

- 285 Acute Traumatic Spinal Cord Injury Surveillance — United States, 1987  
286 Update: Acquired Immunodeficiency Syndrome (AIDS) — Worldwide

## MORBIDITY AND MORTALITY WEEKLY REPORT

---

**Acute Traumatic Spinal Cord Injury Surveillance —  
United States, 1987**

In 1987, the Council of State and Territorial Epidemiologists (CSTE) recommended designating traumatic spinal cord injuries (SCIs) as the first injury condition reportable to state health agencies and to CDC. In that same year, two surveys were conducted to identify existing registries for SCIs in the United States. One survey, which was conducted by the Spinal Cord Injury Program in Florida, used a computer-based information exchange system to gather information from vocational rehabilitation agencies. Agencies in 82% (42 of 51) of the states and the District of Columbia replied. The second, a telephone survey, was conducted independently by the National Spinal Cord Injury Association (NSCIA).<sup>\*</sup> State health departments in all 50 states<sup>†</sup> were contacted.

Each survey identified eight states as having SCI registries; however, the results of the surveys differed. These results and information obtained by personal communication indicate that the following 14 states have registries for traumatic SCI: Alabama, Arkansas, Colorado, Florida, Georgia, Iowa, Louisiana, Maryland, Missouri, Oklahoma, New Jersey, North Dakota, Virginia, and West Virginia. In ten states, reporting is mandated by law; it is voluntary in the remaining four states. In most states, SCI data are collected to aid in planning for rehabilitative services.

*Reported by: the Spinal Cord Injury Program, Div of Vocational Rehabilitation, Dept of Labor and Employment Security, Tallahassee, Florida. J Spack, JD, National Spinal Cord Injury Assoc, Woburn, Massachusetts. GR Istre, MD, State Epidemiologist, Oklahoma State Dept of Health. Div of Injury Epidemiology and Control, Center for Environmental Health and Injury Control, CDC.*

**Editorial Note:** CSTE's recommendation to designate SCIs as reportable was based on the magnitude of the morbidity and mortality due to traumatic SCIs, the cost associated with these injuries, and the potential for their prevention. It is a practical choice because the number of cases is manageable and consensus can be reached on the case definition.

Estimates of the incidence of acute traumatic SCI in the United States range between 28 and 50 injuries per million persons per year (1). At present, there are over 200,000 cases of SCI in the United States (2). Older adolescent and young adult males are at high risk for SCI. The consequences of injury for persons in these age groups include reduced lifetime employment, limited productivity, and decreased quality of life. Injured individuals may also need special services throughout life (1). The direct medical costs of these injuries to the federal government exceed \$4 billion per

<sup>\*</sup>NSCIA is a private, nonprofit national health agency that serves as a resource and clearing-house for information on SCIs, including prevention and rehabilitation.

<sup>†</sup>The District of Columbia was not contacted.

### *Spinal Cord Injury – Continued*

year (3). Lost earnings associated with SCI are estimated to be \$3.4 billion (in 1987 dollars) annually (Department of Rehabilitation Medicine, University of Alabama/Birmingham, unpublished data).

Surveillance is needed to better define the national incidence of acute traumatic SCI, to identify high-risk groups in order to target prevention strategies, and to determine etiologies so that prevention programs can be developed. The data presently collected by SCI registries may be useful in targeting high-risk groups and determining etiologies. However, case definitions, reporting sources, and level of information collected vary among registries.

CDC is working with CSTE and other interested groups to 1) review existing surveillance systems and registries for acute traumatic SCI, 2) determine the information needs of public health and clinical practice, 3) develop a workable case definition, 4) determine the information to be collected, and 5) identify reporting sources. SCI is one of the disabilities targeted for support by CDC's disabilities prevention program. This program will provide state and local agencies with funding to prevent primary and secondary disabilities such as those caused by acute traumatic SCIs.

The public health benefit of registries at the local level can be realized only if the information collected is useful to those planning intervention strategies. The implementation of these strategies may involve the participation of many agencies within the state or local government, along with private interest groups. Registries will be useful at the national level only if a standard case definition is used and if information is collected, analyzed, and interpreted consistently and systematically.

### **Update: Acquired Immunodeficiency Syndrome (AIDS) – Worldwide**

As of March 21, 1988, 136 countries or territories throughout the world had reported a total of 84,256 cases of acquired immunodeficiency syndrome (AIDS) to the Global Programme on AIDS (GPA) (formerly the Special Programme on AIDS) of the World Health Organization (WHO) (Table 1).<sup>\*</sup> Thirty-seven countries or territories had reported no AIDS cases. Reports are based on either the CDC/WHO surveillance definition (1,2), the WHO clinical definition (3), or a physician's diagnosis. From 1979 through March 21, 1988, the number of AIDS cases increased markedly in all geographic regions (Figure 1). The cumulative world total increased from 11,965 in 1984 to 25,150 in 1985 (a 110% increase) and to 48,413 in 1986 (a 92% increase). Because of reporting lags, the global total of AIDS cases reported for 1987 is not yet complete; however, as of March 21, 1988, 34,913 cases had been reported for 1987

<sup>\*</sup>Because of varying reporting practices, AIDS case data are not available for all countries for the same time period.

AIDS – Continued

(a 72% increase). Data on the distribution of AIDS cases by region are presented below, followed by a discussion of the findings.

Americas

Forty-two countries in the Americas have reported 73% of the world total of AIDS cases. As of March 21, 1988, the United States had reported a total of 54,233 cases. The case count in Brazil was 2,325; the number had increased from 801 at the end of June 1986 to 1,695 at the end of June 1987. Canada has reported a total of 1,517 cases. The following additional countries reported over 100 cases: Haiti (912), Mexico (713), Dominican Republic (352), Trinidad and Tobago (206), Bahamas (163), Colombia (153), Argentina (120), and Venezuela (101).

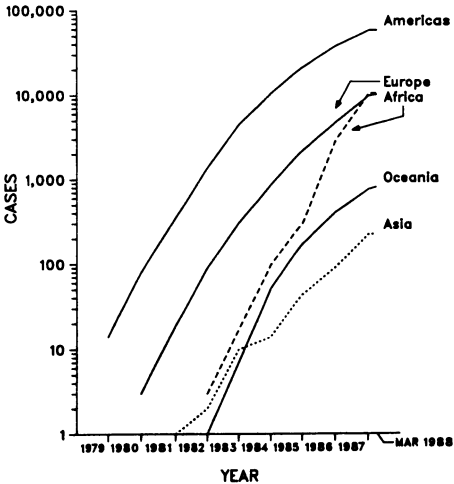

Europe

Twenty-eight countries in Europe have reported 13% of the world's total AIDS cases. Between December 1986 and December 1987, the number of cases reported from Europe to the WHO Collaborating Centre on AIDS (4) in Paris, France, increased by 124%. The greatest number of cases has been reported from France (3,073), the Federal Republic of Germany (1,669), Italy (1,411), the United Kingdom (1,227),

TABLE 1. AIDS cases reported to the World Health Organization (WHO), by continent, 1979 – March 21, 1988

Continent	Number of Cases	Number of Countries or Territories Reporting		Total Number of Countries Reporting
		No Cases	1 or More Cases	
Africa	10,973	8	42	50
Americas	61,602	2	42	44
Asia	231	16	21	37
Europe	10,616	1	27	28
Oceania	834	10	4	14
Total	84,256	37	136	173

FIGURE 1. Total AIDS cases reported to the World Health Organization, 1979 – March 21, 1988

*AIDS – Continued*

and Spain (789). The highest rates per population size are in France, Switzerland, and Denmark. Four countries with over 100 cases (Austria, France, Italy, and Spain) reported increases of more than 100% between December 1986 and December 1987. The lowest rates were reported from the Eastern European countries.

Ninety-two percent of patients reported from Europe were European; 4% were African; 1% were from the Caribbean; and 3% were from other countries (4). The relative percentage of patients who have been reported from Europe but whose country of origin is Africa has been decreasing over the past 2 years.<sup>†</sup>

The age distribution of patients in Europe (Table 2, see page 293) is similar to that in the United States except that Europe has a higher percentage of patients under 19 years of age (3% compared with 2%). Europe has a lower percentage of adult patients in the homosexual and homosexual/intravenous-drug-user transmission categories

<sup>†</sup>Such patients accounted for 12% of cases reported for Europe in June 1985, 6% in June 1986, and 4% in December 1987.

\*Mortality data in this table are voluntarily reported from 121 cities in the United States, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

\*\*Pneumonia and influenza.

†Because of changes in reporting methods in these 3 Pennsylvania cities, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.

††Total includes unknown ages.

‡Data not available. Figures are estimates based on average of past available 4 weeks.

*AIDS – Continued*

than the United States and a higher percentage in the heterosexual, blood-related, and undetermined/other categories (Table 3). In addition, Europe has a higher percentage of pediatric patients in the hemophilia/coagulation-disorder category than the United States and a lower percentage with a parent with AIDS or at increased risk for AIDS.

Intravenous (IV) drug users account for 64% of adult patients in Italy and 53% of adult patients in Spain. Both countries together reported 66% of the IV-drug-related cases in Europe. In the following six countries reporting more than 50 cases, 75% or more of the patients were homosexual males: the Netherlands (88%), the United

Kingdom (87%), Denmark (86%), Sweden (81%), Norway (79%), and the Federal Republic of Germany (76%).

**Africa**

Thirty-eight countries in the African Region have reported 13% of the world's total AIDS cases. Fifteen African countries reported more than 50 cases each. Zimbabwe<sup>5</sup> and Zaire have each reported 300 to 500 cases, and Uganda, Tanzania, Congo, Kenya, Burundi, Rwanda, Malawi, and Zambia have each reported more than 500 cases. Central, eastern, and southern Africa have reported the largest number of cases. Although cases were first officially reported from Africa in the second half of 1982, over 70% of all cases (7,906) were reported in 1987.

**Other Areas**

Oceania has reported a total of 834 AIDS cases; Asia, a total of 231 cases; and the eastern Mediterranean countries, 100 cases. The major reporting countries (>20 cases) from these areas were Australia (758 cases), New Zealand (74), Japan (59), Qatar (32), and Turkey (21).

**Discussion**

Worldwide AIDS surveillance is coordinated by GPA at WHO in Geneva. Reports are received from collaborating centers, including CDC in the United States, the WHO Collaborating Centre in Paris, and WHO regional offices and ministries of health. Accuracy and completeness of AIDS reporting vary in different areas of the world. In 1985, a review of death certificates in the United States suggested that 89% of AIDS cases meeting the surveillance definition were reported (5). In Africa, reporting has only recently started in some countries and is, therefore, incomplete. Consequently, the proportion of AIDS cases that are reported in Africa is unknown. The WHO clinical case definition, used in areas where the prevalence of HIV is high, has a specificity of over 90% (6).

Epidemiologic studies indicate three broad yet distinct geographic patterns of transmission. Pattern I is typical of industrialized countries with large numbers of reported AIDS cases, such as North America, Western Europe, Australia, New Zealand, and parts of Latin America. In these areas, most cases occur among homosexual or bisexual males and urban IV drug users. Heterosexual transmission is responsible for only a small percentage of cases but is increasing. Transmission due to exposure to blood and blood products occurred between the late 1970s and 1985 in these countries but has now been largely controlled through the self-deferral of persons at increased risk for AIDS and by routine blood screening for human immunodeficiency virus (HIV) antibody. The ratio of male to female patients ranges from 10:1 to 15:1, and, to date, perinatal transmission is relatively uncommon. Overall population seroprevalence is estimated to be less than 1% but has been measured at up to 50% in some groups practicing high-risk behaviors, such as IV drug users and men with multiple male sex partners.

Pattern II is observed in areas of central, eastern, and southern Africa and in some Caribbean countries. In these areas, most cases occur among heterosexuals; the male to female ratio is approximately 1:1; and perinatal transmission is relatively more common than in other areas. IV drug use and homosexual transmission either do not occur or occur at a very low level. In a number of these countries, overall population seroprevalence is estimated at more than 1%, and, in a few urban areas, up to 25% of

<sup>5</sup>As of April 1988, Zimbabwe officially retracted its report of 380 cases pending a national review of the accuracy of its reporting system.

*AIDS – Continued*

the sexually active age group is infected. Transmission through contaminated blood and blood products has been a significant problem and continues in those countries that have not yet implemented nationwide donor screening.

Pattern III is found in areas of Eastern Europe, the Middle East, Asia, and most of the Pacific. HIV appears to have been introduced into these areas in the early to mid-1980s, and only small numbers of cases have been reported. Homosexual and heterosexual transmission have only recently been documented. Generally, cases have occurred among persons who have traveled to endemic areas or who have had sexual contact with individuals from endemic areas, such as homosexual men and female prostitutes. A small number of cases due to receipt of imported blood products has been reported.

Under its charter, the World Health Assembly of WHO has authorized GPA to develop and coordinate a global strategy for AIDS prevention and control. As of March 1988, 115 member states had agreed to collaborate in supporting and developing short-term (<1 year) plans for AIDS control. Between February 1987 and March 1988, GPA provided over 250 consultant visits to assist countries in developing these plans.

WHO is conducting worldwide surveillance of AIDS, developing standardized methods for HIV serosurveys, and creating a Global Commission on AIDS to provide GPA with scientific and technical guidance. In addition, experts have met in Geneva to discuss a variety of HIV-related issues. Health promotion and HIV prevention strategies have also been developed.<sup>†</sup> GPA is organizing a network of specimen banks for geographically and temporally representative retroviral isolates and sera. GPA is also collaborating with a working group of leading AIDS virologists to standardize the characterization of HIV and related human retroviruses.

Although the number of AIDS cases is expected to increase significantly over the next few years, there is growing confidence that the spread of HIV can be stopped. Stopping HIV infection, however, will require a commitment that goes beyond geographic boundaries. Education and the means to eliminate or modify risk factors and risk behaviors will be the key. The global control of AIDS will require both committed national AIDS programs and strong international coordination, cooperation, and leadership.

FIGURE I. Reported measles cases – United States, Weeks 14–17, 1988

The *Morbidity and Mortality Weekly Report* is prepared by the Centers for Disease Control, Atlanta, Georgia, and available on a paid subscription basis from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402, (202) 783-3238.

The data in this report are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the succeeding Friday. The editor welcomes accounts of interesting cases, outbreaks, environmental hazards, or other public health problems of current interest to health officials. Such reports and any other matters pertaining to editorial or other textual considerations should be addressed to: Editor, *Morbidity and Mortality Weekly Report*, Centers for Disease Control, Atlanta, Georgia 30333.
