## National Drunk and Drugged Driving Prevention Month — December 1997

Persons who drive while impaired by alcohol or other drugs are a public health hazard to themselves and to others. During 1996, alcohol-related motor-vehicle crashes resulted in 17,126 deaths in the United States (1). From 1987 to 1996, the total number of traffic fatalities decreased by approximately 10\% (from 46,390 to 41,907, respectively), and the proportion of traffic fatalities that were alcoholrelated decreased by approximately $20 \%$ ( $51 \%$ versus $41 \%$, respectively) ( 1,2 ). Despite these reductions, alcohol-related motor-vehicle crashes remain a leading cause of death for teenagers and young adults.

December has been designated National Drunk and Drugged Driving Prevention Month by the National Drunk and Drugged Driving Prevention Month Coalition, a nationwide public- and private-sector coalition for the prevention of crashes related to impaired driving. Additional information about National Drunk and Drugged Driving Prevention Month is available from the Impaired Driving Division, Office of Traffic Injury Control Programs (NTS-11), National Highway Traffic Safety Administration, 400 7th Street, S.W., Washington, DC 20590; telephone (202) 366-9588; World-Wide Web site http://www.nhtsa.dot.gov.

## Alcohol-Related Traffic Fatalities Involving Children United States, 1985-1996

Motor-vehicle-related injuries are the leading cause of death for persons aged $1-24$ years in the United States (1). Although the relation between alcohol use and motor-vehicle-related deaths involving teenagers is well established (2), understanding of the role of alcohol in such deaths among younger children is limited. To characterize the involvement of alcohol in motor-vehicle-related deaths of U.S. children aged <15 years during 1985-1996, CDC analyzed data from the Fatality Analysis Reporting System (FARS) of the National Highway Traffic Safety Administration (NHTSA). This report summarizes the results of that analysis, which indicate that approximately one fourth of all traffic deaths among children aged $<15$ years involved alcohol and that in nearly two thirds of passenger deaths involving a legally drunk driver, the child was in the car driven by the legally drunk driver.

FARS is a census of police-reported traffic crashes on public roadways that result in the death of at least one occupant or nonmotorist within 30 days of the crash. NHTSA considers a fatal motor-vehicle crash to be alcohol related if either a driver or nonoccupant (e.g., pedestrian) had a blood alcohol concentration (BAC) $\geq 0.01 \mathrm{~g} / \mathrm{dL}$. Because BACs are not available for all persons involved in fatal crashes, NHTSA estimates the number of alcohol-related traffic fatalities based on a discriminant analysis of information from all cases for which driver or nonoccupant BAC data are available (3). Age adjustment of rates was performed by the direct method using the 1970 U.S. population.

During 1985-1996, of the 35,547 children aged $<15$ years who died in motor-vehicle crashes, 8482 ( $24 \%$ ) were killed in alcohol-related motor-vehicle crashes. From 1985 to 1996, the proportion of all motor-vehicle-related deaths that involved alcohol decreased from $25 \%$ ( 773 of 3126 deaths) to $21 \%$ ( 568 of 2761 ). The death rate per 100,000 population attributable to alcohol-related crashes declined among children aged $0-4,5-9$, and $10-14$ years (Figure 1). Among all children aged $<15$ years, the average annual death rate from alcohol-involved crashes was 1.3 times greater for males than for females ( 1.47 compared with 1.11).

During 1985-1996, a total of 5771 children died while traveling as occupants in a motor vehicle involved in an alcohol-related crash, composing 68\% of all alcoholrelated traffic fatalities among persons aged <15 years; an additional 1854 (22\%) children who died were pedestrians, and 719 (8\%) were bicyclists (for 137 [2\%] fatalities, the status was unknown). From 1985 to 1996, the age-adjusted death rate for children who were motor-vehicle occupants in alcohol-involved crashes declined $26 \%$ (from 0.95 to 0.70 ); for those who were pedestrians, the rate declined $51 \%$ (from 0.39 to 0.19 ). For bicyclists aged $5-14$ years, the rate of involvement in alcohol-related motorvehicle crashes declined $62 \%$ (from 0.24 to 0.09 ).

From 1985 through 1996, a total of 3830 children aged <15 years were killed as passengers in a motor-vehicle crash involving a driver whose BAC was $\geq 0.10 \mathrm{~g} / \mathrm{dL}$. Of these, 2280 ( $60 \%$ ) died while riding in the same vehicle with the drunk driver. Only 16\% (336 of 2094) of these children were restrained at the time of the crash (information on restraint use was unknown for 186 children) (Figure 2). For each age group, the percentage of children restrained varied inversely with their driver's BAC. Restraint use was lowest ( $11 \%$ ) for children aged $10-14$ years whose drivers had BACs $\geq 0.10 \mathrm{~g} / \mathrm{dL}$.

Alcohol-Related Traffic Fatalities - Continued
FIGURE 1. Age-specific death rates* from alcohol-related motor-vehicle crashes among children aged <15 years, by year - United States, 1985-1996

*Per 100,000 population.

Reported by: Div of Unintentional Injury Prevention, National Center for Injury Prevention and Control, CDC.
Editorial Note: The findings in this report indicate that approximately one fourth of all motor-vehicle-related deaths among children aged $<15$ years involved alcohol and that in nearly two thirds of passenger deaths involving a legally drunk driver, the child was in the car driven by the legally drunk driver. The decline in the death rate for alcohol-involved crashes among children aged $<15$ years is consistent with a recent decline in the proportion of alcohol-involved deaths among drivers of all age groups (4). This decline coincides with passage of stricter laws about drinking and driving. In 33 states, driving with a BAC of $\geq 0.10 \mathrm{~g} / \mathrm{dL}$ is illegal, and in 15 states the limit has been lowered to $0.08 \mathrm{~g} / \mathrm{dL}$ (six states with a legal limit of $0.08 \mathrm{~g} / \mathrm{dL}$ have adopted this lower limit since 1993) (5).

The proportion of children killed in crashes while in the same car as a driver with a $B A C \geq 0.10 \mathrm{~g} / \mathrm{dL}$ is consistent with findings at a state level: during a 4 -year period in North Carolina, of 51 child passengers who died in alcohol-related crashes, 36 (70\%) were killed as passengers in vehicles in which their driver had been drinking and driving (6). The legislatures of 21 states have enacted child-endangerment laws that create a separate violation for persons who drive while legally intoxicated with a child in the vehicle (5); however, the effectiveness of these laws has not been evaluated.

FIGURE 2. Percentage of children restrained among those who died in motor-vehicle crashes, by child's age group and the blood alcohol concentration (BAC) of the driver of the vehicle in which the children were passengers — United States, 1985-1996*

*Does not include 1595 children for whom restraint use was unknown, 1325 children who were killed while in the driver's position of the vehicle, or 152 children killed for whom driver information was unknown.

Despite recent declines in rates for alcohol-related traffic deaths, U.S. drivers continue to drink and drive at a high rate. During 1993, approximately 123 million episodes of self-reported alcohol-impaired driving occurred in the United States (7). Further reduction in alcohol-involved motor-vehicle-related fatalities among children will require a variety of interventions designed to change drinking and driving behaviors of adults, including altering drivers' perceptions of risk to themselves and to others riding with them, increasing efforts to screen for alcoholism among persons convicted of driving while intoxicated, and changing public policy to deter adult drinking and driving, especially when adults are transporting young children. The proportion of children in this analysis who died while riding unrestrained in the same vehicle as the drunk driver underscores the need for continuing efforts to increase safety-belt and child safety-seat usage among all motor-vehicle occupants. Drivers with a BAC $\geq 0.10 \mathrm{~g} / \mathrm{dL}$ are less likely than drivers with lower BACs to wear safety belts (8), and this analysis indicates that their young passengers are at increased risk for riding unrestrained. Rigorous enforcement of primary safety-belt and child safety-seat laws by police, in addition to reducing drinking and driving, can protect children and other passengers from the hazards of alcohol-impaired driving.

## Abortion Surveillance: Preliminary Analysis - United States, 1995

For 1995, CDC received data about legal induced abortions from the 50 states, New York City, and the District of Columbia. This report presents preliminary data for 1995; final abortion data for 1995 will be published during spring 1998.

In 1995, a total of 1,210,883 legal induced abortions were reported to CDC (Table 1), a decrease of $4.5 \%$ from the number reported for 1994 (1). The number of live births decreased by $1.5 \%$ over the same period. From 1994 to 1995, the number of reported abortions decreased in 40 of 52 reporting areas. From 1994 to 1995, the national abortion ratio (number of legal abortions per 1000 live births reported by all reporting areas) decreased from 321 to 311, respectively (Table 1, Figure 1), and the national abortion rate (number of legal abortions per 1000 women aged 15-44 years) decreased from 21 to 20, respectively. Consistent with previous years, approximately $92 \%$ of women who had legal abortions were residents of the state in which the procedure was performed.

Women who obtained legal abortions in 1995 were predominately white and unmarried. As in 1994, one fifth of women who obtained legal abortions in 1995 were adolescents (aged $\leq 19$ years); $33 \%$ were aged $20-24$ years. Curettage (suction and sharp) remained the primary abortion procedure ( $99 \%$ of all procedures). As in previous years, more than half of legal abortions ( $54 \%$ ) were performed during the first 8 weeks of gestation; specifically, $16 \%$ were at $\leq 6$ weeks; $17 \%$ at 7 weeks; and $21 \%$ at 8 weeks. Approximately $88 \%$ of abortions were performed during the first 12 weeks of pregnancy.
Reported by: Statistics and Computer Resources Br, Div of Reproductive Health, National Center for Chronic Disease Prevention and Health Promotion, CDC.
Editorial Note: During 1980-1995, the annual number of legal induced abortions in the United States varied by $\leq 5 \%$ (Table 1). However, since 1990 (the year in which the number of abortions was highest), the number of reported abortions has steadily de-

* Number of legal induced abortions per 1000 live births.
$\dagger$ Number of legal induced abortions per 1000 women aged 15-44 years.
${ }^{\S}$ Preliminary data. The number of areas reporting a given characteristic varied. For 1995, the number of areas reporting residence was 43; age, 44; race, 36; ethnicity, 23; marital status, 33; number of live births, 37; type of procedure, 40; and weeks of gestation, 40.

I Percentage distributions are based on known values in data from all areas reporting a given characteristic, except where the proportion of unknown values exceeded $15 \%$.
** Reported as "other" race.
${ }^{\dagger \dagger}$ For years 1972 and 1976, data indicate number of living children.
§§ Includes hysterotomy and hysterectomy.
ITI Data are for 36 of 39 areas reporting weeks of gestation.
*** Data are for 38 of 41 areas reporting weeks of gestation.
${ }^{\dagger \dagger \dagger}$ Data are for 38 of 40 areas reporting weeks of gestation.

## Abortion Surveillance - Continued

FIGURE 1. Fertility rate* and abortion ratio ${ }^{\dagger}$ and rate ${ }^{\S}$, by year - United States, 1972-1995

* Number of live births per 1000 women aged 15-44 years.
${ }^{\dagger}$ Number of legal induced abortions per 1000 live births.
${ }^{\S}$ Number of legal induced abortions per 1000 women aged 15-44 years.
creased. In 1995, 77\% of reporting areas reported fewer abortions than in 1994. During 1972-1980, the national abortion rate increased each year; during 1981-1993, the rate remained stable, fluctuating between 22 and 24 per 1000 women of reproductive age (i.e., aged 15-44 years) (Figure 1). The 1995 rate of 20 was the lowest rate recorded since 1975 (2).

In 1995, the national ratio of abortions to live births ( 311 abortions per 1000 live births) was lower than for any year since 1976 (Figure 1) (3). The denominator of this ratio (the number of live births) peaked in 1990 and has declined each subsequent year; although the numerator of this ratio (the number of abortions) also peaked in 1990, the percentage decline from 1994 to 1995 in the annual number of abortions exceeded the percentage decline in the annual number of births ( $4.5 \%$ compared with $1.5 \%$, respectively). Factors potentially associated with the decrease in the proportion of pregnancies that ended in an abortion include reduced access to abortion services, attitudinal changes concerning the decision to have an abortion or to carry a pregnancy to term, and a reduction in the number of unintended pregnancies (4-6).

Although the number of women of reproductive age in the United States has increased by $13 \%$ since 1980 , the proportion who are older (i.e., in later, less fertile reproductive years) has increased (7). For example, from 1980 to 1995, the percentage of women of reproductive age who were aged <30 years (the age group having high-

## Abortion Surveillance - Continued

est fertility) declined from $58 \%$ to $46 \%$, respectively ( 8 ), while women aged $35-$ 44 years (the age group having lowest fertility) accounted for $25 \%$ and $36 \%$ of repro-ductive-aged women, respectively. The final report for 1995 will assess the impact of changes in the age distribution of reproductive-aged women on the long-term trend in the abortion rate and ratio.

Many states emphasize prevention of unintended pregnancy, particularly among teenagers. During 1995, the total number of legal induced abortions was available for all 52 reporting areas. However, approximately $36 \%$ of abortions were reported from states without centralized reporting of abortions (four states) or from states whose state health departments did not collect, and therefore could not provide, information about characteristics (e.g., age or race) of women obtaining legal abortions (four states). To assist efforts to prevent unintended pregnancy, each state needs an accurate assessment of abortion on an ongoing basis (including the number and characteristics of women obtaining legal abortions). Since 1992, most reporting areas have reported abortions by gestational age in weeks of gestation for abortions performed at $\leq 8$ weeks. As new medical methods are used for terminating pregnancies primarily at $\leq 8$ weeks of gestation, these data will continue to assist in monitoring trends in legal abortions ( 9,10 ).

Additional statistical and epidemiologic information about legal induced abortions is available from CDC's automated Reproductive Health Information line, telephone (888) 232-2306, which provides information by fax, by voice recordings, or through the mail.

## Use of Clinical Preventive Services by Medicare Beneficiaries Aged $\geq 65$ Years - United States, 1995

Delivery of clinical preventive services to older adults can reduce premature morbidity and mortality while preserving function and enhancing overall quality of life $(1,2)$. Until recently, the use of such services has been low among older adults because Medicare coverage has not been extended to many preventive services (3). Medicare coverage now includes four clinical preventive services: a single lifetime pneumococcal polysaccharide vaccination (vaccine plus any required revaccination and administration) (since 1981); annual influenza vaccination (vaccine and administration) (since 1993); and for women, biennial mammography screening (since 1991) and Papanicolaou smear screening every 36 months (since 1990) (4,5). To assess current state-specific levels of use of these services among Medicare beneficiaries, CDC and the Health Care Financing Administration (HCFA) analyzed data from the 1995 Behavioral Risk Factor Surveillance System (BRFSS). This report summarizes the findings of this analysis, which indicate that, despite Medicare coverage of these preventive services, many U.S. adults aged $\geq 65$ years did not receive such services in 1995, and state-specific use of these services varied substantially.

The BRFSS is an ongoing, state-based, random-digit-dialed telephone survey of U.S. civilian, noninstitutionalized adults aged $\geq 18$ years. In 1995, all 50 states participated in the survey (6). All persons responding to the BRFSS questionnaire were asked 1) "Do you have any kind of health-care coverage, including health insurance, prepaid plans such as HMOs [health-maintenance organizations], or government plans such as Medicare?" and 2) what specific preventive health services they had received and the duration since they had received the service(s). Of the 113,934 survey participants, 22,849 were aged $\geq 65$ years. Because the 1995 survey did not ask specifically whether the respondent had Medicare insurance, a "yes" response to the health insurance status question was used as a proxy for Medicare coverage. A total of $22,500(98.5 \%)$ respondents aged $\geq 65$ years indicated having such coverage. Male survey respondents were excluded from estimates of prevalences of mammography and Pap smear screenings. Female respondents from California also were excluded from these estimates because of the different wording of the survey questions in that state. Statistical Analysis Software (SAS) was used to calculate the prevalence estimates, and Software for Survey Data Analysis (SUDAAN) was used to calculate $95 \%$ confidence intervals (Cls). Although differences in state-specific prevalence estimates may reflect, in part, disparate age distributions, the sizes of the samples did not permit age adjustment of prevalence rates.

In 1995, state-specific estimates of the percentage of persons aged $\geq 65$ years who had received influenza vaccinations during the 12 months preceding the survey ranged from $46.2 \%$ ( $95 \% \mathrm{Cl}=40.3 \%-52.1 \%$ ) (Alabama) to $70.3 \%$ ( $95 \% \mathrm{Cl}=65.4 \%-75.2 \%$ ) (Utah) (median: 60.6\%) (Table 1). The prevalences for most southeastern states were in the lowest quartile ( $46.2 \%-56.1 \%$ ) and for most western states were in the highest quartile (64.1\%-70.3\%) (Figure 1).

Estimates of the percentage of persons aged $\geq 65$ years who had ever received a pneumococcal vaccination ranged from $13.1 \%$ ( $95 \% \mathrm{Cl}=8.0 \%-18.2 \%$ ) (New Jersey) to 49.3\% ( $95 \% \mathrm{Cl}=43.0 \%-55.6 \%$ ) (Arizona) (median: 38.5\%). Prevalences were higher in western states.

The percentage of women aged $\geq 65$ years who had received a mammogram during the 2 years preceding the survey ranged from $52.7 \%$ ( $95 \% \mathrm{Cl}=44.3 \%-61.1 \%$ ) (New Jersey) to $80.4 \%$ ( $95 \% \mathrm{Cl}=68.8 \%-92.0 \%$ ) (Alaska) (median: 65.0\%), and prevalences did not vary by region. Percentages of women aged $\geq 65$ years who had obtained Pap smears during the 3 years preceding the survey ranged from $52.2 \%$ ( $95 \% \mathrm{Cl}=44.9 \%-$ 59.5\%) (Kentucky) to $88.5 \%$ ( $95 \% \mathrm{Cl}=83.4 \%-93.6 \%$ ) (Arizona) (median: 70.0\%); a substantial number of states in the Midwest ranked in the second lowest quartile (range: 63.7\%-67.3\%) (Figure 2).

Reported by: Behavioral Risk Factor Surveillance System coordinators. L Rhodes, MPH, Klemm Analysis Group; D Arday, MD, S Arday, MHS, Office of Clinical Standards and Quality, Health Care Financing Administration. Health Care and Aging Studies Br and Behavioral Surveillance Br, Div of Adult and Community Health, National Center for Chronic Disease Prevention and Health Promotion, CDC.
Editorial Note: This report documents substantial variation in the state-specific prevalences of four preventive services (pneumococcal polysaccharide vaccination, influenza vaccination, mammography screening, and Pap smear screening) used recently by Medicare-eligible adults. Although all four services are covered by Medicare and endorsed by many organizations and agencies (7), many states have not met the national health objectives for 2000 for use of these services ( $60 \%$ coverage with influenza and pneumonia vaccines [objective 20.1] and use of Pap smears by $70 \%$ of women aged $\geq 70$ years with an intact cervix [objective 16.12]*) (3). These findings also indicate that health-care coverage alone does not ensure use of preventive services, even though previous national studies have documented that uninsured persons were less likely to receive preventive health services (8). The use of a state-specific survey such as BRFSS enables individual states and HCFA's peer review organizations to estimate prevalences and tailor intervention strategies.

The findings in this report are subject to at least four limitations. First, because BRFSS includes only households with a telephone, the findings may underestimate prevalences among groups with lower socioeconomic status, resulting in overestimation of the prevalences of use of preventive services. Second, because limitations in the sample sizes precluded age-adjustment by state, disparities in state-specific age distributions may account for some of the variation in rates of service delivery. Third, self-reported data are subject to recall bias, especially telescoping (i.e., the tendency to recall an event as having occurred later or earlier than it actually did). Women often report having had a mammogram or Pap smear in the recommended time frame when the actual interim since their last screening has been longer, resulting in overestimates of state-based prevalences. Finally, although age and health insurance status were used as a proxy for Medicare coverage of preventive services, other factors that may have affected out-of-pocket costs (e.g., "medi-gap" programs that supplement Medicare, Medicaid, and employer health insurance programs) were unaccounted for in the analysis (9). For example, although the Supplementary Medical Insurance Program (i.e., Medicare Part B) reimburses all the services included in this report, enrollment is voluntary and requires payment of a monthly premium; persons not enrolled could incur substantial out-of-pocket expenses after receipt of services. In $1995,5 \%-6 \%$ of the population aged $\geq 65$ years was not covered by Medicare Part B.

The likelihood of use of clinical preventive services is decreased among persons without a usual source of care and among those in lower income and education

groups ( 7,8 ). Other barriers to receipt of such services include 1) provider knowledge and attitudes (lack of training or disagreement with guidelines); 2) patient knowledge and attitudes (anxiety, discomfort, or apathy); and 3) system factors (lack of provider staff or reminder systems). Elimination of barriers will require changes in policy, legislation, and the development of outreach programs of clinical preventive services targeted to older adults. Although provider-directed strategies emphasizing continuing medical education has had limited success in changing professional practice patterns, some office-based interventions (e.g., prompting, monitoring, and providing performance feedback) have modestly increased delivery of preventive services (10). Additional efforts should assess the effectiveness of patient-directed interventions that specifically address the needs and attitudes of older adults. The delivery of preventive services to older adults also will require broad-based interventions implemented simultaneously at several levels. These interventions should include changes in the structure of the delivery of preventive services in health care and increased consensus regarding prevention guidelines.

## Efforts to Quit Smoking Among Persons With a History of Alcohol Problems — lowa, Kansas, and Nebraska, 1995-1996

In 1991, approximately 13.8 million adults in the United States met diagnostic criteria for alcohol abuse, alcohol dependence, or both (1). In addition, at least $80 \%$ of persons in this group were likely to be daily tobacco smokers and, therefore, at increased risk for oral and pharyngeal cancers (2,3). In Minnesota, among adult smokers with a history of alcohol abuse during 1972-1983, the number of tobacco-related deaths was higher than the number of alcohol-related deaths (4). To assess rates of smoking cessation among adults with a history of alcohol problems, the University of Nebraska Medical Center conducted an intervention study with 1 year of follow-up during 1995-1996 in 12 residential alcohol-treatment centers in lowa, Kansas, and Ne braska. This report summarizes the findings, which suggest that a substantial proportion of adults recently treated for alcoholism attempted to quit smoking, even though actual quit rates were low.

All participants ( $n=575$ ) were daily tobacco smokers who voluntarily enrolled in the study while undergoing residential treatment for alcohol abuse. Of these 575 persons, $288(50 \%)$ were receiving care at six alcohol-treatment centers testing a brief smokingcessation intervention for recovering alcoholics. The intervention consisted of four 10 -minute individually tailored counseling discussions about quitting smoking ( 3,5 ). Nicotine-replacement products were not provided. The remaining 287 participants received alcohol treatment at six other centers but not the additional counseling discussions about quitting smoking.

Characteristics of participants in the centers that provided smoking-cessation counseling and those that provided only usual care were similar in age, sex, race/ethnicity, and drug-abuse history. Overall, $67 \%$ of the participants were male, and the overall mean age was 33 years. Approximately $33 \%$ of the participants self-identified as racial minorities, including 121 American Indians/Alaskan Natives who were clients at the two centers that served only persons who were American Indian/Alaskan Native. During the 30 days preceding admission for treatment, participants reported drinking a mean of 12 alcoholic drinks per day. The average number of days in residential treatment before discharge to outpatient care was 34 . The mean number of cigarettes smoked per day was 20 (range: 1-80 cigarettes).

At 1, 6, and 12 months after discharge from residential treatment, participants completed a mail survey about their recent drug use that included 10 questions about tobacco. The survey asked about attempts to quit smoking since the previous assessment and the number of days of nonsmoking; 1 day was defined as "at least 24 hours." Saliva samples were obtained from and analyzed for cotinine for the $70 \%$ of persons who reported they no longer smoked. For a randomly selected subset of 176 ( $33 \%$ ) of all respondents, a friend or relative named by the participant at study enrollment was interviewed by telephone to confirm questionnaire data. At least one follow-up survey was completed by most (540 [94\%]) participants; the 12-month questionnaire was completed by 448 ( $78 \%$ ). In this analysis, a successful quitter was defined as a person who reported at the 12-month follow-up no longer smoking and not having smoked a cigarette for at least the preceding 7 days.

Of the participants who completed the 12-month follow-up, 36 ( $8 \%$ ) reported being successful quitters; of these persons, 29 ( $80 \%$ ) reported not having smoked a cigarette

## Efforts to Quit Smoking - Continued

for at least the preceding 30 days. Analysis of cotinine scores of successful quitters indicated that most ( $88 \%$ ) saliva samples had nondetectable cotinine levels; $12 \%$ had been obtained from participants who relapsed to smoking after completing their questionnaire or who had detectable levels below the cut-point, suggesting recent tobacco use. Data from friends and relatives confirmed 165 ( $94 \%$ ) of 176 participant drug-use reports. Quit rates for participants from the centers providing the smoking-cessation counseling were similar to those of participants from centers providing usual care ( $9 \%$ compared with $7 \%$, respectively; $p>0.05$ ). Sex-specific quit rates were $9 \%$ for males and $6 \%$ for females ( $p>0.05$ ). Rates for other subgroups were not meaningful because of small sample sizes.

When quit attempts were analyzed without consideration of tobacco smoking status at the 12-month assessment, the rates were higher. For these analyses, unsuccessful quitters (i.e., persons who had quit smoking but had relapsed back to tobacco smoking by follow-up) were combined with successful quitters. A quit attempt of $\geq 24$ hours was reported by $45 \%$ of the study sample; $25 \%$ of all participants reported quitting for $\geq 7$ days sometime during the year of follow-up (Table 1). Quit attempt rates for participants from the smoking-cessation and usual-care treatment centers were similar ( $p>0.05$ ).

Race/ethnicity was the only sociodemographic variable significantly associated with attempts to quit smoking ( $p<0.05$ ). Based on logistic regression models that adjusted for age, sex, education, and the provision of smoking-cessation counseling, American Indian/Alaskan Native participants were more likely than non-Hispanic white participants to report having quit smoking for $\geq 24$ hours and having quit for $\geq 7$ days (Table 2).

Of the participants who reported having quit smoking for $\geq 7$ days by the 12-month follow-up, $73 \%$ reported having relapsed at some time during the preceding year. Relapse rates were similar by race/ethnicity, age, sex, education, and provision of smok-ing-cessation counseling during alcohol treatment ( $p>0.05$ ). For example, relapse rates for non-Hispanic whites, American Indians/Alaskan Natives, and participants of other racial/ethnic groups were $75 \%, 68 \%$, and $75 \%$, respectively.
Reported by: JK Bobo, PhD, Univ of Nebraska Medical Center, Omaha. Div of Cancer Prevention and Control and Office on Smoking and Health, National Center for Chronic Disease Prevention and Health Promotion, CDC.
Editorial Note: The findings in this report suggest that, although a substantial proportion of clients receiving treatment for alcohol abuse also were willing to attempt smoking cessation, actual quit rates were low. Failure of the tobacco intervention to increase quit rates significantly and high relapse rates among those who reported quitting for $\geq 7$ days probably reflect the brevity of the smoking-cessation intervention, the addictive nature of nicotine, and the concurrent challenges of the other lifestyle changes required for successful recovery from alcohol abuse ( 6,7 ).

Despite restrictions on the sample population in this trial that limit generalization of the findings, the quit rates in this study are similar to those reported previously for a nationwide sample of persons aged $\geq 18$ years ( 8 ). In that survey, $42 \%$ of daily smokers reported having abstained from cigarettes for at least 1 day during the preceding year, and $86 \%$ subsequently resumed smoking ( 8 ); only $6 \%$ of those who were daily smokers 1 year before the interview quit smoking and maintained abstinence for at least 1 month. In this study, the finding that attempts to quit smoking were more common

${ }^{\S}$ Confidence interval.
"Four respondents indicated Hispanic ethnicity. These persons were included in the "other" category.
among American Indian/Alaskan Native participants than among non-Hispanic whites may reflect the effect of race as a marker for other sociodemographic characteristics previously associated with tobacco and smoking cessation (e.g., income, education, occupation, and community traditions) (9).

In the United States and other countries, recovering alcoholics have not been encouraged to quit smoking as consistently as have smokers in the total population because of concerns that the stress of nicotine withdrawal might provoke a relapse to alcohol abuse (10). However, this position has not been substantiated by rigorous trials or investigation (10). In the study described in this report, recovering alcoholics who were encouraged to quit smoking were less likely to relapse to drinking during the 1 -year follow-up period (10). Public health departments can facilitate smokingcessation efforts among recovering alcoholics by encouraging community chemicaldependency treatment programs to routinely screen for and treat tobacco use. The findings in this report suggest that more intensive interventions, similar to those employed for treatment of alcohol problems, may be needed to markedly increase tobacco smoking-cessation rates among such groups.

## Alcohol Involvement in Fatal Motor-Vehicle Crashes United States, 1995-1996

The table and figure on page 1155 compare alcohol involvement in fatal motorvehicle crashes for 1995 and 1996. A fatal crash is considered alcohol-related by the National Highway Traffic Safety Administration (NHTSA) if either a driver or nonoccupant (e.g., pedestrian) had a blood alcohol concentration (BAC) of $\geq 0.01 \mathrm{~g} / \mathrm{dL}$ in a police-reported traffic crash. Because BACs are not available for all persons in fatal crashes, NHTSA estimates the number of alcohol-related traffic fatalities based on a discriminant analysis of information from all cases for which driver or nonoccupant BAC data are available (1).

Overall, the number of alcohol-related traffic fatalities decreased by <1\% from 1995 to 1996 ; for BACs of $0.01-0.09 \mathrm{~g} / \mathrm{dL}$, the decrease was $0.5 \%$, for BACs $\geq 0.10 \mathrm{~g} / \mathrm{dL}$ (the legal limit of intoxication for adults in most states), the decrease was $1.0 \%$. A notable increase ( $9.8 \%$ ) occurred among those aged 15-20 years where a driver or nonoccupant had a BAC $\geq 0.10 \mathrm{~g} / \mathrm{dL}$.

${ }^{*}$ Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
${ }^{\dagger}$ Preumonia and influenza.
${ }^{\S}$ Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
TTotal includes unknown ages.

Changes in the estimated number and percentage of traffic fatalities (including drivers, occupants, and nonoccupants), by age group* and highest blood alcohol concentration (BAC) ${ }^{\dagger}$ of driver ${ }^{\S}$ or nonoccupant in crashes - United States, January 1-December 31, 1995, compared with January 1-December 31, 1996

*Age was unknown for 84 traffic fatalities in 1995 and 130 traffic fatalities in 1996.
${ }^{\dagger}$ BAC distributions are estimates for drivers and nonoccupants involved in fatal crashes. Fatalities include all occupants and nonoccupants who died within 30 days of a motor-vehicle crash on a public roadway and whose age was known.
§Driver may or may not have been killed.
TAlthough usually too young to drive legally, persons in this age group are included for completeness.
**The number of fatalities for each BAC category is rounded to the nearest whole number.
Source: Fatality Analysis Reporting System, National Highway Traffic Safety Administration.

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to listserv@listserv.cdc.gov. The body content should read SUBscribe mmwr-toc. Electronic copy also is available from CDC's World-Wide Web server at http://www.cdc.gov/ or from CDC's file transfer protocol server at ftp.cdc.gov. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly MMWR are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the MMWR Series, including material to be considered for publication, to: Editor, MMWR Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (888) 232-3228.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.

[^0]:    *The national health objective for use of mammography is combined with clinical breast examination (CBE). Medicare does not pay specifically for CBE.

[^1]:    *All persons responding to the BRFSS questionnaire were asked "Do you have any kind of health-care coverage, including health insurance, prepaid plans such as HMOs [health-maintenance organizations], or government plans such as Medicare?" A "yes" response was used as a proxy for Medicare coverage.
    ${ }^{\dagger}$ Vaccination received during the 12 months preceding the survey.
    ${ }^{\S}$ Vaccination received during their lifetime.
    $\uparrow$ Service received during the previous 2 years.
    **Service received during the previous 3 years. Excludes women with no uterine cervix.
    ${ }^{\dagger \dagger}$ Confidence interval
    ${ }^{\S}$ Female respondents from California were excluded from these estimates because of the different wording of the survey questions in that state.

[^2]:    Confidence interval
    ${ }^{\dagger}$ Numbers for other racial/ethnic groups were too small for meaningful analysis.

[^3]:    Not noifia cases
