## Epidemiologic Notes and Reports

## Outbreak of Measles Following an Imported Case - Florida

As of December 13, 1982, 203 confirmed cases of measles, with rash onsets from September 10 through December 3, were reported from Dade County, Florida. Three additional cases in Florida were linked to the outbreak.

The source of the outbreak was an imported case* in a 14-year-old male resident of Dade County, who lacked documentation of immunity to measles. ${ }^{\dagger}$ He had vacationed in Peru from July 31 to August 31. From August 24 to 26, he had face-to-face contact with a cousin in Peru who had fever and a generalized maculopapular rash. After returning to the United States, he attended Junior High School A from September 1 until rash onset on September 10. He transmitted measles to seven students at Junior High School A, all of whom lacked documentation of measles immunity. They had rash onsets from September 20 through September 27. This led to a county-wide outbreak concentrated primarily in school children (Figure 1).

The highest attack rate, 3.9\%, occurred in Junior High School A, which accounted for 73 ( $36.0 \%$ ) of the 203 cases. The outbreak was concentrated in Junior High School A from September 10 through October 12 (Figure 1). However, by October 28, measles cases were reported in 11 additional schools, geographically widespread across the county. Ultimately, measles cases occurred in 32 of 186 schools in south Dade County and in 25 of 270 schools in north Dade County. In addition, four day care centers, one community college, and one military school were affected.

As part of the response to the outbreak, local authorities ordered a review of immunization records of all students in public and private schools in Dade County; 286,000 immunization records were reviewed to identify all students who had inadequate evidence of immunity to measles. Initially, susceptible students were excluded from those schools in which there were measles cases. On October 28, a county-wide measles emergency was declared by the County Health Director permitting non-compliant students, including those with medical or religious exemptions to vaccination, to be excluded from school attendance beginning on November 8 in south Dade County, and on November 22 in north Dade County. Specially assigned State Immunization Program staff joined county health personnel to review records and to administer vaccines. No measles cases were reported among non-compliant students more than 9 days after the school exclusion day.

After control measures were implemented, changes occurred in the age distribution and

[^0]
## Measles - Continued

measles immunity status of reported cases. From September 10 through October 15 (the date the immunization clinic was held in Junior High School A), 54 ( $85.7 \%$ ) of 63 measles cases occurred among students aged 10-14 years, whereas $18(20.5 \%)$ of 88 cases occurred in that age group with rash onsets from October 28 through December 3 (Table 1). In Junior High School A, all nine cases with rash onset from September 10 through October 3 were classified as preventable.§ However, no preventable cases were reported in Junior High School A one incubation period after the control clinic.

Overall, 55 ( $27.1 \%$ ) of 203 cases are classified as preventable; 42 persons ( $20.7 \%$ ) lacked documentation of immunity to measles ( 24 of whom were vaccinated before the first birthday), and 13 ( $6.4 \%$ ) had been vaccinated less than 2 weeks before rash onset. Of the $148(72.9 \%)$ cases classified as not preventable, 110 persons ( $54.2 \%$ ) had physician-signed records of immunity to measles, ${ }^{\dagger} 18$ ( $8.9 \%$ ) were less than 16 months old, 12 ( $5.9 \%$ were born before 1957, and 8 ( $3.9 \%$ ) had religious exemptions to vaccination.
Reported by: RA Morgan, MD, MP Allison, MT Brown, MD, MB Enriquez, MD, O Fajardo, RE Foden, HO Garcia, MD, S Jones, AC Kimbler, D Kumjian, C Link, P Onley, A Marler, ZB Reece, Dade County Dept of Public Health, PW Bell, RF Adams, BJ Lisko, Dade County Public Schools, Miami, TL Cook, RW Curtiss, BJ Downs, SH King, MD, DL Roach, MB Rothman, JA Spencer, SM White, NS Windham, JL Velez, J Youngblood, JJ Sacks, MD, Acting State Epidemiologist, Florida Dept of Health and Rehabilitative Svcs; Immunization Div, Center for Prevention Svcs, CDC.
Editorial Note: This outbreak resulted from an imported measles case in a U.S. citizen who transmitted infection to seven other students in a junior high school. All eight cases were preventable; none of the eight had documentation of immunity to measles, although five had received vaccine before 12 months of age. An earlier imported case had occurred while

[^1]FIGURE 1. Measles cases by date of rash onset - Dade County, Florida, 1982

Measles - Continued
school was in summer recess, but that case caused only one import-associated case. This outbreak might not have occurred if the first eight persons with measles had been appropriately vaccinated. Before these importations, Dade County, like most of the United States, was probably free of measles. Imported cases are an important source of measles throughout the country (1). Over $25 \%$ of reported cases during the first 26 weeks of 1982 were imported or import-associated (2). While such cases are generally not preventable, transmission to others is usually limited when immunization levels are high (1-3).

In Dade County schools, identification of susceptible students was difficult, because many health records merely certified vaccination without specifying dates of vaccination. Dated records allow reviewers to identify students who had been vaccinated before their first birthdays and need revaccination. Florida law now requires use of a dated form.

The high proportion of cases with documentation of adequate vaccination does not imply a low vaccine efficacy. If an outbreak occurs in a highly vaccinated population, a substantial proportion of cases would be expected among vaccinees (4). For example, if an outbreak were to occur in a population of which $90 \%$ was vaccinated with a $90 \%$-effective vaccine, approximately half the cases would be expected among prior vaccine recipients. When highly effective vaccines, such as the current measles vaccine, have been given to very large proportions of a population, disease occurrence is infrequent and usually short lived. Measles vaccine efficacy has usually been greater than $90 \%$ when determined in settings similar to Dade County (5).

Successful control of this outbreak was facilitated by the collaboration of teachers, nurses, physicians, the news media, education and health officials, and parents and children. The mandatory policy to exclude non-compliant students from school attendance led to the vaccination of over 35,000 school children. The declining number of new measles cases among school children and the declining proportion of preventable cases suggested the policy's success.

Experience during other outbreaks has demonstrated that transmission was usually interrupted shortly after a decline in school-age preventable cases ( 6,7 ). The available data indicate that mandatory exclusion of non-compliant students, under the recently amended Florida statutes (8), was an effective strategy to interrupt measles transmission.

## Update, Influenza Activity - United States and Canada

United States: New York: On November 16, 1982, the New York State Health Department was informed that an outbreak of febrile respiratory illness was developing among the 390 residents enrolled at a job corp training center located in Sullivan County, New York. On November 18, an epidemiologist from the New York State Health Department visited the center and interviewed the residents who reported having a febrile respiratory illness in November. Only one resident was ill before November 13, but 24 more cases were reported through November 18. The residents and several staff members described having an acute illness with myalgia and cough, usually accompanied by fever ( $\geqslant 38.9 \mathrm{C}$ [102 F]) and sore throat. Specimens were collected from six residents who were ill at the time of the investigation, and influenza type $A(H 3 N 2)$ virus was later isolated from two of the six specimens.

Ten residents had onset of influenza on November 18 when the outbreak abruptly terminated as the residents were dispersed to their homes for a Thanksgiving holiday vacation. When they returned after vacation, no unusual prevalence of respiratory illness was observed. This episode represents the first documented outbreak of influenza in the 48 continental states this season.

Texas: The first reported influenza virus isolates have been identified from specimens collected on November 22 and 23 from children in Houston with sporadic influenza illness. This

## Influenza - Continued

report brings the number of states reporting influenza virus isolates of type $A(H 3 N 2)$ virus, to 8: Alaska, New York, Oregon, Pennsylvania, Tennessee, Texas, Virginia, and Washington.

Canada: Several isolates of influenza type A(H3N2) virus have been reported by Canadian health officials from specimens collected from persons ranging in age from 10 to 64 . Six of the isolates were from British Columbia, three from Alberta, and two from Saskatchewan. Influenza activity was described at low levels throughout British Columbia and as sporadic in two locations in Alberta and around the area of Regina, Saskatchewan.
Reported by R Deibel, MD, R Rothenberg, MD, State Epidemiologist, New York State Dept of Health; P Glezen, MD, Baylor College of Medicine, Houston, C Webb, Jr, MD, State Epidemiologist, Texas State Dept of Health; Bureau of Epidemiology, Laboratory Centre for Disease Control, Ottawa, Ontario; WHO Collaborating Center for Influenza, Influenza Br, Center for Infectious Diseases, CDC.

## Unexplained Immunodeficiency and Opportunistic Infections in Infants - New York, New Jersey, California

CDC has received reports of four infants (under 2 years of age) with unexplained cellular immunodeficiency and opportunistic infections.

Case 1: The infant, a black/hispanic male weighing 5 lb 14 oz , was born in December 1980 following a 36-38-week pregnancy. Pregnancy had been complicated by bleeding in the fourth month and by preeclampsia in the ninth month. The infant was well until 3 months of age, when oral candidiasis was noted. At 4 months, hepatosplenomegaly was observed, and at 7 months, he had staphylococcal impetigo. Growth, which had been slow, stopped at 9 months. Head circumference, which had been below the third percentile, also stopped increasing. At 9 months, serum levels of $\lg G$ and $\lg A$ were normal; $\lg M$ was high-normal. T-cell studies were normal, except for impaired in-vitro responses to Candida antigen and alloantigen.

At 17 months of age, the infant had progressive pulmonary infiltrates, as well as continuing oral candidiasis, and was hospitalized. Mycobacterium avium-intracellulare was cultured from sputum and bone marrow samples. A CAT scan of the head revealed bilateral calcifications of the basal ganglia and subcortical regions of the frontal lobes. Repeat immunologic studies done at age 20 months showed lymphopenia, decreased numbers of T-lymphocytes, and severely impaired T-cell function in vitro; immunoglobulin determinations are pending. The infant remains alive and is receiving therapy for his mycobacterial infection.

The infant's mother, a 29-year-old resident of New York City, gave a history of intravenous drug abuse. Although she was in apparently good health at the time of the infant's birth, she developed fever, dyspnea, and oral candidiasis in October 1981. One month later, she was hospitalized and died of biopsy-proven Pneumocystis carinii pneumonia (PCP). She had been lymphopenic during the hospitalization; further immunologic studies were not done. At autopsy, no underlying cause for immune deficiency was found.

Case 2: The infant, a Haitian male weighing 6 lb 11 oz, was born in January 1981 following full-term pregnancy. The immediate postpartum period was complicated by respiratory distress. Diarrhea developed at 2 weeks of age and persisted. His physical development was retarded. At 5 months, he was hospitalized because of fever and diarrhea. On examination, he had hepatosplenomegaly, lymphadenopathy, and otitis media. While on antibiotics, he developed pulmonary infiltrates. An open lung biopsy revealed Pneumocystis carinii, Cryptococcus

Immunodeficiency in Infants - Continued
neoformans, and cytomegalovirus. Serum $\operatorname{lgG}, \lg A$, and $\lg M$ concentrations were elevated. The percentage of T-lymphocytes was decreased, but $T$-cell response to mitogens was normal. The infant died of respiratory insufficiency at $7 \frac{1}{2}$ months of age. At autopsy, the thymus, spleen, and lymph nodes showed lymphocyte depletion. His parents were residents of Brooklyn, New York; their health status is unknown.

Case 3: The infant, a Haitian male weighing 8 lb , was born in November 1981 following a normal, full-term pregnancy. He was apparently healthy until 5 months of age, when he was hospitalized with fever and respiratory distress. On examination, he had hepatosplenomegaly. A chest x-ray showed bilateral pulmonary infiltrates. Despite antibiotic therapy, the infant's condition deteriorated, and an open lung biopsy revealed PCP. Immunologic studies showed elevated serum concentrations of $\lg G, \lg A$ and $\lg M$, decreased percentage of $T$-lymphocytes, and impaired T-cell function in vitro. The infant died in May 1982. At autopsy, no cardiovascular anomalies were seen; the thymus was hypoplastic, but all lobes were present. His parents were residents of Newark, New Jersey; their health status is unknown.

Case 4: The infant, a white female weighing 5 lb, was born in April 1982 following a normal 35-week pregnancy. She was well until 2 months of age, when oral and vaginal Candida infections were noted. She responded to antifungal therapy, but at 5 months, candidiasis recurred, and she had hepatosplenomegaly. Immunologic evaluation showed that serum $\operatorname{lgG}$, $\lg A$, and $\lg M$ levels, normal at 2 months, were now elevated. The percentage of $T$ lymphocytes was decreased, and lymphocyte response to alloantigen was impaired. At 6 months of age, the infant was hospitalized because of fever and cough. Open lung biopsy revealed PCP. Despite appropriate antibiotic therapy, she died in November 1982.

The infant's mother, a 29-year-old resident of San Francisco, is a prostitute and intravenous drug abuser with a history of oral candidiasis and mild lymphopenia. She has had two other female children by different fathers. These half-sisters also have unexplained cellular immunodeficiency; one died of PCP. The children had not lived together.

None of the four infants described in the case reports was known to have received blood or blood products before onset of illness.

Other cases with opportunistic infections: Six additional young children with opportunistic infections (five with PCP, one with $M$. avium-intracellulare) and unusual cellular immunodeficiencies are under investigation. Three are male. All six children have died. One was a half-sister of the infant in Case 4.

Other cases without opportunistic infections: Physicians from New York City, New Jersey, and California have reported another 12 young children with immunodeficiencies similar to those seen in cases 1-4 but without life-threatening opportunistic infections. One is the other half-sister of the infant in Case 4. All the children are living; their ages range from 1 to 4 years. Eight are male. Clinical features seen in these 12 infants include: failure to thrive ( $83 \%$ ), oral candidiasis ( $50 \%$ ), hepatosplenomegaly ( $92 \%$ ), generalized lymphadenopathy ( $92 \%$ ), and chronic pneumonitis without a demonstrable infection ( $83 \%$ ). Of the nine mothers for whom information is available, seven are reported to be intravenous drug abusers. None is Haitian.

Reported by R O'Reilly, MD, D Kirkpatrick, MD, Memorial Sloan-Kettering Cancer Center, C Butkus Small, MD, R Klein, MD, H Keltz, MD, G Friedland, MD, Montefiore Hospital and Medical Center, K Bromberg, MD, S Fikrig, MD, H Mendez, MD, State University of New York, Downstate Medical Center, A Rubinstein, MD, Albert Einstein College of Medicine, M Hollander, MD, Misericordia Hospital Medical Center, F Siegal, MD, Mt Sinai School of Medicine, J Greenspan, MD, Northshore University Hospital, M Lange, MD, St Lukes-Roosevelt Hospital Center, S Friedman, MD, New York City Dept of Health, R Rothenberg, MD, State Epidemiologist, New York State Dept of Health; J Oleske, MD, C Thomas MD, R Cooper, MD, A de la Cruz, MD, St Michaels Medical Center, A Minefore, MD, St Josephs Medical Center, I Guerrero, MD, B Mojica, MD, W Parkin, DVM, State Epidemiologist, New Jersey State Dept of Health; M Cowan, MD, A Ammann, MD, D Wara, MD, University of California at San Francisco, S Dritz, MD,

Immunodeficiency in Infants - Continued
City/County Health Dept, San Francisco, J Chin, MD, State Epidemiologist, California State Dept of Health Svcs; Field Svcs Div, Epidemiology Program Office, AIDS Activity, Div of Host Factors, Center for Infectious Diseases, CDC.
Editorial Note: The nature of the immune dysfunction described in the four case reports is unclear. The infants lacked the congenital anomalies associated with Di George's syndrome. The immunologic features of high-normal or elevated immunoglobulin levels and Tlymphocyte depletion are not typical of any of the well-defined congenital immunodeficiency syndromes. They have, however, been described in a few children with variants of Nezelof's syndrome, a rare, poorly characterized illness of unknown etiology (1,2). The occurrence of immune deficiency in the infant in case 4 and in her half-sisters raises the possibility of an inherited disorder. However, inheritance would have to have occurred in a dominant manner, an inheritance pattern not previously described for immunodeficiency resembling that seen in these half-sisters.

It is possible that these infants had the acquired immune deficiency syndrome (AIDS). AIthough the mother of the infant in case 1 was not studied immunologically, her death from PCP was probably secondary to AIDS. The mothers of the other three infants were Haitian or intravenous drug abusers, groups at increased risk for AIDS (3). The immunologic features described in the case reports resemble those seen both in adults with AIDS (4) and in a child reported to have developed immunodeficiency following receipt of blood products from a patient with AIDS (5). Case 2 had essentially normal T-cell responses to mitogens in vitro. This finding is atypical for AIDS, but it has been seen in a few adult AIDS cases (6).

Although the etiology of AIDS remains unknown, a series of epidemiologic observations suggests it is caused by an infectious agent ( $3,5,7-9$ ). If the infants described in the four case reports had AIDS, exposure to the putative "AIDS agent" must have occurred very early. Cases 2-4 were less than 6 months old when they had serious opportunistic infections. Case 1 had oral candidiasis beginning at 3 months of age, although M. avium-intracellulare infection was not documented until 17 months. Transmission of an "AIDS agent" from mother to child, either in utero or shortly after birth, could account for the early onset of immunodeficiency in these infants.

The relationship between the illnesses seen in the reported cases with severe opportunistic infection and the 12 infants without such infections is unclear at present. The immune dysfuction seen in the children and the sociodemographic profiles of the mothers appear similar in both groups. Prospective study of the 12 children is necessary to define the natural history of their illnesses and the possible relationship of their illnesses to AIDS.
