## Epidemiologic Notes and Reports

## Mumps in the Workplace - Chicago

Between August 18 and December 25, 1987, 116 employees at three futures exchanges in Chicago developed clinically diagnosed mumps* (Figure 1). Three cases subsequently occurred in household contacts of affected exchange employees. Twenty-one persons developed complications; nine were hospitalized.

In September 1987, the employee health nurse at one of Chicago's four futures exchanges notified the Chicago Department of Health (CDOH) of a cluster of mumps cases among employees. Of the 119 cases subsequently identified among employees of three exchanges and their household contacts, three patients were tested for and had mumps-specific lgM antibody. Seventy-six cases occurred in persons working at exchange $A ; 39$ cases, in persons at exchange $B$; and one case, in a person at exchange $C$.

Eighty-two (69\%) of the affected exchange employees completed questionnaires. Two men at exchange A reported the onset of facial swelling on August 18. One was a 23 -year-old phone clerk; the other was a 30 -year-old trader working in a different area of the exchange. The first case at exchange B occurred in a 27 -year-old man who had no known contact with an exchange A employee with mumps; he had onset of facial swelling on September 6. The only case at exchange C occurred in a 29 -year-old woman whose facial swelling developed on October 13; she had no known contact with anyone with mumps from exchanges $A$ or $B$.

Cases at exchanges A, B, and C could not be epidemiologically linked. Based on a median incubation period of 16-18 days, up to eight generations of cases occurred at exchanges $A$ and $B$ (Figure 1).

Because some employees work at multiple exchanges, the actual numbers of persons at risk, their ages, and their genders were not known for each of the exchanges. Based on estimates by exchange officials of the population at risk (approximately 7300 persons at each of exchanges $A$ and $B$ ), the crude attack rate for exchange A ( 10 cases $/ 1000$ workers) was twice that of exchange B ( 5 cases/1000 workers). No denominator estimates were available for exchange $C$.

[^0]
## Mumps - Continued

Age was known for 104 of the 119 patients and ranged from 17 to 70 years (median: 25 years). Persons $<30$ years of age accounted for $77 \%$ of the cases. By comparison, during January-July 1987, a period of widespread mumps activity in Chicago and its six metropolitan counties, 106 cases were reported in persons $\geqslant 20$ years old. In the futures exchanges, almost twice as many men (79) as women (40) developed mumps. Of 92 patients for whom race/ethnicity was known, 84 ( $91 \%$ ) were white, non-Hispanic, seven ( $8 \%$ ) were black, and one was Hispanic. Although demographic data were not available for the population at risk, it was predominantly young, male, and white. Of the 99 patients for whom occupation was known, 94 (95\%) worked on the trading floor.

Although more than one third of the 82 patients for whom information was available believed they had previously been vaccinated against mumps, only three could provide an immunization record as documentation. Almost three fourths of the patients had attended elementary or secondary school in Illinois, which did not have a mumps immunization law for school attendees until 1987.

In cooperation with exchanges A and B , the CDOH sponsored four voluntary vaccination clinics during the outbreak (Figure 1). Four hundred fifty-one doses of monovalent mumps vaccine were administered free of charge to nearly $6 \%$ of the workers at the two exchanges. The number of vaccinated persons who were actually susceptible was not known.

Twenty-three complications occurred in 21 patients (Table 1). Fifteen (31\%) of the 48 ill men reported epididymo-orchitis that lasted an average of 9 days (range: 2-21 days). One of two cases of pancreatitis and one case of aseptic meningitis occurred in men with epididymo-orchitis. One case each of oophoritis and arthritis was reported.

FIGURE 1. Reported mumps cases, by date of onset* - Chicago futures exchanges, August-December 1987

Mumps - Continued
Three women with mumps were pregnant; one developed premature labor that was subsequently arrested.

Nine (11\%) of the 82 patients for whom data are available required hospitalization for a total of 41 days (range: 1-9 days; mean: 5 days) (Table 1). Epididymo-orchitis was responsible for four of nine hospital admissions.

Direct costs associated with health-care visits, medications, and hospitalizations for mumps were $\$ 56,406$. Seventy-eight employees for whom data were available missed a total of 538 days of work (median: 7 days). The average cost per case was \$1473 (Table 2).
Reported by: M Ahrens, Highland Park Hospital; E Gary, W Martin, Immunization Program, D Marder, MD, LR Murray, MD, Chicago Dept of Health; K McMahon, C Jennings, R March,

TABLE 1. Clinical findings of 21 persons with complications of mumps - Chicago futures exchanges, August-December 1987

| Complication | No. persons | No. hospitalized | Total days hospitalized |
| :---: | :---: | :---: | :---: |
| Epididymo-orchitis | 15 | 4 | 17 |
| Pregnancy-related | 2 | 2 | 8 |

## Mumps - Continued

Immunization Program, BJ Francis, MD, State Epidemiologist, Illinois Dept of Public Health. Div of Immunization, Center for Prevention Svcs, CDC.
Editorial Note: Since licensure of live-virus mumps vaccine in 1967, the United States has made great strides in the control of mumps. Reported cases of mumps declined to a record low of 2982 in 1985 ( 1.2 cases/100,000 population), a $98 \%$ decrease from the 152,000 reported in 1968, the year mumps became a nationally notifiable disease. In 1986, however, the number of reported cases more than doubled ( 7790 mumps cases; 2.8 cases $/ 100,000$ ), a trend that continued through 1987, when the total was almost 12,900 cases. Through the first 30 weeks of 1988,3166 cases have been reported, a 67\% decrease from the same period in 1987.

Recent outbreaks have occurred in high schools and on college campuses, reflecting a change in the epidemiology of mumps and a shift in risk from elementary school-aged children to adolescents and young adults (1-4). During 1986-1987, 183 cases of clinically diagnosed mumps were reported from outbreaks at 10 llinois colleges and universities $(1,5)$. The increase in mumps cases in adolescents and young adults is particularly important in view of the more severe illness, higher frequency of complications, and greater costs associated with mumps in these age groups than in younger persons (4-8).

The types and rates of complications found during this investigation were similar to those found in other studies. For example, epididymo-orchitis affects 10\%-38\% of postpubertal males with mumps (6). The incidence of laboratory-verified aseptic meningitis increases with age and affects an estimated $0.6 \%$ of mumps cases in persons $\geqslant 20$ years of age ( 9 ). Clinically symptomatic meningitis, characterized by headache and neck stiffness, is considerably more common. Mumps illness during the first trimester of pregnancy has been associated with an increased rate of spontaneous abortion possibly because of its effect on hormonal function of the placenta (10).

Benefit-cost analyses have shown that \$7-\$14 are saved for every dollar spent on mumps prevention (11,12). In the futures exchanges outbreak, the nearly $\$ 1500$ cost for each mumps case contrasted dramatically with the cost of mumps vaccine, $\$ 4.47 /$ dose in the public sector and $\$ 8.80 /$ dose in the private sector in Chicago.

The age-specific changes in mumps epidemiology observed since vaccine licensure are similar to those noted for measles and rubella and reflect a vaccination policy oriented toward preschool and elementary school children. Although mumps vaccine was licensed in December 1967, it was less widely distributed than measles and rubella vaccines because of its relative expense ${ }^{\dagger}$ and its lower public health priority. Mumps vaccine was not recommended for universal use in children $\geqslant 12$ months of age until 1977. Consequently, during 1967-1977, when mumps vaccine was used less prevalently, children may have had less exposure to mumps virus and no opportunity to receive mumps vaccine. As a result, a cohort of unvaccinated young adults may have remained susceptible as they entered the work force.

Direct evidence from field evaluations of vaccine efficacy and indirect evidence from vaccine use suggest that the failure to vaccinate susceptible persons, rather than vaccine failure or waning immunity, led to this outbreak (3,4). Most cases at the futures exchanges were reported in unvaccinated young adults, most of whom had been born and educated in Illinois, a state that until recently lacked a mumps immunization school law.

[^2]Mumps - Continued
The effectiveness of school immunization laws in reducing the incidence of mumps has been consistently demonstrated ( $2,4,13$ ). Illinois adopted comprehensive legislation in 1987 requiring mumps immunization for children enrolling in kindergarten through grade 12. Such legislation is unlikely to markedly affect the current cohort of susceptible older adolescents and young adults but will probably reduce the number of mumps cases among school attendees and among future cohorts of young adults.

Closed environments such as the trading floors of the Chicago futures exchanges facilitate contact with respiratory secretions and person-to-person transmission of mumps. A peak in the number of mumps cases corresponded to the surge in futures trading activity that preceded the October 19, 1987, market decline (Figure 1). Anecdotal information from interviews with patients suggests that the intense activity at the futures exchanges may have encouraged some employees with mumps to work despite their illness, thus possibly exposing susceptible co-workers to mumps. Furthermore, the peak infectiousness of mumps occurs during the 48 hours before the onset of overt clinical illness (14). Outbreaks of mumps in the prevaccine era characteristically occurred in closed populations such as prisons, orphanages, and among classes of military recruits (15). Whether outbreaks similar to the Chicago one will occur in other workplace settings will depend on the mumps susceptibility of the work force and the nature of the workplace setting.

The outbreak among the Chicago futures exchanges was costly and could have been averted. It should alert both employers and the health-care community to the existence of mumps in adults and should remind persons of the 'need to have documented immunity to mumps. Furthermore, employers should report promptly to public health authorities cases of suspected mumps among employees. Current recommendations for measles vaccination of adults assume that most persons born before 1957 were likely to have been naturally infected and thus generally do not require routine measles immunization (16). Based on the pattern of gradual introduction of mumps vaccine into use since 1967 and the preponderance of adult mumps cases in persons $<30$ years of age, it may be both useful and practical to follow a similar guideline as that used for measles as a means of preventing other mumps outbreaks in adult populations.

## Perspectives in Disease Prevention and Health Promotion

## Premature Mortality Due to Homicides - United States, 1968-1985

In 1985, homicides accounted for 612,556 years of potential life lost before age 65 (YPLL) or $5.2 \%$ of total YPLL. Assault by firearms and explosives, the major cause of homicides, resulted in 376,291 YPLL or 61.4\% of homicide-attributable YPLL. Seventysix percent of the homicide-attributable YPLL occurred in males (Table 1). As in past years (1), the YPLL rate per 100,000 persons was highest for black males (1669.3) and lowest for white females (99.4).

Homicide-attributable YPLL were calculated for 1968 through 1985 using final mortality data for ICD E-codes* 960-969 from the National Center for Health Statistics, CDC. During these years, homicide-attributable YPLL increased $44 \%$ from 424,718 to 612,556. This increase contrasts with total YPLL, which declined $25 \%$ from 15,888,756 to $11,851,397$ during the same 18 -year period. As a proportion of total YPLL, homicide-attributable YPLL increased 93\% from 1968 through 1985 from 2.7\% to 5.2\% (Figure 1). Homicides by firearms and explosives increased from 1.8\% of total YPLL in 1968 to $3.1 \%$ in 1985.

Since 1968, the average age at death from all causes before age 65 has been steadily increasing; thus the average YPLL per death (i.e., 65 minus the average age at death) has been decreasing. In contrast, the average age at death attributed to homicides before age 65 decreased steadily through the 1970 s but appears to be stabilizing in the 1980s (Figure 2). For the 18-year period, the $44 \%$ increase in homicide-attributable YPLL reflects the $36 \%$ increase in the number of homicide deaths multiplied by the $6 \%$ increase in the average YPLL per homicide $(1.44=1.36 \times 1.06)$. The $25 \%$ decrease in total YPLL during this period reflects a $17 \%$ decrease in all deaths multiplied by a 10\% decrease in the average YPLL per death. Reported by: Biometrics Br and Epidemiology Br, Div of Injury Epidemiology and Control, Center for Environmental Health and Injury Control, CDC.
*International Classification of Diseases, External Causes of Injury and Poisoning.

Year

FIGURE 2. Average age at death for persons <65 years of age - United States, 1968-1985

Premature Mortality - Continued
Editorial Note: The dramatic increase in homicide-attributable YPLL since 1968 highlights the need for public health efforts directed toward the prevention of interpersonal violence. Recent data from the Federal Bureau of Investigation (FBI) show a $5.9 \%$ increase in homicides from 1985 through 1987 (2).

The increased impact of homicides in the United States has helped strengthen the Public Health Service's commitment to focus on violence as a public health problem. One effort, the Surgeon General's Workshop on Violence and Public Health, held in 1985 (3), led to regional conferences that have fostered interdisciplinary efforts directed toward this problem. Cooperation among sectors such as criminal justice, social services, health care, and mental and public health may enable development of effective programs for prevention of homicides and for identification, treatment, and referral of victims of nonfatal interpersonal violence.

Since 1978, the homicide rate for black males 15-24 years of age has decreased $13 \%$, suggesting that the 1990 objective for this target group $(60 / 100,000)$ can be attained (4). However, YPLL data suggest that future public health objectives also should target other population groups.

Comprehensive surveillance of homicides in the United States uses both vital statistics and FBI data. In contrast, surveillance of nonfatal injuries from intentional interpersonal violence is almost nonexistent, although the incidence of this related problem is estimated to be at least 100 times that of homicides (4). Uniform hospital discharge data systems and trauma registries that include cause-of-injury information can serve as the basis for surveillance of nonfatal injuries from violence. These systems can also aid communities in defining priorities for preventing violence and evaluating the effectiveness of interventions.

## Notice to Readers

## Publication of NIOSH Criteria Documents on Welding, Brazing, and Thermal Cutting and on Radon Progeny

The National Institute for Occupational Safety and Health (NIOSH) periodically issues criteria documents that examine health risks associated with various occupations. Two such documents were recently published* and are described below.

[^5]NIOSH Criteria - Continued
Criteria for a Recommended Standard: Welding, Brazing, and Thermal Cutting. This document examines the occupational health risks associated with welding, brazing, and thermal cutting and provides criteria for eliminating or minimizing the risks encountered by workers in these occupations. An estimated 700,000 workers in the United States are involved in the welding of various materials. The major health concerns associated with these occupations are increased risks of lung cancer and acute or chronic respiratory diseases.

The etiologic basis for this excess risk is difficult to determine because of uncertainties about smoking habits, possible interactions among the various components of welding emissions, and possible exposures to other occupational carcinogens. For workers who weld on stainless steel, the increased risk for lung cancer appears to be associated with exposure to fumes that contain nickel and chromium.

The prevalence and severity of nonmalignant respiratory conditions are not well characterized among welders, but these conditions have been observed in both smoking and nonsmoking workers in welding-associated occupations. Excess morbidity and mortality exist among welders even when reported exposures are below current Occupational Safety and Health Administration (OSHA) permissible exposure limits (PELs) for the many individual components of welding emissions.

An occupational exposure limit for total welding emissions cannot be established because the composition of welding fumes and gases varies for different welding processes and because the various components of a welding emission may interact to produce adverse health effects. Therefore, exposures to all welding emissions should be reduced to the lowest feasible concentrations using state-of-the-art engineering controls and work practices. Any applicable exposure limits for individual chemical and physical agents associated with welding (i.e., NIOSH recommended exposure limits [RELs], OSHA PELs, or limits recommended by consensus groups) should be considered upper boundaries of exposure.

The criteria document contains NIOSH recommendations for medical monitoring of exposed workers and for engineering controls, good work practices, and worker education. Guidelines are also provided for respiratory protection and protective clothing.

A Recommended Standard for Occupational Exposure to Radon Progeny in Underground Mines. This document examines the occupational health risks associated with exposures to radon progeny (radon and its short-lived, alpha-radiationemitting, radioactive decay products) in underground mines, and it establishes criteria for minimizing the risks encountered by miners.

Data from studies on both humans and animals demonstrate a direct link between exposure to radon progeny and lung cancer. Epidemiologic studies provide a basis for quantitatively estimating human risk at various exposure levels. Exposure is quantified using the working level month (WLM), which is a standard measure of occupational exposure to alpha radiation. Analyses show that an exposure to radon of 4 WLM per year over a 30 -year working lifetime (the current Mine Safety and Health Administration standard) poses a substantial risk of lung cancer. To determine a REL, NIOSH has weighed this evidence along with uncertainties in the data and the feasibility of controlling exposure to radon progeny in mines. The resulting REL for radon progeny is a cumulative total of 1 WLM per year and an average workshift concentration of one twelfth of 1 working level. These limits are to be considered the upper boundaries of exposure, and every effort should be made to reduce exposures

NIOSH Criteria - Continued
to the lowest concentrations possible. In addition to the REL, the criteria document contains specific provisions for medical monitoring, recordkeeping, respiratory protection, worker education, and sampling and analytical methods. Implementation of all these recommendations will help minimize risk for exposed workers.

FIGURE I. Reported measles cases - United States, Weeks 31-34, 1988

The Morbidity and Mortality Weekly Report is prepared by the Centers for Disease Control, Atlanta, Georgia, and available on a paid subscription basis from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402, (202) 783-3238.

The data in this report are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the succeeding Friday. The editor welcomes accounts of interesting cases, outbreaks, environmental hazards, or other public health problems of current interest to health officials. Such reports and any other matters pertaining to editorial or other textual considerations should be addressed to: Editor, Morbidity and Mortality Weekly Report, Centers for Disease Control, Atlanta, Georgia 30333.

[^0]:    *A case of mumps was defined as the acute onset of facial or jaw swelling (parotitis) lasting $\geqslant 2$ days or as acute epididymo-orchitis without parotitis.

[^1]:    *Data available on 78 persons.

[^2]:    ${ }^{\top}$ The mumps component makes up slightly more than one half of the cost of combined measles-mumps-rubella (MMR) vaccine.

[^3]:    *Because AIDS cases are not received weekly from all reporting areas, comparison of weekly figures may be misleading.

[^4]:    *Mortality data in this table are voluntarily reported from 121 cities in the United states, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
    **Pneumonia and influenza.
    †Because of changes in reporting methods in these 3 Pennsylvania cities, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks
    total includes unknown ages.
