## Minors' Access to Cigarette Vending Machines - Texas

The sale of tobacco products to persons aged <18 years has been prohibited by law in Texas since September 1989*. This law requires cigarette vending machine owners to post signs on their machines stating the illegality of tobacco product sales to persons aged <l8 years and that merchants convicted for selling tobacco products to underaged persons be fined a maximum of $\$ 500$. In August 1991, Arlington, Texas, enacted legislation requiring installation of electronic locking devices on all cigarette vending machines. These devices render the vending machine inoperable until the store owner electronically unlocks the machine on customer request. To assess minors' access to cigarettes through vending machines, in October 1993 the Texas Department of Health conducted a study in Arlington and five neighboring communities. This report summarizes the study findings.

In September 1993, the health department obtained a list of business establishments with cigarette vending machines owned by the largest cigarette vending company in the Arlington area. A total of 116 establishments were identified in the study area; 59 (51\%) machines were in establishments considered easily accessible to minors (i.e., restaurants, gas stations, motel lobbies, food stores, and recreational facilities). Data were collected for 42 of the 59 sites.

Four investigative teams consisted of one adult paired with one minor (aged 1517 years). One purchase attempt was made at each of the 42 establishments. During each purchase attempt, the adult entered the establishment first and asked for street directions. The adult then observed while the minor entered and attempted to purchase cigarettes from the vending machine. Minors were instructed to answer, if asked, that the cigarettes were for themselves.

While attempting to purchase cigarettes from vending machines, no minors were challenged by business owners. Of the 42 attempts, 41 were successful. Of the 41 sites where purchase attempts were successful, 24 (59\%) were located within $1 / 2$ mile of a school. Most (35 [83\%] of 42) purchase attempts occurred in restaurants; however, cigarettes were bought at every type of establishment where purchases were at-

[^0]U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES / Public Health Service

Cigarette Machines - Continued
tempted. Warning signs prohibiting cigarettes sales to minors were posted on vending machines in 32 (76\%) establishments.

Of the 16 vending machines located in business establisments in the city of Arlington, one was equipped with an electronic locking device. The single unsuccessful purchase attempt occurred at this electronically locked machine.
Reported by: JM Gomez, Arlington Police Dept; GJ Flores, SR Tobias, Office of Smoking and Health, CR Allen, MD, Public Health Region 2, PP Huang, MD, Bur of Chronic Disease Prevention and Control, DM Simpson, MD, State Epidemiologist, Texas Dept of Health. Office on Smoking and Health, National Center for Chronic Disease Prevention and Health Promotion; Div of Field Epidemiology, Epidemiology Program Office, CDC.
Editorial Note: The findings in this report indicate that, despite laws prohibiting cigarette sales to persons aged $<18$ years, minors readily purchased cigarettes from vending machines in Arlington and five neighboring communities. Although the only failed purchase attempt in this study resulted from a vending machine equipped with a remote-controlled locking device, compliance with legislation requiring these devices has been minimal (1). The finding that only one of 16 vending machines in Arlington was equipped with the device is similar to findings of studies about locking device usage in other areas (1).

The findings in this report are subject to at least two limitations. First, data in this report were obtained for only one vending machine company in the Arlington area because the Texas Department of the Treasury does not require vending machine companies to specify the locations of their machines. Second, because of time constraints during the study, data were not collected for 17 establishments considered easily accessible to minors; however, sites included in the analysis probably do not differ from sites that were not included.

Approximately $82 \%$ of adult smokers report that they first tried a cigarette by age 18 years, and $53 \%$ were daily smokers by that age (2). The initiation rate for smoking increases rapidly after age 11 years (3); in Texas, a 1989 survey of 4400 high school students found that $55 \%$ of 12 -year-olds had already tried cigarette smoking (4). Because vending machine sales are not monitored actively by adults, cigarette vending machines can be an important source for younger adolescents (i.e., aged 12-15 years), who are more likely than older adolescents (i.e., aged 16-18 years) to be refused an over-the-counter cigarette sale (5). Studies indicate that younger adolescent smokers are more likely to buy cigarettes from vending machines than older adolescent smokers $(6,7)$.

Unregulated cigarette vending machines may facilitate initiation of smoking among younger adolescents; therefore, more effective regulation of these sales may be an important preventive measure. Prevention of adolescent smoking may be enhanced by the recently enacted Synar Amendment to the Alcohol, Drug Abuse, and Mental Health Administration (ADAMHA) Reorganization Act. ${ }^{+}$The Synar Amendment requires that states demonstrate effective prohibition of the sale of tobacco products (including cigarettes from vending machines) to persons aged $<18$ years as a condition of receiving full ADAMHA block grants. As a result of this study, the Arlington City Council enacted legislation prohibiting cigarette vending machines in all business establishments that admit persons aged $<18$ years.

## Epidemiologic Notes and Reports

## Interstate Measles Transmission from a Ski Resort Colorado, 1994

During April 1-May 25, 1994, a chain of measles transmission began in Breckenridge, Colorado, and extended into nine additional states; a total of 247 measles cases were reported, representing $36 \%$ of all U.S. measles cases reported to the National Notifiable Diseases Surveillance System (excluding those reported from U.S. territories) through J uly 2 (week 26). The source of exposure was unknown but is believed to have been an out-of-state tourist who probably visited Breckenridge during March because 1) no measles cases had previously been reported in Colorado during 1994, and 2 ) the only common exposure appeared to have been at a ski resort visited by many out-of-state travelers. Persons associated with spread of measles from Breckenridge were predominately school- and college-aged. This report summarizes the investigation of this chain of interstate measles transmission.

A total of 15 measles cases with rash onset during A pril 4-21 occurred in Breckenridge. Persons with measles ranged in age from 16 years to 46 years (median: 27.6 years). All cases met the CDC measles clinical case definition (1); 12 were serologically confirmed. All 15 ill persons either lived in Summit County (Breckenridge) or three neighboring counties (Arapahoe, Chaffee, and Park) or worked in tourismrelated services in or near Breckenridge. Twelve of the 15 ill persons are believed to have been exposed to the unidentified source, and three cases resulted from secondary transmission. Two cases occurred among high school students; no further transmission in schools was reported.

Interstate transmission of measles occurred through four out-of-state travelers and a Silver Thorn, Colorado, resident-all of whom had visited Breckenridge during

## Measles Transmission - Continued

March 18-25. All five visitors are believed to have been exposed to the unidentified source. Two persons (a 46-year-old Texas resident [rash onset: April 16] and a 29-yearold Missouri resident [rash onset: April 4]) developed measles on return home but have not been linked to additional cases. The other three persons-an Illinois resident, a Maryland resident, and the Silver Thorn resident-became sources for further transmission.

Illinois. A 14-year-old unvaccinated female high school student returned home to J ersey County, Illinois; she developed a rash on April 4. The student was identified as the source of an outbreak involving 51 unvaccinated persons (age range: 1-24 years; median: 18 years; last rash onset: J une 3) in her community-which was associated with a Christian Science college in the county. She also was identified as the source of an outbreak involving 156 persons (age range: 4-25 years; median: 15 years; rash onsets: April 17-May 15) at the Christian Science boarding high school she attended in St. Louis County, Missouri. After several unvaccinated persons from other states visited the school during the outbreak, six additional cases occurred. Five persons developed measles on return home (two persons to M aine and one each to California, New York, and Washington); the California patient was the source of exposure for a sibling. No further transmission associated with these six cases is known.

Maryland. A 24-year-old woman returned home to Baltimore County, Maryland; she developed a rash on April 4. The woman was the source of exposure for her 56-year-old father, who had rash onset on April 21.

Michigan. A 25-year-old Silver Thorn man visited his family in Wayne County, Michigan; he developed rash on April 17. The man was identified as the source of an outbreak involving 12 persons (age range: 9 months-37 years; median: 24 years; rash onsets: April 17-May 18) who were exposed at a wedding and a restaurant. One additional case (rash onset: April 16) was reported in a 12-year-old Chicago resident who had visited Wayne County. No further transmission associated with the Michigan or Chicago cases is known.
Reported by: GW Rutherford, III, MD, State Epidemiologist, California State Dept of Health Svcs. RE Hoffman, MD, State Epidemiologist, Colorado Dept of Health. BJ Francis, MD, State Epidemiologist, Illinois Dept of Public Health. KF Gensheimer, MD, State Epidemiologist, Bur of Health, Maine Dept of Human Svcs. E Israel, MD, State Epidemiologist, Maryland State Dept of Health and Mental Hygiene. KR Wilcox, J r, MD, State Epidemiologist, Michigan Dept of Public Health. HD Donnell, J r, MD, State Epidemiologist, Missouri Dept of Health. D Morse, MD, State Epidemiologist, New York State Dept of Health. DM Simpson, MD, State Epidemiologist, Texas Dept of Health. W Lasota, Immunization Program, Washington Dept of Health. National Immunization Program, Office of the Director; Epidemiology Program Office, CDC.
Editorial Note: The sustained interstate measles outbreak described in this report demonstrates the ability of measles virus to spread rapidly and widely among a highly mobile population. The dates of rash onset for the five Breckenridge visitors suggest that they had been exposed to measles during the same period the Breckenridge cases were exposed; therefore, exposure to the common, unidentified source-not the Breckenridge cases-probably led to this widespread interstate outbreak. Direct contact of the five visitors with the unidentified source resulted in primary transmission of measles in five other states ( 222 reported cases), and further contact resulted in secondary transmission in four additional states (six reported cases) before the chain of transmission ended.

## Measles Transmission - Continued

Factors that may have contributed to this interstate measles outbreak include 1) the timing of the initial exposure during school spring break; 2 ) exposure of an unvaccinated student who subsequently returned home to a community and school with many susceptible, unvaccinated persons; and 3) special events at the Missouri boarding school that drew susceptible, unvaccinated visitors from other states.

Although measles spread from Colorado to nine other states, transmission in six states stopped with the index case or after one additional case. In some of these states, spread may have been limited because the sources were adults whose routine activities may not have involved close contact with groups containing susceptible persons. Only two outbreaks (Illinois/Missouri and Michigan) resulted in substantial numbers of reported cases, and both were associated with contact with large groups (e.g., high school and college populations, wedding guests, and restaurant patrons). The extended outbreak in Illinois and Missouri has been the largest measles outbreak in the United States (excluding territories) in 1994 (2).

The primary strategy to prevent measles outbreaks is achieving and sustaining measles vaccination coverage levels of at least $90 \%$ for a single dose among all age groups. Efforts are under way to increase measles vaccination coverage among preschool children and implement a recommendation that all school-aged and collegeaged persons receive two doses of measles-mumps-rubella vaccine. However, additional strategies may be needed to ensure complete vaccination of adults and to prevent outbreaks in settings where large groups of adults gather (e.g., resorts and restaurants). Large groups that do not routinely accept vaccination will remain potential problems for measles-control programs.

To achieve the Childhood Immunization Initiative's goal of eliminating indigenous measles in the United States by 1996 (3), continued efforts to assure rapid detection of measles cases and implementation of control measures are necessary. To define disease transmission patterns more completely, state and local health departments should rapidly investigate and report all suspected measles cases, obtain laboratory confirmation, determine the vaccination status of each suspected case, and determine the source or chain of disease transmission. Identification of measles cases by transmission category (i.e., international importation, linked to an importation, or indigenously acquired) also will be necessary to track progress toward achieving the 1996 elimination goal.

## Emerging Infectious Diseases

## Arenavirus Infection - Connecticut, 1994

On August 20, 1994, the Connecticut Department of Public Health and Addiction Services received a report of a case of acute illness in a virologist suspected to be associated with Sabiá virus, a newly described arenavirus. This report presents preliminary findings from the case investigation.

On August 19, 1994, the virologist presented to the Tropical Medicine Clinic at YaleNew Haven Hospital with a 4-day history of fever, malaise, backache, stiff neck, and myalgias that he attributed to a recurrence of a Plasmodium vivax infection. On evaluation at the clinic, his temperature was 99.8 F ( 37.6 C ) on antipyretics, and he had a normal physical examination. Laboratory evaluation included a negative malaria smear, a total white blood cell count (WBC) of 2600 cells $/ \mathrm{mm}^{3}$ (normal: 400010,000 cells $/ \mathrm{mm}^{3}$ ), a platelet count of 138,000 cells $/ \mathrm{mm}^{3}$ (normal: 150,000-350,000 cells $/ \mathrm{mm}^{3}$ ), $2+$ proteinuria, and alanine aminotransferase (ALT) of $6356 \mathrm{U} / \mathrm{L}$ (upper limit normal: $35 \mathrm{U} / \mathrm{L}$ ).

A history of a possible laboratory exposure to Sabiá virus was obtained, and the man was hospitalized for prompt treatment with intravenous ribavirin, an antiviral drug that is effective against other arenavirus infections such as Lassa fever (1).

On admission, the patient had a temperature of 103 F (39.4 C). Within 24 hours of hospitalization, his total WBC and platelet count had declined to a low of 1400 cells $/ \mathrm{mm}^{3}$ and 92,000 cells $/ \mathrm{mm}^{3}$, respectively. His ALT peaked at $128 \mathrm{U} / \mathrm{L}$ on the 9 th day of hospitalization. No hemorrhagic manifestations of the infection were observed during hospitalization. A diagnosis of Sabiá infection was confirmed on acute serum by amplification of a portion of the viral genome by polymerase chain reaction and by isolation of the virus from blood. The patient recovered and was discharged on August 26.

On August 8, the virologist was apparently exposed to an aerosol of Sabiá virus when a centrifuge bottle developed a crack, and tissue culture supernatant containing the virus leaked into the high-speed centrifuge. At the time of the incident, the virologist was working alone in the biosafety level-3 laboratory (negative pressure with HEPA-filtered exhaust system). He cleaned the spilled material from the centrifuge while wearing a gown, surgical mask, and gloves.

Persons who came in contact with the patient or with his biological specimens in the hospital laboratories since onset of his illness were notified and enrolled in a surveillance program. None of these persons have had exposure to the patient that would suggest a high risk for secondary infection. As of August 31, none of the persons under surveillance have reported a febrile illness.

A DeMaria, J r, MD, State Epidemiologist, Massachusetts Dept of Public Health. Div of Field Epidemiology, Epidemiology Program Office; Special Pathogens Br, Div of Viral and Rickettsial Diseases, National Center for Infectious Diseases, CDC.

## Arenavirus Infection - Continued

Editorial Note: Sabiá virus was isolated by scientists in Sáu Paulo, Brazil, in 1990 and characterized by scientists in Belém, Brazil, and at the Yale Arbovirus Research Unit (2). Only two cases of Sabiá virus infection (both in Brazil) have been reported (2). One was a naturally acquired infection in an agricultural engineer who was probably infected by exposure to an infected rodent (the natural reservoir of other known arenaviruses). The engineer died approximately 2 weeks after becoming ill. The second case was in a laboratory technician who was working with the virus. He had a severe illness characterized by 15 days of fever, chills, malaise, headache, generalized myalgia, sore throat, conjunctivitis, nausea, vomiting, diarrhea, epigastric pain, bleeding gums, and leukopenia. He recovered after hospitalization and treatment with intravenous fluids.

Little is known about the modes of transmission of the Sabiá virus. Based on the pathogenesis of other arenaviruses, the Sabiá virus is not believed to be infectious until the patient exhibits symptoms. Other arenaviruses can be transmitted by needlestick but do not readily spread from person to person. Persons in casual contact with persons with arenavirus infection are not at risk for disease and do not require medical follow-up.

## Notice to Readers

## NIOSH Alert: Request for Assistance in Preventing Scalping and Other Severe Injuries from Farm Machinery

CDC's National Institute for Occupational Safety and Health (NIOSH) periodically issues alerts on workplace hazards that have caused death, serious injury, or illness to workers. One such alert, Request for Assistance in Preventing Scalping and Other Severe Injuries from Farm Machinery (1), was recently published and is available to the public.*

This alert warns that farm workers are at high risk for avulsion of the scalp and other severe injuries when they work near farm machinery with inadequately guarded drivelines or shafts driven by power take-offs (PTOs). Entanglement of hair, clothing, or body parts around these drivelines or shafts kills and injures many farm workers each year: according to the NIOSH National Traumatic Occupational Fatalities Surveillance System, at least 346 farm workers aged $\geq 16$ years died from farm-related entanglement injuries during 1980-1989; 112 of those deaths were caused by entanglement in PTO-driven drivelines and shafts of farm machinery. Approximately 10,000

[^3]
## Notice to Readers - Continued

nonfatal entanglement injuries also occurred on farms during 1982-1986; 864 of these injuries included the loss of a body part (1).

The alert describes five persons who were severely injured when their hair became entangled around the inadequately guarded rotating drivelines or shafts of farm machinery driven by PTOs (1,2). Recommendations are given for farm owners and workers to prevent injuries from primary and secondary drivelines and other PTOdriven shafts.

## Monthly Immunization Table

To track progress toward achieving the goals of the Childhood Immunization Initiative (CII), CDC publishes monthly a tabular summary of the number of cases of all diseases preventable by routine childhood vaccination reported during the previous month and year-to-date (provisional data). In addition, the table compares provisional data with final data for the previous year and highlights the number of reported cases among children aged $\leq 5$ years, who are the primary focus of CII. Data in the table are derived from CDC's National Notifiable Diseases Surveillance System.

## Number of reported cases of diseases preventable by routine childhood vaccination — United States, J uly 1994 and 1993-1994*

| Disease | No. cases, J uly 1994 | Total cases J anuary-J uly |  | No. cases among children aged $<5$ years ${ }^{\dagger}$ J anuary-J uly |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 1993 | 1994 | 1993 | 1994 |
| Congenital rubella |  |  |  |  |  |
| syndrome (CRS) | 0 | 5 | 2 | 4 | 2 |
| Diphtheria | 0 | 0 | 0 | 0 | 0 |
| Haemophilus influenzae§ | 114 | 795 | 718 | 248 | 194 |
| Hepatitis B ${ }^{\text {a }}$ | 1046 | 7229 | 6724 | 68 | 68 |
| Measles | 71 | 224 | 794 | 80 | 178 |
| Mumps | 119 | 1043 | 830 | 183 | 131 |
| Pertussis | 247 | 2295 | 1810 | 1329 | 1024 |
| Poliomyelitis, paralytic** | 1 | 3 | 1 | 1 | 1 |
| Rubella | 28 | 138 | 199 | 21 | 18 |
| Tetanus | 3 | 20 | 22 | 0 | 1 |

* Data for 1993 are final and for 1994, provisional.
†For 1993 and 1994, age data were available for $90 \%$ or more cases, except for 1993 age data for CRS, which were available for $80 \%$ of cases.
§Invasive disease; H. influenzae serotype is not routinely reported to the National Notifiable Diseases Surveillance System.
IBecause most hepatitis $B$ virus infections among infants and children aged $<5$ years are asymptomatic (although likely to become chronic), acute disease surveillance does not reflect the incidence of this problem in this age group or the effectiveness of hepatitis B vaccination in infants.
** One case with onset in 1994 has been confirmed; this case is vaccine-associated. In 1993, three of 10 suspected cases were confirmed; two of the confirmed cases of 1993 were vaccine-associated, and one was classified as imported.

## Addendum: Vol. 43, No. 30

In the article "Hantavirus Pulmonary Syndrome-Northeastern United States, 1994," on page 549, the following authors should be added to the reported by section: M Hibberd, MD, M Mayer, MD, R Meyer, Suffolk County Dept of Health Svcs, Hauppauge, New York.

The Morbidity and Mortality Weekly Report (MMWR)Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available on a paid subscription basis from the Superintendent of Documents, U.S. Govemment Printing Office, Washington, DC 20402; telephone (202) 783-3238.

The data in the weekly MMWR are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the succeeding Friday. Inquiries about the MMWR Series, including material to be considered for publication, should be directed to: Editor, MMWR Series, Mailstop C-08, Centers for Disease Control and Prevention, Atlanta, GA 30333; telephone (404) 332-4555.

All material in the MMWR Series is in the public domain and may be used and reprinted without special permission; citation as to source, however, is appreciated.
