October 14, 1988 / Vol. 37 / No. 40

613 Progress Toward Achieving the
National 1990 Objectives for Immunization
617 ACIP: Cholera Vaccine
624 Poliomyelitis - Israel

## Perspectives in Disease Prevention and Health Promotion

## Progress Toward Achieving the National 1990 Objectives for Immunization

The 1990 health objectives for the nation included 18 objectives on immunization (1). This update reports on progress toward achievement of these objectives through 1987.

## IMPROVED HEALTH STATUS

The first eight objectives cite the morbidity reduction targeted for eight diseases by 1990 (Table 1).

The targets for diphtheria and poliomyelitis appear to have been met, and substantial progress toward the targets for tetanus, rubella, and congenital rubella syndrome has been achieved: Morbidity from mumps had been declining until 1986, when the incidence of mumps increased $161 \%$ (2). The 12,848 cases reported in 1987 are the most since 1979. This increase largely reflected outbreaks in high schools and colleges and probably resulted from the absence or lack of enforcement of school immunization requirements in some states (2-4). Ilinois and Tennessee had the highest mumps incidence rates in 1986 and 1987; these two states began enforcing comprehensive school laws requiring mumps vaccination in September 1987 and September 1988, respectively. During the first 26 weeks of 1988, 2945 cases were reported in the United States, representing a $69 \%$ decrease from the same period in 1987.

TABLE 1. Progress toward the 1990 immunization objectives for improved health status of children, by disease - United States, 1979-1987

|  | No. reported cases |  |  |
| :--- | ---: | ---: | ---: |
| Disease | $\mathbf{1 9 7 9}$ | $\mathbf{1 9 8 7}$ | 1990 $\mathbf{\text { Objective }}$ |
| Diphtheria | 59 | 3 | $<50$ |
| Measles | 13,597 | 3,655 | $<500$ |
| Mumps | 14,225 | 12,848 | $<1,000$ |
| Pertussis | 1,623 | 2,823 | $<1,000$ |
| Poliomyelitis (paralytic) | 26 | 0 | $<10$ |
| Rubella | 11,795 | 306 | $<1,000$ |
| Congenital rubella syndrome | 62 | 5 | $<10$ |
| Tetanus | 81 | 48 | $<50$ |

[^0]
## 1990 Objectives - Continued

Between 1981 and 1987, the number of reported measles cases stabilized, with slightly more than 3000 average annual cases (range: 1497 cases in 1983 to 6282 cases in 1986). Outbreaks have occurred among both preschool-aged children, many of whom were unvaccinated, and high school- and college-aged persons, many of whom had been vaccinated. In many recent outbreaks, persons who received measles vaccine at 12-14 months of age have been at higher risk for measles than those vaccinated at $\geqslant 15$ months of age (5). Intervention strategies to eliminate measles continue to be evaluated (6).

Improved surveillance indicates that pertussis also occurs in adolescents and adults as well as in infants and young children, although the illness is milder in these older persons (7). Increases in reported cases in 1985 and 1986 may be due to improved diagnosis and surveillance since diphtheria-tetanus-pertussis vaccine coverage in children does not appear to have declined.

## IMPROVED SERVICES AND PROTECTION

By 1990, at least $90 \%$ of all children by age 2 should have completed their immunization series-measles, mumps, rubella, polio, diphtheria, pertussis, and tetanus.

Although evaluation of progress toward this objective is difficult because of limited base-line data, it appears likely that this objective will not be met. In 1979, an estimated $70 \%-80 \%$ of 2 -year-old children had received their basic immunization series. In the most recent U.S. Immunization Survey in 1985, 77\% of 2-year-olds whose parents had records at home had received their basic series. Recent outbreaks of measles among unimmunized preschoolers also have shown that inadequate immunization levels still occur. To ensure that infants begin and complete their immunization series on schedule, efforts to develop recall and outreach systems must be continued.
By 1990, at least 95\% of children attending licensed day-care facilities and kindergarten through 12th grade should be fully immunized.

Although national data are not available for children beyond the first grade, extrapolation of school entry data since 1980 suggests that this objective will be met. For the 1986-87 school year, immunization levels in licensed day-care facilities exceeded $90 \%$. Of children entering kindergarten or first grade, $97 \%$ had been immunized.
By 1990, at least 60\% of high-risk populations, as defined by the Immunization Practices Advisory Committee (ACIP) of the Public Health Service, should be receiving annual immunization against influenza.

This objective is unlikely to be met unless efforts are substantially intensified. The 1985 U.S. Immunization Survey indicates that only approximately $20 \%$ of high-risk persons received influenza vaccine during the preceding year.

## INCREASED PUBLIC AND PROFESSIONAL AWARENESS

By 1990, all mothers of newborns should receive instruction on immunization schedules for their babies before leaving the hospital or after home births.

This objective will probably be met because substantial progress has been made in educating mothers of newborns about immunizations. As of 1986, 39 of 52 jurisdictions ( 50 states, the District of Columbia, and New York City) had hospitalbased maternal education programs in at least $90 \%$ of targeted hospitals.

1990 Objectives - Continued

## IMPROVED SURVEILLANCE AND EVALUATION

By 1990, at least 95\% of all children 18 years of age and under should have up-to-date official immunization records in a uniform format using common guidelines for completion of immunization.

Standardized immunization records are now available in all states. Given the likelihood of achieving immunization level targets, this objective probably will be met. Although all states recommend the same immunization series, school immunization requirements vary from state to state. Consequently, the definition of "complete series" may vary.
By 1990, surveillance systems should be sufficiently improved that (1) at least 90\% of those hospitalized and $50 \%$ of those not hospitalized with vaccine-preventable diseases of childhood are reported and (2) uniform case definitions are used nationwide.

Meeting the target for hospitalized persons may be feasible, but it is less likely that the target for persons who are not hospitalized can be met. The completeness of reporting varies by disease. Most cases of poliomyelitis, tetanus, and diphtheria are probably diagnosed, and nearly all are reported. As a result of the measles elimination initiative, measles reporting is now considered to be nearly complete. However, because of the variability in clinical manifestations of rubella, mumps, and pertussis, reporting of these diseases is probably incomplete. An estimated $22 \%$ of confirmed and compatible cases of congenital rubella syndrome diagnosed during the neonatal period are reported (8).

Uniform case definitions exist for measles, mumps, rubella, congenital rubella syndrome, poliomyelitis, diphtheria, tetanus, pertussis, and Haemophilus influenzae type b.
By 1990, at least 60\% of high-risk populations, as defined by the ACIP, should have received vaccination against pneumococcal pneumonia.

The 1985 U.S. Immunization Survey indicates that approximately 10\% of high-risk persons had received pneumococcal polysaccharide vaccine. Although administration of this vaccine is reimbursed under Medicare, this objective is unlikely to be met. By 1990, at least 50\% of people in populations designated as targets by the ACIP should be immunized within 5 years of licensure of new vaccines for routine clinical use.

Recently licensed vaccines include hepatitis B vaccine (licensed in 1982), Haemophilus influenzae type b polysaccharide vaccine (HbPV, licensed in 1985), and Haemophilus influenzae type b conjugate vaccine (HbCV, licensed in 1987). Hepatitis $B$ vaccine is recommended for persons who are at risk of contact with blood or blood products (primarily health-care workers), homosexual men, household contacts of carriers of hepatitis B surface antigen, and users of illicit injectable drugs. Since data suggest that coverage for high-risk groups varies from $2 \%$ to $50 \%$, this objective may be met in some target groups. HbCV is recommended for all children at 18 months of age and will likely replace most use of HbPV in 1988. Evaluating progress toward the objective for HbCV is not possible because of a lack of national data concerning coverage with this vaccine.
By 1990, no comprehensive health insurance policies should exclude immunizations.
Comprehensive data about insurance coverage of immunizations are not available. However, approximately 20 million persons are receiving services from health

1990 Objectives - Continued
maintenance organizations that provide both preventive and treatment services. Medicaid provides reimbursement for childhood vaccines, and Medicare provides reimbursement for pneumococcal polysaccharide vaccine. In 1987, Congress authorized the Health Care Financing Administration to conduct a cost-effectiveness study beginning during the 1988-89 influenza season to determine whether influenza vaccine should be covered under Medicare.
By 1985, the nation should have a plan in place to mount mass immunization programs in the face of possible epidemics of influenza or other epidemic diseases for which vaccines may exist.

This objective has been met.
Reported by: Office of Disease Prevention and Health Promotion, Office of the Assistant Secretary for Health, Public Health Svc. Center for Biologics Evaluation and Review, Food and Drug Administration. Microbiology and Infectious Diseases Program, National Institute of Allergy and Infectious Diseases, National Institutes of Health. Div of Viral Diseases and Div of Bacterial Diseases, Center for Infectious Diseases; Div of Immunization, Center for Prevention Sves, CDC.
Editorial Note: Overall progress toward the 1990 objectives relating to childhood vaccines is encouraging, although full immunization of children at the earliest appropriate age has not yet been assured. Of greater concern is the relative lack of progress toward the objectives relating to vaccines used primarily for adults. Improving immunization coverage for adults is difficult because regular immunization is not traditional among this age group and because target groups vary for different vaccines. In January 1985 and April 1987, CDC convened adult immunization community forums to discuss development and implementation of programs to ensure appropriate immunization of adults. These forums led to the formation of the National Coalition for Adult Immunization to promote adult immunizations. This coalition represents voluntary organizations, professional physician groups, and manufacturers of vaccines.

As a result of an internal assessment by the National Institute of Allergy and Infectious Diseases and a priority-setting study by the Institute of Medicine (9), priority has been placed on the rapid development of several new vaccines (Table 2). Introduction of any of these new vaccines would pose additional challenges in achieving the target of $50 \%$ coverage in designated target groups within 5 years of licensure.

Although efforts to reduce mumps, measles, and pertussis must be continued, improved surveillance of these and other infectious diseases will allow for more accurate assessment of future efforts toward prevention of these diseases. In

TABLE 2. Vaccines targeted for priority development for use in the United States National Institute of Allergy and Infectious Diseases, 1986

1. Pertussis (improved)
2. Hepatitis $B(r D N A)^{*}$
3. Haemophilus influenzae type b (conjugated)
4. Respiratory syncytial virus
5. Influenza viruses A and B (live, attenuated)
6. Varicella
7. Gonorrhea

[^1]addition, increased educational efforts that stress the importance of childhood and adult immunizations will assure future strides in reduction of vaccine-preventable diseases.

Recommendations of the Immunization
Practices Advisory Committee

## Cholera Vaccine

## INTRODUCTION

Historically, endemic and epidemic cholera commonly has occurred in parts of southern and southeastern Asia. Since 1961, cholera caused by the El Tor biotype has been epidemic throughout much of Asia, the Middle East, and Africa and in certain parts of Europe. Infection is acquired primarily by consuming contaminated water or food; person-to-person transmission is rare. Travelers who follow the usual tourist itinerary and who use standard accommodations in countries affected by cholera are at virtually no risk of infection.

## CHOLERA VACCINE

Cholera vaccines*, whether prepared from Classic or El Tor strains, are of limited usefulness. In field trials conducted in areas with endemic cholera, vaccines have been only about 50\% effective in reducing the incidence of clinical illness for 3-6 months. They do not prevent transmission of infection. Therefore, the Public Health Service no longer requires cholera vaccination for travelers coming to the United States from cholera-infected areas, and the World Health Organization (WHO) no longer recommends cholera vaccination for travel to or from cholera-infected areas. Surveillance and treatment are sufficient to prevent spread of the disease if it were introduced into the United States.

Vaccine available in the United States is prepared from a combination of phenolinactivated suspensions of classic Inaba and Ogawa strains of Vibrio cholerae grown on agar or in broth.

[^2]
## Cholera - Continued

## VACCINE USAGE

## General Recommendations

Vaccine should not be used to manage contacts of persons with imported cases or to control the spread of infection. Repeated vaccination is required or advised sometimes for laboratory workers and airline and ship crews. However, such groups are unlikely to acquire or transmit cholera. Because information on the long-term safety of repeated vaccination is limited, such practices should be discontinued for airline and ship crews except when resolutely demanded by some countries for international travel.

Vaccine is not recommended for infants $<6$ months of age and is not required for travel by most countries.

## Vaccination for International Travel

The risk of cholera to U.S. travelers is so low that the vaccine is not likely to benefit most U.S. travelers. Persons using standard tourist accomodations in countries

[^4]
## Cholera - Continued

affected by cholera are at virtually no risk of infection. The traveler's best protection against cholera, as well as against many other enteric diseases, is to avoid food and water that might be contaminated.

However, many countries affected or threatened by cholera require evidence of cholera vaccination for entry. One dose of vaccine will usually satisfy entry requirements for persons who anticipate travel to such countries and who will be vaccinated in the United States.

With the threat or occurrence of epidemic cholera, health authorities of some countries may require evidence of a complete primary series of two doses or a booster dose within 6 months before arrival. The complete primary series is otherwise suggested only for special high-risk groups that work and live in highly endemic areas under less than sanitary conditions (Table 1).

Vaccination requirements published by WHO are regularly updated and summarized for travelers by the Public Health Service and distributed to state and local health departments, airlines, travel agents, many physicians, and others. Physicians and travelers should seek information on requirements from these sources.

Physicians administering vaccine to travelers should emphasize that an International Certificate of Vaccination against cholera must be validated for it to be acceptable to quarantine authorities. Validation can be obtained at most city, county, and state health departments as well as many private clinics and physicians' offices. Failure to secure validation may cause travelers to be revaccinated or quarantined. A properly documented certificate is valid for 6 months, beginning 6 days after vaccination or beginning on the date of revaccination if this revaccination is within 6 months of a previous injection.

Data have indicated that persons given yellow fever and cholera vaccines simultaneously or 1-3 weeks apart had initially lower-titered antibody responses to both vaccines. However, seroconversion rates were unaffected, and the clinical importance of these data are unknown. In view of these data, yellow fever and cholera vaccines ideally should be given at least 3 weeks apart. If that is not possible, and both vaccines must be given, then they can be given simultaneously or at any time within the 3-week interval, although a delay in expected yellow fever protection may occur.

## Primary Immunization

Complete primary immunization consists of two doses of vaccine given at least 1 week apart. The intradermal route is satisfactory for persons $\geqslant 5$ years of age (Table 1).

## Booster Doses

Booster doses may be given every 6 months if necessary for travel or for residence in highly endemic, unsanitary areas. In areas where cholera occurs in a 2-3 month

TABLE 1. Recommended doses, by volume, for immunization against cholera

| Dose no. | Route and age |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $\frac{\text { Intradermal* }}{\geqslant 5 \mathrm{yrs}}$ | Subcutaneous or intramuscular |  |  |
|  |  | 6 mos-4 yrs | 5-10 yrs | $>10 \mathrm{yrs}$ |
| 1 and 2 | 0.2 mL | 0.2 mL | 0.3 mL | 0.5 mL |
| Boosters | 0.2 mL | 0.2 mL | 0.3 mL | 0.5 mL |

*Higher levels of protection (antibody) may be achieved in children $<5$ years old by the subcutaneous or intramuscular routes.

Cholera - Continued
season, protection is best if the booster dose is given at the beginning of the season. The primary series does not need to be repeated for booster doses to be effective.

## PRECAUTIONS AND CONTRAINDICATIONS

## Reactions

Vaccination often results in 1-2 days of pain, erythema, and induration at the site of injection. The local reaction may be accompanied by fever, malaise, and headache.

Serious reactions following cholera vaccination are extremely rare. If a person has had a serious reaction to the vaccine, revaccination is not advised. Most governments will permit an unvaccinated traveler to proceed if he/she carries a physician's statement of medical contraindication. However, some countries may quarantine such unvaccinated persons or place them under surveillance if they come from areas with cholera.

## Pregnancy

No specific information exists on the safety of cholera vaccine during pregnancy. Its use should be individualized to reflect actual need.

International Notes

## Poliomyelitis - Israel

From July 31 to September 28, 1988, 16 persons in Israel (population 4.6 million) were reported with confirmed or suspected paralytic poliomyelitis. Thirteen cases were reported from the District of Hadera (population 180,000), located approximately 30 miles northeast of Tel Aviv.

Eight cases occurred in persons 20-33 years old, four in persons 11-19 years old, one in a 5 -year-old child, and three in children 2-21 months old. Of the three cases not occurring in residents of Hadera, two were in children 9 and 21 months of age. To date, Type I poliovirus has been isolated from eight persons.

## Poliomyelitis - Continued

Israel began vaccination against polio with inactivated polio vaccine (IPV) in 1957. In the early 1960s, oral polio vaccine (OPV) replaced IPV nationwide. The vaccine schedule consisted of OPV given at 2, 4, 6, and 12-14 months of age. Between 1971 and 1981, an average of 14 paralytic poliomyelitis cases was reported annually in Israel. Hadera had reported the highest incidence of paralytic polio before 1982. In 1982, the use of an enhanced potency IPV (eIPV) was instituted in Hadera and one other of the 15 districts in Israel. Between 1982 and 1987, fewer than two cases of paralytic poliomyelitis were reported annually in Israel. None of the cases in the current outbreak occurred in eIPV recipients.

Because of the outbreak, vaccination of all persons $\leqslant 39$ years was carried out in Hadera and in the second eIPV district, primarily with OPV. Vaccination in other districts is in progress. It is anticipated that vaccination of the entire national population $\leqslant 39$ years will be completed within 2 weeks.
Reported by: Dept of Epidemiology, Ministry of Health, Jerusalem, Israel. Div of Immunization, Center for Prevention Svcs, CDC.
Editorial Note: In developed countries, such as Japan, Australia, New Zealand, Canada, and the countries of industrialized Europe, the risk of acquiring poliomyelitis is usually no greater than in the United States. In contrast, all developing countries should generally be considered endemic for poliomyelitis. Proof of poliomyelitis immunization is not required for international travel. However, the Immunization Practices Advisory Committee (ACIP) recommends that travelers to countries where poliomyelitis is occurring, which now temporarily includes Israel, be immunized. Schedules for primary immunization against poliomyelitis require three or more doses. In general, OPV is the vaccine of choice for persons $<18$ years of age. Unimmunized adults $\geqslant 18$ years should receive at least two doses of eIPV at least 4 weeks apart, and preferably a complete primary series, before traveling. If travel plans do not permit this interval, one dose of OPV or eIPV is recommended. For adults incompletely immunized with OPV or IPV, the remaining doses should be given to complete the primary series, regardless of the interval since the last dose or the type of vaccine previously received; either OPV or eIPV can be used to complete the series. One additional dose of either OPV or eIPV should be given to travelers of all ages who completed a primary series of OPV or IPV. Ideally, this booster dose should be administered at least 2 months before scheduled departure to ensure maximum protective benefit. ACIP recommendations on poliomyelitis prevention should be consulted for further details (1,2).

World Health Organization consultants in Israel expect that the containment measures in progress and those planned will terminate the outbreak.

FIGURE I. Reported measles cases - United States, Weeks 36-39, 1988

The Morbidity and Mortality Weekly Report is prepared by the Centers for Disease Control, Atlanta, Georgia, and available on a paid subscription basis from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402, (202) 783-3238.

The data in this report are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the succeeding Friday. The editor welcomes accounts of interesting cases, outbreaks, environmental hazards, or other public health problems of current interest to health officials. Such reports and any other matters pertaining to editorial or other textual considerations should be addressed to: Editor, Morbidity and Mortality Weekly Report, Centers for Disease Control, Atlanta, Georgia 30333.

Director, Centers for Disease Control James O. Mason, M.D., Dr.P.H.
Acting Director, Epidemiology Program Office Michael B. Gregg, M.D.

[^0]:    U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES / PUBLIC HEALTH SERVICE

[^1]:    *Recombinant DNA derived (rDNA).

[^2]:    *Official name: Cholera Vaccine.

[^3]:    *Because AIDS cases are not received weekly from all reporting areas, comparison of weekly figures may be misleading.
    ${ }^{t}$ One of the 3 reported cases for this week was imported from a foreign country or can be directly traceable to a known internationally imported case within two generations.

[^4]:    *Mortality data in this table are voluntarily reported from 121 cities in the United states, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
    **Pneumonia and influenza.
    $\dagger$ Because of changes in reporting methods in these 3 Pennsylvania cities, these numbers are partial counts for the current week.
    Complete counts will be available in 4 to 6 weeks.
    $\dagger \dagger$ Total includes unknown ages.
    5Data not available. Figures are estimates based on average of past available 4 weeks.
