

```
/*
By Dr Raoul Kamadjeu, Novermber 2008
Submitted as additional material for the IJHG article
This approach is quick and dirty and is just one of the many possible. So please
feel free to use your own and even better method.
The bottom line is that you should be able to parse the xml, identify the tags of
interest and get their values
-----
-----
WHAT THIS SCRIPT
-----
The script parses the XML file (a kml file saved with the xml extension in this
case), extract the values of the <name> and <coordinate> tags and output a |
separated file that can be easily loaded in the database.

HOW TO USE THE SCRIPT
-----
Save your kml file as an xml file (*.xml).
Create an html file on your server (example: LoadKml.html). Make sure the xml is
in the same directory as the html

This first function reads the xml file in the memory.
=====FUNCTION
LoadXMLDocument=====
Copy this function on js file (loadxml.doc.js)
link the html file to the javascript by inserting the <script
type="text/javascript" src="loadxml.doc.js"></script> in the head of the document.
*/
function loadXMLDocument(dname)
{
    var xmlDoc;
    // code for IE
    if (window.ActiveXObject)
    {
        xmlDoc=new ActiveXObject("Microsoft.XMLDOM");
    }
    // code for Mozilla, Firefox, Opera, etc.
    else if (document.implementation && document.implementation.createDocument)
    {
        xmlDoc=document.implementation.createDocument("", "", null);
    }
    else
    {
        alert('Your browser cannot handle this script');
    }
    xmlDoc.async=false;
    xmlDoc.load(dname);
    return(xmlDoc);
}
=====
=====Script 2 =====
Your final html file should look like this
<html>
<head>
    <script type="text/javascript" src="loadxml.doc.js"></script>
</head>
```

```
<body>
<script type="text/javascript">
*/
xmlDoc=loadXMLDocument( "DRC.xml" );
//Identifying the <name> tag inside the xml document
var x=xmlDoc.getElementsByTagName('name');
//identifying the <coordinates> tag inside the xml document
var y=xmlDoc.getElementsByTagName('coordinates');
//we loop into all the <name> tags and for each of them, we pick the value for
<name> and <coordinates>
for (i=0;i<x.length+1;i++)
{
    document.write("<strong><font color='FF0000'>"); //the names will be
bolded to make them more visible
    document.write(x[i].childNodes[0].nodeValue);
    document.write("</font></strong>");
    document.write(" | "); // we use this separator to separate name and
coordinates for each of the placemark. This is just to improve readability.
    document.write(y[i].childNodes[0].nodeValue);
    document.write("<br />"); //Write each output on a separate line.
}
/*</script>
</body>
</html>
The resulting file is a / seperated file that can be loaded into the database
```
