Question

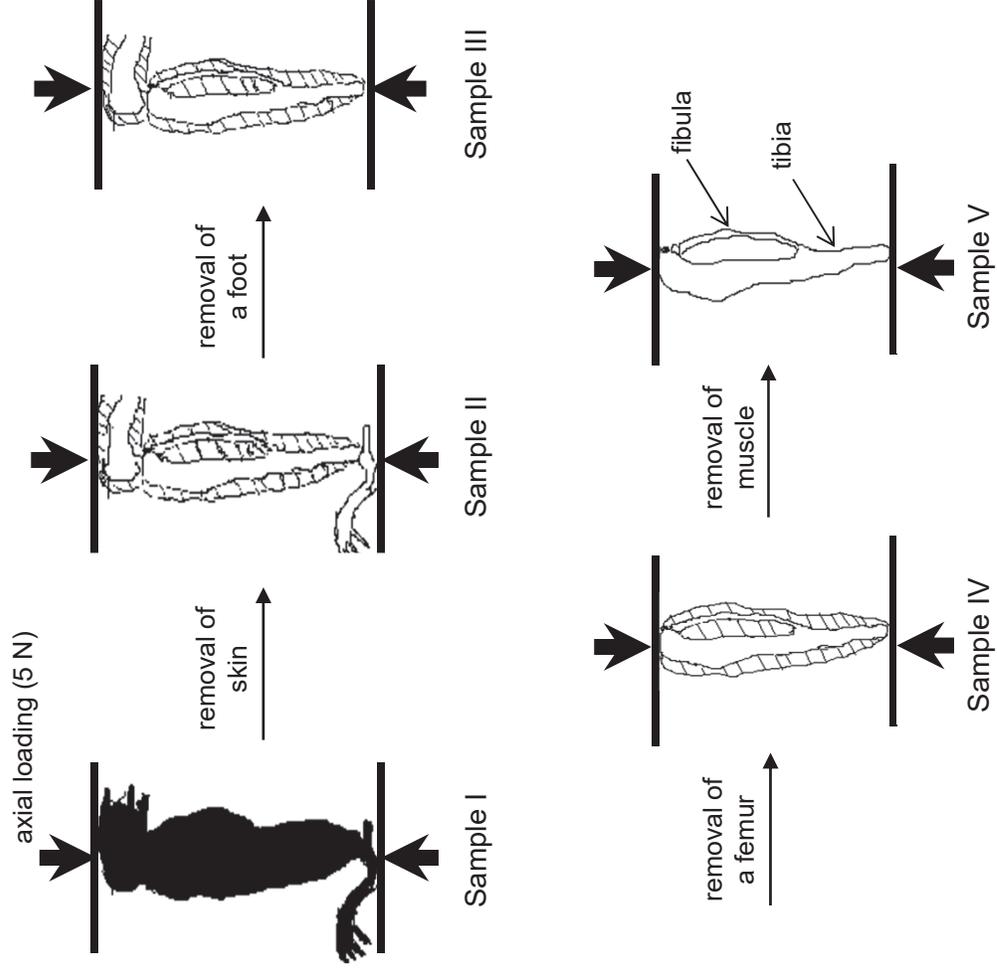

Damping values at various anatomical sites for osteoporosis patients (right leg heel strike)

Damping is lowered in osteoporotic patients, particularly in patients with bone fracture. **Mechanism?**

Approach (experiment)

Mouse loading experiment with/without connective tissues

Phase shift angle

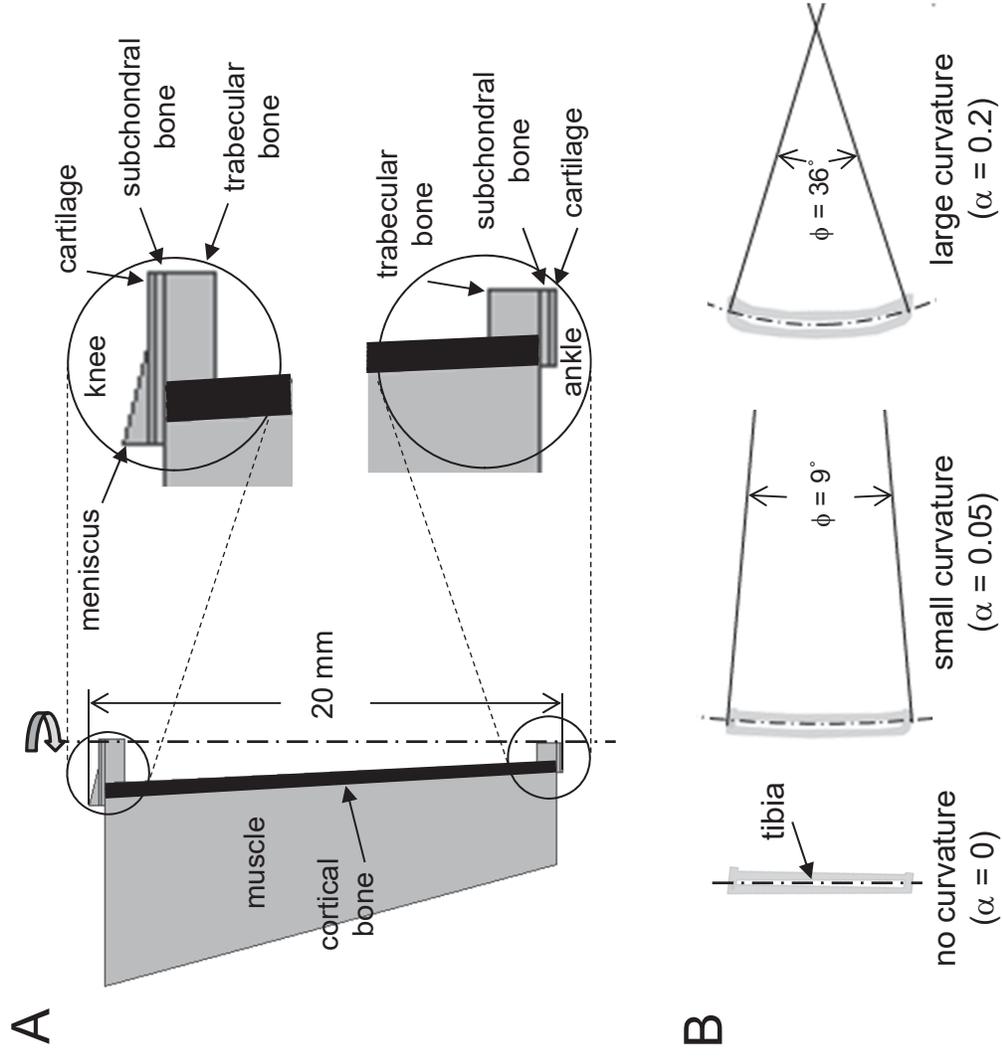

Determination of a phase shift angle

- $f = A_f \sin(\omega t + \theta_f) + B_f$
- $L = A_L \sin(\omega t + \theta_L) + B_L$

$$\Delta\theta = \theta_f - \theta_L$$

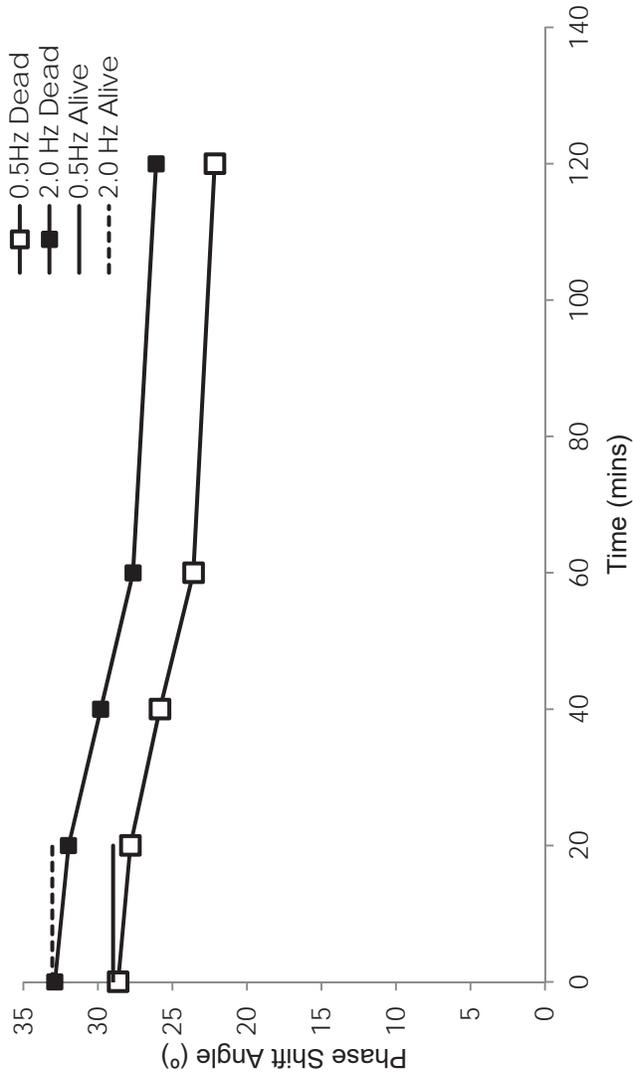

Approach (FE model)

Finite element analysis

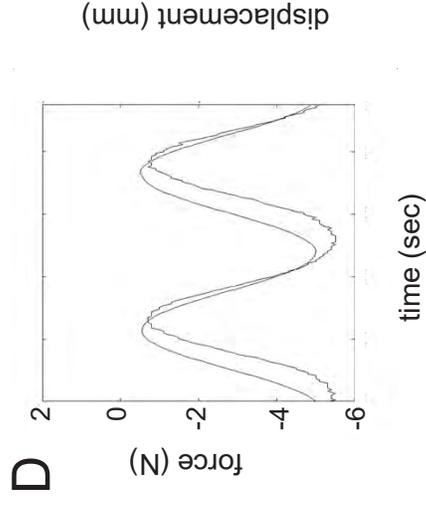

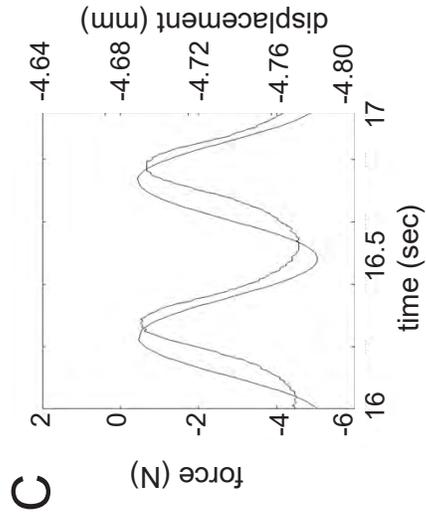

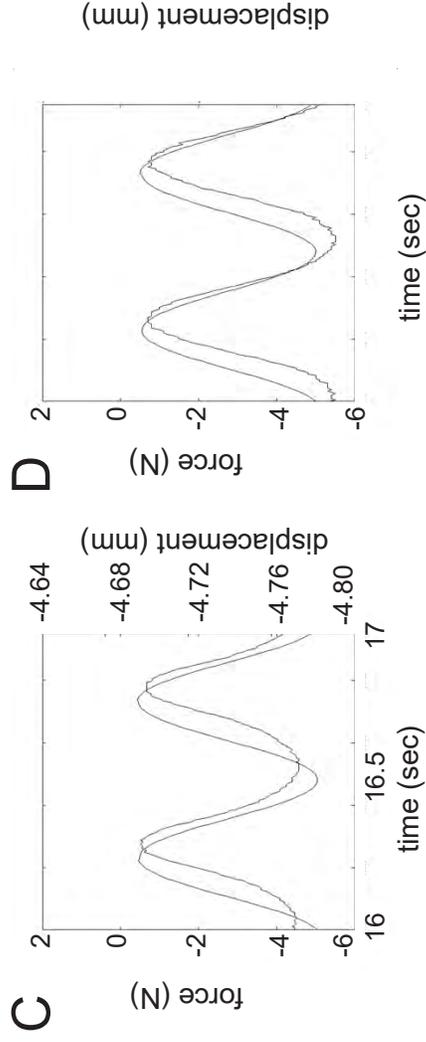

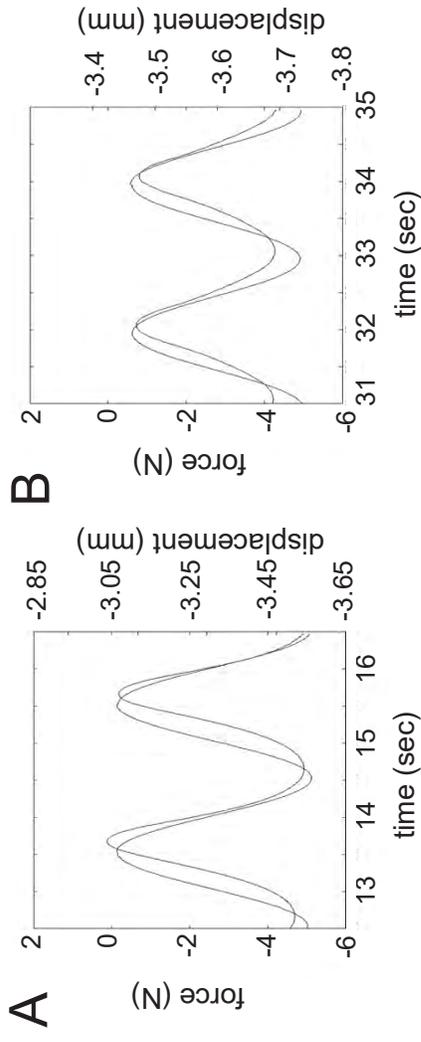

Model system

Anesthesia vs. euthanasia

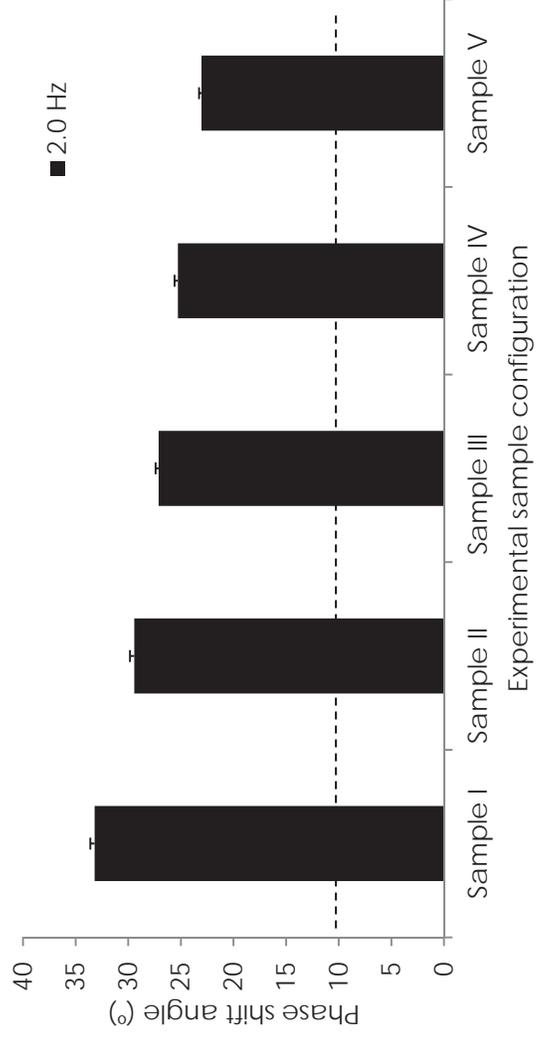

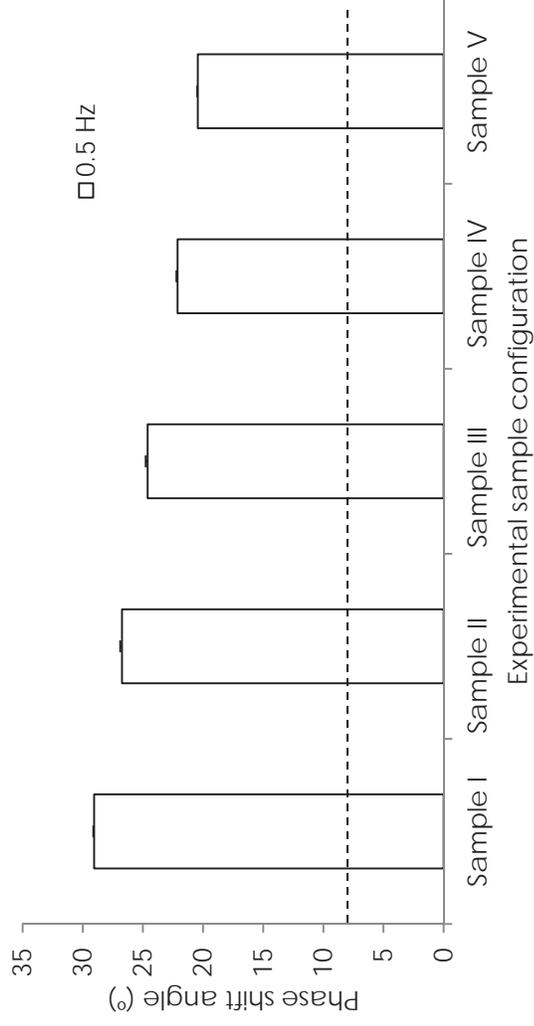

Result (experiment)

Force/displacement diagram

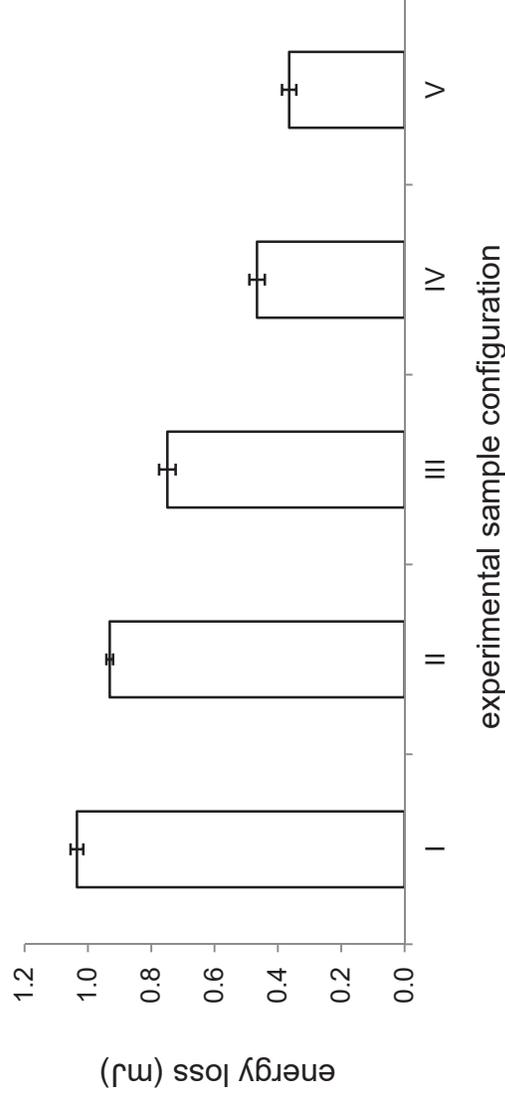

Result (experiment)

Phase shift angles

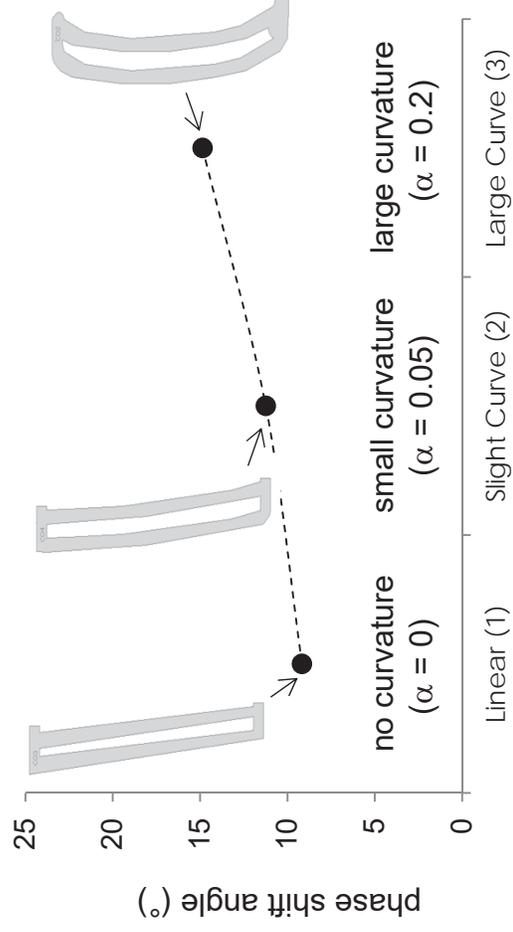

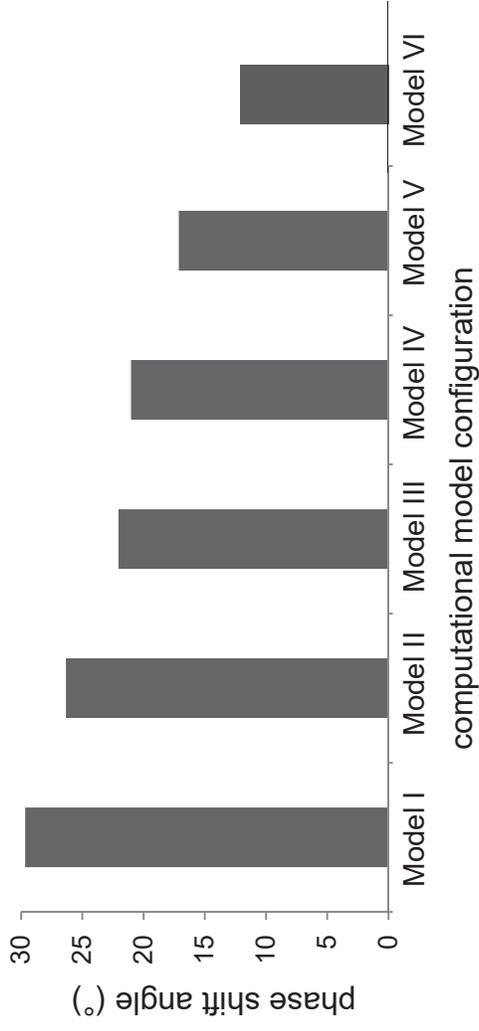

Result (experiment)

Energy loss for the sample configurations I-V

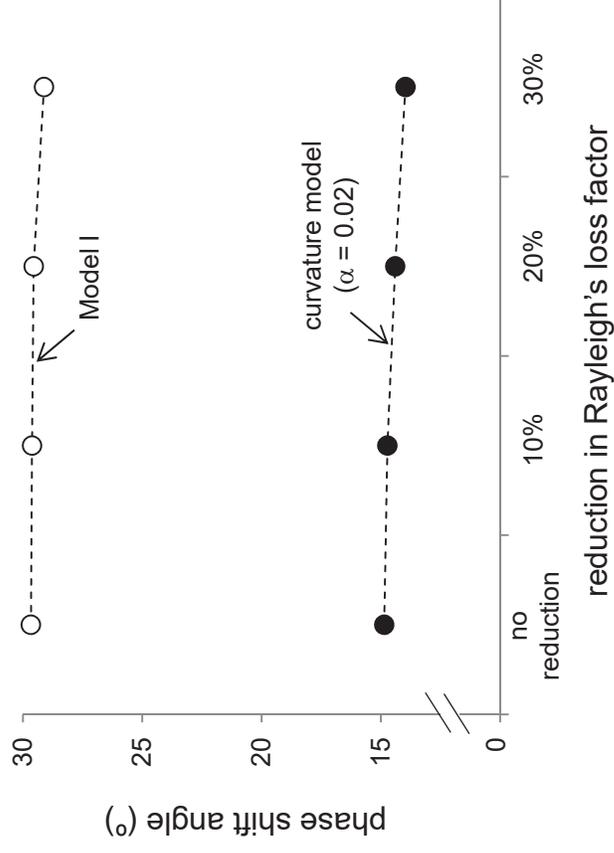

Result (FE model)

Prediction of phase shift angles

Result (FE model)

Predicted sensitivity

Summary

- The experimental and computational results revealed that both surrounding tissues and bone contributed to load damping.
- Approximately 60% of phase shift was induced by bone itself and this shift was increased with bone curvature.
- Although structural curvature reduces critical loads for buckling in a beam theory, evolution apparently favors maintaining curvature in the tibia.
- In addition to bone's compressive damping capacity, surrounding tissues as well as naturally occurring bone curvature are contributors to mechanical damping, which may ultimately affect bone remodeling and bone quality.
