469 Urine Testing for Detection of Marijuana: An Advisory

MORBIDITY AND MORTALITY WEEKLY REPORT

## Current Trends

## Urine Testing for Detection of Marijuana: An Advisory

Within the past several years, two U.S. companies (SYVA Co., Palo Alto, California, and Roche Diagnostics, Nutley, New Jersey") have introduced tests to detect traces of marijuana in urine. Concern about the effects of marijuana on a person's ability to perform such tasks as driving, flying, or operating machinery has prompted various governmental and industrial groups to establish policies about marijuana use, which often include chemical screening of biologic fluids. Until recently, testing of plasma has been the only means by which exposure to marijuana has been detected. Three years ago, however, the first urine-screening test became available to make such screening possible at moderate cost (SYVA).

The urine test is based on detection of 11-nor- $\Delta$-9-tetrahydrocannabinol-9-carboxylic acid ( 9 -carboxy-THC), a metabolite of $\triangle-9-$ THC, which is the primary pharmacologically active component of marijuana. Studies involving humans indicate that $80 \%-90 \%$ of the total dose of $\triangle-9-$ THC is excreted within 5 days-approximately $20 \%$ in urine and $65 \%$ in feces (1). Plasma concentrations of $\Delta-9-$ THC peak by the time a smoked dose is completed and usually fall to approximately $2 \mathrm{ng} / \mathrm{ml}$ within 4-6 hours. 9 -carboxy-THC is detectable in plasma within minutes after a dose is smoked and remains in plasma considerably longer than THC itself. Urine from marijuana users contains quantities of 9 -carboxy-THC in both free and conjugated form, as well as other cannabinoids (THC and its metabolites) detectable by the test.

When the manufacturer's instructions are followed, urine samples containing at least the stated detection level of 9 -carboxy-THC will test positive at least $95 \%$ of the time. In a CDC field-test survey of 64 laboratories, those using the SYVA system for urine screening for cannabinoids had an incidence of 4\% false-positive results (2) ; whether these errors were analytical or clerical in nature was not determined. The manufacturer states that any positive test result should be confirmed by an alternative method.

Only blood-sample measurements are likely to correlate with a person's degree of exposure (3); attempts to correlate urine concentration with impairment or time of dose are complicated by variations in individual metabolism, metabolite accumulation in the chronic user: and urine volume changes due to diet, exercise, and age. Therefore, a positive result by the urine cannabinoid test indicates only the likelihood of prior use. Smoking a single marijuana cigarette produces THC metabolites that are detectable for several days with the cannabinoid assay (4). THC can accumulate in body fat, creating higher excretion concentrations and longer detectability. If an affect on performance is the main reason for screening, the urine cannabinoid test result alone cannot indicate performance impairment or assess the degree of risk associated with the person's continuing to perform tasks. If a history of marijuana use is

[^0]Urine Testing for Marijuana - Continued
the major reason for screening, the urine test for cannabinoids should be able to detect prior use for up to 2 weeks in the casual user and possibly longer in the chronic user.

A chain of custody for the sample must be maintained by the testing laboratory, as well as during the steps that bring the sample to the laboratory. All urine samples positive by the cannabinoid assay need to be confirmed by an alternate method that is as sensitive as the screening test, a condition not always met. Methods employed for cannabinoid confirmation are gas chromatography (5), gas chromatography/mass spectrometry (6), and high performance liquid chromatography (7). Because of costs involved in more complex confirmatory procedures, confirmatory tests have not always been conducted to verify presumed positive test results. Since the screening tests are immunologically based and measure both conjugated and free forms of THC metabolites, any confirmatory procedure should either measure both forms or should include a hydrolysis step to increase analytical sensitivity. Confirmatory techniques may be specific for a particular THC metabolite, while the screening kits react with virtually all THC metabolites, a further complication in confirming screening results. SYVA markets two different cannabinoid assay kits with a twofold to fourfold difference in the amount of THC metabolite required to produce a positive test result. Regardless of which assay kit is used, test results should be interpreted by qualified personnel and positive results verified so that there is a very limited possibility of a false-positive result.
Reported by Div of Preclinical Research, Div of Epidemiology and Statistical Analysis, National Institute on Drug Abuse; Div of Technology Evaluation and Assistance, Laboratory Program Office, CDC.
Editorial Note: Marijuana is the most widely used illicit drug in the United States; an estimated 50 million people have tried it at least once (8). A recent U.S. Department of Defense survey showed that chronic marijuana use exceeded $30 \%$ among some members of the military. Although further study is needed on the long-term health effects of marijuana use, short-term effects include impaired motor coordination and perception, as well as slowed learning and decreased short-term memory (9).

Urine cannabinoid assays permitting extension of testing to nonlaboratory settings, such as industrial sites, probation offices, and schools have been developed. The relative ease with which the test can be performed encourages its use by nontechnical personnel.

Those who interpret data from laboratory or nonlaboratory settings should be aware of possible pitfalls in such testing (10). Whether test results are used for counseling or determining compliance with orders to desist from marijuana use, the laboratory must perform the test according to the manufacturer's recommendations, including confirmation of any positive test results. A recent report indicates that passive inhalation of marijuana smoke by a nonuser is not likely to produce a positive urine test result (11), but since some passive inhalation does occur, establishment of minimum sensitivity limits by a laboratory must be done cautiously.

## Epidemiologic Notes and Reports

## Measles Among Children of Migrant Workers - Florida

A total of 93 clinical measles cases,* with rash onsets from January 1 through April 27, 1983, were reported from Dade County, Florida (Figure 1). Eighty-seven (93.5\%) of these occurred among migrant workers and their dependents; 21 of these 87 resided in migrantworker camps. The 93 cases occurred after an outbreak of over 200 cases in another part of Dade County (rash onsets September 10-December 3, 1982) (1).

The 1982 outbreak was concentrated in schoolchildren; the 1983 outbreak occurred principally among preschoolers-71 (76.3\%) children under 5 years old. Complications from measles occurred principally in children under 5 years old. During the first 8 weeks of the outbreak, four of 36 children ( $11.1 \%$ ) under 5 years old had otitis media and three ( $8.3 \%$ ) had pneumonia. The highest complication rates occurred in infants under 15 months of age. Of these 22 infants, three ( $13.6 \%$ ) developed otitis, and two ( $9.1 \%$ ) had pneumonia. One child was hospitalized (a 2-week-old with pneumonia); no deaths occurred.

Two major chains of transmission were defined-one at a medical clinic and one in migrant-worker camps. Twelve ( $22.6 \%$ ) of the 53 cases occurring in the first 8 weeks of the outbreak were believed to have been acquired at the medical clinic.

A door-to-door survey was conducted in all three affected migrant-worker camps in the county by bilingual teams from the Dade County Department of Public Health. In one camp, rosters from 244 of the 387 housing units were studied. Ninety-three percent of these units housed individuals under 26 years of age. Of 985 occupants identified, 649 (65.9\%) had documented histories of vaccination or were over 20 years old. ${ }^{\dagger}$ Nineteen of the remaining
-Confirmed and probable cases.
${ }^{\dagger}$ All persons born after 1956 were urged to be vaccinated in accordance with ACIP recommendations. For purposes of this analysis, the highest risk group for disease was considered persons 6 months to 19 years old.
FIGURE 1. Reported measles - Dade County, Florida, January 1-April 27, 1983

## Measles - Continued

336 were under 6 months old-the minimum age of vaccination recommended for outbreak control (2) -leaving 317 persons at risk of disease, an average of 1.3 persons ( $317 / 244$ ) per household. ${ }^{\dagger}$ Assuming the same average occupancy for homes that were not surveyed, an estimated 186 additional susceptibles were present. Special on-site immunization clinics delivered 264 vaccinations, providing vaccine to $52.4 \%$ of the estimated population at risk. Despite these clinics, transmission persisted (Figure 1). Door-to-door vaccinations were provided on April 14; transmission ended shortly afterward.
Reported by M Enriquez, MD, H Garcia, MD, A Kimbler, RA Morgan MD, Dade County Dept of Public Health, Miami; HT Janowski, MB Rothman, JL Velez, JJ Witte, MD, JJ Sacks, MD, Acting State Epidemiologist, Florida State Dept of Health and Rehabilitative Services; Office of Migrant Health, Bureau of Health Care Delivery and Assistance, Health Resources and Svcs Administration; Div of Field Svcs, Epidemiology Program Office; Div of Immunization, Center for Prevention Svcs, CDC.
Editorial Note: Although the source of this outbreak could not be identified, transmission may have occurred from the 1982 outbreak among schoolchildren in Dade County (1). Physician- and school-based reporting systems could have failed to detect the link between the two outbreaks because many of the cases in the 1983 outbreak occurred in preschoolers who often did not seek medical care. As in other outbreaks among preschoolers, transmission in the medical clinic played an important role in sustaining this outbreak (2-4).

- Mortality data in this table are voluntarily reported from 121 cities in the United States, most of which have populations of 100.000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed Fetal deaths are not included.
-- Pneumonia and influenza
† Because of changes in reporting methods in these 4 Pennsyivania cities, these numbers are partial counts for the current week Complete counts will be available in 4 to 6 weeks.
t† Total includes unknown ages.

## Measles - Continued

To minimize the risk of transmission, it is important to separate potentially infectious children from others in waiting rooms (2). In this outbreak, the clinic staff established a triage system at the facility. It was recommended that children who arrived with symptoms compatible with the prodrome of measles be isolated from other patients. Staff also reviewed the immunity status of other clinic patients and vaccinated susceptible patients from 6 months to 25 years old.

The Immunization Practices Advisory Committee (ACIP) recommends routine measles vaccination at 15 months of age ( 5 ). However, in this outbreak, a substantial proportion of cases (47.3\%) occurred among infants under 15 months of age. Because the risk of complications is high among such infants, the ACIP also recommends that, during outbreaks, infants as young as 6 months of age may be vaccinated when exposure to measles is likely. Infants under 12 months old should receive single-antigen measles vaccine rather than measles-rubella (MR) or measles-mumps-rubella (MMR) vaccines, because rubella and mumps vaccines are not recommended for that group. To ensure protection against measles, such infants should be revaccinated when they are about 15 months old.

The recommendation to vaccinate at a younger age is made in consideration of the risk of measles complications in such infants and the benefit of vaccination, as well as the possible risk that some persons vaccinated before 11 months of age may have less predictable immune responses to measles vaccine when revaccinated on or after their first birthdays. After revaccination, approximately half the infants who fail to seroconvert initially will develop persistent hemagglutination inhibition ( $\mathrm{H} \|$ ) antibody; the remaining half will not develop sustained levels of HI antibody. However, all such children, whether HI -antibody negative or positive, have antibody detectable by a sensitive plaque neutralization test (6). There is no evidence to suggest that such children are susceptible to measles.

Immune globulin (IG) may also be used to prevent or modify measles in infants (5). However, IG should not be used in an attempt to control outbreaks. IG may be especially indicated for susceptible household contacts of measles patients (particularly if under 1 year of age). The recommended dose is $0.25 \mathrm{ml} / \mathrm{kg}(0.11 \mathrm{ml} / \mathrm{lb})$ of body weight (maximum dose, 15 ml ), intramuscular, within 6 days of exposure. Measles vaccine should be given about 3 months later when the passive measles antibodies should have disappeared (if the child is then about 15 months old).

Because a majority of the cases in this outbreak occurred among migrant workers and their dependents, control was difficult. Special clinics in the camps reached an estimated 52\% of the targeted population, but transmission persisted. Higher immunization levels were probably needed to interrupt transmission. In future outbreaks in the migrant population, it may be necessary to consider door-to-door immunizations early in the outbreak.

Rapid case-reporting systems are necessary in areas with migrant populations because migrant workers and their dependents may reside only transiently in any one location. Prompt follow-up and control measures should be instituted within 48 hours of a case report. Following this outbreak, no transmission occurred to other migrant populations in the United States. CDC and the Office of Migrant Health, Bureau of Health Care Delivery and Assistance, Health Resources and Services Administration, recommend that all migrant workers and their dependents have documentation of immunity to measles. ${ }^{\S}$ Standard immunization records of the type issued by state health departments should be filled out and given to patients at the time of vaccination to avoid repeated doses at subsequent locations.
$\S_{\text {For persons }} 15$ months of age or older and born after 1956, a written record showing date of vaccination with live measles vaccine on or after the first birthday, or a documented history of physiciandiagnosed measles. During certain outbreaks, the minimum age for vaccination has been lowered to 6 months of age or older, with revaccination at 15 months of age or older of children who were vaccinated before their first birthdays.

## Current Trends

## Tuberculosis - United States, 1982

In 1982, 25,520 cases of tuberculosis (TB) were reported to CDC, for a case rate of 11.0 per 100,000 population. Compared with 1981, this represents a $6.8 \%$ decrease in the number of cases reported and a decline of $7.6 \%$ in the case rate (Table 1).

Rates for the 50 states ranged from 25.4/100,000 in Hawaii to 2.0/100,000 in Wyoming. The rate increased in 13 states, remained unchanged in two, and decreased in 35 states and the District of Columbia (Figure 2). The rate among persons living in 56 cities of more than 250,000 population was $22.1 / 100,000$-twice the national rate and $5.6 \%$ less than the rate for the same cities in 1981. Urban rates ranged from $61.4 / 100,000$ in Miami, Florida, to 3.8/100,000 in Omaha, Nebraska. The rate increased in 21 of the country's 56 largest cities. Eight cities had rates at least three times the national rate: Miami, Florida; Newark, New FIGURE 2. Tuberculosis case rates per 100,000 population, by state - United States, 1982

${ }^{3}(-)$ Not ranked.
(n.c.) No cases.

Tuberculosis - Continued
19,050. The proportion of culture-positive cases increased from 70.5\% of total cases in 1981 to 74.6\% in 1982.
Reported by Div of Tuberculosis Control, Center for Prevention Svcs, CDC.
Editorial Note: From 1968 through 1978, the average annual decrease in TB cases in the United States was 5.6\%. From 1979 through 1981, when there was a large influx of Southeast Asian refugees, the average annual decline was only $1.4 \%$. The $6.8 \%$ decrease in the number of cases in 1982 may indicate that the previous downward trend has resumed. This may be explained in part by the smaller number of refugee arrivals in 1982. Another factor that may have influenced the reported morbidity figures for 1982 is the implementation of a new individual case-reporting system that requires more accurate verification of cases before they are counted. In January 1982, 20 additional areas began using the new system, which is being phased in over several years.

Despite the decline in the number of cases reported in 1982, TB persists as a public health problem. Transmission of infection continues, as evidenced by the continued occurrence of disease in young children. It is estimated that more than 10 million persons in this country are infected with tubercle bacilli. They have a lifelong risk of developing disease, unless given preventive treatment. Cases will continue to occur in this group for years to come, and additional cases will occur in new residents of this country who come from areas of the world where TB incidence and infection rates are much higher than in the United States.

State and local health departments are responsible for ensuring the control of TB at the community level. Currently, 40,000-45,000 persons on health department registers require treatment and follow-up for TB. Each year, over 200,000 persons exposed to new cases must be examined, and many of these should receive preventive treatment. TB control has been complicated by the global emergence of organisms resistant to antituberculosis drugs, and community outbreaks of drug-resistant disease continue to occur in the United States.
