## Progress in Chronic Disease Prevention

## Cigarette Smoking - Behavioral Risk Factor Surveillance System, 1988

Cigarette smoking prevalence during 1988 was examined in relation to generation cohort and level of education using data from the Behavioral Risk Factor Surveillance System (BRFSS). In 1988, health departments from 36 states and the District of Columbia participated in the BRFSS monthly random-digit-dialed telephone interviews of adults aged $\geqslant 18$ years ( 1 ). Respondents were asked if they had ever smoked at least 100 cigarettes, if they had ever quit smoking, and if they currently smoked. Current smokers are defined as persons who have smoked at least 100 cigarettes and who continue to smoke; former smokers, as persons who have smoked 100 cigarettes but who no longer smoke; and ever smokers, as current and former smokers combined (2).

Smoking rates among persons aged 18-34 years varied widely by state (Table 1). The proportion of persons who ever smoked ranged from $27.1 \%$ in Utah to $53.1 \%$ in Maine (median: 41.1\%). The proportion of former smokers ranged from 9.1\% in Utah to $20.3 \%$ in Maine (median: 15.1\%). The proportion of persons who currently smoked ranged from 18.1\% in Utah to 37.9\% in Kentucky (median: 26.2\%).

Smoking rates also varied by generation and level of education (Figure 1). Three generations were defined: persons $18-34$ years of age, persons $35-54$ years of age, and persons $\geqslant 55$ years of age. From the older to middle generation, the likelihood of being a current smoker increased substantially with each decrease in level of education. From the middle to younger generation, the likelihood of being a current smoker decreased substantially only for persons with more than a high school education.

## Cigarette Smoking - Continued

Editorial Note: Based on findings from the 1988 BRFSS, young adults with low educational attainment (a correlate of low socioeconomic status) were more likely to be current smokers than were other persons. These results indicate that limited progress has been made in reducing the prevalence of cigarette smoking among young adults of low educational attainment levels-a finding consistent with data from other surveys (3).

Differences in socioeconomic levels by state may account for some of the variation in observed prevalences. Cultural factors, such as emphasis among the largely Mormon population of Utah to limit or abstain from tobacco use, may also affect smoking rates by state (4). Other determinants that may vary by state include: the extent of smoking prevention activities (including school programs emphasizing smoking prevention [5]); state cigarette excise tax rates (2); and the intensity of tobacco advertising or promotional events sponsored by the tobacco industry (6).

Recent smoking prevention strategies have been directed toward young persons through the school, home, workplace, and community (2). Life-skills instruction on resisting smoking has been effective in reducing smoking initiation (7). Data from the BRFSS and National Health Interview Surveys (3) show that educational attainment levels are becoming an increasingly important factor in determining whether young persons smoke; therefore, effective smoking prevention strategies need to be targeted toward children and adolescents in groups with generally low educational attainment.

## International Notes

## Nutritional and Health Status of Displaced Persons - Sudan, 1988-1989

Since 1987, more than 1.3 million persons have fled civil strife in southern Sudan and settled in urban areas (e.g., the capital city of Khartoum) or in camps in the northern regions of the country (Figure 1). In August 1988, after extensive flooding destroyed the dwellings of 750,000 displaced persons (DP) living in outlying areas around Khartoum, $23 \%$ of children < 5 years of age were moderately or severely undernourished (1). In response to recommendations for continued health-status monitoring, from September 1988 through February 1989, 71 surveys (each with 30 randomly chosen clusters of 10 children) were conducted in 27 different sites in Khartoum. A total of 17,639 children $<5$ years of age (or $<110 \mathrm{~cm}$ in height if age was unknown) were weighed and measured. Children $<80 \%$ of the median weight-forheight ( $\mathrm{Wt} / \mathrm{Ht}$ ) for children $<5$ years of age (2) were classified as acutely undernourished (children $70 \%-79 \%$ of the median $\mathrm{Wt} / \mathrm{Ht}$ were classified as moderately undernourished and children $<70 \%$ of the median $\mathrm{Wt} / \mathrm{Ht}$ as severely undernourished).

FIGURE 1. Location of displaced persons - Sudan, 1988-1989

Displaced Persons - Continued
In September and October 1988, the mean prevalence of acute undernutrition among displaced children in surveyed communities in Khartoum was 19.9\%. By February 1989, the mean prevalence in those communities resurveyed at least once had declined to $10.9 \%$.

In southern Darfur, approximately 500 km southwest of Khartoum, >80,000 additional DP live in temporary camps. Cluster surveys were conducted in seven camps where food rations were distributed biweekly. The surveys showed a decline in the prevalence of acute undernutrition in children <5 years of age from May 1988 (mean: 35.9\%; range: 25.0\%-43.0\%) through February-March 1989 (mean: 6.4\%; range: $4.6 \%-9.4 \%$ ). The mean monthly crude mortality rate (CMR) for all ages in these camps also declined from April 1988 (11.8 deaths per 1000 population; range: 4.9-18.3) to January 1989 ( 0.4 per 1000; range 0-0.7) (Figure 2). In April 1988, the mean monthly CMR for children $<5$ years of age was 19.0 deaths per 1000 children; diarrhea and meningitis were the leading reported causes of childhood death. By January 1989, this rate had declined to 6.0 deaths per 1000 children, and the leading causes of death were diarrhea and acute respiratory infections.

To reduce the risk of measles, mass immunization campaigns were conducted in the seven camps targeting all children 6 months to 5 years of age. By March-April 1989, measles vaccination coverage levels were $80 \%-95 \%$ in children aged 12-23 months in these camps.

Technical Support Div, International Health Program Office, CDC.
Editorial Note: In refugee and displaced populations, mortality rates in children $<5$ years of age increase in relation to the prevalence of acute undernutrition $(3,4)$.

FIGURE 2. Range and mean of crude mortality rates per 1000 population in seven camps for displaced persons, by month - southern Darfur, Sudan, April 1988January 1989

## Displaced Persons - Continued

For the southern Darfur camps, the monthly CMR in April 1988 (11.8 per 1000) is more than five times that expected in the poorest developing nations in Africa ( $<2$ deaths per 1000 per month) (5). In a DP camp located in southern Kordofan (Figure 1), the monthly CMR in July 1988 ( 120 per 1000) was among the highest reported for any famine-affected population since 1969 (CDC, unpublished data). Mortality data collected under adverse conditions such as those in southern Darfur must be interpreted with caution. However, the observed decline in mortality is consistent with the reported decline in undernutrition prevalence.

Most undernutrition-related childhood deaths can be prevented by provision of food of adequate caloric content (minimum of 1900 kilocalories per person per day [all ages]) and quality (appropriate amounts of carbohydrates, proteins, fats, and essential micronutrients [e.g., vitamins A, B complex, and C]) $(6,7)$. The prevalence of undernutrition has declined in most areas surveyed while the number of children in the camps in southern Darfur has reportedly increased; however, the deaths of the most severely undernourished children could account, at least in part, for the lower prevalence of undernutrition reported (8).

[^2]**Pneumonia and influenza.
$\dagger$ Because of changes in reporting methods in these 3 Pennsylvania cities, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
$\dagger$ tTotal includes unknown ages.
\$Data not available. Figures are estimates based on average of past available 4 weeks.

Displaced Persons - Continued
In urban areas, general food rations were not distributed, although some communities have had supplementary and/or therapeutic feeding programs for acutely undernourished children. The administration of (and access of DP to) these feeding programs, as well as the local availability of food and employment, may have influenced levels of childhood undernutrition. In the camps in southern Darfur, food rations were routinely distributed to displaced families, although rations were sometimes inadequate because of local shortages of foodstocks and difficulties in transporting supplies through the affected areas.

Measles has been a leading cause of childhood death in some refugee and displaced populations (4). The high measles vaccination coverage in displaced children living in the seven camps in southern Darfur may have prevented many measles-related deaths in those locations. CDC has recommended that measles vaccination of children be an early priority in the care of refugees and DP (9).

## Surveillance of Influenza-Like Diseases through a National Computer Network - France, 1984-1989

In France, national surveillance of influenza-like syndromes has been continuous since November 1984 through the French Communicable Diseases Computer Network (FCDN). This report describes epidemics documented from 1984 to 1989 and emphasizes the 1988-89 epidemic.

FCDN was initiated under the joint auspices of the Institut National de la Sante et de la Recherche Médicale (comparable to the National Institutes of Health in the United States) and the Direction Générale de la Santé (the national department of health). FCDN uses electronic communications to facilitate collection, analysis, and redistribution of epidemiologic information about communicable diseases (1,2). Notifiable disease data collected by France's 96 regional departments of health are

## Influenza Surveillance - Continued

forwarded to the national department of health, analyzed, and redistributed to all users of the network through a weekly electronic bulletin.

FCDN collects epidemiologic data from general practitioners who volunteer to provide sentinel notification of epidemics. In November 1984, 50 sentinel general practitioners (SGPs) participated in FCDN; the number of participants has increased steadily and, since January 1988, has included 550, or approximately $1 \%$ of, French general practitioners. The SGPs were selected to be demographically representative of all general practitioners (i.e., by age, sex, geographic distribution, and type of practice). SGPs use terminals or personal computers with modems to report influenza-like syndromes and other selected conditions (e.g., measles, mumps, and viral hepatitis) to FCDN's host computer. SGPs can access the host computer 24 hours a day but must access the computer at least once a week-even if they have no cases to report. In particular, SGPs report the age, sex, and vaccination status of patients meeting the World Health Organization definition of influenza-like syndromes (i.e., a sudden fever of $>39 \mathrm{C}$, myalgia, and respiratory symptoms) (3). Estimates of the incidences of influenza-like syndromes are determined by geographic regions and redistributed on FCDN 4-10 days after the report of diagnosis.

From November 1984 through April 1989, a total of 89,705 cases of influenza-like syndromes were reported. In the 1984-85, 1985-86, and 1986-87 epidemics, increased activity began in the second half of December, peaked in early February, and ended by mid-April (Figure 1). During the respective three periods, maximal incidences were 12.7, 9.4, and 5.6 cases per 1000 residents. Although the 1987-88 epidemic began considerably later (late February), the maximal estimated incidence was comparable ( 5.8 cases per 1000).

In 1988-89, however, increased activity began in mid-November, peaked at 18.3 cases per 1000 residents during the second week of December, and ended in late January. In addition, the 1988-89 epidemic was characterized by a different distribution among age groups (Figure 1)-predominating in persons aged 0-17 years and affecting a smaller proportion of elderly persons than previous epidemics. Among

FIGURE 1. Weekly incidence rate per 1000 cases of influenza-like syndrome, by patient age group - France, 1984-1989

## Influenza Surveillance - Continued

persons aged 5-17 years, the peak incidence was 31.4 cases per 1000, compared with 2.4 cases per 1000 persons aged $\geqslant 65$ years. Thus, the $1988-89$ epidemic occurred earlier, was of shorter duration, and affected primarily younger age groups while sparing the elderly.

From 1984 to 1989, the French Reference Centers on Influenza ("France Nord" and "France Sud") provided weekly results of viral isolates. For the 1984-85, 1985-86, and 1986-87 epidemics, most influenza isolates were $A(H 3 N 2)$ and $A(H 1 N 1)$ viruses. In 1987-88, influenza B virus was most frequently isolated. In 1988-89, influenza $\mathrm{A}(\mathrm{H} 1 \mathrm{~N} 1)$ predominated, although sporadic $\mathrm{A}(\mathrm{H} 3 \mathrm{~N} 2)$ activity occurred (4). Respiratory syncytial virus (RSV) was also isolated during each of the five periods. The predominance of illness reported in the 0-4-year age group (peak incidence: 23.5 cases per 1000 persons) may reflect RSV activity during the 1988-89 epidemic.
Reported by: J Ménarès, Ph Garnerin, AJ Valleron, Unité de Recherches Biomathématiques et Biostatistiques de I'Institut National de la Santé et de la Recherche Médicale, Université Paris 7, Paris. Influenza Br and Epidemiology Office, Div of Viral and Rickettsial Diseases, Center for Infectious Diseases, CDC.
Editorial Note: A major strength of the FCDN system for surveillance of infectious diseases is the rapidity of the collection, analysis, and distribution of data. The reports of influenza-like illness from SGPs, combined with information on virus isolations provided by the French Reference Centers, provide timely information for physicians who need to make decisions each year about both the administration of influenza vaccine and use of antiviral agents that are effective only against type A influenza viruses. Rapid diagnostic techniques to determine the type of influenza reported by the SGPs would further enhance the usefulness of this innovative system.

## Current Trends

## National Survey of Trauma Registries - United States, 1987

In 1988, a National Academy of Sciences panel recommended that CDC promote the development of a national data set for injury epidemiology, including standardized trauma registries in each state (1). The panel emphasized that existing deficiencies in injury surveillance have hampered the implementation of effective public health measures for injury control. In January 1988, a workshop* was held at CDC to develop standard case criteria and a uniform, minimum data set for trauma registries (TRs) (2). TRs are information systems maintained primarily to monitor the pre-

[^3]
## Trauma Registries - Continued

hospital and hospital care of severely injured persons (3). Hospital TRs are located at individual institutions; regional and state TRs are central registries that aggregate data from two or more hospital TRs.

In 1987, two mailout surveys were conducted by the emergency services department of the San Francisco General Hospital, under the auspices of the National Association of State Emergency Medical Services Directors. In the first survey, emergency medical service directors responded from all 50 states and the District of Columbia. Ten states ${ }^{\dagger}$ had legal requirements for the establishment of central TRs; six of these states required participation by all acute-care hospitals, and four required participation by only trauma center hospitals.

In the second survey, of 248 trauma coordinators (TCs) responsible for maintaining TRs at the hospital, regional, and state levels, 147 ( $59 \%$ ) responded. TRs were operational in a minimum of 105 hospitals in 35 states. TRs differed in case criteria, data content, coding conventions, and the manner in which data were used.

Emergency medical service directors, TCs, and others responsible for developing TRs must choose from a variety of existing systems or develop their own. Consensus development of standards for TRs was endorsed by $80 \%$ of the state emergency medical service directors and 66\% of TCs who participated in the surveys.
Reported by: RH Cales, MD, San Francisco General Hospital. ST Kearns, MSN, Palm Beach County Emergency Medical Svcs; LS Jordan, Office of Emergency Medical Svcs, Florida Dept of Health and Rehabilitative Svcs. Biometrics Br, Div of Injury Epidemiology and Control, Center for Environmental Health and Injury Control, CDC.
Editorial Note: Hospital and central TRs can be used to evaluate the quality of trauma care. For example, in San Diego County, California, the Division of Emergency Medical Services monitors hospital trauma care using data from three sources: TRs maintained at six trauma center hospitals, traumatic injury reports (a subset of the TR data) submitted by 24 nontrauma center hospitals, and the county coroner's records of deaths of patients who received hospital care for trauma (4). The San Diego County Medical Audit Committee (MAC), composed of representatives from the Division of Emergency Medical Services, trauma center and nontrauma center hospitals, and the coroner's office, meets monthly and reviews morbidity and mortality among patients hospitalized for major trauma. The MAC classifies the deaths as nonpreventable, potentially salvageable, or preventable if treatment had been altered. These reviews have found that preventable deaths declined among hospital trauma patients following the implementation of a regional trauma system in San Diego County in $1984(5,6)$.

Data from TRs can be used to support primary prevention initiatives. For example, in Virginia, a legislative subcommittee used data from the Virginia Statewide Trauma Registry and other data sources to recommend legislation regulating the use of all-terrain vehicles (ATVs) (7). From January 1987 through August 1988, at least 120 persons sustained ATV-related injuries in Virginia, including 27 persons $<12$ years of age and 19 persons aged 12-16 years. Legislation enacted in 1989 by the General Assembly of Virginia prohibits use of ATVs by persons $<12$ years of age, restricts use by those aged 12-16 years, requires operators to wear helmets, and forbids passengers (8).

[^4]Trauma Registries - Continued
TRs are also a potential source of data for ongoing surveillance of morbidity and mortality resulting from specific types of injuries, such as blunt trauma, penetrating trauma, and burns (9).

The TR workshop provided the first opportunity for a multidisciplinary group of researchers, medical practitioners, public health officials, and health-care administrators to participate in the formulation of standards for TRs. Based on the results of the workshop, recommendations for TRs (2) and a comprehensive guide to the recommended data definitions and coding formats for TRs have been developed and are available from CDC. ${ }^{5}$

## Notice to Readers

## Announcement of Symposium on Statistical Methods for Evaluation of Intervention and Prevention Strategies

CDC and the Agency for Toxic Substances and Disease Registry will cosponsor the Symposium on Statistical Methods for Evaluation of Intervention and Prevention Strategies, December 5 and 6, 1990, in Atlanta. There is no registration fee. The symposium will provide a forum for current research in 1) statistical methods for evaluation and 2) innovative applications of methods for evaluation of health program intervention and disease prevention strategies.

Abstracts must be postmarked by April 20 and may be submitted on the following evaluation topics: study design, analytic methods, statistical modeling, use of survey or surveillance data, and innovative applications of methods.

Abstract forms and additional information are available from Gladys H. Reynolds, Ph.D., Chair, 1990 Symposium on Statistical Methods for Evaluation of Intervention and Prevention Strategies, Office of the Director, Mailstop D39, CDC, Atlanta, GA 30333.

The Morbidity and Mortality Weekly Report is prepared by the Centers for Disease Control, Atlanta, Georgia, and available on a paid subscription basis from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402, (202) 783-3238.

The data in this report are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the succeeding Friday. The editor welcomes accounts of interesting cases, outbreaks, environmental hazards, or other public health problems of current interest to health officials. Such reports and any other matters pertaining to editorial or other textual considerations should be addressed to: Editor, Morbidity and Mortality Weekly Report, Centers for Disease Control, Atlanta, Georgia 30333; telephone (404) 332-4555.
