand molds OP 40–82
Zirconium-hafnium, anhydrous separation techniques, review ..... IC 8963
Zirconium-hafnium separation, by countercurrent extraction, computer simulation ..... OP 14–82
sodium sulfate removal from separation solution, patent ..... P 30–80
Zirconium iodide, high-temperature enthalpy.... RI 8418
X-ray powder diffraction data ..... RI 8418
Zirconium nitride, chemical vapor deposition, literature review ..... IC 8928
Zirconium oxide, investment mold use, for molybdenum castings ..... RI 8624
nuclear-grade, from zirconyl chloride strip liquors, hydrothermal precipitation .....OFR 124–80
reactor-grade, from chloride-sulfate strip liquor RI 8850
Zirconyl sulfate, purification, by solvent extraction RI 8849
Zirconyl sulfate solution, from zircon sand, method RI 8718
Zunyite, potential as refractory-grade bauxite substitute OP 18–82

AUTHOR INDEX

In the following index, a comma following the name of the first author in an entry indicates that the first author is the senior author; all other authors in the entry are junior authors.

A semicolon following the name of the first author in an entry indicates that the first author is a junior author; the name of the senior author immediately follows.
