## FOREWORD

Each year the Bureau of Mines Minerals Yearbook features an annual energy balance by source and end-use. It has been suggested that this national balance would be improved if it were prepared within the context of prior State and regional balances, and interregional energy flows.

Unfortunately, supply and demand data on a State-by-State basis for various energy sources, forms, and markets are not readily available. This study attempts to correct this deficiency by constructing an energy model at the State and regional levels and quantifying this with available data and information. The integrated balances in this report were prepared from commodity balances presented in four parts: (1) Coal, (2) Utility Electricity, (3) Natural Gas, and (4) Petroleum and Natural Gas Liquids. Data are shown for the years 1960 and 1965.

The State and regional energy balances presented in the other four parts of the study are compatible with and additive to the Yearbook's national balances for 1960 and 1965. This compatibility was achieved by using the national energy model as a base for the State and regional models; by standard presentation of energy components with a 50-State, three-region, and seven-subregion framework; and by the use of standard units and energy equivalents (British thermal units). The separate commodity balances and flows were designed to serve as inputs for the construction of integrated energy balances at the State, regional, and national levels.

SUPPLY AND DEMAND FOR ENERGY IN THE UNITED STATES  
BY STATES AND REGIONS, 1960 AND 1965

Integrated Energy Balances and Energy Flows

(Prepared From Four Parts)

by

R. F. Zaffarano,<sup>1</sup> P. N. Yasnowsky,<sup>2</sup> L. H. Crump,<sup>3</sup> and W. Y. Mo<sup>4</sup>

---

ABSTRACT

Integrated energy balances and energy flows were constructed and quantified for State, regional, and national levels from four separate supply and demand commodity balances for coal, dry natural gas, petroleum and natural gas liquids, and utility electricity. These commodity balances were integrated by source and sectors through conversion and aggregation of their components to energy equivalents expressed in British thermal units (Btu). A summarization of the total gross energy components of supply and demand for commercial energy derived from direct fuels, hydropower and nuclear power, based on individual States and regions, is tabulated for 1960 and 1965. Pertinent computerization details and more than 500 individual State and regional printout tables, in both original commodity units and Btu's, are shown. Using these data, energy flows between States and regions were calculated to identify surplus and deficit energy areas. Report emphasis is on the conceptual aspects of integrated energy balances, rather than on the development of missing State energy data.

INTRODUCTION

Energy balances are simplified quantitative models that relate to the overall energy industry dynamics. Limited to gross energy consumption in this report, energy balances describe the level of input energy sources and their derivatives, as well as their distribution among the consuming sectors. The energy resources presented in the balances are those used to produce, transform, and transport energy to the point of consumption.

Increasing sophistication is being achieved in simulating future energy patterns and flows within the framework of simplified energy models constructed on a national basis. Improvements in quantification of major energy components have led to the construction of projections and contingency forecasts by energy components. Most of these have, however, also been national models. Geographic shifts can occur in energy demand or sources of supply that alter projected or forecast patterns. Consequently, the quality of national forecasts would be improved if prior analysis and projections were made at the State and regional levels. Such analysis has been limited in the past by the difficulty of obtaining detailed, reliable energy data by State and region on a standardized basis.

The scope of this experimental study is conceptual in nature and restricted to the methodology of constructing and quantifying energy balances at the national, State, and regional levels. The State-by-State feature is believed to be unique for U.S. energy balances.

The earlier supply-demand balances for coal, dry natural gas, petroleum and natural gas liquids, and utility electricity (1-4)<sup>5</sup> were required to construct the integrated balances in this report. A key factor was the need to quantify every sector of the model on a State basis. Many State energy data were unavailable. Therefore, it was necessary to quantify State components for energy by estimates of partial data or by working toward controlled totals for the regions and subregions. The derived estimates are sensitive to varying degrees of statistical precision depending upon the availability of data in each instance and on individual judgments.

In view of this approach to overcoming State-by-State deficiencies in energy supply-demand data, readers should not attempt to use the State data as firm figures. The regional and national energy balance data may be used with a higher degree of certainty.

In the preparation of the integrated energy balances from the four commodity balances, an operation research team devised a systematic approach to integrating the commodity balances using computer flexibility and speed. Using a total energy base that combines the energy equivalent inputs for coal, dry natural gas, petroleum and natural gas liquids, hydropower, and nuclear power, the balances show the distribution of energy within the four major energy sectors by source. Thus it was possible to show the proportional market size and the sources of energy supply and to identify energy surplus and deficit subregional areas.

Historic supply-demand energy data used in the four commodity balances are expressed in both conventional units and theoretical energy equivalents, British thermal units (Btu). The latter permits conversion of energy data to a common denominator; it makes the construction of the integrated balances possible, and also permits the disaggregation and comparative analysis between energy sources and sectors. The 50-State and arbitrarily selected regional and subregional components are given in appendix B. A tabular summarization of the total gross energy in Btu for all combined sources of energy is shown in tables 1 and 2. Figures 1 to 10 were prepared to assist the reader to digest the pertinent regional comparisons within energy sources and markets.

---

<sup>5</sup>Underlined numbers in parentheses refer to items in the list of references preceding the bibliography.

The primary source data used in the balances is Bureau of Mines Information Circular 8384 (5). The basic energy model and national control totals for both sources and uses of energy within the balances for 1960 and 1965 were obtained from this publication. Within this data source, Bureau of Mines data on fossil fuels in the Minerals Yearbook are supplemented by data for the utility electricity sector obtained from publications and reports of the Federal Power Commission; for the nuclear power industry, from reports of the U.S. Atomic Energy Commission; and for electricity sales and distribution, from the annual issues of the Edison Electric Institute Statistical Yearbook of the Electric Utility Industry. Historical data on energy demand by major industry groups in the mineral and industrial sectors were obtained from the U.S. Department of Commerce Censuses of the Mineral Industries and the Censuses of Manufacturers.

Results of the individual commodity balances in the four part study are compatible with and additive to the national balances featured in the Minerals Yearbook chapter, "Review of the Mineral Fuel Industries." Readers interested in the details concerning the conversion of respective energy sources and uses to theoretical thermal units are referred to the individual commodity balance reports.

## PRELIMINARY ANALYSIS

National

Oil was the leading energy source in 1960 and 1965, supplying 44 and 42 percent, respectively, of the gross energy sources, including both direct and electric generation use (fig. 1). Natural gas ranked second, with 28 and 31 percent of the total gross energy supply, respectively, for 1960 and 1965. Thus all petroleum sources (oil and natural gas) provided from 72 to 73 percent of the Nation's energy requirements in those respective years. Coal captured 24 and 23 percent of the energy market, with the remaining 4 percent of overall energy derived from water; an insignificant share came from nuclear power.

In 1960, as in the past, oil continued to dominate the transportation market, coal the electric utility sector, with oil and gas capturing and

FIGURE 1. - National Energy Consumption by Source and Percentage Distribution of Total Gross Energy, 1960 and 1965.

sharing the household and commercial energy use. Five years later, fossil fuels had retained their relative share of the energy market, with the exception of coal. By 1965, coal use increased both absolutely and relatively to the extent that approximately 50 percent of the electric utility power was coal derived. Coal's advance in electric utility power was a continuation of a gradual growth trend that began in 1950.

In the western regions, hydroelectric power was an important segment of power generation. Hydropower maintained a relatively stable portion and minor role in the competitive fuel market. The limited growth of hydropower is the result of its concentration in remote locations which imposes high transmission costs to large consumer areas. During 1960 and 1965, hydropower represented 4 percent of the total energy consumed. This proportion of total energy is comparable to that shared since 1950.

By 1965, nuclear energy as a fuel source for electric power was only barely approaching a competitive level. At that time, economic studies of prototype nuclear plants showed an advantage for nuclear power based upon improvements in reactor design and decline in future operating costs. As demonstrated in figure 1, nuclear power represented only an insignificant percentage of total energy used to generate electricity in 1960 and 1965.

Utility electricity is considered a secondary energy source, generated by one or more primary sources. This major secondary source accounted for approximately 20 percent of the Nation's gross energy consumption in both 1960 and 1965. Fossil fuels were the major primary energy contributor to utility electric conversion. In 1960, coal served 64 percent of the utility electric fossil inputs; gas, 27 percent; and oil, 9 percent. By 1965, these shares were 65, 27, and 8 percent, respectively.

Energy consuming sectors are broadly classified as four major markets: household and commercial, industrial, transportation, and electricity generation utilities. As shown in figure 3, the transportation sector represents approximately a quarter of the Nation's overall energy consumption within the 2 study years. The remainder of energy consumption was absorbed in the stationary energy markets (household and commercial, industrial, and electricity generation). Portions of energy supply that could not be distributed among the various consuming sectors are listed as miscellaneous. For both 1960 and 1965, miscellaneous uses accounted for 4 to 6 percent of the total energy market.

The relative size of the energy markets are indicated in figure 3. In both years the industrial market was the largest segment of consumption, with approximately one-third of the total energy consumed. Some 20 percent of the industrial market stems from the iron and steel industry. The household and commercial and electric utility markets shared a lesser portion of the total energy market.

Most crude oil is consumed as a secondary energy, in the form of crude petroleum products. Consequently, their use was treated as a separate entity

FIGURE 2. - National Energy Markets by Fossil Fuel Source, 1960 and 1965.

FIGURE 3. - National Markets for Primary Energy, 1960 and 1965.

in the energy balances for both the supply and demand data apart from primary energy sources.

### Subregional

The regional flows of net energy are shown graphically in figures 4 and 5. The flow pattern indicates that central subregion IIb and western subregion IIIa are the primary surplus energy areas and all other subregions are deficit areas. As shown in figures 7 and 8, the major energy markets during 1960 and 1965 were located within subregions Ia, Ib, IIb, and IIIb, which coincide with the heavily populated and industrialized areas of the country.

The data demonstrate that energy market size varies from region to region. The extent of the variations for 1960 and 1965 are shown in figures 6, 7, and 8 with the industrial market and the major area of energy utilization in subregions Ia, Ib, and IIb. The IIb subregion requirements in the industrial market are allied to major industry operations attracted to the region because of low prices of delivered oil and gas energy. The major energy market for subregion IIa is concentrated in the household and commercial use, which because of colder weather requires more energy for heating. Transportation is the major energy market in subregions IIIa, IIIb, and IIIc. Business and family automobile uses are main contributors to this market.

The proportion of the Nation's total gross energy that is contributed by each of the seven subregions and their relative Btu market size are shown in figure 6. Subregion IIb was a surplus energy area in 1960 and 1965, producing more than twice the energy consumed (see figs. 4 and 5). In 1960, subregion IIIa barely qualified statistically as a surplus total energy area. By 1965, this subregion's total energy status reverted to a deficit because of the net effect within the petroleum segment of an increase in demand and a corresponding reduction in indigenous production. All other subregions for both 1960 and 1965 were deficit energy areas.

## USES OF STATE AND REGIONAL ENERGY BALANCES

State and regional energy balances permit the analysis of the entire energy industry on a geographical basis, rather than on a limited commodity-by-commodity basis at the national level. As such, they can show the change in flow patterns within the energy resources supplied to the consuming sectors from energy surplus to energy deficit States and regions. Application of the energy balance approach by geographic breakdown falls within the following four major analytical uses (6):

State and regional forecasting - forecasts of source and use of energy and of flows between surplus and deficit areas.

Resource adequacy - depicts the highest degree of economic and geographic substitutability between energy sources.

Resource efficiency - gross energy inputs required to transform energy sources into usable energy forms in terms of regional or State availability and requirements.

Consumption shift analysis - changing energy patterns within consumption sectors relative to given energy sources by States, regions, and at the national level.

## COMPETITION AND SUBSTITUTION

As shown in figures 9 and 10, the energy market is equal to the sum of its parts. Major developments in price and efficiency of one or more of the fuels in application not only leads to substitution of one fuel for another but also to changes in the regional demand for energy.

Regional energy flow patterns (figs. 4 and 5) demonstrate the intricate interrelationships among the consuming markets and uses in which all energy sources compete in the various regions and subregions. Factors responsible for the change in energy sources and for substitution within regional markets include, but are not limited to, one or a combination of the following:

(1) change in technology, markets, or transportation of energy; (2) environmental considerations; (3) growth in total energy demand; (4) price changes; and (5) changes in energy efficiencies.

Transportation is a key factor in energy selection within States and regions. The primary energy resources of the United States are not located in areas of highest population density; therefore, some bulk transportation is required for most energy consumed. Consequently, there is a substantial transportation cost involved in moving energy, and sizable fuel cost differentials exist between source and use areas of the country. For example, the geographic distribution of delivered fuel costs to electric utilities favor most of subregion IIb, the western extremity of Ia, and the northeastern portion of subregion IIIa. In these locations, gas, coal, and hydropower, respectively, are indigenously produced in abundant, economic quantities.

FIGURE 9. - Subregional Energy Markets by Sources, 1960.

In comparing subregion IIIb's electric utilities market for 1960 with that of 1965, it can be seen that nuclear power and coal made inroads into the electric utility market (figs. 9 and 10). The 1965 nuclear power plants were located on the shores of the Pacific Ocean where availability of large amounts of water was assured. Because of the relative lack of rivers in California, the potential number of additional nuclear power plant sites of this type is somewhat limited for indigenous power. Other subregions showing nuclear power advances or entrances in electric utilities market are Ia, Ib, and IIa (see figs. 9 and 10).

Regional and State cost of all energy sources during 1960 and 1965 increased unequally because of differences in the ratios of labor costs to total costs of production, dislocation, and geographic losses. Electricity costs increased at a moderate rate by States and regions because of the

FIGURE 10. - Subregional Energy Markets by Sources, 1965.

relatively low labor component and the increase in fuel efficiency of the thermal utilities power plants.

Within the States and regions where coal is consumed, principally region I, increased costs have been overcome by improved productivity of coal miners and the reduced rail transportation rates, brought about by the use of integral-train concept. Construction of large mine-mouth powerplants has been an effective alternative to rising delivered coal costs within regions I and III.

To reduce labor costs, the petroleum industry is moving more and more to large, packaged, and automated production operations within subregions IIb, IIIa, IIIb, and IIIc. In addition, numerous improvements and refinements in technology have helped to counter rising costs of material and supplies.

APPENDIX A.--COMPUTER PROGRAMS AND IDENTIFICATION OF VARIABLES USED  
IN THE PROGRAM AND SEQUENCES OF INPUT-DECK

Three computer programs were prepared in FORTRAN IV to facilitate the construction of State-by-State and regional energy balances for the years 1960 and 1965 (see tables in appendix B). Data consist of physical measures of energy consumption and supply, and their thermal equivalents, British thermal units (Btu). The Btu's serve as a common denominator to compare market size and growth of the different energy sources and utilizations and as a common measure for aggregation. By including the program in this publication, other investigators may use this program in further regional energy balance work related to any desired regional configuration.

The programs are named ENRGY, BALNE, and REPRO. ENRGY and BALNE elements are designed for executing the Btu and physical unit balance sectors. The card detail and order for both the REPRO and ENRGY program elements are given in tables A-1 and A-2, figures A-1 and A-2. The BALNE element is identical to the ENRGY card order. The REPRO program segment is developed to calculate the complexities of the petroleum products in Btu and physical units.

On the basis of using the program stored in a magnetic tape, an annual energy balance can be completed in less than 20 minutes of computer running time on a Honeywell - 1200<sup>1</sup> involving a printout of 256 tables. Thus the tedious calculations, checking, and typing are eliminated. Moreover, the data bank of approximately 5,000 IBM data cards can readily be retrieved for other studies requiring these energy data.
