# MORBIDITY AND MORTALITY WEEKLY REPORT 

## Epidemiologic Notes and Reports

## IIInesses Possibly Associated with Smoking Clove Cigarettes

Between March 1984 and May 1985, 12 cases of severe illnesses possibly associated with smoking clove cigarettes were reported to CDC. Signs and symptoms reported in the 11 hospitalized patients included pulmonary edema, bronchospasm, and hemoptysis. Milder symptoms reported with clove cigarette use included nausea and vomiting, angina, increased incidence of respiratory tract infections, exacerbations of chronic bronchitis, increased incidence and severity of asthma attacks, dyspnea, chronic cough, and epistaxis. Blood-streaked sputum and mild hemoptysis have been reported with particular frequency. Following are two examples of reported severe illnesses possibly resulting from smoking clove cigarettes.

Case 1: On August 4, 1984, a 19-year-old white male athlete was admitted to a California hospital after the sudden onset of acute respiratory distress. Three weeks before he was admitted, he had noted 7-10 days of cough and yellow sputum, but he had been feeling well for the week before admission. On the night before admission, he smoked two clove cigarettes and fell asleep for 3 hours. He awoke short of breath and noted a fever to 39.3C (102.8 F). Fourteen hours later, he was admitted to the hospital in acute respiratory distress, with a pulse of $144 /$ minute, respiratory rate of $48 /$ minute, temperature of $39.3 \mathrm{C}(100.8 \mathrm{~F})$, and blood pressure of $138 / 74$ ). Chest examination revealed a few scattered rhonchi and basilar rales, diminished breath sounds at the lung bases, and no dullness to percussion. A chest roentgenogram showed diffuse interstitial pulmonary edema with a small amount of pleural fluid. His room air arterial $\mathrm{pO}_{2}$ was 56 mm Hg . His white blood count (WBC) was $21,500 / \mathrm{cm}^{2}$, with $88 \%$ neutrophils, $10 \%$ bands, $1 \%$ lymphocytes, and $1 \%$ monocytes. Blood and sputum cultures were negative. He responded rapidly to intravenous corticosteroids, diuretics, and bronchodilators. No antibiotics were given. He was discharged 2 days later with a near-normal chest roentgenogram and no apparent sequelae. He had previously smoked clove cigarettes without adverse consequences.

Case 2: On December 6, 1984, a 16 -year-old black Ethiopian male living in the United States for the past 12 years was admitted to a California hospital. He had been in good health until the night before admission, when he developed symptoms of an upper respiratory tract infection, fever, and nonproductive cough. The next day, he noted increasing dyspnea, nausea, and vomiting. By early evening, he was admitted to the hospital in severe respiratory distress, with a pulse of $124 /$ minute, respiratory rate of $40 /$ minute; and temperature of $38.1 \mathrm{C}(100.6 \mathrm{~F})$. Chest examination revealed rare rhonchi but no rales or wheezing. Chest roentgenogram showed bilateral diffuse interstitial infiltrates without pleural effusions. His room air arterial $\mathrm{pO}_{2}$ was 47 mm Hg . His WBC was $30,200 / \mathrm{cm}^{2}$, with $91 \%$ neutrophils, $6 \%$ bands, $2 \%$ lymphocytes, and $2 \%$ monocytes. Blood and sputum cultures were negative. He was first treated with broadspectrum antibiotics for presumed infectious pneumonia of unknown etiology. Bilateral pleural

## Clove Cigarettes-Continued

effusions developed over the ensuing 2 days, and diagnostic thoracentesis showed an exudative pleural fluid with a protein of $5.2 \mathrm{~g} / \mathrm{dl}$. The same day, it became known that he had smoked clove cigarettes the night before being hospitalized. Antibiotics were discontinued, and a course of intravenous corticosteroids was begun. He continued to improve and was discharged without sequelae. Both the pulmonary and infectious disease consultants believed the clinical course and laboratory findings were most consistent with a toxic rather than an infectious process.
Reported by FG Schechter, MD, Presbyterian Intercommunity Hospital, Whittier, P Hackett, MD, Q Rodriguez, MD, Northern Inyo Hospital, Bishop, AD Dauer, MD, NA Sagle, MD, University of Southern California, DK Houston, MD, LW Wilson, MD, Brotman Hospital, Los Angeles, JA Kerley, MD, B Sanger, MD, Coronado Hospital, Coronado, HM Lee, MD, WT Nishigaya, MD, Humana Hospital, West Anaheim, RE Perez, MD, University of California at Irvine, Orange, JW Stratton, MD, Epidemiological Studies Section, California Dept of Health Svcs; TL Guidotti, MD, University of Alberta, Edmonton, Alberta, Canada; G Churchill, MD, Wayne State University, Detroit, Michigan; M Tafeen, MD, Plantation Pediatric Group, Plantation, SH King, MD, JJ Sacks, MD, Acting State Epidemiologist, Florida Dept of Health and Rehabilitative Svcs; Div of Field Svcs, Epidemiology Program Office, Special Studies Br, Chronic Diseases Div, Center for Environmental Health, CDC.
Editorial Note: The passive reporting system through which these reports were received is useful for detecting rare and serious adverse effects occurring shortly after exposure to a possibly toxic substance, but it is not possible to establish the exact incidence or an etiologic relationship. In evaluating the relationship between common exposures and uncommon outcomes, clinicians and public health officials must maintain a high index of suspicion. With clove cigarettes, there is a disturbing pattern in the anecdotal reports of pulmonary illness in previously healthy young adults, temporally linked to clove cigarette smoking. This is especially true, since hemoptysis and pulmonary edema are biologically plausible effects of smoking clove cigarettes. Further toxicologic and epidemiologic data are needed to clarify the acute health effects, if any, of clove cigarettes in humans.

Since 1968, clove cigarettes have been imported into the United States from Indonesia. Sales in the United States have increased from 12 million in calendar year 1980 to 150 million in fiscal year 1984 (1). The cigarettes are sold throughout the United States. The majority of persons buying the cigarettes are between the ages of 17 and 30 years (2).

Clove cigarettes contain about 60\%-70\% tobacco and 30\%-40\% cloves. Exposure to tar, nicotine, and carbon monoxide is higher from clove cigarettes than from regular American cigarettes. In smoking machine tests, clove cigarettes averaged over twice as much tar, nicotine, and carbon monoxide delivery as moderate tar-containing American cigarettes (3). Also, in the United States, clove cigarette smoke is inhaled deeply and retained in the lungs.

Eugenol-the major active ingredient in cloves-has been used as a topical dental anesthetic for years. Although eugenol has caused dermal and mucosal hypersensitivity reactions in dental patients and occupationally exposed health-care workers (2), pulmonary toxicity has not been reported. Pharmacologic effects associated with eugenol include topical anesthesia, diminished smooth muscle activity, anticonvulsant activity, and cyclooxygenase inhibition. Although eugenol has not been shown to be mutagenic in the Ames assay or carcinogenic in laboratory animais, some of its metabolites are mutagenic.

Although a cause-and-effect relationship between clove cigarette smoking and the illnesses described in these patients is not proven, inhaling clove cigarette smoke may produce severe lung injury in a limited number of susceptible persons. Prodromal respiratory tract infections reported by persons who have become severely ill after smoking the cigarettes may contribute to the development of severe illness or may reflect repeated aspirations into an airway anesthetized by eugenol in clove cigarette smoke.

In addition to adverse health effects that may result from inhaled eugenol and pyrolyzed cloves, use of clove cigarettes may be changing the smoking patterns of American teenagers.

## Clove Cigarettes-Continued

Some researchers have suggested that eugenol, which is present in substantial quantities in clove cigarette smoke (4), anesthetizes the backs of smokers' throats and tracheas, permitting deeper inhalation and possibly encouraging smoking in persons who might otherwise be dissuaded by the harshness of regular cigarettes. Whether the higher tar and nicotine content of clove cigarettes leads clove cigarette smokers to smoke higher tar American cigarettes is unknown (2).

In Indonesia, clove cigarettes are smoked by most adult males (5); health effects have not been systematically studied. In the United States, despite publicity in the popular press and an apparently large number of smokers, relatively few cases of severe illness linked to clove cigarettes have been reported.

Cloves are only one of hundreds of ingredients currently being added to cigarettes to manipulate cigarette flavor, aroma, and burning quality. The inhalation toxicology of cigarette additives has been infrequently studied.

In April 1985, New Mexico outlawed sales of clove cigarettes; Michigan has introduced legislation to ban clove cigarettes.

Additional cases of illness possibly associated with smoking clove cigarettes should be reported to CDC through state and local health departments.

## Current Trends

## Tuberculosis - United States, 1984

In 1984, 22,255 cases of tuberculosis were reported to CDC, for a rate of 9.4 cases per 100,000 population. Compared with 1983 , this is a $6.7 \%$ decrease in the number of cases reported and a decline of $7.8 \%$ in the case rate.

Case rates for the 50 states ranged from 21.0/100,000 in Hawaii to 1.0/100,000 in Wyoming (Table 1). The rate increased in eight states, remained unchanged in two, and decreased in 40.

The case rate for persons living in 57 cities with populations of 250,000 or more was 19.3/100,000-more than twice the national rate (Table 2). Urban rates ranged from 49.9/100,000 in Miami, Florida, to $2.3 / 100,000$ in Omaha, Nebraska. Eight cities had rates at least three times the national rate: Miami, Florida; Newark, New Jersey; Atlanta, Georgia; San Francisco, California; Tampa, Florida; Oakland, California; Honolulu, Hawaii; and Washington, D.C.

In 1984, 1,236 tuberculosis cases were reported among children under 15 years of age, including 759 cases among children under 5 years of age; in 1983, there were 1,360 and 818 such cases, respectively.

Official tuberculosis mortality statistics for the United States are compiled by the National Center for Health Statistics. Final tuberculosis mortality data for 1982 show 1,807 deaths. This is a $6.7 \%$ decrease from 1981 in the number of deaths reported.
Reported by Div of Tuberculosis Control, Center for Prevention Svcs, CDC.

## Tuberculosis-Continued

Editorial Note: The 6.7\% decrease in new reported tuberculosis cases in 1984 continues the downward trend noted for 1982 and 1983. Contributing factors include: (1) the participation of almost all states in a new national case reporting system requiring more accurate verification of cases and (2) a decline in the actual number of indigenous cases. During the past 3 years, health departments have implemented expanded outreach programs in high-incidence areas to ensure complete treatment of diagnosed cases and to strengthen contact investigation and follow-up activities.

When antituberculosis drugs were first introduced over 35 years ago, there was hope that the disease would soon be eliminated in the United States, even though over 100,000 new active cases and about 40,000 deaths from tuberculosis were reported annually. Given the current rate of decline, the elimination of tuberculosis appears unlikely before the year 2100. Over 20,000 new cases and 1,800 deaths still occur each year. Transmission of infection also continues, as evidenced by the continued occurrence of hundreds of cases in young children, most of whom are under 5 years of age. An accelerated rate of decline must be achieved if tuberculosis is to be fully controlled in this century.

Control of tuberculosis has been hampered by a number of factors. Unfortunately, many public and private sector health-care providers do not consider tuberculosis a problem. This

## Tuberculosis-Continued

perception has been fostered in part by the closing of tuberculosis sanatoriums and the institution of outpatient treatment programs.

Another problem that hampers control efforts for state and local health departmentswhich have the major responsibility for controlling this disease in the community-is noncompliance with prescribed therapy. Most patients require a minimum of 9 months' treatment, with monthly monitoring for drug toxicity, compliance, and response to therapy. Many patients are unwilling or unable to complete a self-administered course of therapy and may require directly observed therapy or other special assistance from the health department. An estimated 34,000 persons in health department registers are currently under medical supervision for tuberculosis, and each year, an estimated 200,000 persons exposed to new cases must be examined. Many of these persons, as well as other high-risk individuals, are placed on isoniazid preventive treatment for up to 12 months and also require monthly monitoring for drug toxicity and compliance.

A third obstacle to the effective control of tuberculosis is the emergence of tuberculosis organisms that are resistant to antituberculosis drugs, especially isoniazid and streptomycin. Such resistance is relatively more common among persons from Asia, Africa, and Central and South America. However, the problem of drug resistance is not limited to the foreign-born. Community outbreaks of drug-resistant tuberculosis have occurred in Mississippi (1), Montana (2), New York, and more recently, Massachusetts and North Carolina.

Preventing the majority of new tuberculosis cases is difficult to achieve in a short period of time with currently available technology. An estimated 10 million persons in this country are infected with tubercle bacilli and carry a life-long risk of developing tuberculosis. Even if health departments could identify all the infected individuals in the country who are at high risk of developing disease and provide them with preventive therapy, tuberculosis would still continue to occur in some infected individuals over the age of 35 years for whom preventive therapy is not recommended because the risk of isoniazid toxicity outweighs the benefits of therapy.

An acceleration of the decline can be achieved with: (1) full implementation of existing prevention and control methodology; (2) development of new treatment, diagnostic, and prevention technologies; and (3) rapid implementation of these new technologies in all areas of the country as they are developed.

CDC, state and local health departments, and other public agencies and organizations will continue to work together to achieve the first step. In June 1985, a small group of scientists will meet in Pittsfield, Massachusetts, to explore obstacles to tuberculosis elimination and to identify feasible new technologies that could be developed and used to accelerate the elimination of tuberculosis. This effort is sponsored by the U.S. Public Health Service, including CDC and the National Institutes of Health, the American Thoracic Society, and the Pittsfield Antituberculosis Association. Within the next few months, CDC will also identify a group of outside experts who will advise on the further development and implementation of a tuberculosis elimination plan. Successful accomplishment of the three action steps could bring about the elimination of tuberculosis in the United States a century earlier than is now projected.

## Measles - United States, 1984

During 1984, a provisional total of 2,534 cases of measles was reported in the United States (incidence rate 1.1 per 100,000 population) (Figure 1). This is a $69.3 \%$ increase over the 1,497 cases reported during $1983(0.7 / 100,000)$. A total of 2,079 cases $(82.0 \%)$ was reported from seven states-Texas, 602 (29.0\%); Michigan, 465 (22.4\%); California, 330 (15.9\%); Illinois, 182 ( $8.8 \%$ ); Washington, 172 (8.3\%); New York, 165 (7.9\%); and Hawaii, 163 (7.8\%).

Although the overall incidence rate increased, the number of states reporting measles decreased during 1984, compared with 1983. Fifteen states reported no measles cases lindigenous or imported), compared to 12 states and the District of Columbia during the same period in 1983. Nine states were free of measles during both 1983 and 1984. In 1984, 193 ( $6.1 \%$ ) of the nation's 3,139 counties reported measles cases, compared with 137 (4.4\%) during 1983 (Table 3).

Two hundred twenty-two cases ( $8.8 \%$ ) were associated with international or out-of-state importations, an average of 5.4 cases per week, compared with 334 cases during the same period in 1983 (1).

During 1984, detailed information was provided to CDC's Division of Immunization on 2,543 cases. The differences between this number and the 2,534 cases reported to the MMWR reflect delays in reporting.

Of 2,543 cases, $2,491(98.0 \%)$ met the clinical case definition,* and $1,036(40.7 \%)$ were serologically confirmed. Seasonality continued to be observed, with most onsets of rash occurring from week 9 through week 21, peaking at week 14 (134 cases) (Figure 2).

The age distribution of reported measles cases changed from 1983 to 1984 (Table 4). In 1983, the highest incidence rates were reported for preschoolers. In contrast, the rates for 1984 were highest for children 10-14 years of age; preschoolers (under 5 years of age) were the next most frequent group. Of the 622 preschoolers who had measles in 1984, 168 ( $27.0 \%$ ) were under 12 months of age; 127 ( $20.4 \%$ ) were $12-14$ months of age; 41 ( $6.6 \%$ ) were 15 months; and 286 ( $46.0 \%$ ) were 16 months to 4 years of age. Persons 12-14 months of age accounted for $5.0 \%$ of the 2,543 cases.

Of the 2,543 measles patients, 1,184 ( $46.6 \%$ ) had been vaccinated; 999 ( $39.3 \%$ ) had been vaccinated on or after the first birthday; and 185 (7.3\%) had been vaccinated before the first birthday (Table 5). A total of 1,359 ( $53.4 \%$ ) patients were either unvaccinated or of unknown vaccination status.
-Defined as fever $38.3 \mathrm{C}(101 \mathrm{~F}$ ) or higher, if measured, generalized rash of 3 days duration or longer, and at least one of the following: cough, coryza, and/or conjunctivitis.

## Measles-Continued

Of the 2,543 cases, 874 ( $34.4 \%$ ) were classified as preventable ${ }^{\dagger}$ (1) (Table 6). The highest proportion of preventable cases occurred among persons who were not of school age. More than $75 \%$ of the cases among children 16 months to 4 years and adults 20-24 years of age were preventable. Although more than half of the preventable cases occurred among persons 5-19 years of age, only $30.2 \%$ of cases occurring in that age group were considered pre-
${ }^{\dagger}$ A case is considered preventable if measles illness occurs in a U.S. citizen: (1) at least 16 months of age; (2) born after 1956; (3) lacking adequate evidence of immunity to measles (documented receipt of live measles vaccine on or after the first birthday and at least 2 weeks before onset of illness or a physician-diagnosed measles disease or laboratory evidence of immunity); (4) without a medical contraindication to receiving vaccine; and (5) with no religious or philosophical exemption under state law.

## Measles-Continued

ventable. The proportion of preventable cases in this age group increased progressively with increasing age.

Of the 1,669 persons who had nonpreventable measles, 336 ( $20.1 \%$ ) were too young for routine vaccination (under 16 months of age) (Table 7). Eighty-six ( $5.2 \%$ ) were born before 1957; vaccination is not ordinarily recommended for this group. Of the 1,247 persons 16 months to 27 years of age whc acquired measles, $992(79.6 \%)$ had been vaccinated on or after the first birthday; 24 (1.9\%) had prior physician-diagnosed measles; 57 ( $4.6 \%$ ) were international importations and were not U.S. citizens (an additional 94 importations occurred among U.S. citizens returning from abroad) ; and 120 ( $9.6 \%$ ) had exemptions under state law. In addition, 54 (4.3\%) persons - recruits at Great Lakes Naval Training Station-were considered immune because they had positive results on an indirect immunoperoxidase assay for measles antibody before their illness.
Reported by Div of Immunization, Center for Prevention Services, CDC.

| Total | 2,543 | $(100.0)$ |

[^3]
## Measles-Continued

Editorial Note: Although the number of reported measles cases in 1984 has increased from 1983, it is still far lower than the number in the prevaccine era (1950-1962), when an average of more than 525,000 cases was reported annually. Despite the increased occurrence of measles during 1984, its geographic distribution is restricted and focal.

Preventable cases represent a failure to fully implement existing recommendations for measles prevention, and maximal efforts should be directed toward eliminating these cases. By eliminating the preventable cases with çurrent strategies, it should be possible to substantially reduce the number of cases, both preventable and nonpreventable, since the source of many nonpreventable cases is a person with preventable measles.

Although there have been changes in the relative ranking of age groups affected, the actual numbers of cases are small, and it is not possible to draw definitive conclusions about

TABLE 6. Number of measles cases and preventability, by age group - United States, 1984*

| Age group | No. cases | No. preventable (\%) | No. nonpreventable (\%) |

*Provisional data.
TABLE 7. Reasons measles cases were classified as nonpreventable - United States, 1984*

[^4]
## Measles-Continued

their importance. School-aged children still comprise the majority of preventable cases, and further efforts need to be directed at ensuring that all children covered by state school immunization laws are adequately immunized. Persons who are younger or older represent a more complex problem. Preschoolers who are not in licensed day-care facilities are not reached by existing regulations. Every effort should be made to identify and vaccinate these young children whenever they come in contact with the health-care system. Young adults are perhaps the most susceptible cohort, with estimates of $5 \%-15 \%$ susceptibility in this age group (2). Universities and state health officials need to continue to develop and implement regulations that will ensure immunity for college students and other congregations of young adults (3).
