590 Recommendations of the Advisory Committee on Immunization Practices: Revised Recommendations for Routine Poliomyelitis Vaccination

## Intussusception Among Recipients of Rotavirus Vaccine United States, 1998-1999

On August 31, 1998, a tetravalent rhesus-based rotavirus vaccine (RotaShield ${ }^{\circledR * *}$, Wyeth Laboratories, Inc., Marietta, Pennsylvania) (RRV-TV) was licensed in the United States for vaccination of infants. The Advisory Committee on Immunization Practices (ACIP), the American Academy of Pediatrics, and the American Academy of Family Physicians have recommended routine use of RRV-TV for vaccination of healthy infants (1,2). During September 1, 1998-July 7, 1999, 15 cases of intussusception (a bowel obstruction in which one segment of bowel becomes enfolded within another segment) among infants who had received RRV-TV were reported to the Vaccine Adverse Event Reporting System (VAERS). This report summarizes the clinical and epidemiologic features of these cases and preliminary data from ongoing studies of intussusception and rotavirus vaccine.

## VAERS

VAERS is a passive surveillance system operated by the Food and Drug Administration (FDA) and CDC ( 3,4 ). Vaccine manufacturers are required to report to VAERS any adverse event reported to them, and health-care providers are encouraged to report any adverse event possibly attributable to vaccine. Vaccine recipients and their families also can report adverse events to VAERS. For this report, VAERS case reports of intussusception following rotavirus vaccination were reviewed, and health-care providers, parents, or guardians of patients were contacted by telephone for additional clinical and demographic information. Data on RRV-TV distribution were obtained from the manufacturer. To estimate the expected rate of intussusception among infants aged <12 months, hospital discharge data from New York for 19911997 were reviewed.

Of the 15 infants with intussusception reported to VAERS, 13 ( $87 \%$ ) developed intussusception following the first dose of the three-dose RRV-TV series, and 12 (80\%) of 15 developed symptoms within 1 week of receiving any dose of RRV-TV (Table 1). Thirteen of the 15 patients received concurrently other vaccines with RRV-TV. Intussusception was confirmed radiographically in all 15 patients. Eight infants required surgical reduction, and one required resection of 7 inches ( 18 cm ) of distal ileum and

[^0]Rotavirus Vaccine - Continued

proximal colon. Histopathologic examination of the distal ileum indicated lymphoid hyperplasia and ischemic necrosis. All infants recovered. Onset dates of reported illness occurred from November 21, 1998, to June 24, 1999 (Figure 1). The median age of patients was 3 months (range: 2-11 months). Ten were boys. Intussusception among RRV-TV recipients was reported from seven states (Table 1). Of the 15 cases reported to VAERS, 14 were spontaneous reports and one was identified through active postlicensure surveillance.

The rate of hospitalization for intussusception among infants aged $<12$ months during 1991-1997 (before RRV-TV licensure) was 51 per 100,000 infant-years ${ }^{\dagger}$ in New York (95\% confidence interval $[\mathrm{CI}]=48-54$ per 100,000). The manufacturer had distributed approximately 1.8 million doses of RRV-TV as of June 1, 1999, and estimated that 1.5 million doses ( $83 \%$ ) had been administered. Given this information, 14-16 intussusception cases among infants would be expected by chance alone during the week following receipt of any dose of RRV-TV. Fourteen of the 15 case-patients were vaccinated before June 1, 1999, and of those, 11 developed intussusception within 1 week of receiving RRV-TV.

## Postlicensure Studies of Adverse Events Following RRV-TV

As part of a preliminary analysis of ongoing postlicensure surveillance of adverse events following vaccination with RRV-TV, cases of intussusception during December 1, 1998-June 10, 1999, were identified among infants aged 2-11 months at Northern California Kaiser Permanente (NCKP) by review of hospital discharge diagnoses, admitting diagnoses for the records for which discharge summaries were not yet

complete, and computerized records of all barium enemas performed on children aged $<1$ year. Relative risks were age-adjusted because of differences in the ages of vaccinated and unvaccinated infants, and $p$ values were calculated by Poisson regression.

At NCKP, 16,627 doses of RRV-TV were administered to 9802 infants during December 1, 1998-June 10, 1999. Nine cases of intussusception among infants were identified with onset during that same period, all of which were radiographically or surgically confirmed. Three were among vaccinated children, with intervals of 3,15 , and 58 days following vaccination. The rate of intussusception among nevervaccinated children was 45 per 100,000 infant-years, and among children who had received RRV-TV was 125 per 100,000 infant-years (age-adjusted relative risk [RR]=1.9, $95 \% \mathrm{Cl}=0.5-7.7, \mathrm{p}=0.39$ ). The rate among children who had received RRV-TV during the preceding 3 weeks was 219 per 100,000 infant-years (age-adjusted RR=3.7,95\% $\mathrm{Cl}=0.7-19, \mathrm{p}=0.12$ ). Among children who had received RRV-TV during the previous week, the rate was 314 per 100,000 infant-years (age-adjusted $\mathrm{RR}=5.7,95 \% \mathrm{Cl}=0.7-50$, $\mathrm{p}=0.11$ ).

Rotavirus Vaccine - Continued

## Minnesota

In Minnesota, intussusception cases were identified among infants aged 30 days11 months who were born after April 1, 1998, and were hospitalized with radiographically or surgically confirmed intussusception with onset during November 1, 1998June 30, 1999. During October 1, 1998-June 1, 1999, 62,916 doses of vaccine were distributed. Eighteen cases of intussusception were identified, five of which were among infants who had received RRV-TV. Vaccinated children had a median age of 4 months (range: 3-5 months), and unvaccinated children had a median age of 7 months (range: 5-9 months). Four of the five RRV-TV recipients with intussusception required surgical reduction, and five of 13 unvaccinated children required surgical reduction. Intussusception occurred after receipt of dose one (two children), dose two (two children), and dose three (one child). The five RRV-TV recipients developed intussusception within 2 weeks of receipt of vaccine; intervals were 6 days (two children), 7 days, 10 days, and 14 days after receipt of vaccine. Assuming 85\% of RRV-TV doses distributed in Minnesota were administered, the observed rate of intussusception within 1 week of receipt of RRV-TV was 292 per 100,000 infant-years.
Reported by: K Ehresman, MPH, R Lynfield, MD, R Danila, PhD, Acting State Epidemiologist, Minnesota Dept of Health. S Black, MD, H Shinefield, MD, B Fireman, MS, S Cordova, MS, Kaiser Permanente Vaccine Study Center, Oakland, California. Div of Biostatistics and Epidemiology, Food and Drug Administration. Editorial Note: Rotavirus is the most common cause of severe gastroenteritis in infants and young children aged $<5$ years in the United States, resulting in approximately 500,000 physician visits, 50,000 hospitalizations, and 20 deaths each year. Worldwide, rotavirus is a major cause of childhood death, accounting for an estimated 600,000 deaths annually among children aged $<5$ years. Rotavirus vaccines offer the opportunity to reduce substantially the occurrence of this disease (1).

In prelicensure studies, five cases of intussusception occurred among 10,054 vaccine recipients and one of 4633 controls, a difference that was not statistically significant (5). Three of the five cases among vaccinated children occurred within 6-7 days of receiving rotavirus vaccine. On the basis of these data, intussusception was included as a potential adverse reaction on the package insert, and the ACIP recommended postlicensure surveillance for this adverse event following vaccination (1).

Because of concerns about intussusception identified in prelicensure trials, VAERS data were analyzed early in the postlicensure period. The number of reported intussusception case-patients with illness onset within 1 week of receiving any dose of vaccine is in the expected range; however, because reporting to VAERS of adverse events following vaccination is incomplete (6), the actual number of intussusception cases among RRV-TV recipients may be substantially greater than that reported.

In response to the VAERS reports, a preliminary analysis of data from an ongoing postlicensure study at NCKP was performed, and a multistate investigation was initiated to determine whether an association exists between administration of RRV-TV and intussusception in infants. Preliminary data from Minnesota and from NCKP also suggest an increased risk for intussusception following receipt of RRV-TV. Observed rates of intussusception among recently vaccinated children were similar in both

## Rotavirus Vaccine - Continued

studies. However, the number of cases of intussusception among vaccinated children is small at both NCKP and in Minnesota, and neither study has adequate power to establish a statistically significant difference in incidence of intussusception among vaccinated and unvaccinated children. Available data suggest but do not establish a causal association between receipt of rotavirus vaccine and intussusception, and additional studies are ongoing.

Although neither these studies nor the VAERS reports is conclusive, the consistency of findings from these three data sources raises strong concerns. Because more data are anticipated within several months and rotavirus season is still 4-6 months away in most areas of the United States, CDC recommends postponing administration of RRV-TV to children scheduled to receive the vaccine before November 1999, including those who already have begun the RRV-TV series. Parents or caregivers of children who have recently received rotavirus vaccine should promptly contact their healthcare provider if the infant develops symptoms consistent with intussusception (e.g., persistent vomiting, bloody stools, black stools, abdominal distention, and/or severe colic pain). Health-care providers should consider intussusception in infants who have recently received RRV-TV and present with a consistent clinical syndrome; early diagnosis may increase the probability that the intussusception can be treated successfully without surgery. Vaccine providers, parents, and caregivers should report to VAERS intussusception and other adverse events following vaccination.

Information on reporting to VAERS and case report forms can be requested 24 hours a day by telephone, (800) 822-7967, or the World-Wide Web, http://www.nip.gov/nip/vaers.htm.

# Outbreak of Salmonella Serotype Muenchen Infections Associated with Unpasteurized Orange Juice United States and Canada, June 1999 

During June 1999, Public Health-Seattle and King County (PHSKC) and the Washington state health department and the Oregon Health Division independently investigated clusters of diarrheal illness attributed to Salmonella serotype Muenchen infections in each state. Both clusters were associated with a commercially distributed unpasteurized orange juice traced to a single processor, which distributes widely in the United States. As of July 13, 207 confirmed cases associated with this outbreak have been reported by 15 states and two Canadian provinces; an additional 91 cases of $S$. Muenchen infection reported since June 1 are under investigation. This report summarizes the two state-based investigations and presents preliminary information about the outbreak in the other states and Canada.

## Washington

On June 19, state health officials were notified of three cases of Salmonella serogroup C2 infection, which were confirmed subsequently as S. Muenchen. Interviews of the ill persons revealed one common feature: drinking a fruit smoothie containing unpasteurized orange juice from different outlets of restaurant chain A. PHSKC and the Washington State Department of Health initiated an investigation. A case was defined as illness with onset after June 9, with isolation of $S$. Muenchen from stool or blood or isolation of Salmonella serogroup C2 with a pulsed-field gel electrophoresis (PFGE) or restriction fragment length polymorphism pattern that was indistinguishable from the outbreak strain.

In a case-control study by PHSKC of nine ill and 29 well restaurant A patrons, illness was significantly associated with drinking smoothies containing orange juice ( $100 \%$ of cases exposed compared with $14 \%$ of controls; odds ratio=undefined, $\mathrm{p}<0.001$ ). By July 9, 85 persons with onset of illness during June 10-30 were identified in Washington. Sixty-seven patients reported either drinking unpasteurized orange juice produced by Sun Orchard* of Tempe, Arizona or eating at an establishment where the juice was served. Among 79 patients for whom information was available, the median age was 27 years (range: 9 months- 95 years), and $51 \%$ were male. The predominant symptoms reported were diarrhea (94\%), fever (75\%), and bloody diarrhea (43\%). Eight ( $10 \%$ ) patients were hospitalized, and one man had a stroke coincident with his Salmonella infection. No patients died.

## Oregon

On June 23, the Washington County Department of Health received a report of a case of salmonellosis; the isolate was serotyped subsequently as S. Muenchen. An investigation by the Oregon Health Division identified four ill persons among a group of 13 that had eaten a brunch buffet in Portland. A case was defined as diarrhea (three or more loose stools within 24 hours) or vomiting in a person who attended the buffet. Illness was significantly associated with drinking unpasteurized orange juice produced by Sun Orchard (relative risk=undefined; $p<0.001$ ).

[^2]Outbreak of Salmonella - Continued
By July 12, 57 persons with S. Muenchen infection with onset of illness during June 14-29 were identified in Oregon. The median age was 36 years (range: 9 months-95 years), and 54\% were female. Forty-four patients were known to have drank unpasteurized orange juice before illness onset. Among the 39 patients for whom information was available, the predominant symptoms were diarrhea ( $100 \%$ ), fever ( $89 \%$ ), abdominal cramps ( $85 \%$ ), chills ( $82 \%$ ), and bloody diarrhea ( $59 \%$ ). Seven persons were hospitalized; no patients died.

## Recall of Orange Juice

On June 25, on the basis of the epidemiologic information from the investigations in Washington and Oregon and discussions with the Food and Drug Administration (FDA), Sun Orchard voluntarily issued a recall. Unpasteurized orange juice produced by Sun Orchard is distributed to Arizona, California, Colorado, Nevada, New Mexico, Oregon, Texas, Utah, Washington, Wisconsin, and the Canadian provinces of Alberta and British Columbia under the brand names Aloha, Earls and Joeys Tomato's, Markon, Sysco, Trader Joe's, Voila, and Zupan. Other states and provinces received these products through secondary distribution. The juice was distributed to hotels, restaurants, and supermarkets, and was served in individual glasses as "freshsqueezed" juice in hotels and restaurants. In addition, a frozen form of the unpasteurized juice was sold under the brand name Vareva for use in restaurants and institutions.

On June 28, samples from a previously unopened container of unpasteurized Sun Orchard orange juice analyzed at an FDA laboratory and the Washington State Public Health Laboratory yielded $S$. Muenchen; samples from the smoothie blender and juice dispenser at an outlet of restaurant A analyzed by the Washington State Public Health Laboratory yielded Salmonella serogroup C2. Isolates from both sources had a PFGE pattern that was indistinguishable from strains isolated from patients. Subsequently, orange juice collected from the Sun Orchard factory, cultured in an FDA laboratory and serotyped by the California State Public Health Laboratory, yielded S. serotype Javiana, S. serotype Gaminara, S. serotype Hidalgo, and S. serotype Alamo in addition to $S$. Muenchen. Efforts are ongoing to determine the source of all orange juice components, whether they might have been used in other brands, and the source of the Salmonella contamination.

## Other States and Canada

An outbreak-related case was defined as $S$. Muenchen infection after June 1 in a person who drank unpasteurized orange juice or whose isolate had a PFGE pattern with no more than one band difference from the Washington outbreak strain. In addition to the Washington and Oregon cases, 66 cases were reported in persons in 13 other states: Arizona (four), California (21), Connecticut (one), Florida (one), Illinois (one), lowa (two), Massachusetts (seven), Michigan (three), Minnesota (six), New Mexico (10), Texas (five), Utah (four), and Wisconsin (one). Cases also were reported from the Canadian provinces of Alberta (four) and British Columbia (eight). Among the 66 patients for whom information was available, the median age was 32 years (range: 6 months-66 years), and $58 \%$ were female. Six persons were hospitalized. An additional 78 cases of $S$. Muenchen infection occurring after June 1 reported by nine other states and the two Canadian provinces are under investigation.

Bur of Infectious Diseases Laboratory, Center for Disease Control, Health Canada. Center for Food Safety and Applied Nutrition and Office of Regional Operations, Food and Drug Administration. Foodborne and Diarrheal Diseases Br, Div of Bacterial and Mycotic Diseases, National Center for Infectious Diseases; and EIS officers, CDC.
Editorial Note: S. Muenchen is one of approximately 2400 Salmonella serotypes that can cause illness in humans. Salmonella infection typically causes gastroenteritis characterized by diarrhea, abdominal cramps, fever, and dehydration. Bacteremia, meningitis, osteomyelitis, and abscesses also can occur. Each year in the United States, 800,000-4 million Salmonella infections result in approximately 500 deaths (1). S. Muenchen is an infrequently isolated serotype, accounting for approximately $1.6 \%$ of human Salmonella isolates reported in 1997 to the Public Health Laboratory Information System (2,3). Oregon typically reports $<6$ isolates per year and Washington <10 per year.

Juice has been implicated as the vehicle of transmission in at least 15 outbreaks in the United States in this century involving pathogens, including Escherichia coli O157:H7, Cryptosporidium parvum, and other Salmonella serotypes (e.g., S. Typhi and $S$. Hartford) (4). In an outbreak of E. coli O157:H7 infections attributed to unpasteurized apple juice, one child died, and 14 children developed hemolytic uremic syndrome (5). The outbreak described in this report is the second and largest Salmonella outbreak associated with unpasteurized orange juice (6). The acidic nature of orange juice ( pH of $3.4-4.0$ ) previously was believed to inhibit bacterial growth and protect against foodborne illness; however, recent outbreaks and laboratory investigations have demonstrated otherwise. Salmonella serotypes Gaminara, Hartford, Rubislaw, and Typhimurium have survived in orange juice for up to 27 days at pH 3.5 and 60 days at pH 4.1 (7).

In 1998, FDA proposed Hazard Analysis and Critical Control Point (HACCP) and labeling regulations to improve the safety of juice products (8). The proposed HACCP regulation requires juice to be produced using methods such as pasteurization or an equivalent process to ensure that pathogenic microorganisms are destroyed. In the outbreak described in this report, the implicated company had a HACCP plan. Investigations are under way to determine where these control measures failed and how the juice became contaminated. FDA published a final rule for the labeling of fruit and vegetable juices that includes a warning statement to advise consumers of the risks associated with drinking unprocessed juices (9). However, the labeling requirements

Outbreak of Salmonella - Continued
do not apply to juice or products containing juice that are not packaged (i.e., sold by the glass) in retail establishments, such as the product implicated in this outbreak. In Washington, some consumers were unaware that they were drinking unpasteurized commercial orange juice in their fruit smoothies.

Because the source of contamination of the orange juice is unknown and to facilitate outbreak investigation, local and state health departments are encouraged to investigate all cases of $S$. Muenchen infections occurring since June 1 using a questionnaire from CDC's Foodborne and Diarrheal Diseases Branch, Division of Bacterial and Mycotic Diseases, National Center for Infectious Diseases, telephone (404) 6392206, and to consider referring isolates for PFGE with the standardized PulseNet Salmonella protocol by the Washington State Public Health Laboratory or by another PulseNet laboratory. Health departments also should consider investigating cases of S. Alamo, S. Gaminara, S. Hidalgo, and S. Javiana in which illness onset occurred after June 1.

## Progress Toward Measles Elimination Southern Africa, 1996-1998

Despite routine measles vaccination coverage of $>70 \%$ in southern Africa during the early 1990s, low-level endemic transmission and periodic epidemics of measles continued. Since 1995, six southern African nations (Botswana, Malawi, Namibia, South Africa, Swaziland, and Zimbabwe) have launched measles-elimination initiatives in accordance with the recommendations of the World Health Organization (WHO) African Regional Office (AFR) (1). Strategies include programs to 1) achieve routine vaccination coverage of $\geq 95 \%$ with one dose of measles vaccine administered at age 9 months; 2) implement a one-time national catch-up* measles vaccination campaign to interrupt indigenous transmission of measles; 3 ) implement periodic

[^3]Progress Toward Measles Elimination - Continued
national follow-up ${ }^{\dagger}$ measles campaigns to maintain interruption of measles transmission; and 4) establish case-based measles surveillance with laboratory confirmation (2). This report presents preliminary data about the progress toward measles elimination in the six southern Africa countries.

Campaigns in each country were planned and implemented by national ministries of health with technical assistance from AFR. The South African government funded its measles campaign. In the other countries, campaigns received primary support from the national governments, the United Kingdom Department for International Development, the United Nations Children's Fund (UNICEF), WHO, and CDC. The campaigns emphasized safe injection practices, safe disposal of used injection equipment, and monitoring for adverse events following vaccination. All countries used disposable syringes and packed used equipment in disposal boxes for incineration or deep burial.

Because the number of qualified vaccinators was limited, particularly in countries where National Immunization Days (NIDs) for poliomyelitis were ongoing, national catch-up measles campaigns were divided into phases by geographic area or target population. The national measles campaign in South Africa was combined with polio NIDs and conducted in 1996 and 1997. Three of nine provinces conducted campaigns in both years, targeting children aged 9 months-4 years during 1996 and children aged 5-14 years during 1997 (Table 1), and the remaining six provinces targeted all children aged 9 months- 14 years in a single campaign. Botswana divided the campaign geographically, covering approximately half the districts in 1997 and the remaining districts in 1998. In Swaziland, children aged 9 months-4 years were targeted in the catch-up campaign in 1998 in combination with polio NIDs followed by a second phase for children aged 5-14 years scheduled for May 1999. The remaining three countries-Malawi, Namibia, and Zimbabwe-completed the catch-up campaign in 1 year.

A total of 23 million children were vaccinated during the catch-up campaigns. Overall, reported coverage was $92 \%$ in the six countries (range: $85 \%-114 \%$ ) (Table 1). Namibia and South Africa conducted additional mopping-up ${ }^{\S}$ vaccination activities in 1997 in districts where initial coverage was $<70 \%$. No deaths or cases with persisting sequelae associated with vaccination were reported. In Zimbabwe, four children died within 30 days after vaccination; however, independent review of the case histories of these four children determined that none of the deaths were attributable to vaccination (N. Halsey, The Johns Hopkins University, personal communication, 1998).

During 1980-1989, when routine measles vaccination was being introduced in Botswana, South Africa, Swaziland, and Zimbabwe, the average annual number of reported measles deaths was 544 (range: 299-1089). During 1990-1996 in these four countries, when routine coverage was $>70 \%$, the average annual number of measles deaths was 118 (range: 59-183). Measles mortality data were not reported routinely during 1980-1989 in Malawi and Namibia. To calculate measles morbidity and mortality reduction after the catch-up campaigns, data from Malawi were excluded because

*Same three provinces that conducted campaigns in August 1996 for children aged 9 months4 years.
${ }^{\dagger}$ Coverage based on a survey in 1998.
${ }^{\S}$ Fourteen of 22 districts conducted the campaign in 1997 and the remaining eight districts in 1998.
its campaign was conducted in October 1998, after the peak measles season had occurred. Following the implementation of measles catch-up vaccination campaigns in the remaining five countries, the number of reported measles cases decreased by 93\% (Figure 1); 56,123 cases were reported by the five countries in 1996, compared with 3672 cases in 1998. Reported measles-associated deaths decreased 99\%, from 166 in 1996 to two in 1998.

Since completion of catch-up vaccination campaigns, case-based surveillance of suspected measles cases has been initiated in four of the six countries, using the WHO case definition (i.e., any case with rash and fever and at least one of the following symptoms: cough, coryza, or conjunctivitis). Following training for national laboratory technicians of the six countries in July 1998, laboratory capacity to investigate suspected measles cases using a measles IgM enzyme-linked immunoassay (ELISA) was introduced in four countries. Because of the limited availability of measles IgM ELISA kits, serum was tested from 425 ( $14 \%$ ) of the 3035 persons with suspected measles in Botswana, Namibia, South Africa, and Zimbabwe since the catch-up campaigns. Of 425 suspected measles cases tested, 17 (4\%) were measles IgM-positive (Table 2). In South Africa, of the 275 measles IgM-negative serum samples that were tested for rubella $\operatorname{lgM}, 140$ ( $46 \%$ ) were positive.

of Viral and Rickettsial Diseases, National Center for Infectious Diseases, and Vaccine Preventable Disease Eradication Div, National Immunization Program, CDC.
Editorial Note: Despite the availability of a safe and effective vaccine since 1963, measles still accounts for nearly 1 million deaths annually (3). In 1990, the World Summit for Children adopted the goal of vaccinating $90 \%$ of children against measles by 2000. Regional measles elimination goals have been established in the Americas (by 2000), Europe (by 2007), and the Eastern Mediterranean (by 2010) (3).

The six countries described in this report achieved and sustained routine vaccination coverage of approximately $80 \%$ before initiation of measles elimination campaigns. Routine vaccination had a substantial impact on measles epidemiology: measles morbidity declined, the interval between epidemics was lengthened, the

## Progress Toward Measles Elimination - Continued

average age of patients increased, and measles mortality was reduced to low levels. As a result of these conditions and successful polio eradication strategies, measles elimination campaigns were initiated in the six countries.

High vaccination coverage was achieved during the mass campaigns in the six countries. Reported campaign coverage may overestimate true coverage (e.g., in countries reporting coverage of $>100 \%$ ) because children outside the target age range who were vaccinated in the campaign were included in the numerator or the target population was underestimated.

The catch-up vaccination campaigns have been highly effective in reducing morbidity and mortality resulting from measles in the six countries. Since the campaigns were completed, none of the 70 suspected measles cases tested in Botswana and Zimbabwe was laboratory-confirmed, suggesting that measles transmission in those countries may have been interrupted. Circulation of measles virus has been reduced to very low levels in Namibia and South Africa.

To sustain the elimination initiative, the six southern African countries will need to continue to implement all WHO-recommended strategies. First, to increase routine vaccination coverage to $\geq 95 \%$, these countries should eliminate missed opportunities for vaccination, introduce tracking systems to find children who miss appointments for vaccination, and strengthen outreach services to reach communities not routinely covered. Second, epidemiologic analysis of measles cases and data about districtspecific routine and catch-up measles vaccination coverage will help ministries monitor the accumulation of susceptible persons in the population and plan appropriate follow-up vaccination campaigns. Finally, case-based surveillance of suspected measles cases should be strengthened. A serum specimen should be obtained for measles lgM testing from at least five patients in each outbreak and from $80 \%$ of persons with sporadic cases; specimens should be obtained at the time the patient first seeks health care. In addition, measles virus for each outbreak should be isolated to distinguish importations of measles virus from ongoing indigenous transmission (4).

Experience from the Americas has highlighted the need to ensure that all WHOrecommended strategies are fully implemented (5). To sustain progress toward measles elimination in southern Africa, continued national commitment to support and implement WHO strategies is needed to prevent the re-establishment of measles transmission, and possibly to avoid large outbreaks, in countries where elimination has been achieved.

## Notice to Readers

## Recommendations of the Advisory Committee on Immunization Practices: Revised Recommendations for Routine Poliomyelitis Vaccination

Since 1979, the only indigenous cases of poliomyelitis reported in the United States ( $\mathrm{n}=144$ ) have been associated with use of the live oral poliovirus vaccine (OPV) (an additional six imported cases have been reported since 1979, the last of which occurred in 1993). Until recently, the benefits of OPV use (i.e., intestinal immunity, secondary spread) outweighed the risk for vaccine-associated paralytic polio (VAPP) (one case per 2.4 million doses distributed) (1). In 1997, to decrease the risk for VAPP while maintaining the benefits of OPV, the Advisory Committee on Immunization Practices (ACIP) recommended a sequential schedule of inactivated poliovirus vaccine (IPV) followed by OPV (2). Since 1997, the global polio eradication initiative has progressed rapidly, and the likelihood of poliovirus importation into the United States has decreased substantially. In addition, since 1997, the sequential schedule has been well accepted. No declines in childhood vaccination coverage were observed, despite the need for additional injections (3).

On the basis of these data, on June 17, 1999, to eliminate the risk for VAPP, the ACIP recommended an all-IPV schedule for routine childhood polio vaccination in the United States. As of January 1, 2000, all children should receive four doses of IPV at ages 2 months, 4 months, $6-18$ months, and $4-6$ years.

OPV should be used only for the following special circumstances:

1. Mass vaccination campaigns to control outbreaks of paralytic polio.
2. Unvaccinated children who will be traveling in $<4$ weeks to areas where polio is endemic.
3. Children of parents who do not accept the recommended number of vaccine injections. These children may receive OPV only for the third or fourth dose or both; in this situation, health-care providers should administer OPV only after discussing the risk for VAPP with parents or caregivers.
Availability of OPV is expected to be limited in the future in the United States. ACIP reaffirms its support for the global polio eradication initiative and use of OPV as the vaccine of choice to eradicate polio from the remaining countries where polio is endemic.

*Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
${ }^{\dagger}$ Preumonia and influenza.
${ }^{\S}$ Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
TTotal includes unknown ages.

## Contributors to the Production of the MMWR (Weekly) Weekly Notifiable Disease Morbidity Data and 122 Cities Mortality Data

Samuel L. Groseclose, D.V.M., M.P.H.

State Support Team
Robert Fagan
Jose Aponte
Gerald Jones
David Nitschke
Carol A. Worsham

CDC Operations Team
Carol M. Knowles

Willie J. Anderson
Patsy A. Hall
Kathryn Snavely

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to listserv@listserv.cdc.gov. The body content should read SUBscribe mmwr-toc. Electronic copy also is available from CDC's World-Wide Web server at http://www.cdc.gov/ or from CDC's file transfer protocol server at ftp.cdc.gov. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly MMWR are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the MMWR Series, including material to be considered for publication, to: Editor, MMWR Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (888) 232-3228.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.

[^0]:    * Use of trade names and commercial sources is for identification only and does not imply endorsement by CDC or the U.S. Department of Health and Human Services.

[^1]:    ${ }^{\dagger}$ An infant-year is a unit of measurement combining infants and time used as a denominator in calculating incidence. In this report, it is the sum of the individual units of time (days, weeks, or months) converted to years that the infants in the study population have been followed.

[^2]:    * Use of trade names and commercial sources is for identification only and does not imply endorsement by CDC or the U.S. Department of Health and Human Services.

[^3]:    * Catch-up is a one-time, nationwide vaccination campaign targeting all children, usually those aged 9 months-14 years, regardless of history of measles or vaccination.

[^4]:    ${ }^{\dagger}$ Follow-up campaigns are subsequent nationwide vaccination campaigns conducted every 2-5 years targeting all children born after the catch-up campaign, usually those aged 9 months-4 years.
    §In this context, "mopping-up" vaccination is intended to increase coverage in pockets of low coverage occurring during "catch-up" or "follow-up" campaigns; vaccination preferably should be conducted house-to-house.

[^5]:    -:no reported cases

    * Not notifiable in all states.
    ${ }^{\dagger}$ Updated weekly from reports to the Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases (NCID).
    $\S$ Updated monthly from reports to the Division of HIV/AIDS Prevention-Surveillance and Epidemiology, National Center for
    HIV, STD, and TB Prevention (NCHSTP), last update June 27, 1999.
    $\llbracket$ Updated from reports to the Division of STD Prevention, NCHSTP.

[^6]:    N : Not notifiable U: Unavailable $\quad-$ no reported cases
