INTRODUCTION

This is the initial version of the WLN Index to the *Toxic Substances List (TSL).* This index provides to *TSL* users the capability both of looking up a specific compound and performing substructure searches on more than 6,000 of the compounds reported in *TSL.*

Permuted WLN indexes have been in use for some time and are now widely accepted. The incorporation of such an index in *TSL* is intended to make the wealth of data in *TSL* more readily accessible to users.

The basic index consists of a computer printout showing WLN notations for significant compounds in the current issue of *TSL.* Space requirements have limited the number of compounds that can be included. The compounds indexed have been selected on the basis of widest general interest.

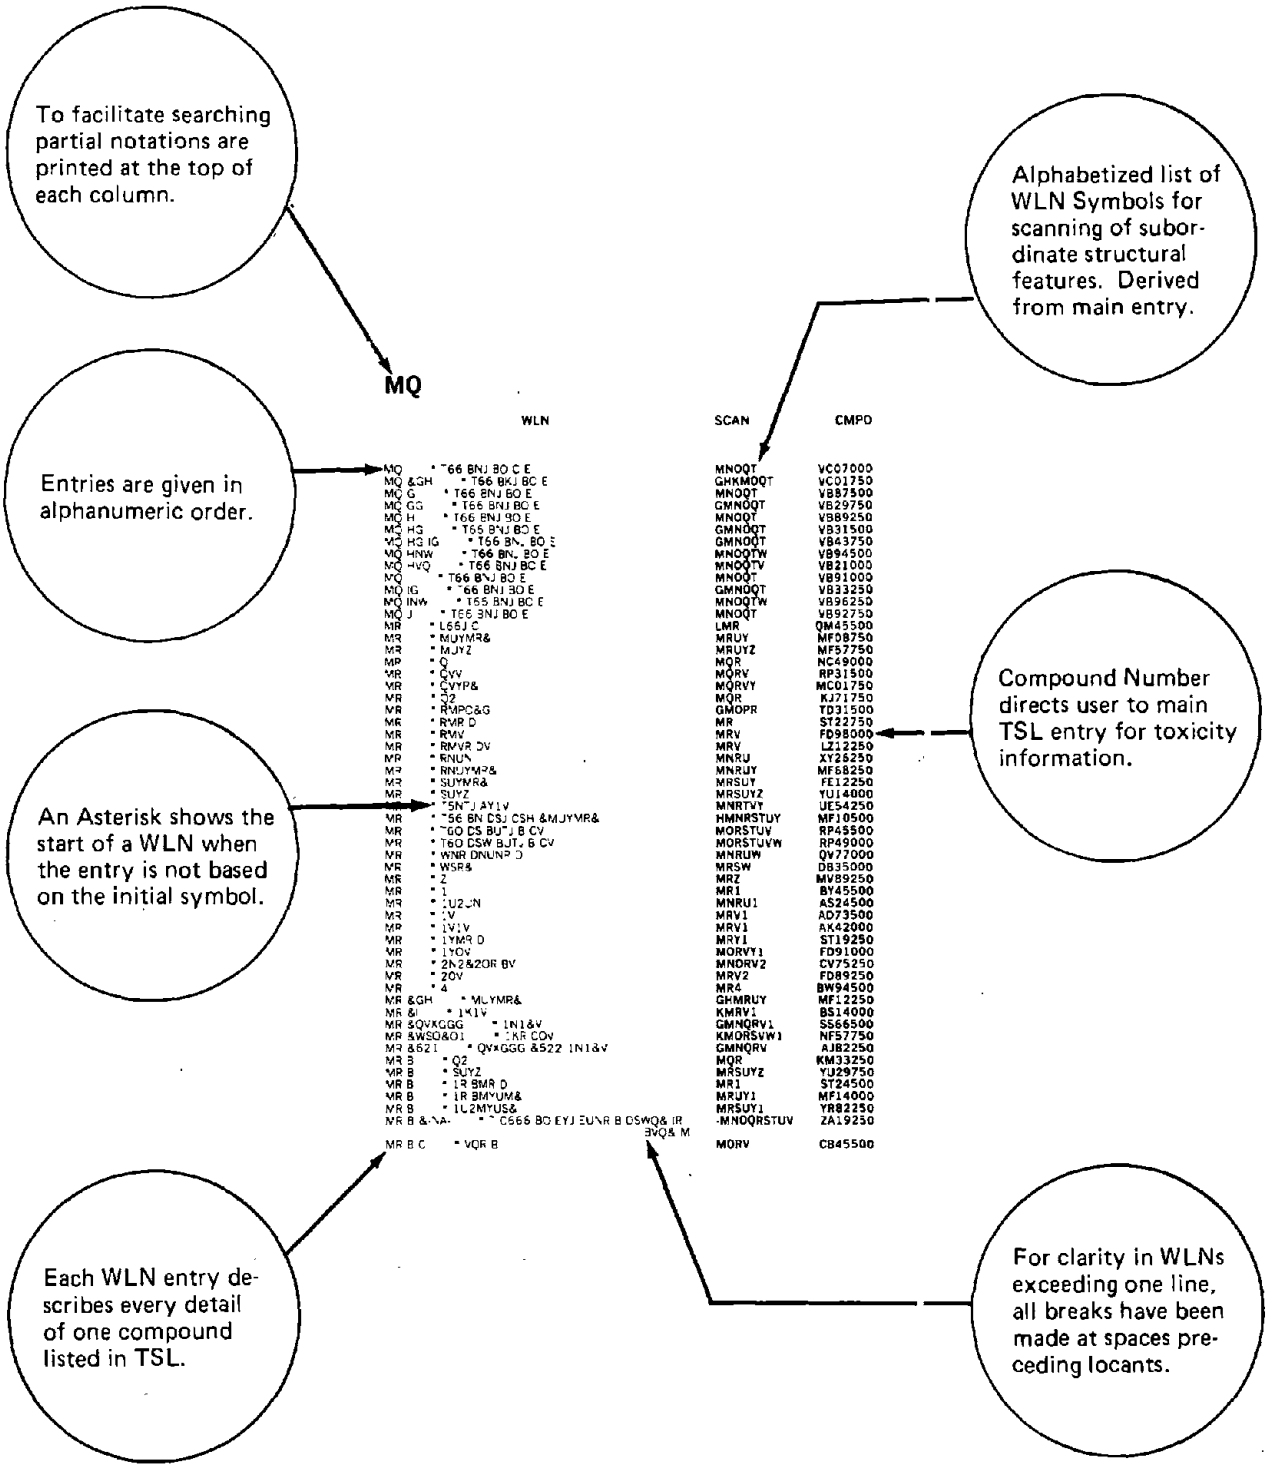
Use of this index assumes and requires a knowledge of WLN. A short but comprehensive description of WLN is contained in "Wiswesser Chemical Line-Notation", a paper by Gerald W. Gibson and Charles E. Granito that appeared in American Laboratory, 4, 27-37 (1972).

Several user aids designed to enhance the utility of the index are also provided herein. These user aids include:

- An explanatory chart showing the basic elements of the index listing. Note particularly the Scan column, a device that allows the user to make a rapid visual search of the index listings to locate compounds of interest.
- A chart listing and defining all Wiswesser symbols.
- A summary of WLN permutation rules.

In future issues of *TSL,* the WLN index will be continued and expanded. Reader comments are invited. Particular attention will be given to suggestions for increasing the usefulness of the index.

EXPLANATORY CHART OF WLN INDEX



EXPLANATORY CHART OF WLN INDEX

WISWESSER SYMBOLS

The Wiswesser Line Notation (WLN) comprises 42 symbols. Following is a listing and brief description of the use of the symbols. The listing is included here as a reference tool for the reader preparing a notation in order to search the index.

CAPITAL LETTERS (26)	
LETTER	**DESCRIPTION**
A (Not used in this index)	Generic alkyl
B	Boron
C	Unbranched carbon atom multiply bonded to atom other than carbon or doubly bonded to two carbons (allenes)
D (Not used in this index)	Chelate bond and first symbol in chelate notation
E	Bromine
F	Fluorine
G	Chlorine
H	(1) Hydrogen (2) When preceded by a locant, shows position of carbon atom bonded to four other atoms
I	Iodine
J	End of a ring description
K	Nitrogen bonded to more than three other atoms
L	Initial symbol in carbocyclic ring notation
M	Imino or imido -NH- group
N	Nitrogen (hydrogen-free) bonded to no more than three other atoms
O	Oxygen (hydrogen-free)
P	Phosphorous
Q	Hydroxyl group, -OH
R	Benzene ring
S	Sulfur
T	(1) Initial symbol in heterocyclic ring notation (2) ring containing two or more carbon atoms, each attached to four other atoms
U	Double bond
V	Carbonyl connective
W	Dioxygen group
X	Carbon attached to four atoms other than hydrogen
Y	Carbon attached to three atoms other than hydrogen
Z	Amino or amido $-NH_2$ group
NUMERALS (10)	
0 1 2	Preceded by a blank space: • Multiplies preceding symbols • Shows multicyclic points in ring structure
3 4 5 6 7 8 9	Not Preceded by a blank space: • Shows length of internally saturated, unbranched alkyl chains and segments • Shows size of ring structure
SPECIAL CHARACTERS (6)	
Blank Space Space ( )	Preceding a letter: • Locates ring position Preceding a number: • Multiplies previous symbols • Shows multicyclic points in ring structure
Hyphen (-)	Separates or connects elements within a notation
Ampersand (&)	• Indicates a ring not containing two or more carbon atoms bonded to four other atoms • Preceded by a space-letter-hyphen combination, shows spiro connections • Shows end of a side chain • Preceded by a blank space, indicates ionic salt, addition compound, or suffixed information
Slash (/)	(1) Shows end of polymer (2) Stops action of multiplier (3) Encloses symbol groups
Period (.)	Used in totally inorganic structures. Initiates such notations and separates atoms and/or ions
Asterisk (*)	Used within slashes to denote repeating units in polymers

PERMUTATION RULES

FIRST CHARACTER

The first character of each WLN is included as an entry; this permits specific compound lookup in addition to substructure searching.

SPECIAL CHARACTERS

All special characters, except hyphens which initiate metals, are excluded as entries.

HYPHENS

Only hyphens which initiate metals are included as entries, e.g., -ZN- is only indexed by the first hyphen. Therefore, all metals containing organic compounds may be found at the front of the index.

NUMERALS

All numerals denoting ring size, multicyclic points and alkyls of 3 or less carbons are excluded as entries. However, straight chain alkyls of 4 or more carbons are indexed.

R and Y

Occur very frequently and thus have little primary indexing value. Excluded as primary entry symbol, but retained in SCAN.

X

Creates an entry when representing a ring spiro point.

J

Excluded as primary entry symbol.

H

Cited after the symbol to which it is attached. For example, VH for aldehydes. Excluded as a primary entry symbol, but retained for the SCAN Table.

T

Primary entry symbol when used to initiate a heterocyclic ring; also included in SCAN Table. When used as a saturation mark, T is excluded as primary entry symbol and not included in SCAN Table.

SINGLE RING ATOMS

Potential entries starting with the following WLN symbols are excluded: NJ, NTJ, OJ OTJ, SJ, STJ. These ring segments serve little, if any, value as index terms.

Wiswesser chemical line-notation

By Gerald W. Gibson and Charles E. Granito

LINE-NOTATIONS improve communication among chemists. "Communication" for the chemist typically involves time-consuming searches through numerous indexes for answers to structure-oriented questions. In traditional indexes substructure information is widely dispersed and often buried; the following paragraphs describe how line-notations are used to remedy these failings.

To transfer information about a moderately complex organic compound, the chemist concocts a semidescriptive name that serves adequately for discussing it in a lecture or seminar or across the laboratory bench, but offers no confidence that an indexer (or even a fellow chemist) would use the *same* name. Suppose, the novice might ask, one wishes to comb the literature for this compound or others structurally similar to it; how can one be certain that the search is complete? The answer, of course, is: one cannot.

Both designers and users of chemical indexes are handicapped because even the "official" nomenclature system permits alternative choices in naming organic compounds, e.g., in citing substituents along a carbon chain. Nomenclature, then, is necessary for oral and written communication among chemists, but, as the quantity of chemical information grows, its inadequacy as an indexing tool becomes increasingly evident.

A chemical line-notation is inherently better suited than a nomenclature system for confident, rapid, detailed retrieval of structural information — by humans or machines. Three-dimensional structures are condensed into unique, unambiguous, one-dimensional notations; there is only one notation for a given compound, and only one place to look for it in an index. Because the notation is a string of individual symbols that represents functional groups, molecular fragments, bond types, or structural features, it is possible to tailor indexing techniques for general searching. For example, using a permuted notation index, searches for all esters, acids, or pyridine derivatives can be accomplished in a matter of minutes.[1-4]

It is not surprising then that industrial research organizations are turning to the line-notation as a remedy for many indexing ills and as an information retrieval instrument of great versatility. Of the several chemical line-notation systems that have been devised,[5,6] the Wiswesser system[7,8] is the only one that has gained widespread acceptance; it is the basis for more than fifty operational chemical information retrieval programs comprising over one million chemical notations in this and other countries. The advantages offered by Wiswesser line-notation (WLN) should eventually make it a generally employed indexing tool. Regrettably, however, the chemistry student receives little, if any, formal training in chemical information retrieval; he remains unaware of an advance that is increasingly relevant and important to his profession.

Wiswesser line-notation

Wiswesser line-notation provides a topological view of the organic molecule. A unique, unambiguous description of the molecule is assured by using a framework of rules to establish the molecular architecture (how everything is connected), plus a set of symbols to denote the units of construction (what things are connected). These rules are kept to a minimum and are simpler than those for nomenclature; this makes WLN easy to learn and use. WLN's linearity makes it ideal for compiling tables of physical properties or other data, and because there is a *unique* notation for each structure, it makes a good base for organizing and keeping inventory of a chemical stockroom. Also, any file of compounds may be more easily maintained by utilizing WLN.

We hope the following discussion alerts the chemistry teacher to the wide usefulness of WLN and enables him to give basic instructions for encoding the majority of compounds found in an elementary organic chemistry text.

WLN symbols

Wiswesser line-notation retains the majority of element symbols known by chemists. The few new

Dr. Gibson is Professor of Chemistry, College of Charleston; Mr. Granito is President, CG Associates, Cherry Hill, N.J.

Preceding page blank

symbols — used for frequently encountered atoms and functional groups — are mnemonically suggestive. All WLN symbols are standard characters found on unmodified keyboards and computer printers. This makes the notation compatible with machine-use, from typewriter to computer — a significant point as more and more machine handling of chemical information takes place (see, e.g., Refs. 1–3, 9–12). However, the use of WLN is by no means limited to sophisticated equipment; it can also serve as a shorthand for the chemist or student taking notes: it is easier to write QVR than to write benzoic acid or draw Ø-COOH; easier to write QVIG than to write chloroacetic acid or draw ClCH$_2$COOH.

The following are the WLN symbols; all are easily recognized by both humans and machines:

1. The 26 capital letters (A through Z)
2. The 10 digits (Ø through 9); the zero is written Ø to distinguish it from the letter O
3. Four punctuation marks (&-/*)
4. The blank space

WLN atomic symbols correspond to those which the chemist is accustomed to using. One-letter symbols are retained unchanged; two-letter symbols are set off between hyphens; for example, sodium is -NA- and aluminum is -AL-. The only exceptions to these two general rules are summarized in *Table 1*. These exceptions are made: 1) to give the ubiquitous halogens one-letter symbols and 2) to free the symbols K,U,V,W, and Y for more valuable use. These latter five symbols, along with M,Q,R,X, and Z, are used to represent the often-encountered functional groups and moieties shown in *Table 2*.

All unbranched, unsubstituted alkyl chains are topologically equivalent (i.e., they are either links or termini), and all useful information about them is given by simply citing the numeral corresponding to the number of carbons making up the chain. Thus, the symbol for a two-carbon chain is 2; for a three-carbon chain, 3; for a twelve-carbon chain, 12 — and so on. The C symbol itself is retained for an unbranched carbon that is multiply-bonded to a heteroatom (other than O) or two carbons (as in allenes) — a convention that keeps intact and readily recognizable many common functional groups, such as the cyanide group (see *Table 3*). Multiple bonds are cited with the U (double bond) or UU (triple bond) symbols when the double bond is between:

1. Any notation symbol and an alkyl numeral
2. Any notation symbol and a Y symbol
3. Any two atoms that are each singly bonded to at least one other atom in the structural formula (-N=N-, -AS=AS-, etc.)

Encoding compounds

Given a compound for encoding one chooses from among a set of forty symbols arranging them according to a fixed procedure into a word-like sequence that spells out the topology and composition of that compound. Examples of the resulting notations for a variety of chemicals are given in *Tables 4–7*. Three steps are involved in encoding a compound:

1. Redrawing the two-dimensional structure using WLN symbols
2. Choosing a path
3. Converting the drawing into a linear notation

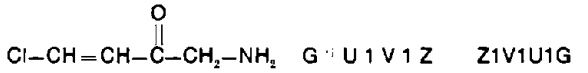
The process is especially simple for straight-chain compounds. Take, for example, the structure in *Figure 1*. To redraw, replace each moiety with its WLN symbol, as it is encountered: G 1 U 1 V 1 Z. To decide on the proper path, select successive alternatives that are resolved in a set order of priority. For an acyclic compound, select the chain path that includes: 1) the most branch symbols (X, Y, K, etc.) and 2) the largest total number of symbols. Other symbols, or groups thereof, are considered substituents on this main symbol chain. The above example contains no branches and the path is the same length (seven symbols) from either direction: G 1 U 1 V 1 Z or Z 1 V 1 U 1 G. So only the choice of a starting point, and hence path direction, need be made. Here the decision is based on the principle of *latest alphanumeric position;*

Figure 1



WLN encoding of straight-chain compound.

Figure 2

& - / ∅ 1

Earliest (Latest

i.e., all other things being equal, the correct notation will always be the one that gives the latest alphanumeric sequence of symbols according to the hierarchy shown in *Figure 2*, with exceptions for hydrogen and the benzene ring discussed subsequently.

Because Z is alphanumerically later than G, it should be cited earlier, and is the correct starting point. All that remains, then, is step 3, writing the notation itself. In the example given, the result of the translation step is a one-dimensional (linear) representation of the structure. Consequently, the correct notation is produced simply by writing the WLN symbols in unbroken sequence, beginning with the Z: ZIVIUIG.

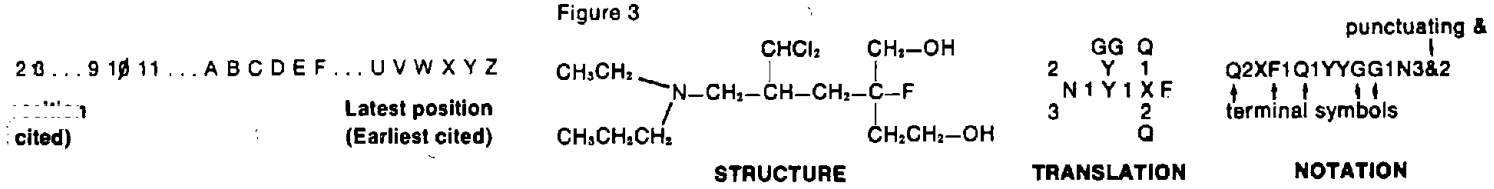
Encoding a branched-chain compound

The coding of branched-chain compounds is complicated only slightly by the presence of side-chains, which must be symbolically "folded" into the main chain of symbols to give a linear notation. *Figure 3* illustrates how this "folding" is accomplished. We begin here, again, by redrawing the structure with WLN symbols. Numerous paths pass through three (the maximum number) *branch symbols:* N, Y, Y or N, Y, X or Y, Y, X. Four of these paths contain eight symbols, the maximum total for this example. The proper path is, therefore, determined by the principle of latest alphanumeric position. Q, 3, and 2 are all potential starting symbols, since they are situated at ends of the paths under consideration, and Q, being the latest alphanumerically, will be the initial notation symbol. But which Q? We look at the symbols *following* each of the two Q's. Q2 is a later sequence than Q1, so the main path begins with Q2. Obviously, if a branched structure is to be represented by a unique linear notation, there must be a single order for citing symbol side-chains on a branch point such as X or Y. This order is fixed by citing, immediately after the symbol for the branch point,

1st: the group with the fewest branch symbols
2nd: the group with the fewest total symbols
3rd: the group giving the latest alphanumeric notation

Numerals and letters that may be *either* links in,

Figure 3



Alphanumeric hierarchy of WLN symbols.

WLN encoding of branched-chain compound.

or ends of, a symbol chain (e.g., M, N, S, etc., as opposed to the strictly *terminal* symbols E, F, H, I, Q, W, and Z) require punctuation with an ampersand (&) when they occur at the end of a side-chain that is "folded" into the line of symbols (see examples 12 and 14 in Table 4). (In the rare instances when one of the groups represented by these symbols is not terminal, its symbol is set off with hyphens.) Knowing this, we are ready to write the notation for the branched example in Figure 3: Q2XF1Q1YYGG1N3&2. The ampersand sign shows that the three-carbon side-chain is not connected to the two-carbon side-chain following it (i.e., $-CH_2CH_2CH_3$, not $-CH_2CH_2CH_2-$, or part of a 32-carbon chain).

For conciseness and coding ease, noninitial methyl groups attached to carbons denoted with the X or Y symbols or to K (quaternary nitrogen) are not expressed. The punctuating ampersands are retained, unless X, Y, or K is the last (or only) branch symbol in the notation. In that case, ampersands are also dropped; this is referred to as *methyl contraction* (see examples 13–15 in Table 4).

Hydrogen is often implied as part of another symbol, such as Q (-OH) or M (-NH-). The H when it must be cited is *always* subordinated to, and written immediately after, the symbol for the atom to which it is attached. Hence the notation for a straight-chain alkane is a numeral followed by an H. (H-citation is shown in examples 17–20 in Table 4.)

Encoding a benzene derivative

Because of the frequency with which it has to be cited, a single WLN symbol, R, was chosen as an efficient way to present an entire benzene or phenyl ring. The very magnitude of this frequency weakens the usefulness of any benzene-ring mark as an indexing symbol; thus, it is subordinated in the alphanumeric hierarchy to all other written symbols, except H.

The approach to encoding benzene derivatives is essentially the same as that for acyclic compounds. The main chain path is determined in the same way, with the ring being viewed as either a terminus link or branch point in a chain, depending on whether the ring is mono-, di-, or poly-substituted. When serving as a link or branch point, the various ring positions must be identified, and are indicated with letters that are preceded in the notation by a space, to prevent confusion with other letter uses. These space-letter combinations are referred to as "locants." Lower case letters are used in assigning locants in order to avoid confusion with ring segment symbols; in the notation only capital letters are used.

The "a" locant position is always assigned to the point of attachment of the symbol (or symbol string) that initiates the notation, with the remaining locants lettered consecutively around the ring in order to give the earliest possible locant to the symbol cited immediately after the R, as is shown in *Figure 4*. Note that the "a" locant need never actually be cited.

When more than two groups are substituted on a benzene ring, the order of citation is fixed the same as it is for substituents on an acyclic branched point (see above), regardless of locant assignments. Thus, for example 21 in Table 5 the chlorine (G) is cited *before* the bromine (E), even though the bromine has an earlier locant: G (not the locant) is a substituent in the translated formula, and G is alphanumerically later than E, the other substituent. A noninitial methyl substituent is indicated by citing the locant alone, dropping the "1"; this is another example of methyl contraction (see example 22 in Table 5).

In compounds containing more than one benzene ring, as in Table 5, two things should be kept in mind: 1) the correct notation path is decided before assigning locants and 2) the "a" locant for any ring is fixed by the point of attachment of "incoming" substituent symbols (see also example 26 in Table 5). Note, too, in Table 5 (example

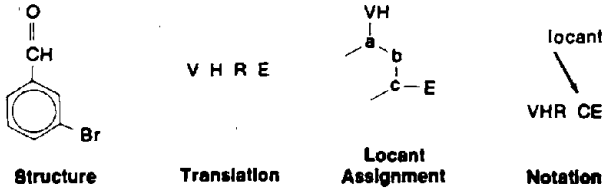


Figure 4 *WLN encoding of benzene derivative.*

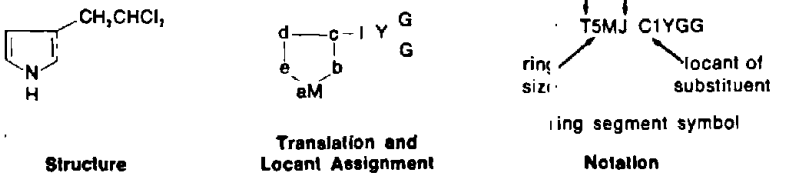

Figure 5 *WLN encoding of monocyclic compound.*

27) that when a ring is *itself* a substituent on a second polysubstituted ring, the punctuating ampersand is required to show when a terminus has been reached, if another substituent on the polysubstituted ring is to be subsequently cited.

Encoding of a monocyclic system

Cyclic compounds other than benzene must be viewed as something more than a simple point (terminal, linking, or branching) in a symbol chain. A more comprehensive topological and chemical description of the ring system is needed. The WLN accomplishes this by enclosing all information about the ring system itself in a fixed order inside L . . . J (carbocyclic) or T . . . J (heterocyclic) "parentheses" (examples 28–33, 35, 38, 41, 42 in Table 6). An initiating L means that the description of a carbocyclic system follows; an initiating T means that the description of a heterocyclic system follows; and the final J means that the description of the ring system is complete. After the J, the symbols for all substituents on the ring are cited in the alphabetic order of their locants, each substituent symbol (or symbol chain) being preceded by its space-letter locant (examples 34, 36, 39, 40). Notice, as is shown in example 36, that Y is used as a ring segment symbol to denote a C-atom that is doubly bonded to an atom other than oxygen outside the ring.

For a monocyclic system (*Figure 5*), the ring is described completely by citing after the initial L or T:

1st: a numeral corresponding to the number of ring atoms (numerals larger than 9 are enclosed in hyphens)
2nd: ring segment symbols, if any ("ring segment" is used here to mean any atom or atom group located in the ring locant path and cited with a unique WLN symbol)
3rd: saturation sign(s), if any
4th: J (to close the ring description)

Three possible saturation conditions exist, and are handled as follows. If there is only one carbon in the ring that has four other atoms bonded to it, its saturation sign is H, and the locant of that position is given (examples 33, 34). If the ring contains two or more such carbons, the ring is considered to be saturated, and the saturation sign is T (not to be confused with a heterocyclic initiating T); no locants are needed (examples 29, 35–39, 41). A double or triple bond (U or UU) in a saturated ring (i.e., one with a T saturation sign) is given the locant of the position that immediately precedes it along the locant path (examples 37, 38). If no saturation marks (H, U, or T) are given, the unsaturation is implied for all positions not especially denoted in the notation (examples 28, 30–32, 40, 42). In example 42 the H attached to the AS is cited immediately after the -AS-, as usual. It cannot be confused with a saturation H, which would be preceded by a locant. In example 30, the presence of the double bond is implicit; the notation for the corresponding saturation compound would be T5SMVTJ.

The "a" locant is dropped when citing either ring segment symbols or unsaturations in the "a" position of a monocyclic compound, as can be seen in the examples. Other locants are retained in the notation, except when two or more segments are located in adjacent positions; then only the earliest of these locants (still excluding "a") is given, and the consecutive ring segment symbols are listed after it (examples 30–34). Locants are always assigned consecutively around the ring in such a way as to give

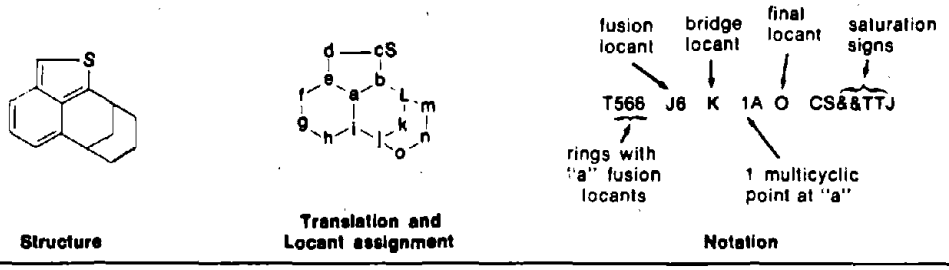
1. *Earliest* set of locants for ring segment symbols
2. *Earliest* alphabetic set of ring segment symbols
3. *Earliest* set of locants for ring substituents (see Ref. 8, p. 168. for more complex cases)

Coding a perifused bridged ring system with a multicyclic point

It is ironic that those compound types which are, statistically speaking, the structural freaks of the chemical world require the most rules (be they nomenclatural or notational) to ensure their complete and unique description. However, even the ring-bridged, spirolinked, polyfused, "chickenwire" monsters lurking between the covers of *The Ring Index*[13] can be translated into unique, unambiguous, decodable, linear Wiswesser notations. The approach to these more complex types is like that for simpler compounds: a priority list establishes the order in which various structural features, ring systems, and/or substituents appear in the notation.

Topologically, ring systems — bridged, fused, spirolinked, or whatever — are merely closed loops that are connected at certain points. The "skeleton" (i.e., topology plus ring sizes) of a fused bicyclic system is revealed completely by the L . . . J or T . . . J parentheses and the ring numerals between them (example 43 in Table 7). When additional structural parameters are necessary to define the skeleton of the more complicated ring systems (see *Figure 6*), they are spelled out in the notation in the following order:

Figure 6 *WLN encoding of polycyclic compound.*



1. *Fusion locants.* The fusion locant is defined as the earliest locant in a given ring. In the simpler cases, one picks a path that will give the lowest sum for these fusion locants and cites the ring numerals with their locants ("a" locants excluded) as the rings are "closed" in tracing out the path (examples 43, 44).
2. *Nonconsecutive ring locants.* When three cited rings share a pair of atoms, it is sometimes nececessary (Ref. 8, p. 162) to designate those pairs that are nonconsecutive. This is done by following the last ring numeral with a slash mark and then the locants of these pairs, omitting spaces (example 45).
3. *Bridge locants.* These denote those atoms constituting the shortest chain of ring atoms shared by more rings than two; they are designated by citing each such locant in descending alphabetic order and each preceded by a space (example 46).
4. *Multicyclic points.* The total number and positions of atoms shared by three or more rings are shown by a space followed by a numeral corresponding to the *number* of such points, then the locants of these points, omitting spaces (examples 45, 47).
5. *Last ring atom.* For rings with multicyclic points, the locant of the atom in the locant path is preceded by a space (examples 45, 47).
6. *Ring segment symbols.* These are cited with their locants, *including* "a" locants but omitting locants for adjacent ring segment symbols (example 48).

Having followed these six steps, in the order required, the ring-system skeleton is completely described. The final step, before the closing J "parenthesis," is to give ring saturation signs. Each U, UU, and H symbol is preceded by its locant (including "a" locants). When some rings are saturated (T = saturation sign) and others are not, the latter are denoted by ampersands (example 49). If all rings are saturated, one T will suffice (examples 45–47, 50); if none are saturated, no saturation mark is used (examples 43, 44, 48).

Summary

The WLN rules are divided into two categories: 1) those necessary for revealing the molecular topology and 2) those necessary for describing the molecular make-up (functional groups, etc.). In approaching this problem, acyclics and benzene derivatives are regarded as chains (linear or branched), and the rules are designed to show the order in which structural units are attached, moving from one end of the chain to the other. Cyclic compounds (excluding benzene) are regarded as loops or loop systems that may have substituents; for these rules concentrate first on describing the entire ring system within L . . . J or T . . . J parentheses before citing substituents.

An exposition of the notational treatment of all possible types of chemical structures has not been undertaken here. Rather, we have attempted to do with the Wiswesser line-notation what authors of introductory organic texts do with IUPAC nomenclature: give only those rules sufficient for handling the large majority (statistically) of organic structures. Those who wish to pursue the subject further are referred to *The Wiswesser Line-Formula Chemical Notation.*[8]

Quinoline	T66 BMJ
Quinoline (N–Substituted)	T66 BNJ
Quinolizine, 4–	T66 AN BHJ
Quinone	L6V DVJ
Quinoxaline	T66 BN ENJ
Quinuclidine	T66 A B ANTJ
Salicylidene	QR B1U or U1R BQ
Salicyloyl	QR BV or VR BQ
Semicarbazido	ZVMM or MMVZ
Semicarbazono	UNMVZ or ZVMNU
Silarenzene	T6–SI–HJ
Silicyl	SI–HHH

SUBSTRUCTURE OR COMPOUND	WLN
Silolene, 3–	T5–SI–HH CUTJ
Steroids (Carbocyclic)	L E5 B666
Steroids (Heterocyclic)	T E5 B666
Styrene	1U1R or U1 . . • . . R . . 1
Succinamyl	V2VZ or ZV2V
Succinimide (N–Substituted)	T5VNVTJ
Succinyl	V2V
Succinic anhydride	T5VOVTJ
Succinimide	T5VMVTJ
Sulfamino	MSWQ or WSQM
Sulfamyl	SZW or ZSW
Sulfanilamido	ZR DSWM or MSWR DZ
Sulfanilyl	SWR DZ or ZR DSW
Sulfinic acids	QSO or SQO
Sulfolane	T5SWTJ
Sulfonamido	MSW or SWM
Sulfonyl	SW or WS
Sulfonic acids	SWQ or WSQ
Sulfur–35 Labeled	S–35
Tauryl	SW2Z or Z2SW
Testosterone	T E5 B666 OV MUTJ A E FQ
Tetrafluoroborate	B–F4
Tetrahydrofuran	T5OTJ
Tetrahydropyran	T6OTJ
Tetralin	L66&TJ
Tetrazole, 1H–	T5MNNNJ
Tetrazole, 1H– (N–Substituted)	T5NNNNJ
Thiadiazole, 1,3,4–	T5NN DSJ
Thiamorpholine (N–Substituted)	T6N DSTJ
Thiamorpholine	T6M DSTJ
Thianaphthene	T56 BSJ
Thianthrene	T C666 BS ISJ
Thiazole	T5N CSJ
Thieno(2,3–b)thiophene	T55 BS HSJ
Thieno(3,2–b) thiophene	T55 BS FSJ
Thietane	T4STJ
Thio	S
Thiocarbamyl	SUYZ or ZYUS or ZY . . U or ZUS . . • . . Y
Thiocareonyl	SUY or OR US . . • . . Y
Thiocyano	NCS or SCN
Thiophene	T5SJ
Thioxanthene	T C666 BS IHJ
Toluino, m–	MR C or 1R CM
Toluino, o–	MR B or 1R BM
Toluino, p–	MR D or 1R DM
Toluyl, o–	R1V or V1R
Toluyl, m–	VR C or 1R CV
Toluyl, o–	VR B or 1R BV
Toluyl, p–	VR D or 1R DV
Triazeno	NUNZ or ZNUN
Triazine, 1,2,4–	T6N CN ENJ
Triazine, 1,3,5–	T6NN DNJ
Triazole, 2H–1,2,3–	T5NMNJ
Triazole, 2H–1,2,3– (N–Substituted)	T5NNNJ
Triazole, 1H–1,2,4–	T5MN DNJ
Triazole, 1H–1,2,4– (N–Substituted)	T5NN DNJ
Triazole, 4H–1,2,4–	T5NN DMJ
Trifluoromethyl	FXFF or FFF . . • . . X
Triphenylene	L B6 H666J
Tritium Labeled	H–3
Urea	ZVZ
Urea (N–Substituted)	MVZ or ZVM
Urea (N, N–Substituted)	N . . . VZ or ZVN
Urea (N,N'–Substituted)	MVM
Urea (N,N,N'–Substituted)	MVN or N . . . VM
Urea (N,N,N',N'–Substituted)	N . . . VN
Valeryl	V4 or 4V or V . . • 4
Vinyl	1U1 or U1 . . • . . 1
Xanthene	T C666 BO IHJ
Xanthone	T C666 BO IVJ

16. Abstract (Limit: 200 words)
The 1974 edition of the Toxic Substances List is the third revision of the list of toxic substances prepared at least annually in accordance with Section 20(a)(6) of the Occupational Safety and Health Act of 1970, Public Law 91-596. This List includes the original list published in June 1971 and the offerings of the subsequent publications. This list contains 42,000 listings of chemical substances: 13,000 are names of different chemicals with qualifying toxic dose information and 29,000 consist of synonymous names and codes which have been acquired from published literature, cooperating industries, and the American Chemical Society. This revision contains approximately 5,000 new compounds which had not appeared in the 1973 edition. The specific data provided on the toxicity of each substance related to: route of administration, animal species involved, type of exposure reported (e.g. lethal), dose which caused toxic response, and body system affected. The bibliographical sources from which the toxicity data were extracted are all listed. Absence of a substance does not imply that it is innocuous.
