## Perspectives in Disease Prevention and Health Promotion

## Premature Mortality Due to Unintentional Injuries United States, 1983

As life expectancy has increased in the United States, the leading causes of death have shifted to those diseases occurring late in life, such as heart disease, cancer, and stroke. Mortality rates have long been used to measure the magnitude of these diseases and to determine resource allocation in public health. However, this traditional measure of mortality does not provide the information needed to compare the amount of premature mortality by cause of death. In 1950, an index was proposed that expressed deaths in terms of years of life lost (YLL) to complement conventional death rates (1). However, the YLL index was little used during the 1950s and 1960s. A 1965 study noted that injuries caused a significant loss of years of life and that the allocation of health resources must consider not only the number of deaths by cause but also by age (2). During the 1970s and early 1980s, the YLL index became an accepted tool for state and local health planners (3). In 1982, CDC began reporting years of potential life lost before age 65 years (YPLL) in Table $V$ of the MMWR. The YPLL index draws attention to potentially preventable mortality occurring early in life.

Unintentional injuries are the leading cause of YPLL. In 1984, they accounted for 2,308,000 YPLL, or about $19.6 \%$ of all YPLL (see Table V, page 365). Overall, unintentional injuries (E800-E949)* accounted for 2,277,000 YPLL in 1983, or about 19.4\% of all YPLL. This report focuses on the 10 leading causes of YPLL due to unintentional injury for 1983, the last year for which complete data are available.

For this report, age- and cause-specific mortality data obtained from the National Center for Health Statistics (NCHS) were used to determine the number of deaths and to calculate the YPLL for each cause of unintentional injury death in the United States during 1983. Population estimates from the U.S. Bureau of the Census were used to calculate YPLL rates.

Among unintentional injuries, motor vehicle traffic crashes (E810-E819) are the leading cause of both YPLL and deaths (Figure 1). Among all other causes of death, motor vehicle traffic crashes rank only below malignant neoplasms and diseases of the heart for YPLL. The remaining 10 leading causes of YPLL from unintentional injuries, in order, are: drownings (E910), ${ }^{\dagger}$ fire and flames (E890-E899), poisonings (E850-E869), falls (E880-E888), firearms

[^0]Unintentional Injuries - Continued
(E922), choking on food or object (E911-E912), water transport (E830-E838), air transport (E840-E845), and motor vehicle nontraffic crashes (E820-E825).

The rank order of the cause-specific numbers of deaths is the same as that of YPLL, except for fire and flames (fourth instead of third) and water transport (ninth instead of eighth).

Crude YPLL rates per 100,000 population and average YPLL per death (equivalent to 65 minus the average age at death) vary by each of the 10 leading causes of unintentional injury YPLL and by the sex of the victim (Table 1). The variation by sex in the YPLL rates is measured in the YPLL rate ratios. Males have higher YPLL rates than females for each of the listed unintentional injury causes of death. The highest YPLL rate ratios for males compared with females are for deaths due to water transport and deaths due to firearms, whereas the lowest are for deaths due to fire and flames and deaths due to choking on food or object. Except for motor vehicle traffic crashes, poisonings, and falls, the average YPLL per death is higher for females than males. The highest average YPLL per death is for that associated with motor vehicle nontraffic crashes for females, and the lowest is for that associated with falls for females.

Both YPLL and mortality rates highlight the importance of injuries as a health problem among children. Annually, about 10,000 children aged 1-14 years die from injuries (4). Injuries account for more deaths among children than any disease. The six leading causes of unintentional injury death among children are: motor vehicles, drownings, fire and flames, choking on food or object, firearms, and falls (5). About 40\% of motor vehicle deaths among children involved the child as a pedestrian (4). Considered as a separate cause of deaths among children, pedestrian death is the third leading cause of unintentional injury death after deaths among motor vehicle occupants and deaths due to drowning.
Reported by Div of Injury Epidemiology and Control, Center for Environmental Health, CDC.

FIGURE 1. Years of potential life lost (YPLL) and number of deaths for the 10 leading causes of unintentional injury YPLL - United States, 1983

## Unintentional Injuries - Continued

Editorial Note: Injury exacts an enormous toll in the United States, causing more than 140,000 deaths and over 3.5 million years of potential life lost per year (see Table V, page 365). Intentional injuries result from interpersonal or self-inflicted violence and include homicide, assaults, suicide and suicide attempts, child abuse, and rape. Unintentional injuries include those resulting from motor vehicle collisions, falls, fires, poisonings, and drownings.

TABLE 1. Years of potential life lost (YPLL) rates per 100,000 population, YPLL rate ratios, and average YPLL per death, by the 10 leading causes of unintentional injury YPLL and by sex - United States, 1983.

| Cause of death | YPLL rate | (YPLL rate ratio*) | Average YPLL perdeath |
| :---: | :---: | :---: | :---: |
| Motor vehicle traffic crashes |  |  |  |
| Male | 953.1 |  | 35.1 |
| Female | 334.3 | (2.9) | 34.6 |
| Drownings ${ }^{\dagger}$ |  |  |  |
| Male | 156.7 |  | 39.9 |
| Female | 33.7 | (4.7) | 43.9 |
| Fire and flames |  |  |  |
| Male | 73.9 |  | 33.7 |
| Female | 47.8 | (1.5) | 38.4 |
| Poisonings |  |  |  |
| Male | 81.7 |  | 30.4 |
| Female | 33.4 | (2.4) | 29.1 |
| Falls |  |  |  |
| Male | 59.5 |  | 23.6 |
| Female | 16.1 | (3.7) | 21.6 |
| Firearms |  |  |  |
| Male | 49.0 |  | 36.8 |
| Female | 7.8 | (6.3) | 38.2 |
| Choking on food or object 27.7 |  |  |  |
| Male | 26.8 |  | 27.7 |
| Female | 14.5 | (1.8) | 29.5 |
| Air transport 28.0 |  |  |  |
| Male | 29.3 |  | 28.0 |
| Female | 5.9 | (5.0) | 31.5 |
| Water transport |  |  |  |
| Male | 32.7 |  | 30.6 |
| Female | 3.8 | (8.6) | 34.5 |
| Motor vehicle nontraffic crashes |  |  |  |
| Male | 26.6 |  | 39.1 |
| Female | 8.3 | (3.2) | 45.8 |

-For males compared with females within each cause-specific category.
${ }^{\dagger}$ Includes those not related to water transport.

## Unintentional Injuries - Continued

Injuries occur during work and include unintentional trauma (e.g., motor vehicle-related injuries, falls, and electrocutions) and intentional injuries. One in every three Americans suffers an injury each year, and 80,000 persons suffer permanent disabling injuries from brain or spinal cord trauma ( 6 ). Direct and indirect costs of injury are estimated at $\$ 75-\$ 100$ billion per year.

The use of YPLL has become a mainstay in the evaluation of the impact of injuries on public health. Although YPLL is a valuable index in analyzing various causes of injury mortality, this report also includes YPLL rates, YPLL rate ratios, and average YPLL per death. The use of YPLL rates allows comparison of YLL between different populations. For each of the 10 leading causes of unintentional injury YPLL, males have a higher rate of YPLL than females. These higher rates in males may reflect a greater involvement in hazardous activities, in use of alcohol (4), and in risk-taking behavior. However, the use of average YPLL per death shows that, among those who die from unintentional injuries, females, on average, are dying at a younger age than males for each of the 10 leading causes of unintentional injury YPLL, except for motor vehicle traffic crashes, poisonings, and falls. Persons are dying from drownings, motor vehicle nontraffic crashes, and firearms at a younger age, on average, than from the other leading causes of unintentional injury YPLL.

When injuries are studied epidemiologically, many opportunities for prevention may become evident. What is known about host, agent, and environment can be translated into programmatically sound interventions that reduce injury morbidity and mortality. A project of the Carter Center of Emory University entitled, "Closing the Gap," examined the impact of the injury problem and its potential reduction by applying existing scientific and technical knowledge (7). The Carter Center estimates that, by applying broad-based mixed strategies, motor vehicle-related fatalities and injuries could be reduced by about 75\% (8). About 23,000 deaths per year result from unintentional injuries that occur in the home (8). The Carter Center estimates that targeted interventions could reduce home injuries by about 50\% (8). Appropriately targeted interventions also could reduce by about $25 \%$ all fatal and serious injuries in which alcohol is an important factor (8).

Past and current research and surveillance efforts have identified many prevention strategies to be applied and evaluated, and a growing number of state and local public health agencies and other organizations are now in the process of meeting this challenge. State agencies, in particular, can assume several responsibilities in injury prevention, including: (1) coordinating their activities with local agencies, academic institutions, and private entities; (2) conducting injury surveillance; (3) developing intervention plans with other involved groups; (4) providing information to the public; and (5) providing technical advice on legislative proposals needed to support injury-control efforts.

## Premature Mortality Due to Suicide and Homicide United States, 1983

In 1984, suicide and homicide together ranked as the fourth leading cause of years of potential life lost before age 65 (YPLL). They accounted for $1,247,000$ YPLL or $10.6 \%$ of all YPLL (Table V, page 365). In this report, YPLL was calculated using data from the National Center for Health Statistics' detailed mortality computer tapes for 1983, the latest year for which tapes are available. Data were analyzed on YPLL attributable to suicide and homicide individually, by sex, race (white, black, other races), weapon or method of injury, and year. To compare differences in YPLL across time and among different race, sex, and age groups independent of changes and differences in population size, crude YPLL rates per 100,000 persons were calculated.

## SUICIDE

Considered alone, suicide is the fifth leading cause of YPLL in the United States, accounting for 631,990 YPLL in 1983. Suicides among white males accounted for $70.6 \%$ of the total suicide-attributable YPLL (Table 2). White females accounted for another 19.7\%. White males had the highest crude YPLL rate due to suicide in $1983(458 / 100,000)$, followed by males of other races (369/100,000), black males $(283 / 100,000)$, and white females (122/100,000).

Suicides committed with firearms accounted for 363,828 YPLL in 1983, comprising $57.6 \%$ of the total YPLL attributable to suicide. This proportion was higher for males (60.9\%) than for females (45.4\%). Among males, hanging accounted for the next highest proportion of total YPLL (17.2\%), followed by poisoning by gas (8.7\%) and poisoning by solids or liquids $(6.7 \%)$. Among females, poisoning by solids or liquids comprised the next highest proportion of YPLL due to suicide ( $25.9 \%$ ), followed by poisoning by gas (10.5\%) and hanging ( $9.8 \%$ ).

The crude YPLL rate attributable to suicide increased for both black and white males from 1968 to 1983 (Figure 2). For white males, the YPLL rate increased 52.7\% from 300/100,000 in 1968 to $458 / 100,000$ in 1983. For black males, the YPLL rate increased $65.5 \%$ from $171 / 100,000$ to $283 / 100,000$. The YPLL rates for white and black females did not change appreciably during this period.

## Suicide and Homicide - Continued

HOMICIDE
Homicide accounted for 609,244 YPLL in 1983, making homicide alone the sixth leading cause of YPLL in the United States. Homicides among males accounted for more than threequarters of the total YPLL due to homicide (Table 2); 40.2\% of homicide-attributable YPLL was due to white males, and $35.0 \%$, to black males. In 1983, the crude YPLL rate due to homicide was highest for black males $(1,604 / 100,000)$, followed by black females $(373 / 100,000)$, males of other races $(334 / 100,000)$, and white males $(252 / 100,000)$.

Firearm homicides accounted for 375,369 YPLL in 1983, or $61.6 \%$ of the total homicideattributable YPLL. This proportion was higher for males ( $66.2 \%$ ) than females (46.4\%). Homicides committed with cutting and piercing instruments accounted for $21.6 \%$ of the total YPLL for males and 18.6\% of the total YPLL for females.

From 1968 to 1983, the crude YPLL rate due to homicide increased by $24.4 \%$, from $209 / 100,000$ to $260 / 100,000$. During this period, the crude YPLL rate was 6-11 times higher for black males than for white males and 5-7 times higher for black females than white females (Figure 3). From 1968 to 1983, the crude YPLL rate increased for white males and females by $60.5 \%$ and $43.6 \%$, respectively, and decreased for black males and females by 8.7\% and 4.6\%, respectively.

Reported by Div of Injury Epidemiology and Control, Center for Environmental Health, CDC.
Editorial Note: The number of YPLL is a measure of public health impact and is dependent on population size. For this reason, YPLL alone is inadequate to compare premature mortality across different years or across subpopulations, such as blacks and whites. This consideration is important, for example, when comparing homicide-attributable YPLL among blacks with that among whites. While whites accounted for a greater proportion than blacks of the total homicide-attributable YPLL in 1983 (53.6\%, compared with 44.0\%), the crude YPLL rate was

FIGURE 2. Suicide-attributable years of potential life lost, by year, race, and sex United States, 1968-1983

Suicide and Homicide - Continued
5.9 times higher for blacks than whites in that year. Moreover, although the crude suicideattributable YPLL rate increased only $0.8 \%$ for white females from 1968 to 1983, the total number of suicide-attributable YPLL for white females increased 15.1\% (from 108,099 to 124,475), mainly due to population increases.

Relative to other important causes of premature death, intentional injuries take their heaviest toll among the young. Over two-thirds of YPLL due to both suicide and homicide is attributable to deaths among persons under 35 years of age. In contrast, almost two-thirds of YPLL due to heart disease is attributable to deaths among persons 45 years of age or older. This observation is underscored by the fact that the average YPLL per death for heart disease is 2.1 years, compared with 22.3 years for suicide and 30.6 years for homicide. Injury prevention is, therefore, an appropriate focus for programs designed to target young populations, such as maternal- and child-health programs.

Firearms have been previously noted to be the weapon used in the largest proportion of deaths due to suicide and homicide (1,2). These data clearly indicate that their role in intentional injury should be examined more closely.

For both homicide and suicide, persons of nonblack minority races were noted to be at intermediate risk between blacks and whites. However, this finding is difficult to interpret. Nonblack minority races comprise a relatively small, heterogeneous population with varying risks of homicide and suicide. It has been reported that Native Americans are at higher risk of both homicide and suicide than whites, but that, in general, Asian/Pacific Islanders are not (3). Further research is needed to identify specific Native American populations at highest risk of death from intentional injuries and develop interventions appropriate for these high-risk groups.

Black males comprised only $7.0 \%$ of the total population in 1983 (4), but homicides

FIGURE 3. Homicide-attributable years of potential life lost by year, race, and sex United States 1968-1983

## Suicide and Homicide - Continued

among black males accounted for $35.0 \%$ of the total YPLL attributable to homicide in that year. Future research should clarify the role that various factors play in homicide deaths so that preventive interventions might be devised.

Although the overall suicide rate has not changed much since 1968, the crude suicideattributable YPLL rate has increased considerably because of the changing age distribution of suicide victims. In the past, suicide rates were relatively low among the young and increased with increasing age. However, beginning in the early 1950s, suicide rates have gradually increased among young persons, particularly among young white males, while decreasing among older persons $(5,6)$. In the past, many ideas about the causes of suicide and ways to prevent it were derived from concepts of suicide as a phenomenon primarily affecting older people. This marked increase in the rate of suicide among young people suggests a need to reexamine past assumptions.

YPLL due to suicide is probably substantially underestimated because suicides are thought to be underreported on death certificates $(4,5)$. Reasons for underreporting include difficulties in establishing suicidal intent, certifier error or bias, and the lack of awareness of a suicide because a body was never recovered (e.g., drowning after jumping off a bridge).
(Continued on page 365)

## Current Trends

## Measles - United States, 1985

Through December 28, 2,704 cases of measles in the United States were reported to MMWR for 1985. Detailed information reported to CDC's Division of Immunization is available for a provisional total of 2,813 cases for 1985 , which includes some late reported cases. The 2,813 cases represent an $8.7 \%$ increase over the 2,587 cases reported in 1984 . The overall incidence rate increased from 1.1 cases per 100,000 population in 1984 to $1.2 / 100,000$ in 1985. Ten states accounted for 2,106 ( $74.9 \%$ ) cases: Texas ( 443 cases), Illinois (360), California (270), Arizona (240), Washington (174), Montana (139), Idaho (132), Massachusetts (118), Maryland (115), and Florida (115). Ten reporting areas had incidence rates greater than 2/100,000 population: Arizona, District of Columbia, Hawaii, Idaho, Illinois, Maryland, Massachusetts, Montana, Texas, and Washington. During 1984 and 1985, 14 and 12 states, respectively, reported no measles cases (indigenous or imported). Of the nation's 3,139 counties, $220(7.0 \%)$ reported measles cases in 1985, compared with 210 (6.7\%) in 1984.

Of the 2,813 cases, 2,718 ( $96.6 \%$ ) met the standard case definition for measles, ${ }^{*}$ and 1,071 ( $38.1 \%$ ) were serologically confirmed. Most of the patients ( $68 \%$ ) had rash onset between weeks 8 and 25 (weeks ending February 23 and June 22) (Figure 4).

In 1984, the highest incidence rate was reported among children 10-14 years of age (Table 3). By comparison, in 1985, the highest incidence rate occurred among preschoolaged children (4.7/100,000), followed by persons $15-19$ years of age (4.5/100,000). Of the 826 preschool-aged children with measles, 211 ( $25.5 \%$ ) were infants under 1 year of age; 143 ( $17.3 \%$ ) were $12-14$ months of age; 41 ( $5.0 \%$ ) were 15 months of age; and 431 ( $52.2 \%$ ) were 16 months 4 years of age.
*Fever (38.3 C [101 F] or higher, if measured); generalized rash lasting 3 or more days; and at least one of the following: cough, coryza, conjunctivitis.

FIGURE 4. Reported measles cases, by week of rash onset - United States, 1985

## Measles - Continued

The setting of transmission was reported for $1,864(66.3 \%)$ measles patients: 1,129 (60.6\%)-school ${ }^{\dagger}$; 278 (14.9\%)-home; 87 ( $4.7 \%$ )-medical settings; 94 ( $5.0 \%$ )-day care; $94(5.0 \%)$-church; and 182 ( $9.8 \%$ ) - other (including sporting events and summer camp). Of the 2,813 total cases, 354 ( $12.6 \%$ ) were reported on 26 college campuses (Table 4).

One hundred twenty-one cases (4.3\%) were international importations. An additional 166 ( $5.9 \%$ ) cases were epidemiologically linked to an international importation within two generations of infection. Therefore, 287 ( $10.2 \%$ of all cases) were classified as international importations during this period (1).

Vaccination status of patients in 1984 and 1985 was similar. Of the 2,813 measles patients in 1985, 1,239 (44.0\%) had been appropriately vaccinated (on or after the first birthday); 381 had been vaccinated at 12-14 months of age (Table 5). A total of 1,442 measles patients were unvaccinated, and 132 had histories of inadequate vaccination (vaccinated before the first birthday).

Of the 2,804 cases with known preventability status, 820 ( $29.2 \%$ ) were classified as preventable (1). The highest proportion of preventable cases occurred among persons who
$\dagger$ Includes kindergarten through college.

TABLE 3. Age distribution and estimated incidence rates of measles - United States, 1984 and 1985

| Age group (yrs.) | 1984 |  |  | 1985* |  |  | Rate change § |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | No. | (\%) | Rate ${ }^{\text {¢ }}$ | No. | (\%) | Rate ${ }^{\dagger}$ |  |

## Measles - Continued

were not of school age: $73.8 \%$ of cases among children 16 months-4 years of age were preventable (Table 6). Only $21.7 \%$ of cases among school-aged persons ( $5-19$ years of age) were preventable. However, 347 ( $42.3 \%$ ) of all 820 preventable cases occurred in this age group.

Of the 1,984 nonpreventable cases, 395 (19.9\%) were among children too young for routine vaccination (under 16 months of age), and 71 ( $3.6 \%$ ) persons were too old (born before 1957). Of the 1,518 between 16 months and 28 years of age, $1,207(79.5 \%)$ had been vaccinated on or after the first birthday; 14 ( $0.9 \%$ ) had a prior physician diagnosis of measles; 48

## Measles - Continued

( $3.2 \%$ ) were non-U.S. citizens; and 248 (16.3\%) had medical contraindications or other exemptions under state law (Table 7).
Reported by Div of Immunization, Center for Prevention Svcs, CDC.
Editorial Note: In the prevaccine era, an average of 500,000 cases were reported each year (2). Since measles vaccine was licensed in 1963, the incidence of measles has declined markedly. While the number of cases increased $8.7 \%$ from 1984 to 1985 , the provisional total of 2,813 cases still represents only $0.6 \%$ of the average number of reported cases in the prevaccine era. Since 1981, the reported occurrence of measles has stabilized between approximately 1,500 and 3,200 cases. However, slight increases have been noted annually since the record low 1,497 cases reported in 1983.

The highest incidence rate in 1985 occurred in the preschool-aged population, which accounted for approximately $30 \%$ of all reported cases. Recent outbreaks involving a substantial proportion of preschool-aged children have also occurred ( 3,4 ). The increased incidence of measles among preschoolers is a source of concern, since the risk of serious complications of measles illness is highest in the youngest age groups (2). Seventy-four percent of cases among children 16 months to 4 years of age were preventable, emphasizing the need to vaccinate children promptly at the recommended age for routine vaccination (15 months).

The next highest incidence rate in 1985 occurred among persons 15-19 years of age, who accounted for another $30 \%$ of total cases. The increased rate in this age group over 1984 was due in part to the large number of outbreaks on college campuses. The proportion of total cases occurring on college campuses in 1985 was higher than that of any of the previous 6 years, except 1983 (Table 4). An increased number of colleges and universities are now requiring evidence of immunity to measles for matriculation, which should decrease measles in this population (5).

Persons of school age accounted for the largest percentage of all preventable cases, and schools were the setting of transmission for the majority of cases. Therefore, continued enforcement of current school immunization laws is important for further reduction of measles in the United States.

TABLE 7. Reasons measles cases were classified as nonpreventable - United States, 1985*

| Causes of nonpreventability | No. cases (\%) |  |  |  | Percentage of total cases ${ }^{\dagger}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Persons > 16 mos. of age |  |  | 395 | (19.9) | 14.1 |
| Persons born before 1957 |  |  | 71 | (3.6) | 2.5 |
| Persons 16 mos.-28 yrs. of age |  |  | 1,518 | (76.5) | 54.1 |
| Appropriately vaccinated | 1,207 | (79.5) |  |  |  |

FIGURE I. Reported measles cases - United States, weeks 18-21, 1986

The Morbidity and Mortality Weekly Report is prepared by the Centers for Disease Control, Atlanta, Georgia, and available on a paid subscription basis from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402, (202) 783-3238.

The data in this report are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the succeeding Friday.

The editor welcomes accounts of interesting cases, outbreaks, environmental hazards, or other public health problems of current interest to health officials. Such reports and any other matters pertaining to editorial or other textual considerations should be addressed to: ATTN: Editor, Morbidit y and Mortality Weekly Report, Centers for Disease Control, Atlanta, Georgia 30333.
