Achievements in Public Health, 1900-1999

## Family Planning

During the 20th century, the hallmark of family planning in the United States has been the ability to achieve desired birth spacing and family size (Figure 1). Fertility decreased as couples chose to have fewer children; concurrently, child mortality declined, people moved from farms to cities, and the age at marriage increased (1). Smaller families and longer birth intervals have contributed to the better health of infants, children, and women, and have improved the social and economic role of women ( 2,3 ). Despite high failure rates, traditional methods of fertility control

FIGURE 1. Fertility rates* - United States, 1917-1997

[^0]
## Family Planning - Continued

contributed to the decline in family size (4). Modern contraception and reproductive health-care systems that became available later in the century further improved couples' ability to plan their families. Publicly supported family planning services prevent an estimated 1.3 million unintended pregnancies annually ( 5 ). This report reviews the history of family planning during the past century; summarizes social, legal, and technologic developments and the impact of family planning services; and discusses the need to ensure continued technologic improvements and access to care.

## Early History

Family size declined between 1800 and 1900 from 7.0 to 3.5 children (4). In 1900, six to nine of every 1000 women died in childbirth, and one in five children died during the first 5 years of life.* Distributing information and counseling patients about contraception and contraceptive devices was illegal under federal and state laws (8,9); the timing of ovulation, the length of the fertile period, and other reproductive facts were unknown.

In 1912, the modern birth-control movement began. Margaret Sanger (see box), a public health nurse concerned about the adverse health effects of frequent childbirth, miscarriages, and abortion, initiated efforts to circulate information about and provide access to contraception (9). In 1916, Sanger challenged the laws that suppressed the distribution of birth control information by opening in Brooklyn, New York, the first family planning clinic. The police closed her clinic, but the court challenges that followed established a legal precedent that allowed physicians to provide advice on contraception for health reasons. During the 1920s and 1930s, Sanger continued to promote family planning by opening more clinics and challenging legal restrictions. As a result, physicians gained the right to counsel patients and to prescribe contraceptive methods ( 10,11 ). By the 1930s, a few state health departments (e.g., North Carolina) and public hospitals had begun to provide family planning services.

During the first part of the 20th century, family planning focused on the need of married couples to space children and limit family size. Among a national probability sample ${ }^{\dagger}$ of 1049 ever-married white women born during 1901-1910 and interviewed in $1978,71 \%$ reported having practiced contraception; common techniques used were the condom ( $54 \%$ ), contraceptive douche ( $47 \%$ ), withdrawal ( $45 \%$ ), rhythm ( $24 \%$ ), and the cervical diaphragm (17\%) (12). Other reported methods included infrequent sexual intercourse ( $8 \%$ ), intermittent abstinence ( $6 \%$ ), and contraceptive sterilization $(4 \%) .{ }^{\S}$ Using abstinence to prevent pregnancy was limited by uncertainty about the timing of a woman's ovulation. In 1928, the timing of ovulation was established medically, but the safe interval for intercourse was mistakenly understood to include half

[^1]
## Margaret Sanger

Sometimes social factors slow progress toward improving health more than lack of awareness or the absence of technology. No 20th century public health achievement demonstrates this more clearly than the struggle to provide women in the United States with safe and effective birth control. Margaret Sanger (September 14, 1879-September 6, 1966) risked scandal, danger, and imprisonment to challenge the legal and cultural obstacles that made controlling fertility difficult and illegal.

Margaret Louise Higgins was born in Corning, New York, the sixth of 11 children. Her free-thinking father's politics might have ignited her activism, but watching the process of her mother, aged 50 years, die after 18 pregnancies probably had an even deeper impact. Higgins was a nursing student in 1902 when she married architect William Sanger. Although

Photograph by Ira Hill's Studio, New York City, 1939 Sophia Smith Collection, Smith College weakened by bouts of tuberculosis, she bore three children between 1902 and 1910. The Sangers immersed themselves in the radical political and intellectual world of Greenwich Village in New York City. She worked as a visiting nurse in the city's tenements and wrote about sex education and women's health.

In 1914, Sanger's articles in The Woman Radical brought her a federal indictment for violating federal postal obscenity laws, prompting her to flee to England. As soon as the ship left U.S. waters, she cabled a radical publisher in New Jersey to distribute 100,000 copies of her pamphlet, Family Limitation. Sanger remained exiled in Europe until late 1915; William Sanger had been arrested and jailed for distributing one copy of Family Limitation, and Margaret Sanger returned to face the charges against her. Personal tragedy intervened when the Sanger's 5 -year-old daughter died suddenly from pneumonia; public sentiments resulted in dismissal of the charges against Margaret Sanger.

Rather than backing away from controversy, Sanger and her sister Ethel Byrne, also a nurse, opened the first birth control clinic in the United States, modeled after those Sanger had seen in Holland. On October 16, 1916, dozens of Jewish and Italian immigrant women from Brooklyn's crowded Brownsville section lined up to receive counseling and birth control information. Nine days later police closed the clinic and arrested Sanger, Byrne, and the clinic's interpreter. Byrne was tried and convicted first, and went on a hunger strike. Sanger was convicted and served 30 days in jail. Legal failure had brought victory, however. The publicity surrounding Sanger's activities had made birth control a matter of public debate.

After World War I, Sanger continued her U.S. leadership role, although during the 1920s and 1930s, she refocused her energy toward international birth control, traveling and lecturing throughout Asia and Europe. In 1952, she founded the International Planned Parenthood Federation and served as its first president until 1959. Sanger died in Tucson, Arizona, aged 87 years, a few months after the 1965 Supreme Court decision, Griswold vs. Connecticut, that made birth control legal for married couples, the culmination of events Sanger had started 50 years earlier.

## Family Planning - Continued

TABLE 1. Milestones in family planning — United States, 1900-1997

| 1900 | First standard certificate of death created |
| :---: | :---: |
| 1914 | Margaret Sanger arrested for distributing birth control information |
| 1915 | First federal birth registration area created |
| 1916 | First birth control clinic, Brooklyn, New York (closed after 10 days by the New York Vice Squad) |
| 1925 | First manufacture in the United States of diaphragms |
| 1928 | Timing of ovulation established |
| 1937 | American Medical Association endorses birth control |
| 1937 | First state (North Carolina) includes birth control in a public health program |
| 1942 | Planned Parenthood Federation of America established |
| 1955 | First national fertility survey conducted |
| 1960 | The birth control pill approved by Food and Drug Administration (FDA) |
| 1960 | Intrauterine device approved by FDA |
| 1965 | Supreme Court (Griswold vs. Connecticut) declares unconstitutional state laws prohibiting contraceptive use by married couples |
| 1970 | Family Planning Services and Population Research Act creates Title X of the Public Health Service Act |
| 1972 | Medicaid funding for family planning services authorized |
| 1973 | Supreme Court (Roe vs. Wade) legalizes abortion |
| 1973 | First National Survey of Family Growth conducted |
| 1990 | Norplant ${ }^{\circledR *}$ approved by FDA |
| 1992 | Depo-Provera ${ }^{\circledR}$ approved by FDA |
| 1993 | Female condom approved by FDA |
| 1997 | Emergency use of oral contraceptive pills approved by FDA |

the menstrual period (13). Nevertheless, by 1933, the average family size had declined to 2.3 children.

## Modern Contraception

Family size increased from 1940 until 1957 (Figure 1), when the average number of children per family peaked at 3.7 ( 14,15 ; CDC, unpublished data, 1999). In 1960, the era of modern contraception began when both the birth control pill and intrauterine device (IUD) became available. These effective and convenient methods resulted in widespread changes in birth control ( 16 ). By 1965, the pill had become the most popular birth control method, followed by the condom and contraceptive sterilization (16). In 1965, the Supreme Court (Griswold vs. Connecticut) (17) struck down state laws prohibiting contraceptive use by married couples.

In 1970, federal funding for family planning services was established under the Family Planning Services and Population Research Act, which created Title X of the Public Health Service Act (18). Medicaid funding for family planning was authorized in 1972. Services provided under Title X grew rapidly in the 1970s and 1980s; after 1980, public funding for family planning continued to shift to the Medicaid program (18).

Since 1972, the average family size has leveled off at approximately two children, and the safety, efficacy, diversity, accessibility, and use of contraceptive methods has increased (Table 2). During the 1970s and 1980s, contraceptive sterilization became more common and is now the most widely used method in the United States

## Family Planning - Continued

$(16,19,20)$. IUD use increased during the early 1980s, then declined because of concerns about intrauterine infections (16). In the 1980s and 1990s, the use of condoms increased among adolescents, presumably because of growing concern about human immunodeficiency virus infection and other sexually transmitted diseases (STDs) (21-23). Since 1991, increased use of long-acting hormonal contraception (DepoProvera ${ }^{\circledR}$ [Pharmacia \& Upjohn, Inc., Peapack, New Jersey] and Norplant ${ }^{\circledR}$ [WyethAyerst Laboratories, St. Davids, Pennsylvania]) ${ }^{\text {I }}$ also have contributed to the decline in adolescent pregnancy rates (24,25). Emergency use of oral contraceptive pills might reduce the risk for pregnancy after unprotected intercourse by at least $74 \%$ (26). Noncontraceptive health benefits of oral contraceptives include lower rates of pelvic inflammatory disease, cancers of the ovary and endometrium, recurrent ovarian cysts, benign breast cysts and fibroadenomas, and discomfort from menstrual cramps (27).

[^2]TABLE 2. Efficacy of commonly used methods of contraception* and percentage of couples using the method - United States, 1995

|  | \% women <br> experiencing unintended pregnancy <br> in first year of use |  |  |
| :--- | :---: | :---: | :---: |
| Contraceptive method | Perfect use | Typical use | \% couples <br> using the method |
| Implant |  |  |  |
| (Norplant ${ }^{\circledR}$ and Norplant-2 ${ }^{\circledR}$ ) | $0.05 \%$ | $0.05 \%$ | $1.3 \%$ |
| Male sterilization | $0.10 \%$ | $0.15 \%$ | $10.1 \%$ |
| Pill | $0.1 \%$ | $5.0 \%$ | $24.9 \%$ |
| Injectable (Depo-Provera ${ }^{\circledR}$ ) | $0.3 \%$ | $0.3 \%$ | $2.7 \%$ |
| Female sterilization | $0.5 \%$ | $0.5 \%$ | $25.6 \%$ |
| Intrauterine device | $0.6 \%{ }^{\dagger}$ | $0.8 \%$ | $0.7 \%$ |
| Condom (male) | $3.0 \%$ | $14.0 \%$ | $18.9 \%$ |
| Withdrawal | $4.0 \%$ | $19.0 \%$ | $2.9 \%$ |
| Diaphragm | $6.0 \%$ | $20.0 \%$ | $1.7 \%$ |
| Spermicides | $6.0 \%$ | $26.0 \%$ | $1.3 \%$ |
| Periodic abstinence | $9.0 \%$ | $25.0 \%$ | $2.2 \%$ |

*For spermicides, periodic abstinence, the diaphragm, male condom, and pill, these estimates for typical use were derived from the experiences of married women in the 1976 and 1988 National Surveys of Family Growth (NSFG) and of all women in the 1988 NSFG. The estimates for the intrauterine device, sterilization, Depo-Provera ${ }^{\circledR}$, and Norplant ${ }^{\circledR}$ were from large clinical investigations. The estimate for withdrawal was based on evidence from surveys. Perfect use is a best guess of the probabilities of method failure (pregnancy) during the first year of perfect use, i.e., when it is used consistently according to a specified set of rules. Highly rigorous scientific data are available to support estimates for implants, sterilization, pill, and the IUD. Use of trade names and commercial sources is for identification only and does not imply endorsement by CDC or the U.S. Department of Health and Human Services.

## Family Planning - Continued

In the United States, physicians are the primary providers of surgical sterilization, hormonal contraception, and IUDs. In 1994, 3119 agencies (e.g., health departments, Planned Parenthood affiliates, and hospitals) operated 7122 publicly subsidized family planning clinics for an estimated 6.6 million women (28). These services prevent an estimated 1.3 million unintended pregnancies annually (534,000 unintended births, 632,000 abortions, and 165,000 miscarriages) (5). Publicly supported clinics have been effective in supplying contraception to populations that have high rates of unintended pregnancy and have limited access to private health-care providers. In 1988, of the women who obtained reversible contraception, $22.5 \%$ overall received services from public clinics. Those most likely to receive these services were adolescent (43\%), poor ( $39 \%$ ), and never-married ( $34 \%$ ) women (5).

## Contraception Worldwide

The most important determinant of declining fertility in developing countries is contraceptive use, which explains $92 \%$ of the variation in fertility among 50 countries (29-31). Overall fertility declined by approximately one third from the 1960s through the 1980s, from an average of six to four children per woman (31), with dramatic decreases occurring in some parts of the world (e.g., $24 \%$ decline in fertility in Asia and Latin America, approximately $50 \%$ in Thailand, and approximately 35\% in Colombia, Jamaica, and Mexico). As fertility declined in developing countries, the infant mortality rate decreased from approximately 150 deaths per 1000 live births in the 1950s to approximately 80 per 1000 in the early 1990s ( 2,3 ). Among married women of reproductive age in developing countries, $53 \%$ plan the size of their families (32); $90 \%$ of these women report using modern birth-control methods (e.g., female sterilization, oral contraceptives, and IUDs) (31).

## Challenges

In the United States, unintended pregnancy remains a problem; 49\% of pregnancies are unintended and $54 \%$ of these end in abortion (33). These rates remain significantly higher than rates of many other industrialized countries. During 1982-1986, among 15 Western countries with similar reproductive behavior (e.g., Canada, the Netherlands, and the United Kingdom), the United States ranked fourth highest in total fertility rate and had the second highest abortion rate and the highest pregnancy rate (34). Although pregnancy and childbearing rates for adolescent women have declined since 1991, the proportion of adolescent women who are unmarried at the time of giving birth has increased ( 24,25 ) from $15 \%$ in 1960 to approximately $75 \%$ in 1998.

Despite advances in family planning, population growth remains a worldwide concern. In 1999, world population reached six billion, an increase of 4.4 billion births since 1900 (35). In 1994, an international conference on population and development in Cairo focused international attention on the full scope of family planning that can be addressed during delivery of family planning services, including reproductive and primary-care concerns (36). For example, the introduction of cervical screening has led to a $20 \%-60 \%$ reduction in cervical cancer death rates (37). Screening programs for chlamydia, the leading cause of preventable infertility, can lower the prevalence of chlamydia and reduce complications such as pelvic inflammatory disease (38) The STD prevention benefits of family planning may be enhanced by new femalecontrolled barrier methods such as vaginal microbicides and the female condom.

## Family Planning - Continued

Managed care is rapidly changing patterns of health-care delivery and creating new challenges for primary and reproductive health-care providers (39). Managed-care plans often offer more comprehensive coverage of such services than traditional insurance plans (39). In the late 1990s, legislatures in 19 states mandated partial or comprehensive insurance coverage for reversible methods of contraception (40). Access to high quality contraceptive services will continue to be an important factor in promoting healthy pregnancies and preventing unintended pregnancy in this country (41).

During the 20th century, restrictive policies and laws affecting family planning were largely replaced by legislative and funding support for family planning services by physicians and specialized reproductive health-care providers. Marshaling public support for efforts needed to reduce the high rate of unintended pregnancy and to provide the full array of reproductive health-care services remains a challenge.
Reported by: Div of Reproductive Health, National Center for Chronic Disease Prevention and Health Promotion, CDC.

## Progress Toward Measles Elimination Eastern Mediterranean Region, 1980-1998

In 1997, the 23 member countries of the World Health Organization (WHO) Eastern Mediterranean Region (EMR)* resolved to eliminate measles from the region by 2010. Countries in the region have been divided into two groups according to the status of poliomyelitis eradication and the epidemiology of measles. The criteria used to classify the countries are 1) absence of indigenous transmission of polio for at least 3 years and 2) reliable surveillance for acute flaccid paralysis (AFP). Group 1 countries (Afghanistan, Djibouti, Egypt, Iraq, Libya, Pakistan, Somalia, Sudan, and Yemen) are countries where polio is endemic or was recently endemic and are implementing activities to reduce measles morbidity and mortality. Group 2 countries (Bahrain, Cyprus, Iran, Jordan, Kuwait, Lebanon, Morocco, Oman, Palestine National Authority and Palestinian populations served by United Nations Relief and Works Agency [UNRWA], Qatar, Saudi Arabia, Syria, Tunisia, and United Arab Emirates [UAE]) are polio-free and are implementing strategies to eliminate measles following the recom-men- dations of EMR (1). The measles elimination strategies are 1) achieving and maintaining routine measles vaccination coverage at $\geq 95 \%$ among children aged 1 year; 2) conducting a one-time mass vaccination campaign (catch-up campaign ${ }^{\dagger}$ ) to interrupt indigenous transmission of measles; 3) conducting periodic national followup campaigns ${ }^{\text {§ }}$; and 4) strengthening measles surveillance and laboratory confirmation of cases. This report presents preliminary data from the 14 countries of group 2 and indicates that substantial progress toward measles elimination has been made, especially in countries fully implementing the recommended strategies.

## Routine Vaccination Coverage

In 1998, among the 14 countries in group 2, all except Morocco had a two-dose schedule for measles vaccination (Table 1). Reported coverage with at least one dose of measles vaccine among children aged 1 year was $96 \%$ (range: $86 \%-100 \%$ ).

To achieve and maintain routine measles vaccine coverage of $\geq 95 \%$, the following strategies were implemented in some group 2 countries: 1) identification and tracking of children who have defaulted on a scheduled vaccination (e.g., home visits), 2 ) intensive education of the community and health-care providers, and 3) supervision and feedback to vaccination providers. Seven countries (Bahrain, Iran, Jordan, Kuwait, Oman, Syria, and Tunisia) have started monthly reporting of coverage at the district level.

## Supplemental Vaccination Coverage

Since 1994, Bahrain, Jordan, Kuwait, Oman, Qatar, Saudi Arabia, Syria, Tunisia, and UAE have conducted catch-up campaigns (Table 2). A total of 13 million children in group 2 countries have been vaccinated in nationwide supplementary mass

§Population weighted average.
campaigns conducted during 1994-1999. In Kuwait, a second catch-up campaign was conducted in November 1998 targeting children aged 6-11 years. Timing of follow-up campaigns in the remaining countries that have conducted catch-up campaigns will be based on monitoring the number of susceptible children.

Lebanon, Morocco, and Palestine will implement measles vaccination campaigns in 2000 for children aged 1-14 years, 10 months-19 years, and $5-14$ years, respectively. Iran and Cyprus have no plans to conduct supplemental activities.

The campaigns have been planned, conducted, and funded by the ministries of health of the respective countries. In all campaigns, the ministries of health emphasized the use of safe injection practices including disposal of used syringes.

## Reported Incidence of Measles

Before the introduction of vaccination, approximately 200,000 measles cases were reported each year from group 2 countries (except Palestine). When measles vaccination was introduced during the early 1980s, the number of cases decreased. From 1983 to 1987, measles vaccine coverage increased from $30 \%$ to $70 \%$; the reported number of measles cases decreased from 184,000 in 1980 to 61,000 in 1985 (Figure 1).

From 1980 to 1998, the reported incidence of measles decreased $93 \%$, from 197.8 per 100,000 to 14.4 per 100,000. During the same period, the population of group 2 countries increased from 98 million to an estimated 158 million persons, of which an estimated $39 \%$ were aged $<15$ years.

## Measles Elimination - Continued

TABLE 2. Dates of catch-up campaign,* type of vaccine, target age group, and vaccination coverage during measles vaccination campaigns, by country - World Health Organization, Eastern Mediterranean Region, 1994-1999

| Country | Dates of campaign (month/year) | Type of vaccine | Target age group | Target population ${ }^{\dagger}$ | Coverage campaign |
| :---: | :---: | :---: | :---: | :---: | :---: |

* A one-time, nationwide vaccination campaign targeting all children, usually aged 9 months15 years, regardless of history of measles vaccination or disease.
${ }^{\dagger}$ Based on estimates.
${ }^{\S}$ Measles and rubella vaccine.
${ }^{9}$ Measles, mumps, and rubella vaccine.
** Measles single antigen.
${ }^{\dagger \dagger}$ Including Palestinian refugees at United Nations Relief and Works Agency fields in Jordan and Syria.
${ }^{\S}$ Not available.

FIGURE 1. Reported number of measles cases and measles vaccination coverage, by year - World Health Organization, 14 countries,* Eastern Mediterranean Region, 1980-1998

[^4]
## Measles Elimination - Continued

The interepidemic interval increased during the 1990s with outbreaks in 1992 and 1993 resulting in 39,000 and 28,000 reported cases, respectively. In 1996, the number of measles cases reported in group 2 countries decreased to a record low of 8000 cases. In 1998, the number of cases increased to 23,000. Four countries (Iran, Morocco, Saudi Arabia, and Syria) that had not implemented catch-up campaigns reported $91 \%$ of total cases in 1998. During 1996-1998, the age distribution of 13,225 persons with measles reported to WHO by 10 countries ( $29 \%$ of total cases reported) was 1535 ( $12 \%$ ) among children aged 1 year, 3244 ( $25 \%$ ) among children aged 1 4 years, and 8446 ( $64 \%$ ) among persons aged $\geq 5$ years.

## Enhanced Surveillance

In 1998, case surveillance with laboratory investigations of all suspected measles cases began in Bahrain, Kuwait, Oman, and Tunisia. Collection of information about measles vaccination status began in Cyprus, Iran, Kuwait, Oman, Syria, and Palestinian populations served by UNRWA. In these countries, 5281 ( $63 \%$ ) of 8311 reported measles cases occurred among children who had received one dose of measles vaccine. During 1998-1999, 1735 serum specimens were tested from persons with suspected measles (representing 9\% of total reported cases) reported by Iran, Oman, Syria, and Tunisia to EMR. Of these, 865 ( $50 \%$ ) were measles IgM positive. In Tunisia, from January through June 1999, 251 suspected measles cases were reported; of the 212 with negative measles Ig M results, 133 ( $63 \%$ ) were Ig M positive for rubella.

Laboratory training workshops were conducted in Tunisia for EMR countries in 1997 and 1998. A regional measles laboratory network will be established to support the measles elimination program in EMR (2).

## Impact of Elimination Activities

Since 1990, Oman achieved high routine measles vaccination coverage ( $\geq 95 \%$ ) because of a defaulter system that traces birth registrations, frequent and regular supervision, and outreach visit information. Coverage in the catch-up campaign in 1994 was $93 \%$, and after the campaign, measles incidence decreased to extremely low levels; five cases were confirmed in 1998 (Figure 2). Oman also has implemented case-based surveillance with laboratory confirmation. Kuwait implemented catch-up campaigns in two phases, the first in 1994 and the second in 1998. Cases decreased from 462 in 1994 to a record low 12 cases in 1995, but increased to 90 cases in 1998. Reported by: Ministries of health of Bahrain, Cyprus, Iran, Jordan, Kuwait, Lebanon, Morocco, Oman, Palestine National Authority and Palestinian populations served by United Nations Relief and Works Agency, Qatar, Saudi Arabia, Syria, Tunisia, and United Arab Emirates, World Health Organization, Eastern Mediterranean Region, Alexandria, Egypt. Vaccines and other Biologicals Dept, World Health Organization, Geneva, Switzerland. Respiratory and Enteric Viruses Br, Div of Viral and Rickettsial Diseases; Epidemiology and Surveillance Div; Vaccine Preventable Disease Eradication Div, National Immunization Program; and an EIS Officer, CDC.
Editorial Note: Eradication of polio is the highest vaccination priority in the EMR, and measles elimination activities are being phased in on the basis of the status of polio eradication in the country. In the nine countries where polio is endemic or was recently endemic, measles remains a major cause of morbidity and mortality. Only those countries that have evidence of interruption of indigenous transmission of polio for at least 3 years, based on high quality AFP surveillancef, have started measles elimination activities. Because of the proximity of countries where polio is endemic,

[^5]
## Measles Elimination - Continued

FIGURE 2. Reported number of measles cases and vaccination coverage, by year Oman, 1980-1998

complete and timely surveillance for AFP cases should continue until global eradication is achieved.

The 14 countries that have started measles elimination activities have had high routine measles vaccination coverage since 1994. This has reduced reported measlesassociated morbidity by $>90 \%$, compared with the early 1980s. During 1997 and 1998, the number of measles cases increased to approximately 20,000 each year; however, most cases occurred in Iran, Morocco, Saudi Arabia, and Syria before implementation of supplemental vaccination activities.

Bahrain, Jordan, Saudi Arabia, Syria, Tunisia, and UAE reported high coverage in their catch-up campaigns. Because these campaigns were implemented during 1998 and 1999, annual surveillance data might not yet demonstrate their impact on elimination of measles.

Oman is a model of implementation of the EMR measles elimination strategy. As a result of high coverage with the first dose, introduction of a routine second dose in 1994, and a well-executed catch-up campaign in 1994, measles incidence has been reduced to a low level suggestive of interruption of indigenous transmission of measles virus.

Detailed epidemiologic investigation of all suspected cases with laboratory confirmation and virus isolation from all chains of measles transmission is required to determine interruption of indigenous transmission of measles and evaluate the impact of EMR elimination activities. Monitoring of timeliness and completeness of reporting and other surveillance indicators at district levels should be a priority among these countries (1).

## Measles Elimination - Continued

Priority program activities for the 14 countries in the EMR now targeting measles elimination are 1) to maintain high routine vaccination coverage ( $\geq 95 \%$ ) with the first dose of measles vaccine; 2) to achieve high coverage ( $>90 \%$ ) in catch-up campaigns in Lebanon, Morocco, and Palestine; 3) to either achieve and maintain high coverage with a routine second dose of measles vaccine or implement timely follow-up campaigns in those countries that have conducted catch-up campaigns; and 4) to strengthen case-based measles surveillance and establish a regional measles laboratory network to support laboratory diagnosis of suspected measles cases and virus isolation from all chains of measles transmission. To achieve high routine coverage, countries should monitor and report coverage at the smallest administrative level on a regular basis. Supervision and feedback are necessary to ensure corrective measures in areas with low coverage. Monitoring of age-specific susceptibility based on vaccine coverage is necessary to plan supplemental vaccination activities. To achieve and maintain the regional goal of measles elimination by 2010, high level political commitment and substantial resources will be required to implement the strategies in countries now targeting elimination and gradually expand elimination activities to the rest of the region as polio eradication is completed.

## Alcohol Involvement in Fatal Motor-Vehicle Crashes United States, 1997-1998

The following table compares alcohol involvement in fatal motor-vehicle crashes by age group and blood alcohol concentration (BAC) levels for 1997 and 1998. A fatal crash is considered alcohol-related by the National Highway Traffic Safety Administration (NHTSA) if either a driver or nonoccupant (e.g., pedestrian) had a BAC of $\geq 0.01$ $\mathrm{g} / \mathrm{dL}$ in a police-reported traffic crash. Because BACs are not available for all persons in fatal crashes, NHTSA estimates the number of alcohol-related traffic fatalities on the basis of a discriminant analysis of information from all cases for which driver or nonoccupant BAC data are available (1).

Overall, the percentage of traffic fatalities that were alcohol related remained constant at $38.4 \%$ in 1998 and $38.5 \%$ in 1997. From 1997 to 1998, the number of alcoholrelated traffic fatalities decreased $1.6 \%$ ( $95 \%$ confidence interval $=-3.7 \%-0.6 \%$ ), with a decease of $2.0 \%$ for BACs $\geq 0.10 \mathrm{~g} / \mathrm{dL}$ (the legal limit of intoxication in most states) and no percentage change (but one less death) for BACs of $0.01-0.09 \mathrm{~g} / \mathrm{dL}$.

A decrease of $5.8 \%$ in the number of alcohol-related traffic fatalities is needed to achieve the national health objective for 2000. Effective strategies for reducing alcohol impaired driving include strict enforcement of impaired driving and minimum legal drinking age laws, sobriety checkpoints, and prompt suspension of licenses of persons arrested for driving while impaired. CDC, in collaboration with the Task Force on

## Fatal Motor-Vehicle Crashes - Continued

Community Preventive Services, is evaluating the effectiveness of community-based strategies to reduce alcohol-related motor-vehicle injuries.

## National Drunk and Drugged Driving Prevention Month December 1999

Persons who drive while impaired by alcohol or other drugs are a public health hazard to themselves and others. During 1998, alcohol-related motor-vehicle crashes resulted in 15,935 deaths and approximately 305,000 injuries in the United States (1). During 1988-1998, the proportion of all traffic fatalities that were alcohol-related declined steadily, from $50 \%$ to $38 \%$ ( 1 ). During the same period, the rate of alcohol related motor vehicle deaths decreased $39 \%$, from 9.7 to 5.9 per 100,000 persons (1,2). One of the national health objectives for 2000 is to reduce alcohol related motor vehicle deaths to no more than 5.5 per 100,000 persons (objective 9.23) (3). The Healthy People 2010: Health Objectives for the Nation will call for further reductions in alcohol-related motor vehicle deaths (4).

December has been designated National Drunk and Drugged Driving Prevention Month by the National Drunk and Drugged Driving Prevention Month Coalition, a nationwide public/private sector coalition for the prevention of crashes related to impaired driving. Additional information about National Drunk and Drugged Driving Prevention Month is available from the Impaired Driving Division, Office of Traffic Injury Control Programs (NTS-11), National Highway Traffic Safety Administration, US Department of Transportation, 400 7th Street, SW, Washington, DC 20590; telephone (202) 366-9588; or World-Wide Web site http://www.nhtsa.dot.gov/people/outreach/safesobr/.*

## Notice to Readers

## Epidemiology in Action: Intermediate Methods

CDC and Emory University's Rollins School of Public Health will cosponsor a course, "Epidemiology in Action: Intermediate Methods," on February 7-11, 2000, in Atlanta. The course is designed for state and local public health professionals.

The course will review the fundamentals of descriptive epidemiology and biostatistics, analytic epidemiology and Epi Info 6 but will focus on mid-level epidemiologic methods directed at strengthening participants' quantitative skills, with an emphasis on up-to-date data analysis. Topics include advanced measures of association, normal and binomial distributions, logistical regression, field investigations, and summary of statistical methods. Prerequisite is an introductory course in epidemiology, such as Epidemiology in Action or International Course in Applied Epidemiology. There is a tuition charge.

Additional information and applications are available from Emory University, International Health Dept. (PIA), 1518 Clifton Rd. NE, Room 746, Atlanta, GA 30322; telephone (404) 727-3485; fax (404) 727-4590; or email pvaleri@sph.emory.edu.

*Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
${ }^{\dagger}$ Pneumonia and influenza.
${ }^{\S}$ Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
TTotal includes unknown ages.

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to listserv@listserv.cdc.gov. The body content should read SUBscribe mmwr-toc. Electronic copy also is available from CDC's World-Wide Web server at http://www.cdc.gov/ or from CDC's file transfer protocol server at ftp.cdc.gov. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly MMWR are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the MMWR Series, including material to be considered for publication, to: Editor, MMWR Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (888) 232-3228.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.

[^0]:    *The total fertility rate is the sum of age-specific birth rates for single years of age for women aged 14-49 years. The birth rates for single years of age used to compute total fertility rates are based on births adjusted for underregistration for all years and on population estimates adjusted for undernumeration; therefore, they cannot be compared with birth rates and fertility rates.

[^1]:    *Along with family planning improvements came the public health surveillance systems needed to track population fluctuations. In 1900, the standard U.S. death certificate was created, augmenting the 1880 national death registration area (6) (Table 1); in 1915, the national birth registration area was created, combining state systems into a national system. In 1955, Growth of American Families, the first national survey of women to measure reproductive factors such as the use of contraception, infertility, and pregnancy intentions, was conducted using private funding (7). Five cycles of the federally sponsored National Survey of Family Growth (in 1973, 1976, 1982, 1988, and 1995) have continued to provide data on contraceptive methods, the use of family planning services, and other information on reproductive health of women (cycle six will include men).
    ${ }^{\dagger}$ Weighted data, adjusted to the 1950 census of white, ever-married women by age, education, urban-rural residence, and number of live-born infants.
    ${ }^{\S}$ Although 4\% reported contraceptive sterilization, $28 \%$ reported having surgery before aged 50 years that rendered them infertile.

[^2]:    "Use of trade names and commercial sources is for identification only and does not imply endorsement by CDC or the U.S. Department of Health and Human Services.

[^3]:    *Member countries are Djibouti, Egypt, Libya, Morocco, Somalia, Sudan, and Tunisia in northern and eastern Africa; Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, United Arab Emirates, and Yemen in the Arab Gulf states; Iraq, Jordan, Lebanon, Syria, and the Palestinian National Authority in the Middle East; Afghanistan, Iran, and Pakistan in Asia; and Cyprus.
    ${ }^{\dagger}$ A one-time, nationwide vaccination campaign targeting all children, usually aged 9 months15 years, regardless of history of measles vaccination or disease.
    ${ }^{\S}$ Subsequent nationwide vaccination campaigns conducted every $2-5$ years targeting all children born after the catch-up campaign, usually aged 9 months-4 years.

[^4]:    * Bahrain, Cyprus, Iran, Jordan, Kuwait, Lebanon, Morocco, Oman, Palestine National Authority and Palestinian populations served by United Nations Relief and Works Agency, Qatar, Saudi Arabia, Syria, Tunisia, and United Arab Emirates.

[^5]:    TNonpolio AFP rate $\geq 1$ per 100,000 children aged $<15$ years.

[^6]:    *References to sites of non-CDC organizations on the Internet are provided as a service to $M M W R$ readers and do not constitute or imply endorsement of these organizations or their programs by CDC or the U.S. Department of Health and Human Services. CDC is not responsible for the content of pages found at these sites.

[^7]:    -:no reported cases

    * Not notifiable in all states.
    ${ }_{\$}^{\dagger}$ Updated weekly from reports to the Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases (NCID)
    $\S$ Updated monthly from reports to the Division of HIV/AIDS Prevention-Surveillance and Epidemiology, National Center for
    HIV, STD, and TB Prevention (NCHSTP), last update October 24, 1999.
    $\llbracket$ Updated from reports to the Division of STD Prevention, NCHSTP.
