## Topics in Minority Health

## Homicide Among Young Black Males United States, 1978-1987

In 1987, homicide was the 12th leading cause of death in the United States and a leading cause of premature mortality (i.e., years of potential life lost before age 65). Homicide affects all age, race, and sex groups and is the leading cause of death for young black males (15-24 years of age) (1). Both the 1990 and Year 2000 Health Objectives for the Nation target a reduction in the homicide rate among this population ( 2,3 ). This report uses mortality statistics from CDC's National Center for Health Statistics (NCHS) to characterize homicides* among young black males for 1978-1987.

From 1978 though 1987, 20,315 young black males died as a result of homicide, for an average annual rate of 73.1 per 100,000. In 1987, homicides accounted for $42 \%$ of deaths among young black males, and the homicide rate for this group was 84.6 per 100,000 -the highest rate of the decade and $40 \%$ higher than in 1984. From 1978 through 1987, firearms ${ }^{\dagger}$ accounted for 15,781 ( $78 \%$ ) homicides among young black males. Yearly fluctuations in total homicides corresponded closely with the pattern for homicides committed with firearms (Figure 1). From 1984 through 1987, the nonfirearm homicide rate for young black males increased $7 \%$ (from 14.4 to 15.4 per 100,000 ), and the firearm homicide rate increased by $50 \%$ (from 46.2 to 69.3 per 100,000 ). Overall, firearm-related homicides accounted for $96 \%$ of the increase in the homicide rate for young black males from 1984 through 1987.

The percent increase in homicide rates from 1984 through 1987 was greater for adolescent black males aged 15-19 years ( $55 \%$ [from 38.5 to 59.6 per 100,000]) than for those aged $20-24$ years ( $33 \%$ [from 83.3 to 111.1 per 100,000]). For adolescent black males, both the homicide rate and the proportion of homicides committed with firearms were highest in 1987 ( 59.6 per 100,000 and 83\%, respectively). In 1987, 34\% of deaths among adolescent black males were homicides committed with a firearm.

[^0]Homicide - Continued
From 1978 through 1987, annual homicide rates for young black males were four to five times higher than for young black females, five to eight times higher than for young white males, and 16-22 times higher than for young white females (Figure 2). Since 1984, the disparity between homicide rates for young black males and other racial/sex groups increased substantially; for example, a comparison of 1984 with 1987 indicates that the ratio of homicide rates for black males to those for white males increased $38 \%$, from 5.6 to 7.7 (Table 1).

In 1987, of the 23 states with a population of young black males sufficient to enable stable estimates for homicide rates (4), 14 had a homicide rate for this group that exceeded the 1990 health objective of $<60$ per 100,000 (Figure 3). Rates exceeded 100 per 100,000 in California, Florida, Michigan, Missouri, New York, and the District of Columbia. ${ }^{5}$ In addition, from 1984 to 1987, the homicide rate for young black males increased 22\% in Missouri, 40\% in the District of Columbia, 64\% in New York, 68\% in Florida, $71 \%$ in California, and $76 \%$ in Michigan.
Reported by: Intentional Injuries Section, Epidemiology Br, Div of Injury Control, Center for Environmental Health and Injury Control, CDC.
Editorial Note: The disproportionate impact of homicide among young black males was recognized in the 1990 health objective that targeted a reduction in the homicide rate for this group to $<60$ per 100,000 (2). Although homicides declined among young black males during the early 1980s, from 1984 through 1987, the homicide rate for this group increased sharply. Based on data from the Federal Bureau of Investigation's Uniform Crime Reporting System through June 1990, homicide rates have continued to increase since $1987^{\circ}$ (5).

[^1]FIGURE 1. Firearm- and nonfirearm-associated homicide rates* for black males 15-24 years of age - United States, 1978-1987

*Per 100,000 population.

Homicide - Continued
This report identified four disturbing features in the epidemiology of homicide in young black males. First, firearm-associated homicides accounted for $>80 \%$ of deaths and $>95 \%$ of the recent large increase. Second, the increase since 1984 was especially marked among adolescent black males. Third, the already large disparity in homicide rates between black males and other racial/sex groups has widened. Fourth, certain areas had the highest rates, accounted for most cases, and had considerable recent increases in homicide rates. For example, the six areas with homicide rates $>100$ per 100,000 persons contained $29 \%$ of the young black male population but accounted for $51 \%$ of all homicide-attributable deaths in this group in 1987. If these six areas had attained the 1990 health objective for homicide rates for young black males, the homicide rate for this population in 1987 would have decreased $31 \%$.

Homicide among young black males and other groups can result from behaviors such as domestic violence, child abuse, rape, and physical fighting among acquaintances. Despite a common perception that victims of homicide are usually killed by

## Homicide - Continued

unknown assailants during robberies or drug-related crimes, more than half of all homicide victims are killed by persons known to them. Factors identified as potentially important contributors to homicide include immediate access to firearms, alcohol and substance abuse, drug trafficking, poverty, racial discrimination, and cultural acceptance of violent behavior (6-8).

Because research and evaluation efforts have not yet demonstrated effective programmatic approaches to prevent homicide, priority areas for research and intervention should target 1) the causes for the recent rise in homicide among young black males; 2) prevention of firearm-related morbidity and mortality; 3) improved understanding of the role of alcohol, drugs, and drug trafficking in homicide; 4) prevention of violent, aggressive behavior; and 5) identification of modifiable risk factors for homicide among urban youths of lower socioeconomic status.

Compared with other injury-control priorities, public health efforts to prevent homicide among young black males and other persons in high-risk groups have only recently been implemented. In 1987, only two ( $0.6 \%$ ) of 325 injury-prevention programs based in state health departments focused on homicide (9). Since 1986, only one ( $0.2 \%$ ) of 552 award-winning community-based health promotion projects specifically has included homicide (CDC, unpublished data). Proposed interventions to reduce homicides include drug- and alcohol-abuse prevention, firearm control, interventions directed at the effects of television violence, school-based interventions, and public education (6). Such projects should be carefully designed and rigorously evaluated so that successful programs can be replicated.

FIGURE 3. Homicide rates* for black males 15-24 years of age, by state - United States, 1987

[^3]Homicide - Continued
At the national level, 30 of the year 2000 health objectives target a reduction in the incidence of homicide and violent behaviors among young black males and persons in other high-risk groups (3). At the local level, communities with high homicide rates can develop and implement projects using established principles of health promotion (10). These include the formation of coalitions of community leaders and organizations and reviews of local data concerning homicides and violent behaviors. Local health agencies should consider developing homicide-prevention programs and collaborate with social services, the criminal justice system, and other community services in the planning, implementation, and evaluation of community projects. Coordinated efforts among multiple agencies are likely to be important components of national efforts to reduce homicide rates for young black males and other persons.

The identification of promising approaches to homicide and violence prevention will be the focus of a conference on minority violence cosponsored by Morehouse University and CDC on December 10-12, 1990, in Atlanta.

## Epidemiologic Notes and Reports

## Imported Malaria Associated with Malariotherapy of Lyme Disease - New Jersey

In November 1990, a physician in New Jersey reported two cases of imported vivax malaria to the New Jersey State Department of Health. Both of these patients were among five patients who had been diagnosed with late-stage Lyme disease and referred by the physician to sources in Mexico for intramuscular injections of blood containing Plasmodium vivax parasites. The malaria donors reportedly had been

Malaria - Continued
screened for serologic evidence of syphilis, hepatitis B, and human immunodeficiency virus infection. On return to New Jersey, the two patients were diagnosed with parasitemia 3 days and 14 days after the injection, respectively. Approximately 3 weeks after onset of malaria, the patients were treated with chloroquine with satisfactory response.
Reported by: K Mertz, MD, KC Spitalny, MD, State Epidemiologist, New Jersey State Dept of Health. Bacterial Zoonoses Br, Div of Vector-Borne Infectious Diseases and Malaria Br, Div of Parasitic Diseases, Center for Infectious Diseases, CDC.
Editorial Note: Lyme disease, caused by the tick-transmitted spirochete Borrelia burgdorferi, is a zoonotic disease with protean clinical manifestations, including late-stage arthritic and neurologic manifestations (1). Lyme disease has been reported from 46 states and is highly endemic in some areas of the northeastern and mid-Atlantic regions (including New Jersey), the north central region, and the Pacific coastal region (2). Antibiotics are effective in treating both early and late stages of Lyme disease ( 1,3 ). In some patients, however, symptoms persist despite appropriate treatment $(3,4)$. Causes could include persistent spirochetosis (5), irreversible tissue damage ( 3,4 ), autoimmunity (3), and misdiagnosis (6).

Induced vivax malaria recently was proposed for the treatment of neuroborreliosis (7). The precedent for this approach is the obsolete practice of malariotherapy for the treatment of neurosyphilis, which was widely used in the preantibiotic era (8). Controlled studies of malariotherapy for neurosyphilis never were done; published results suggested that the response to treatment was unpredictable and primarily clinical and that the duration of remission was variable (9). Changes in serologic status generally did not correlate with clinical improvement, suggesting that malariotherapy had minimal, if any, effect on the underlying spirochetal infection (9). Malariotherapy for syphilis was discontinued when penicillin and other effective antibiotics became available.

For at least three reasons, induced malaria is not recommended for the treatment of Lyme disease. First, no scientific studies exist of the efficacy of this procedure for the treatment of this disease. Second, malariotherapy causes iatrogenic morbidity and carries a direct risk for death from complications of $P$. vivax infection (8) or from coinfection with other, undetected, bloodborne pathogens. Third, a small but finite risk exists of local transmission of malaria when parasitemic persons enter the United States (10). latrogenic malaria cases should be reported promptly to local and state public health agencies.

## Current Trends

## Trends in Lung Cancer Incidence and Mortality United States, 1980-1987

Lung cancer is the most common fatal malignant neoplasm in the United States. Based on current smoking patterns, the substantial public health burden of smokingrelated lung cancer will continue during the next several decades. This report describes trends in lung cancer incidence from 1980 through 1986 and lung cancer mortality from 1980 through 1987.

Incident cases* for 1980-1986 were determined using data from the Surveillance, Epidemiology, and End Results program of the National Cancer Institute ( NCl ). Deaths ${ }^{\dagger}$ for 1980-1987 were identified using total mentions from the multiple cause-of-death data files compiled by CDC's National Center for Health Statistics. The denominators for both rates were derived from intercensal population estimates (1). Rates were standardized to the 1970 age distribution of the U.S. population. Racespecific rates are not reported for races other than white and black because appropriate denominators were not available.

From 1980 through 1986, the age-adjusted lung cancer incidence rate per 100,000 persons increased from 52.4 to 55.5 (Table 1). ${ }^{5}$ Although rates fluctuated for males, for females, they increased steadily from 28.4 to 36.3 per 100,000. Incidence in males was higher among blacks than whites; rates for females did not differ by race (Table 1).

[^4]§Data not available. Figures are estimates based on average of past available 4 weeks.

## Lung Cancer - Continued

Trends for lung cancer death rates paralleled those for incidence rates. From 1980 through 1987, the age-adjusted death rate per 100,000 persons increased from 46.2 to 52.1. Although death rates for males did not change substantially, rates were consistently higher for blacks than for whites. For females, the rates increased steadily but did not differ by race.

For males, lung cancer death rates were higher for older age groups but did not change substantially for any age group. For women aged $\geqslant 55$ years, death rates increased consistently for both blacks and whites (Figure 1). The greatest difference by race occurred for men aged $35-44$ years; for this age group, the death rate was 2.3 times higher for blacks than for whites (Figure 2).

FIGURE 1. Age-specific lung cancer death rates,* by race - United States, 1980-1987

*Per 100,000 women.

Lung Cancer - Continued
Reported by: Chronic Disease Surveillance Br, Office of Surveillance and Analysis and Program Svcs Activity, Office on Smoking and Health, Center for Chionic Disease Prevention and Health Promotion, CDC.
Editorial Note: Lung cancer is the second leading cause of death among black males (after coronary heart disease) (2). The excess morbidity and mortality from lung cancer among black men compared with white men is greatest for the 35- to 64-year age group (3).

Cigarette smoking accounts for approximately $85 \%$ of lung cancer cases (4). Since 1914, national surveys have consistently shown that the prevalence of smoking has been higher in black men than in white men ( 5 ); in addition, blacks tend to use brands with higher tar and nicotine content $(6,7)$. However, black men and women initiate smoking at slightly older ages than white men and women (4) and smoke fewer cigarettes per day. The extent to which these differences in smoking patterns or other host or environmental factors contribute to the difference in lung cancer mortality is unknown.

The higher prevalence of smoking among black men and women reflects a decreased likelihood of quitting rather than a difference in initiation; this decreased likelihood is characteristic of all socioeconomic levels and ages (5,6). Smokingcessation programs that recognize the smoking patterns of black men and women may be more effective and ultimately assist in lowering the lung cancer death rate.

For both black and white femaies, the similar increases in age-specific lung cancer incidence and death rates are consistent with historically increasing trends in smoking prevalence. Based on these trends, the increases in lung cancer incidence and mortality for females are not projected to plateau until after the year 2013 (8).

Epidemiologic and clinical studies have provided extensive information on the health benefits of smoking cessation (9). For example, after 10 years of smoking

FIGURE 2. Average annual black-to-white death rate ratio, by age and sex - United States, 1980-1987

Lung Cancer - Continued
cessation, the risk for lung cancer is reduced to $30 \%-50 \%$ of the risk among continuing smokers (9). The national health objectives for the year 2000 include reducing the prevalence of cigarette smoking among adults to $\leqslant 15 \%$, from a 1987 baseline of $29 \%$ ( 10 ). Recent declines in smoking prevalence, especially among black males, are encouraging. However, continued progress in both smoking-prevention and smoking-cessation efforts is essential to achieving this objective and protecting the population from the health hazards of tobacco use. These efforts must take into account the adverse effects of marketing strategies by the tobacco industry that target high-risk groups.

Notices to Readers

## Availability of "Chronic Disease Reports" Compilation

The "Chronic Disease Reports," a series of 12 articles published in volumes 38 and 39 of $M M W R$, has been amended and published in a compilation. MMWR readers may request single copies or make arrangements to borrow a camera-ready copy for reproduction. Write to: Assistant Director for Science, Center for Chronic Disease Prevention and Health Promotion, Mailstop A-37, CDC, Atlanta, GA 30333.

## Report on National HIV Seroprevalence Surveys

CDC collaborates with state and local health departments, other federal agencies, blood collection agencies, and medical research institutions to conduct human immunodeficiency virus (HIV) seroprevalence surveys in a variety of sentinel populations. Together these surveys constitute a serosurveillance network to monitor the prevalence of HIV infection in the United States. This "family" of surveys includes studies among patients at sexually transmitted disease clinics, drug-treatment centers, women's health clinics, and tuberculosis clinics in 44 cities; patients at sentinel hospitals in 30 cities and in a network of ambulatory-care practices; childbearing women in 44 states, the District of Columbia, and Puerto Rico; and blood donors, applicants for military service, and Job Corps entrants (Figure 1).

Single copies of the publication, National HIV Seroprevalence Surveys - Summary of Results: Data from Serosurveillance Activities through 1989 (1), are available free of charge from the National AIDS Information Clearinghouse, P.O. Box 6003, Rockville, MD 20850; telephone (800) 458-5231.

## Fourth Supplement to NIOSH Manual of Analytical Methods, Third Edition

CDC's National Institute for Occupational Safety and Health (NIOSH) has issued the fourth supplement (dated August 15, 1990) to the NIOSH Manual of Analytical Methods (NMAM), third edition. The supplement contains 51 sampling and analytical methods; it includes reprints of 43 second-edition methods, each with a first-page update sheet attached, and eight third-edition methods that are either new or revised. The supplement also contains revisions of analytical procedures for fluoride and hydrogen cyanide, as well as new sampling and analytical methods for several important air contaminants including 4,4'-methylenedianiline, bromine, chlorine, aspartame (1-methyl N-L-alpha-aspartyl-L-phenylalanine), methyl tert-butyl ether, and lead. The supplement includes a cross-index to the seven-volume second edition of the NMAM.

The supplement will be automatically mailed to persons who have previously purchased the NMAM, third edition. For other persons, copies of the NMAM, third edition, and all supplements are available from the U.S. Government Printing Office, Washington, DC 20402; telephone (202) 783-3238. Subscription service consists of a basic manual, Volumes 1 and 2, and four supplements (first supplement, 1985; the second, 1987; the third, 1989; and the fourth, 1990). Subscription price: domestic\$47.00; foreign - $\$ 58.75$.
Reported by: Div of Physical Sciences and Engineering, National Institute for Occupational Safety and Health, CDC.

## Erratum: Vol. 38, No. 54

The MMWR Summary of Notifiable Diseases, United States, 1989 (published October 5, 1990) contains an incorrect graph on page 19. The graph titled "ARBOVIRAL INFECTIONS (of the central nervous system) - Cases due to Eastern equine encephalitis virus, by month, United States, 1975-1989" should be replaced by the following graph.

ARBOVIRAL INFECTIONS (of the central nervous system) - Cases due to Eastern equine encephalitis virus, by month, United States, 1975-1989

Reported cases of measles, by state - United States, weeks 44-48, 1990

The Morbidity and Mortality Weekly Report is prepared by the Centers for Disease Control，Atlanta， Georgia，and is available on a paid subscription basis from the Superintendent of Documents，U．S． Government Printing Office，Washington，D．C．20402，（202）783－3238．

The data in this report are provisional，based on weekly reports to CDC by state health departments．The reporting week concludes at close of business on Friday；compiled data on a national basis are officially released to the public on the succeeding Friday．Accounts of interesting cases，outbreaks，environmental hazards，or other public health problems of current interest to health officials，as well as matters pertaining to editorial or other textual considerations should be addressed to：Editor，Morbidity and Mortality Weekly Report，Mailstop C－08，Centers for Disease Control，Atlanta，Georgia 30333；telephone（404）332－4555．

[^0]:    *International Classification of Diseases, eighth (ICD-8) and ninth (ICD-9) revisions, rubrics E960-E969.
    ${ }^{\dagger}$ Firearm-related homicides are defined as ICD-8 and ICD-9 rubric E965. Although this rubric includes deaths from explosives, such deaths account for $<0.1 \%$ of total homicides from firearms and explosives.

[^1]:    ${ }^{5}$ Florida, 119.7; Missouri, 130.5; New York, 135.3; the District of Columbia, 135.8; California, 153.9; and Michigan, 231.6.
    ${ }^{\top}$ Recently released mortality statistics from NCHS indicate that the homicide rate for young black males increased 19\% from 1987 to 1988.

[^2]:    *Per 100,000 population.
    ${ }^{\dagger}$ Ratios compare rates for black males to rates for other racial/sex groups.

[^3]:    *Per 100,000 population.
    ${ }^{\dagger}$ Population of black males aged 15-24 years was too small to enable stable rate estimates (4).

[^4]:    *Mortality data in this table are voluntarily reported from 121 cities in the United States, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
    **Pneumonia and influenza.
    †Because of changes in reporting methods in these 3 Pennsylvania cities, these numbers are partial counts for the current week.
    Complete counts will be available in 4 to 6 weeks.
    $\dagger \dagger$ Total includes unknown ages.
