## Epidemiologic Notes and Reports

## School Immunization Requirements for Measles - United States, 1982

The record low incidence of measles in the United States observed in 1981 (1) resulted from implementation of the measles elimination strategy. The primary component of this strategy is to achieve and maintain a very high percentage of immunity* to measles in the population. Because schools are the primary site of measles transmission in the United States, a major focus of the Measles Elimination Program has been to document that very high percentages of school-age children are vaccinated against measles. The importance of immunizing school-age children is reflected by the fact that in 1980, the most recent year for which age-specific data on measles cases are available, the school-age population 5-19 years old accounted for almost three-fourths ( $72.1 \%$ ) of the measles cases (2).

An important means of assuring high immunization levels is enactment and enforcement of school immunization laws. The 2 major categories of school immunization laws are schoolentrance laws and comprehensive school-attendance laws. School-entrance laws require documentation of measles immunity at the time of entry into kindergarten or first grade; students already in school when the law goes into effect do not have to comply. Schoolattendance laws, however, cover all students from kindergarten through grade 12.

In recent years, an increasing number of states have adopted comprehensive schoolattendance laws requiring proof of measles immunity for all students from kindergarten through grade 12. In March 1979, only 17 states and the District of Columbia had such comprehensive laws, but by January 1982, this number had increased to 39 states and the District of Columbia (Figure 1). Of the remaining states, 10 have school-entry laws covering only kindergarten and first grade, and 1 has a law covering elementary school only. To ensure that students have been vaccinated with live-measles vaccine on or after their first birthday, most states require that dates of vaccination appear on school records.

Pennsylvania is one of 10 states that lack a comprehensive school immunization law. In the past 2 years, 8 measles outbreaks have occurred in Pennsylvania. In 1980, one such outbreak involved 811 cases in a 6-county area. Of 85,375 students enrolled in schools in these counties, 31,291 (36.7\%) lacked adequate evidence of immunity to measles.

Although Pennsylvania comprises only $5 \%$ of the U.S. population, $607(20.0 \%)$ of the provisional total of 3,032 measles cases reported in the United States for 1981 occurred in that state. The largest outbreak in the United States in 1981 occurred in Philadelphia, which reported 489 cases to CDC. Approximately $70 \%$ of these cases occurred among school-age

[^1]
## Measles - Continued

children (5-19 years). Another large outbreak, in which 156 confirmed cases were reported, occurred in Warren County, Pennsylvania; 86\% of the cases were among school-age children. Of 8,315 students enrolled in Warren County schools, 3,210 (38.6\%) lacked evidence of adequate immunity to measles. A countywide outbreak-control program was rapidly implemented in this outbreak. Philadelphia is currently engaged in a comprehensive vaccination campaign that involves reviewing the vaccination status of all students enrolled in city schools, holding vaccination clinics, and excluding students from school until they provide adequate evidence of immunity. Comprehensive immunization requirements covering kindergarten through 12 th grade are currently being considered in Pennsylvania.
Reported by RG Sharrar, MD, Philadelphia, R Gens, MD, Acute Infectious Disease Div, EJ Witte, VMD, MPH, State Epidemiologist, Pennsy/vania Dept of Health; Immunization Div, Center for Prevention Svcs, CDC.
Editorial Note: In recent years, the relationship of low measles incidence to comprehensive school laws has been demonstrated. In 1977 and 1978, low measles incidence was statistically associated with areas having comprehensive school laws that were rigorously enforced by exclusion of susceptible students from school (3). In the 1979-1980 school year, reporting areas in which laws covered all grades had lower measles incidence than did reporting areas in which laws covered only entry into kindergarten or first grade ( $p=0.05$, Mann Whitney U test) (4).

Vigorous enforcement of school immunization laws is the key to their effectiveness. The most effective means of enforcement is to exclude from school those students who have not provided documented evidence of immunity to measles. Experience with such enforcement

FIGURE 1. School immunization laws for measles, by state, January 31, 1982

## Measles - Continued

programs indicates that necessary vaccinations are quickly obtained by most susceptible pupils and that exclusion from school for significant periods of time is uncommon (5-8).

Continued progress toward eliminating indigenous measles from the United States will be aided considerably if all states have comprehensive immunization laws covering all students. The experience in Pennsylvania indicates that an aggressive surveillance and outbreak-control effort alone cannot interrupt transmission. Enacting and strictly enforcing such comprehensive laws should receive high priority in public health efforts to control or eliminate measles and to maintain the absence of indigenous measles transmission.

## Cat Rabies Exposures in lowa - 1981

In 1981, the number of confirmed cases of animal rabies in lowa rose to 889-a 68\% increase over the 1980 figure of 529 cases. Although skunks remain the most important endemic reservoir, a significant increase in the number of cases of rabies among dogs (49 in 1981 vs 22 in 1980) and cats ( 83 in 1981 vs 44 in 1980) was also observed. The lowa State Department of Health was consulted on 661 animal-contact incidents, as a result of which 452 persons received postexposure therapy (Table 1). Of the treated group, 57 persons received penetrating bites from known rabid animals. Forty-two (74\%) of these bite-associated exposures involved cats. This species was the most common source of human exposure to rabies in lowa in 1981, as it was in the period 1977-1980 (Table 2). No cases of human rabies occurred in lowa in 1981.

## Cat Rabies Exposures - Continued

Although intraspecies transmission of rabies in cats cannot be ruled out, it is presumed that most cases resulted from exposure to rabid skunks. Investigation of 64 rabid cats in lowa in 1981 revealed that none had a history of rabies vaccination (only dogs are required by the lowa State Code to be vaccinated). Investigation of 35 rabid dogs, on the other hand, revealed that the vaccination status of 1 was current and 3 had expired vaccinations.

The cost of this increased incidence of cat rabies is difficult to ascertain. A total of 6,234 doses of human diploid cell vaccine were shipped to lowa in 1981. This suggests that the total number of human treatments was approximately $900( \pm 100)$. If the cost of 1 treatment is estimated at $\$ 350$ for biologics plus $\$ 50$ for administration, the total cost for prophylaxis alone ( $\$ 400$ times a minimum of 800 persons treated) would be $\$ 320,000$. Costs of laboratory services, lost work days, transportation, livestock mortality, and veterinary fees would markedly increase this estimate.
Reported by V Seaton, DVM, Veterinary Diagnostic Laboratory, lowa State University, Ames, WH Hausler, PhD, University Hygienic Laboratory, University of lowa, lowa City, RW Currier, DVM, LA Wintermeyer, MD, State Epidemiologist, Iowa State Dept of Health; Viral Diseases Div, Center for Infectious Diseases, CDC.
Editorial Note: This report reflects the national experience with rabies in recent years. Reports of documented rabies in animals have doubled in the United States in the last 3 years: 3,298 for 1978 and over 7,000 for 1981. In 1981, for the first time, the number of

*Mortality data in this table are voluntarily reported from 121 cities in the United States, most of which have populations of 100,000 or more. A death is
reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
-*Pneumonia and influenza
$\dagger$ Because of changes in reporting methods in these 4 Pennsylvania cities, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
$\dagger \dagger$ Total includes unknown ages.
§Data not available. Figures are estimates based on average of past 4 weeks.

## Cat Rabies Exposures - Continued

rabid cats outnumbered the number of rabid dogs, by approximately $20 \%$. Control of rabies among wild animals is not technically or fiscally practical at this time. Immunization of pets represents the single most important control measure because it is effective in preventing disease and subsequent human exposures. The absence of human rabies in lowa potentially underscores the efficacy of postexposure therapy using the combination of human rabies immune globulin and human diploid cell strain rabies vaccine.

## Influenza Update - United States

Influenza $\mathbf{A}(\mathrm{H} 1 \mathrm{~N} 1)$ virus has been isolated from 1 of 2 patients surveyed in a focal outbreak of influenza at a juvenile correction institution in Sacramento, California. An estimated $40 \%-50 \%$ of the 100 inmates were affected. An additional 4 isolates of influenza $A(H 1 N 1)$ virus and 3 of type $B$ virus, all associated with geographically scattered cases, were reported from California. Two influenza $A(H 1 N 1)$ viruses and 1 type $B$ virus have been isolated in Oregon, the first for that state this season. The isolations were associated with sporadic influenza cases occurring in late January or early February. Influenza activity in Tucson, Arizona, has declined. School absenteeism in Tucson has returned to normal levels, and influenza virus was not isolated there during the first 2 weeks of February. The largest number of virus isolations continues to be reported from Houston, Texas, where the Influenza Research Center has identified a total of 159 type $B$ and 21 type $A(H 1 N 1)$ influenza viruses this season through active clinical surveillance. Despite the large number of isolations, no outbreaks of influenza have been documented in Houston.

## Surveillance Summary

## Human Plague - United States, 1981

For 1981, 13 cases of human plague, 4 of them fatal, were reported from 5 states: Arizona (4), California (1), Colorado (1), Oregon (1 fatal), New Mexico (6, 3 fatal) (Figure 2). Twelve cases were confirmed at CDC by fluorescent antibody testing and by bacteriologic identification and characterization; 1 case was confirmed serologically. The patients ranged in age from 2 to 72 years with a mean age of 38.7 years. Seven patients ( $54 \%$ were male, 6 were white, 6 were American Indian ( 5 Navajo, 1 Hopi), and 1 was Asian. The clinical manifestations included bubonic plague (5 patients), septicemic plague (5), septicemic with confirmed secondary pneumonic plague (2), and presentation unspecified (1).

The various modes of infection were flea bite ( 5 cases), skinning an infected bobcat (1), rabbit hunting (1), bite of an infected domestic cat (1), and undetermined (5). The 5 cases acquired by flea bite occurred in relation to epizootic plague among prairie dogs (Cynomys gunnisond and rock squirrels (Spermophilus variegatus). Two patients with unknown source of infection resided in areas where an epizootic of plague was occurring in prairie dogs.

From 1970 through 1981, enzootic and epizootic plague among rodents and carnivores was documented in 12 western states: Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Texas, Utah, Washington, and Wyoming. Human plague cases were reported from 8 of these states. The geographic distribution of 136 human cases in the period 1970-1981 is shown in Figure 3, and the totals by state for the same period are shown in Table 3.

Editorial Note: Plague is a bacterial disease caused by the organism, Yersinia pestis. It is usually contracted from the bite of an infected wild-rodent flea but can also occur as the result of direct contact exposure to infected rodents, rabbits, and carnivores. The infection can be spread from person to person by patients with pulmonary involvement with Y. pestis. Although this was most likely a major cause of rapid dissemination during great epidemics such as occurred in China (1), pneumonic plague is seen infrequently in modern times. Moreover,

| State | Number of Cases | Percent |
| :--- | :---: | ---: |
| New Mexico | 77 | 56.6 |
| Arizona | 21 | 15.4 |
| California | 16 | 11.8 |
| Colorado | 9 | 6.6 |
| Oregon | 7 | 5.2 |
| Nevada | 3 | 2.2 |
| Utah | 2 | 1.5 |
| Wyoming | 1 | 0.7 |
| TOTAL | 136 | 100.0 |

## Human Plague - Continued

today plague pneumonia usually results from extension of septicemia to involve the lungs (secondary plague pneumonia) rather than from direct seeding of the lungs by inhaled organisms (primary plague pneumonia). Of 105 cases of human plague reported to CDC from 1970 to $1979,82 \%$ were associated with an antecedent flea bite (2). In this same period, 19 cases (18\%) of pneumonic plague secondary to septicemia were reported. Since 1925, only 1 case of primary pneumonic plague has been documented in the United States. This case occurred at Lake Tahoe, California, in 1980, and resulted from exposure to a kitten with plague pneumonia.

The geographic distribution of cases for 1981 generally reflects the same pattern seen since 1970. New Mexico and Arizona continue to be important foci for human cases. Possible explanations for this distribution are the exposure of American Indian populations to enzootic and epizootic plague foci through hunting and food-gathering activities and the growth of non-Indian populations and expansion of their residential areas into previously uninhabited areas of enzootic plague. Faulty environmental sanitation and premises management may also play a role by providing sites for harboring rodents (3).

Addendum, Vol. 31, No. 4

p 37 In the article "Measles-United States, 1981," 16 areas were reported as having no indigenous measles in 1981. Information recently provided to CDC indicates that South Carolina should now be added to this list. Of the 2 cases reported to CDC from South Carolina for 1981, 1 was acquired outside the United States, and the other was acquired out of state. Thus, there were 17 reporting areas that had no indigenous measles transmission in 1981.

Reported by RL Parker, DVM, State Epidemiologist, South Carolina State Dept of Health and Environmental Control; Immunization Div, Center for Prevention Svcs, CDC.
