

SUPPLEMENTARY FIGURE 1. Cases of poisoning associated with consumption of mushroom-containing chocolate products among persons with moderate* or major† clinical effects by symptom onset date (N=155 cases)§— United States, January 1–October 11, 2024

* Moderate clinical effects are symptoms resulting from an exposure that are more pronounced, more prolonged, or more of a systemic nature than minor symptoms (i.e., symptoms that are minimally bothersome to the patient and resolve rapidly with no residual disability or disfigurement). Usually, some form of treatment is indicated for moderate symptoms, but moderate symptoms are not life-threatening, and there is no residual disability or disfigurement. Examples include hypotension that resolves with treatment, isolated brief seizures that resolve spontaneously or rapidly, with treatment, hypoglycemia with confusion.

† symptoms are life-threatening or result in significant residual disability/disfigurement. Examples included status epilepticus, cardiovascular instability, and coma with hypotension.

§ The exact symptom onset date was missing for 25 cases.
