## Perspectives in Disease Prevention and Health Promotion

## Aquatic Deaths and Injuries - United States

In 1980, 7,000 drownings, primarily associated with recreational activities, occurred in the United States. After motor vehicle and fall deaths, drownings are the third leading cause of unintentional injury deaths, and for ages 5 to 44, rank second only to motor vehicle deaths. Data show that death rates from drowning are more than five times greater for males than females (1) and nearly three times greater for blacks than whites (2).

It is often assumed that most aquatic deaths occur in swimming pools, but pools account for only about $10 \%$ of all reported drownings; persons are more likely to drown in lakes, rivers, or oceans. Quarries, pits, ornamental ponds, and bathtubs add to the toll (3). Residential home pools, however, do play a major role in childhood drownings when toddlers fall or wander into them. There is strong evidence that adequate fencing and self-latching gates substantially reduce the number of childhood drownings and virtually eliminate drownings among toddlers (4-6).

Although no precise statistical data exist on the total number of water-related injuries, it is estimated that 140,000 injuries associated solely with swimming activities occur annually (7). Diving and head-first sliding into water account for the most serious aquatic injuries because of damage to spinal cords, often as a result of striking the bottom or side of a shallow body of water. Of the estimated 700 spinal cord injuries resulting from aquatic accidents each year, the majority are sufficiently serious to cause permanent paralysis (8). A 10-year study of 152 sports-related cervical spinal cord injuries shows that three water-related activities-diving, surfing, and water skiing - accounted for $77 \%$ of all reported spinal injuries (9). Spinal cord injuries from diving alone exceed the total reported from all other sports combined (10).

The data below identify three additional factors that significantly influence aquatic deaths and injuries:

1. In recent years, residential spa and hot tub use has markedly increased. In 1980, an estimated 1,100 persons with spa or hot tub injuries required emergency
room treatment, as compared with only 200 the previous year. Alcohol was cited as a contributory factor in 12 of 30 residential spa-associated deaths reported to the Consumer Product Safety Commission since 1979 (11). The high temperatures of spas and hot tubs combined with a moderate level of alcohol in the blood stream tend to accelerate drowsiness. Death often results from drowning after a victim falls asleep (12).
2. Coast Guard data show that $7 \%$ of the boats involved in mishaps lacked available and accessible personal floatation devices, but this $7 \%$ accounted for $29 \%$ of fatalities (3).
3. Onboard and overboard falls contributed from $20 \%$ to over $30 \%$ of water-related fatalities, often when the victim was undertaking an activity other than boating (e.g., fishing) (3).

Many complex factors, both human and environmental, relate to water safety, including pre-existing illness and alcohol. Alcohol consumption is often cited as an indisputable factor in drowning and injury. One study showed that $47 \%$ of adults who drowned had evidence of alcohol in their blood (2). Many other studies support those findings and indicate that positive blood-alcohol tests on drowning victims are especially common, even among experienced swimmers.

A retrospective study to determine the epidemiologic features of recreational injuries and to identify intervention strategies to reduce the incidence of such injuries was recently completed by the Washington Department of Social and Health Services.

> Aquatic recreational activities present a hazard for males, generally less than age 25 . It is clear that the full spectrum of injury, from minor to death, is possible in aquatic activities. Depending on the age under discussion and the injury, the target problems change. For the young, swimming pools present the greatest aquatic hazard due to drownings. Private rather than public pools are more frequently involved. Yet on an overall basis, swimming pools are not the major focal point for drowning prevention. The same appears true for spinal injuries. Here the target group is the diving teenager. The behavioral implications as well as environmental controls are evident in most of the descriptive literature regarding aquatic injuries, and it is clear prevention strategy cannot ignore the realities of either. (3)

## Reported by Environmental Health Svcs Div, Center for Environmental Health, CDC.

Editorial Note: A National Conference on Injury Control, co-sponsored by CDC and held at Johns Hopkins School of Hygiene and Public Health on May 18-19, 1981, (13) brought together 25 leaders in the injury-control field. They represented public health and medical schools, state and local health departments, and other public and private agencies. The conference report suggests strategies or approaches for transforming existing knowledge and technology into measures that prevent injuries. Some of the suggested intervention strategies to prevent aquatic deaths and injuries are:

1. Develop and implement standards that govern safe pool design.
2. Require licensing for private and public pool construction and ownership based on certain safety requirements, including adequate fencing and accessible rescue and resuscitation equipment.
3. Require sign-posting in known hazardous-water areas regarding depth, undertow, or slippery banks.
4. Restrict the sale and consumption of alcoholic beverages in boating, pool, harbor, marina, and beach areas.
5. Impose sanctions for drunken boat drivers.
6. Integrate information into health department home-visit programs to make parents aware of pool, pond, and bathtub hazards.
7. Develop and institute programs for employees, who work in or near bodies of water, on how to recognize hazardous, environmental conditions and about emergency procedures that reduce the consequences of water-related injuries (e.g., procedures for extrication).
8. Conduct surveillance programs using emergency medical service logs, lifeguard data, coroner's records, and data from environmental groups, which are critical to evaluating the effectiveness of interventions.

## Current Trends

## Laboratory Confirmation of Measles Using Capillary Blood Specimens

The Immunization Practices Advisory Committee (ACIP) has recommended that laboratory confirmation be attempted on every suspected case of measles that cannot be linked to another laboratory-confirmed case (1). To that end, a finger- or heelstick method of collecting capillary blood on filter-paper strips was evaluated for sensitivity and specificity in the laboratory diagnosis of measles.

The correlation of measles hemagglutination-inhibition (HI) antibody titers was assessed using 125 sets of capillary blood and venous serum specimens obtained from 81 individuals during investigations of sporadic and outbreak-associated cases. The close correspondence between venous and capillary HI antibody titers is indicated in Figure 1 (correlation coefficient $=0.85$ ). Of the 125 sets, 124 ( $99.2 \%$ ) had a $\leqslant$ two-

FIGURE 1. Relationship of hemagglutination-inhibition antibody titers in capillary blood specimens to venous serum specimens

Measles - Continued
fold difference in titer between the two tests. Only one of the sets ( $0.8 \%$ ) showed a significant difference ( $\geqslant$ four-fold difference in titer) between the two tests.

The ability of capillary blood specimens to confirm recent measles infection was compared with that of venous serum specimens, the standard specimen used to confirm measles.* Paired acute- and convalescent-phase venous and capillary specimens from 44 individuals were tested. These tests showed substantial agreement (Table 1). The sensitivity of tests on capillary blood was $100 \%$, and the specificity was 96.4\%.

Using staphylococcal protein A (SPA) adsorption, measles-specific lgM was assessed on six simultaneously collected venous and capillary specimens (2). IgM was detected in both venous and capillary specimens in three sets of specimens; the remaining three sets were negative for $\lg M$ in both types of specimens.

A pilot program was carried out in Georgia from February through May 1982 to determine whether a higher proportion of specimens could be obtained from suspected measles cases ${ }^{\dagger}$ if capillary-blood testing was available. During the program's initial stages, when filter-paper strips were unavailable for capillary blood testing in several counties and only venipuncture could be used, specimens were obtained from eight of 16 (50\%) suspected cases including two of 10 preschool-age (<5 years) children. In contrast, when filter-paper strips were available, capillary specimens were obtained from 36 of 37 ( $97 \%$ ) suspected cases of measles ( $p=0.0001$ ), including all 21 of preschool age.

Personnel obtaining capillary blood specimens enthusiastically accepted this

method, particularly for use among preschool-age children. All capillary specimens submitted in this pilot program were satisfactory for testing.
Reported by C Baker, S Clark, D Lockridge, S Register, T Seegmuller, G Smith, C Turner, Immunization Program, JW Alley, MD, Div of Public Health, Georgia Dept of Human Resources; DG Ramras, MD, LD Fredericks, MA Harris, MK Hernandez, J Merrill, SJ Parker, CR Peter, PhD, SE Ross, MA Thompson, DrPH, WA Townsend, MD, H Tuller, PB Villalon, M Workman, MD, Dept of Health Svcs, San Diego, L Dales MD, JChin, MD, State Epidemiologist, California Dept of Health Svcs; Viral Exanthems and Herpes Virus Br, Div of Viral Diseases, Center for Infectious Diseases, Surveillance, Investigations and Research Br, Immunization Div, Center for Prevention Sucs, CDC
Editorial Note: Confirmation of indigenous measles transmission in a given area is aided by laboratory assessment of suspected cases. The eagerness of investigators to obtain specimens, the availability of personnel trained in obtaining the specimens, and the likelihood of obtaining permission to collect specimens affect the proportion of suspected measles cases that undergo laboratory testing. The data presented here indicate that a fingerstick/filter-paper method of blood collection and testing is feasible, acceptable, and accurate.

[^1]TABLE V. Years of potential life lost, deaths, and death rates, by cause of death, and estimated number of physician contacts, by principal diagnosis, United States

| Cause of morbidity or mortality (Ninth Revision ICD, 1975) | Years of potential life lost before age 65 by persons dying in $1980^{1}$ | Estimated mortality March 1982 |  | Estimated number of physician contacts March $1982^{4}$ |
| :---: | :---: | :---: | :---: | :---: |
|  |  | Number ${ }^{2}$ | $\begin{gathered} \text { Annual } \\ \text { Rate } / 100,000^{3} \end{gathered}$ |  |
| ALL CAUSES (TOTAL) | 10,006,060 | 172,320 | 879.1 | 103,081,000 |
| Accidents and adverse effect (E800-E807, E810-E825, E826-E949) | 2,684,850 | 7,040 | 35.9 | 5,394,000 |
| Malignant neoplasms (140-208) | 1,804,120 | 36,930 | 188.4 | 1,511,000 |
| Diseases of heart (390-398, 402,404-429) | 1,636,510 | 66,570 | 339.6 | 5,856,000 |
| Suicides, homicides (E950-E978) | 1,401,880 | 4,290 | 21.9 | - |
| Chronic liver disease and cirrhosis (571) | 301,070 | 2,350 | 12.0 | 156,000 |
| Cerebrovascular diseases (430-438) | 280,430 | 13,839 | 70.6 | 440,000 |
| Pneumonia and influenza (480-487) | 124,830 | 4,920 | 25.1 | 1,389,000 |
| Diabetes mellitus (250) | 117,340 | 2,800 | 14.3 | 2,568,000 |
| Chronic obstructive pulmonary diseases and allied conditions (490-496) | 110,530 | 5,700 | 29.1 | 2,187,000 |
| Prenatal care ${ }^{5}$ |  |  |  | 2,452,000 |
| Infant mortality ${ }^{5}$ |  | 3,600 | $11.8 / 1,0$ | ve births |

${ }^{1}$ Years of potential life lost for persons between 1 year and 65 years old at the time of death are derived from the number of deaths in each age category as reported by the National Center for Health Statistics, Monthly Vital Statistics Report (MVSR), Vol. 29, No. 13, September 17, 1981, multiplied by the difference between 65 years and the age at the mid-point of each category. As a measure of mortality, "Years of potential life lost" underestimates the importance of diseases that contribute to death without being the underlying cause of death.
${ }^{2}$ The number of deaths is estimated by CDC by multiplying the estimated annual mortality rates (MVSR Vol. 31, No. 4, July 14, 1982, pp. 8-9) and the provisional U.S. population in that month (MVSR Vol. 31, No. 3, June 21, 1982, p.1) and dividing by the days in the month as a proportion of the days in the year.
${ }^{3}$ Annual mortality rates are estimated by NCHS (MVSR Vol. 31, No. 4, July 14, 1982, pp. 8-9), using the underlying cause of death from a systematic sample of $10 \%$ of death certificates received in state vital statistics offices during the month and the provisional population of those states included in the sample for that month.
${ }^{4}$ IMS America National Disease and Therapeutic Index (NDTI), Monthly Report, March 1982, Section III. This estimate comprises the number of office, hospital, and nursing home visits and telephone calls prompted by each medical condition based on a stratified random sample of office-based physicians $(2,100)$ who record all private patient contacts for 2 consecutive days each quarter.

[^2]Measles - Continued
Measles HI antibody titers in capillary blood and venous sera obtained from the same individuals have been compared previously, with good agreement (3). The data presented here corroborate these findings. This method of collection and testing, if used correctly, can yield valid laboratory assessments. Filter-paper capillary blood assessments were as sensitive as venous serum assessments in detecting seroconversion and were also highly specific. IgM can probably be measured accurately using SPA adsorption.

The fingerstick method of obtaining blood is acceptable to donors, their parents, and blood collectors (4). After a brief orientation, blood collectors were able to obtain satisfactory specimens.

Any laboratory that can perform measles HI antibody tests can measure HI antibody from filter-paper strips after extracting blood from the filter papers by a standardized elution technique. Accurate testing requires a standard volume of blood, which is assured by complete filling of the areas indicated on the filter-paper strips.

The fingerstick method potentially allows all suspected cases, particularly in preschool children, access to laboratory assessment. Persons desiring information about laboratory testing for measles using capillary blood on filter-paper strips should contact the immunization programs of their state health departments.

## The Surgeon General's Warning on Marijuana

The Surgeon General of the Public Health Service has issued the following warning on marijuana:

Marijuana use is a major public health problem in the United States. In the past 20 years, its use has increased 30 -fold; it is estimated that more than a quarter of the American population has used it. The age at which persons first use marijuana has decreased gradually to the junior high school years. Until recently, nearly $11 \%$ of high school seniors used it, and although that figure has declined to $7 \%$, its daily use still exceeds that of alcohol; more high school seniors use marijuana than smoke cigarettes. In a recent study, 32\% of those surveyed had used marijuana during the previous 30 days, while $25 \%$ had smoked tobacco.

On March 24, 1982, the Department of Health and Human Services submitted to Congress a report reviewing the consequences of marijuana use. Marijuana and Health, 1982, ninth in a series, is primarily based on two recently conducted, comprehensive, scientific reviews by the Institute of Medicine of the National Academy of Sciences, the Canadian Addiction Research Foundation, and the World Health Organization (WHO). Both independent reviews corroborate the Public Health Service's findings of health hazards associated with marijuana use: Acute intoxication with marijuana interferes with many aspects of mental functioning and has serious, acute effects on perception and skilled performance, such as driving and other complex tasks involving judgement or fine motor skills.

Among the known or suspected chronic effects of marijuana are:

1. short-term memory impairment and slowness of learning.
2. impaired lung function similar to that found in cigarette smokers. Indications are that more serious effects, such as cancer and other lung disease, follow extended use.
3. decreased sperm count and sperm motility.
4. interference with ovulation and pre-natal development.
5. impaired immune response.
6. possible adverse effects on heart function.
7. by-products of marijuana remaining in body fat for several weeks, with unknown consequences. The storage of these by-products increases the possiblilties for chronic, as well as residual, effects on performance, even after the acute reaction to the drug has worn off.
Of special concern are the long-term developmental effects in children and adolescents, who are particularly vulnerable to the drug's behavioral and psychological effects. The "amotivational syndrome," characterized by a pattern of energy loss, diminished school performance, harmed parental relationships, and other behavorial disruptions, has been associated with prolonged marijuana use by young persons. Although more research is required, recent national surveys report that $40 \%$ of heavy users experience some or all of those symptoms.

The Public Health Service concludes that marijuana has a broad range of psychological and biological effects, many of which are dangerous and harmful to health, and it supports the major conclusion of the National Academy of Sciences' Institute of Medicine.

The Morbidity and Mortality Weekly Report, circulation 111,113, is published by the Centers for Disease Control, Atlanta, Georgia. The data in this report are provisional, based on weekly telegraphs to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the succeeding Friday.

The editor welcomes accounts on interesting cases, outbreaks, environmental hazards, or other public health problems of current interest to health officials. Send reports to: Attn: Editor, Morbidity and Mortality Weekly Report, Centers for Disease Control, Atlanta, Georgia 30333.

Send mailing list additions, deletions and address changes to: Attn: Distribution Services, Management Analysis and Services Office, 1-SB-419, Centers for Disease Control, Atlanta, Georgia 30333. When requesting changes be sure to give your former address, including zip code and mailing list code number, or send an old address label.

## Notice to Readers

## Subscription to MM WR

As announced in the July 23 and 30 issues of the $M M W R$, the $M M W R$ and its allied publications will become available on a paid subscription basis on October 1, 1982. A limited number of health officials and disseminators of public health information will continue to receive these publications without charge. Such officials are now being notified.

Subscribers who do not fall into the above categories may continue their subscriptions to the MMWR and its allied publications using either of the options described below.

1. Pre-publication subscription rate. Receipt of the completed form below by the National Technical Information Service (NTIS) on or before October 31, 1982, qualifies the subscriber for the pre-publication price of $\$ 55$ domestic (United States, Canada, and Mexico) (1 st class mail will cost $\$ 75$.) and $\$ 130$ foreign (airmail letter will cost $\$ 145$ ). This option includes the weekly MMWR for 1 year, the October 1982 Quarterly Surveillance Report, and succeeding four Quarterly Surveillance Reports for the next year, the 1981 MMWR Annual Summary, and the 1982 MMWR Annual Summary.
2. Regular subscription rate. Subscriptions received after October 31, 1982, will be $\$ 70$ (domestic) (1st class mail will cost $\$ 90$.) and $\$ 140$ foreign (airmail letter will cost $\$ 155$ ) and will include the weekly MMWR for 1 year, the four Quarterly Surveillance Reports, and the 1982 MMWR Annual Summary.

## PRE-PUBLICATION ORDER FORM FOR MMWR PUBLICATIONS

|  | Domestic Price* | Foreign Price | Total Price |
| :---: | :---: | :---: | :---: |
|  | 3rd Class Mail | Airmail Printed Matter |  |
| Number of subscriptions | \$55.00 | \$130.00 |  |
|  | Domestic Price* | Foreign Price |  |
|  | 1 st Class Mail | Airmail Letter |  |
| Number of subscriptions | \$75.00 | \$145.00 |  |

*Includes United States, Canada, and Mexico.

These pre-publication prices apply if this form is received by October 31, 1982, after which the domestic price is $\$ 70.00$ (third class) and $\$ 90.00$ (first class) and the foreign price is $\$ 140$ (airmail printed matter) and \$155 (airmail letter).

## METHOD OF PAYMENT

[^0]:    *Laboratory confirmation is defined as $\mathrm{a} \geqslant$ four-fold rise in measles HI antibody titer.
    ${ }^{\dagger}$ An illness with a generalized maculopapular rash (lasting more than a day if the report was delayed) accompanied by fever.

[^1]:    - Mortality data in this table are voluntarily reported from 121 cities in the United States, most of which have populations of 100.000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included
    - Pneumonia and influenza
    $\dagger$ Because of changes in reporting methods in these 4 Pennsylvania cities, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
    t† Total includes unknown ages.
    § Data not available. Figures are estimates based on average of past 4 weeks.

[^2]:    5"Prenatal care" (NDTI) and "Infant mortality" (MVSR Vol. 31, No. 3, June 21, 1982, p.1) are included in the table because "Years of potential life lost" does not reflect deaths of children $<1$ year.
