209 Immunization Practices in Colleges United States
212 Tuberculosis in Blacks - United States 221 Early Syphilis - Broward County, Florida

## Current Trends

## Immunization Practices in Colleges - United States

Outbreaks of vaccine-preventable diseases continue to occur in colleges. In 1985, 354 measles cases were reported on 26 college campuses. In 1986, the United States had a provisional total of 6,273 measles cases; 174 ( $2.8 \%$ ) of these occurred on 21 campuses. Despite longstanding primary school immunization requirements, $5 \%-20 \%$ of college students still do not have documented immunity to measles and/or rubella (1,2).

In May 1983, the American College Health Association (ACHA) adopted a Preadmission Immunization Policy, recommending that, by September 1985, colleges and universities require all students to present documentation of immunity to measles, rubella, and other vaccine-preventable diseases as a prerequisite to matriculation or registration ( 3,4 ). Likewise, since 1980, the Immunization Practices Advisory Committee has recommended that college and university administrations strongly consider establishing such requirements (5). To evaluate implementation of these recommendations, a survey of 3,606 colleges and universities was conducted jointly by the CDC and ACHA in the fall of 1984 (6). The 1984 survey was conducted by state and local immunization program personnel in the 10 Public Health Service regions. In eight of these regions, data were obtained from more than 50\% of colleges. In order to assess further progress, ACHA conducted a follow-up survey in the spring of 1986. For this survey, a questionnaire was mailed to the 3,210 U.S. colleges and universities registered with ACHA or the American Council of Education.

Comparative data from the 1984 and 1986 surveys are presented in Table 1. In 1984, $16 \%$ of 1,861 responding institutions required measles and rubella immunizations as a condition for attendance. Of the 3,210 colleges surveyed in $1986,1,085(34 \%)$ responded. Of those responding, 601 ( $55 \%$ ) reported having a preadmission immunization requirement (PIR); 499 ( $45 \%$ ) included both measles and rubella. In both surveys, there was considerable variation by region.

The 1984 survey did not collect information regarding enforcement of existing requirements; however, the 1986 survey did. Of the 601 colleges reporting a PIR, 305 ( $51 \%$ ) placed a hold on first or second semester registration for noncompliers. Another $21 \%$ reported other sanctions including fines, withholding grades, suspension, and letters to the students or their parents from the Student Health Office or Dean's Office. Some prohibited dormitory residence, use of student health services, or participation in clinical work by students training in health professions.

## Immunization - Continued

Colleges without a PIR were asked whether they considered such a program important and why they did not have one. Of 403 schools responding, 253 ( $63 \%$ ) felt that a PIR was important. The majority (62\%) cited their general policy of not instituting special entrance requirements as their reason for not having a PIR. Twenty-six percent replied that they did not have adequate personnel to administer a program. Lack of access to a computerized data storage system was mentioned by $27 \%$. The major barriers to implementation seemed to involve procedures rather than disagreement concerning the importance of the recommendation.

In the 1986 survey, colleges and universities were also asked about their policy regarding education and vaccination against hepatitis $B$ infection. Twenty-four percent of respondents had a policy recommending hepatitis $B$ vaccine for certain high-risk groups. These high-risk groups included male homosexuals, nursing students, medical students, dental students, other health care students, and foreign students from endemic areas. The survey did not assess the overall representation of these groups in the responding colleges. In general, in the majority ( $>90 \%$ ) of responding institutions, all categories of students had to bear the cost of the vaccine.
Reported by: DS Smith, MD, M Collins, MD, University of Pennsy/vania Student Health Service, Philade/phia, Penns y/vania. Div of Immunization, Center for Prevention Svcs, CDC.
Editorial Note:During the past decade there has been a shift in focus at colleges and universities regarding the necessary content of a PIR. At first, the emphasis was on tetanus and diphtheria prophylaxis (7) as well as tuberculosis skin testing. As campuses continued to experience measles and rubella outbreaks with their potential for significant morbidity and even mortality ( 8 ), colleges began requiring documentation of immunity to measles and rubella, as well as to mumps, diphtheria, tetanus, and poliomyelitis (4). The recent emphasis on hepatitis B infection and acquired immunodeficiency syndrome (AIDS) has led many health care professionals to recommend that colleges require hepatitis B vaccination for those at risk and provide students with information on AIDS. On May 30, 1986, the ACHA Council of Delegates passed a resolution recommending that colleges educate their students at high risk for hepatitis B concerning their need to be vaccinated.

## Immunization - Continued

Since $5 \%-20 \%$ of young adults remain susceptible to measles and/or rubella, colleges have provided a receptive setting for the occurrence of outbreaks of these diseases. Of the more than 12.8 million persons attending American institutions ( 9 ), between 640,000 and 2.6 million susceptible persons could potentially be affected by PIRs. Despite nearly $\mathbf{2}$ decades of intensive public health efforts to immunize all schoolchildren, many students reach college age still susceptible to these diseases. Several factors have contributed to this situation. First, many in the current cohort of college students may have entered primary school before the adoption of state laws requiring proof of prior immunization and may not have been immunized (2). Many may have missed natural infection because naturally-occurring measles and rubella transmission have declined markedly (3). In addition, individuals vaccinated between 1963 and 1967 may have been immunized with killed measles virus vaccine, given further attenuated live measles vaccine in conjunction with immune globulin, or immunized before 1 year of age-all practices which have subsequently been found to produce inadequate long-term immunity in some individuals (10). Furthermore, the high rates of contact among college students in dormitories, lecture halls, and other college facilities increase the chances of transmission to susceptible students. Finally, introduction of disease by students returning from travel to endemic areas in foreign countries has played an important part in recent outbreaks (11).

Outbreaks of measles and rubella at colleges have been costly and have had a tremendous negative impact on student health and campus activities (12,13). An outbreak of measles at Principia College resulted in three deaths (8). A Boston University outbreak spread to Massachusetts Institute of Technology, Boston College, and Northeastern University in Boston (8) and was probably responsible for initiating an outbreak at Villanova University outside of Philadelphia (13). Containment of an outbreak at Indiana University cost \$225,000 (13).

Current efforts to deal with this problem have varied. Many schools resort to de facto outbreak control as their first strategy. Other schools have adopted their own internal PIR, with or without enforcement measures. A few states and other jurisdictions, notably the District of Columbia, Maine, Massachusetts, North Carolina, Puerto Rico, Rhode Island, and Virginia have extended their school immunization requirements to colleges and universities. The governing boards of state institutions in California, Florida, Mississippi, North Dakota, and South Dakota have adopted policies requiring proof of immunity for students registering in state-supported institutions. In the 1986 survey, about $85 \%$ of responding schools in states with a law in effect at the time of the survey (North Carolina, Massachusetts, Rhode Island*, and Mississippi) reported having PIRs. In contrast, $51 \%$ of schools in states and jurisdictions without a law had PIRs.

Data from recent rubella outbreaks suggest that review and enforcement of immunization requirements are important (12,14). In 1983-1985, there were 132 rubella cases in seven college outbreaks. Seventy-four percent of the patients had inadequate previous documentation of immunity to rubella. Three of the colleges had immunization requirements, but none had a mechanism for review or enforcement. In 1985, nearly two-thirds of measles cases on college campuses were reported among persons without adequate evidence of immunity.

Despite questions regarding comparability of the 1984 and 1986 surveys and the low response rates, the data suggest that there has been progress toward implementing comprehensive immunization review processes in colleges. Since voluntary vaccination programs are less effective than mandatory programs, further efforts to implement and enforce matriculation requirements for immunization are essential. Uniform state legislation mandating extending school immunization requirements to colleges would have significant impact on eliminating vaccine-preventable diseases from college campuses. In addition, future efforts should include other vaccine-preventable diseases, such as hepatitis B, and pragmatic issues, such as developing methods to facilitate tracking immunization status (11).

Topics in Minority Health

## Tuberculosis in Blacks - United States

In 1985, 22,201 tuberculosis cases were reported to CDC, for a crude morbidity rate of $9.3 / 100,000$ population. Of the 22,170 tuberculosis cases among persons of known race, $11,524(52.0 \%)$ occurred among whites, and 7,719 ( $34.8 \%$ ) occurred among blacks, for morbidity rates of 5.7 and 26.7 cases per 100,000 population, respectively. In 1984, the National Center for Health Statistics received reports of 1,729 deaths from tuberculosis, for a crude mortality rate of $0.73 / 100,000$ population. Of these, 1,047 ( $60.6 \%$ ) occurred among whites, and 619 ( $35.8 \%$ ) occurred among blacks, for mortality rates of 0.52 and 2.17 deaths per 100,000 population, respectively.

Using a methodology similar to that employed by the Secretary's Task Force on Black and Minority Health (1), age- and sex-specific relative risks and excess morbidity and mortality were determined for the black population, as compared with the white population. Relative risk was defined as the ratio of age- and sex-specific tuberculosis morbidity and mortality rates in the black population compared with the white population. Excess cases and excess deaths were defined as the difference between the number of cases or deaths observed in the black population and the number that would have been expected if the black population had had the same age- and sex-specific morbidity or mortality rates as the white population. This method quantifies the number of cases and deaths that would not have occurred had morbidity or mortality rates for blacks equalled those for whites.

In 1985, the overall age-adjusted relative risk of tuberculosis among persons of known age, race, and sex was 6.2 for black males and 5.1 for black females (Table 2, Table 3). The largest relative risks were among 25- to 44 -year-old blacks and were 9.1 for males and 7.3

## Tuberculosis - Continued

for females. This was also the age group with the largest number of excess cases. Overall, $82.7 \%(6,382)$ of the 7,714 reported tuberculosis cases among blacks of known age and sex were excess cases.

In 1984, the overall age-adjusted relative risk of death from tuberculosis among persons of known age, race, and sex was 6.3 for black males and 5.4 for black females (Table 4, Table 5). The largest relative risks occurred among 25-to 44-year-old blacks and were 16.2 for males and 14.2 for females. The largest number of excess deaths occurred in the 45-to 64-year-old age group. Overall, $83.0 \%$ (513) of the 618 tuberculosis deaths among blacks of known age and sex were excess deaths.

In an analysis by 5-year age groups, the largest number of cases occurred in the 30- to 34-year-old age group for blacks, in the 60- to 64-year-old age group for all whites, and in the 70 - to 74 -year-old age group for non-Hispanic whites. The median age for blacks was 44 years, compared with 57 years for all whites and 62 years for non-Hispanic whites. Of the total 7,714 tuberculosis cases among blacks of known age, $33.1 \%(2,553)$ were $<35$ years of age, as compared with $23.2 \%(2,675)$ among the 11,515 whites and $14.3 \%(1,209)$ among the 8,446 non-Hispanic whites.

The majority of U.S. counties reporting tuberculosis in blacks were in the southeastern and eastern seaboard states and in California (Figure 1). The 10 states with the largest number of tuberculosis cases among blacks were: New York, 1,215; Florida, 714; Georgia, 509; Illinois,

## Tuberculosis - Continued

509; Texas, 468; South Carolina, 435; North Carolina, 401; California, 399; New Jersey, 283; and Alabama, 276. These states reported $67.5 \%(5,209)$ of the 7,719 cases in blacks. Reported by: Div of Tuberculosis Control, Center for Prevention Svcs, CDC.
Editorial Note: 1985 was the first year in which all states reported detailed information on individual cases of tuberculosis, thus allowing for more precise identification of groups at risk for tuberculosis. Two indices were used to summarize tuberculosis morbidity and mortality differentials among blacks as compared with whites. They were 1) relative risk and 2) excess tuberculosis cases and deaths. The relative risks for both morbidity and mortality are disturbingly high among blacks. Age-specific rates of tuberculosis were four- to ninefold higher among blacks than among whites, while mortality rates were 4 - to 16 -fold higher. Eightythree percent of all reported tuberculosis cases among blacks in 1985 represented excess morbidity. Similarly, 83\% of all deaths from tuberculosis occurring among blacks in 1984, represented excess mortality.

- Mortality data in this table are voluntarily reported from 121 cities in the United States, most of which have populations of 100.000 or more.A death is reported by the place of its occurrence and by the week that the death certificate was filed Fetal deaths are not included
- P Pneumonia and influenza
$\dagger$ Because of changes in reporting methods in these 3 Pennsylvania cities. these numbers are partial counts for the current week Complete counts will be available in 4 to 6 weeks
$t+$ Total includes unknown ages.
§ Data not available. Figures are estimates based on average of past 4 weeks

## Tuberculosis - Continued

The Secretary's Task Force on Black and Minority Health examined more than 40 specific causes of death among blacks $<45$ years of age; tuberculosis had the highest relative risk (1). While tuberculosis is becoming more and more a disease of the elderly among whites, particularly non-Hispanic whites (2), it is still a threat to black adults at much younger ages. The finding that $33 \%$ of black tuberculosis patients were $<35$ years of age suggests that many of these cases were potentially preventable (3). The finding that 10 states reported two-thirds of all tuberculosis cases among blacks indicates that the geographic distribution of tuberculosis cases among blacks is largely focal.

Morbidity rates of tuberculosis have progressively declined among both whites and nonwhites over the past three decades; however, it is noteworthy that the ratio of morbidity rates for non-whites compared with those for whites has steadily increased-fro:n 2.9 in 1953 to 5.2 in 1985. This disparity in the burden of tuberculosis experienced by blacks as well as other minority Americans calls for an intensified effort to close this gap and thereby prevent unnecessary disease and death.

In several areas of the nation where both tuberculosis and acquired immunodeficiency syndrome (TB/AIDS) have been investigated, the majority of TB/AIDS patients have been black (Newark, 93\%; Florida, 79\%; Connecticut, 61\%; and New York City, 56\%), while, in San Francisco, blacks comprised a smaller proportion (16\%) (4-8). The degree to which AIDS or human immunodeficiency virus (HIV) infection contributes to tuberculosis morbidity in blacks and other racial/ethnic groups in the nation is currently unknown. It will thus be important for

## Tuberculosis - Continued

health departments to determine the proportion of tuberculosis patients who are seropositive for HIV, as recommended in recently published guidelines ( 9,10 ). Furthermore, the identification of the specific demographic characteristics and geographic distribution of TB/AIDS patients should result in program activities to prevent tuberculosis in persons at increased risk for $\operatorname{AIDS}(9,10)$.

While an earlier MMWR article provided an overview of the health impact of tuberculosis in minorities in the United States (2), this is the first in a subsequent series of articles that will provide more detailed information on tuberculosis in blacks, Asians/Pacific Islanders, American Indians/Alaskan Natives, and Hispanics. Such information indicates that tuberculosis patients in each minority group have specific age/sex characteristics and are located in particular areas within the nation. Such detailed information will allow the development of more precisely targeted programs to prevent and treat tuberculosis in minorities.

FIGURE 1. Counties reporting tuberculosis cases in blacks - United States, 1985

## Epidemiologic Notes and Reports

## Early Syphilis - Broward County, Florida

During the 1980s, the number of early syphilis (primary, secondary, and early latent) cases in Broward County, Florida, has increased-from 328 in 1980 to over 1,150 in 1986 (Figure 2), with a peak in the last half of 1985. From 1984 to 1985, primary and secondary (P\&S) syphilis accounted for most of the increase in Broward County.

This upward trend in P\&S syphilis in Broward County contrasts with the general downward trend observed from 1982 to 1985 in both Florida and the rest of the United States (Figure 3). However, Florida, with 37.6 cases per 100,000 population in 1986, still has the highest rate of P\&S syphilis in the country.

In 1985, rates of early syphilis in Broward County were highest in the 20- to 24-year-old age group and were 446/100,000 for men and 290/100,000 for women in this group. Rates FIGURE 2. Early syphilis cases, by quarter and stage - Broward County, Forida, 1980-1986

*Control measures began in 1986.
FIGURE 3. Rates of primary and secondary syphilis - United States, Florida, and Broward County, 1980-1986

## Syphilis - Continued

of early syphilis adjusted for race were 730/100,000 for blacks, 21/100,000 for whites, and $50 / 100,000$ for Hispanics. Ninety-six percent of cases among women occurred among those of childbearing age (15-44 years of age). As a result, the number of cases of congenital syphilis increased to 25 in 1986; 10 had been reported in 1985, and six, in 1984.

Two studies were performed to identify characteristics of patients reported during the months of greatest increase. First, surveillance data routinely gathered on all patients with early syphilis from 1980 through 1985 were reviewed. Second, detailed clinical and behavioral data were collected from interview records of a systematic $25 \%$ sample of patients diagnosed with syphilis in 1985. These data included reason for seeking medical attention, address of residence, sexual preference for males, and history of prostitution for females. These two data sets were compared with surveillance data from previous years.

In 1985, early syphilis cases occurred primarily among heterosexual blacks in Broward County. Eighty percent (836) of reported cases occurred among blacks; 18\% (187), among whites; and $2 \%$ (20), among Hispanics. In contrast, the percentage of syphilis cases among blacks had ranged from $48 \%$ to $64 \%$ during the 4 previous years. Heterosexual males, who represented $39 \%$ of reported male patients in 1982, constituted $80 \%$ of male patients by 1985. Over 70\% of early syphilis patients reported in 1985 lived in 11 census tracts that together contained less than $15 \%$ of the $1,162,031$ residents of Broward County. The median income in these census tracts is $<\$ 15,000$ per year. The concentration of cases clustered in these census tracts was greater in the latter part of 1985 than in the earlier part of that year.

These results prompted further investigation. The systematic $25 \%$ sample collected for 1985 was extended to include a similar sample of cases reported in the last 6 months of 1984 and the first 3 months of 1986. The sample was then divided into two periods: July 1, 1984, through June 30, 1985, the interval immediately preceding the rapid increase in reporting of cases (endemic cases), and July 1, 1985, through March 31, 1986, the interval of greatest increase (epidemic cases). Female patients diagnosed during the epidemic months were significantly more likely to be prostitutes than those reported during the prior 12 months (odds ratio $[O R]=2.5,95 \%$ confidence interval $[C I]=1.1-6.1$ ). Male patients were significantly more likely to be exclusively heterosexual than those reported in prior months ( $\mathrm{OR}=2.07,95 \% \mathrm{Cl}=1.1-3.9$ ). During the 9 epidemic months as compared with the previous endemic months, more patients were examined for lesions and symptoms, and fewer patients were identified either during screening or as sexual partners of infected persons ( $O R=1.87$, $95 \% \mathrm{Cl}=1.2-2.8$ ). Thus, the ratio of symptomatic (P\&S) to asymptomatic (early latent) patients increased from $0.9: 1$ in the endemic period to $1.3: 1$ in the epidemic period.

The Broward County Department of Health responded to these increases in early syphilis by intensifying surveillance efforts, including active surveillance of laboratories that perform serologic tests for syphilis. Moreover, serologic screening was increased in the highprevalence census tracts and in high-risk populations, including jail inmates of both sexes. County facilities providing prenatal care intensified their rescreening program for asymptomatic women during the third trimester. The ratio of symptomatic to asymptomatic patients decreased, from $1.9: 1$ in the first quarter to $1.4: 1$ in the second quarter of 1986. In the last quarter of 1986, a decrease in early syphilis was observed.

Reported by: C Konigsberg, MD, Broward County Dept of Public Health; JJ Witte, MD, M Wilder, MD, Acting State Epidemiologist, Florida Dept of Health and Rehabilitative Svcs. Epidemiology Research Br, Program Svcs Br, Div of Sexually Transmitted Diseases, Center for Prevention Svcs, CDC.

Editorial Note: The increase in early syphilis in Broward County, as in another outbreak in the 1980s (1), was largely due to heterosexual transmission. In addition, female prostitution,

## Syphilis - Continued

which has contributed to syphilis transmission in other outbreaks (1,2), appears to have played an increasing role in early syphilis occurring in Broward County. Moreover, early syphilis cases are concentrated largely in low-income areas of the county.

Along with national trends (3), early syphilis cases among male homosexuals in Broward County are decreasing both in absolute numbers and in the percentage of total cases. This may be partially explained by changes in lifestyle among male homosexuals in response to the threat of acquired immunodeficiency syndrome. Such changes may reduce their acquisition of syphilis, as it may have reduced their rate of infection with other sexually transmitted pathogens $(4,5)$.

The high rate of early syphilis in women of childbearing age has contributed to increases cases of congenital syphilis. Prenatal serologic testing for syphilis at the initial visit and in the third trimester (6) has been widely implemented and should increase the identification of asymptomatic infected women and prevent congenital syphilis infections. High priority is being given to identifying and treating sexual partners of heterosexual male patients to interrupt transmission to women within the community and to detect infections in womer $\quad$, l : they become pregnant.

The syphilis problem in Florida is not restricted to Broward County. However, serologic screening of sexually active residents of high-incidence areas and in high-risk populations is increasing the number of diagnoses of asymptomatic cases in Broward County. Throughout Florida, contact tracing (7) and serologic screening (8) of populations at risk are being used to identify asymptomatic infected persons and thereby to control the spread of syphilis.

FIGURE I. Reported measles cases - United States, weeks 10-13, 1987

The Morbidity and Mortality Weakly Report is prepared by the Centers for Disease Control, Atlanta, Georgia, and available on a paid subscription basis from the Superintendent of Documents, U.S. Govemment Printing Office. Washington, D.C. 20402, (202) 783-3238.

The data in this report are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the succeeding Friday.

The editor welcomes accounts of interesting cases, outbreaks, environmental hazards, or other public health problems of current interest to health officials. Such reports and anyother matters pertaining to editorial or other textual considerations should be addressed to: ATTN: Editor, Morbidity and Mortality Weekly Report, Centers for Disease Control. Atianta. Georgia 30333.
