Progress in Chronic Disease Prevention

## Chronic Disease Prevention and Control Activities United States, 1989

Although chronic diseases account for $75 \%$ of the mortality and a substantial proportion of serious disability in the United States, data regarding the activities and capacity of public health agencies to control chronic diseases are limited. To assess resources, needs, and priorities in chronic disease prevention and control during fiscal year (FY) 1989, the Association of State and Territorial Chronic Disease Program Directors (ASTCDPD), in cooperation with the Public Health Foundation, recently completed a national survey of all state and territorial health agencies. This report summarizes those findings of the survey that address resources and planning/ evaluation activities (1).

In June 1990, a questionnaire was mailed to the ASTCDPD voting member in each state and territory. The survey addressed five areas: 1) resources, 2) planning and evaluation, 3) links with other organizations, 4) continuing education needs, and 5) policies and standards. Responses were received from the 50 states, the District of Columbia, Guam, and the Virgin Islands.

During FY 1989, the total reported expenditure for chronic disease control activities in the United States was $\$ 245,371,377$ (Table 1), less than $3 \%$ of FY 1989 expenditures by all surveyed public health agencies. Reported per capita expenditures varied widely, from $\$ 3.83$ in California to zero in Oregon. Although certain states (e.g., Alaska and Nevada) ranked high in per capita spending, funding from state sources accounted for a small proportion of total expenditures for chronic disease control and prevention activities. Per capita spending for chronic disease control in the continental United States generally was higher in the southwestern and southeastern states and lower in the south central and midwestern states.

Although fewer than half the states and territories had developed health objectives for 1990 for any chronic disease priority area, most had developed or were planning year 2000 objectives in each area except chronic obstructive pulmonary disease and arthritis (Table 2). When asked an open-ended question on their highest chronic

## Chronic Disease - Continued

disease priorities, the most frequently cited responses were cancer, cardiovascular disease, tobacco use, diabetes mellitus, unintentional injuries, and minority health. As of October 31, 1990, most states and territories were routinely collecting data on chronic disease mortality ( $100 \%$ ), behavioral risk factors ( $92 \%$ ), cancer incidence ( $72 \%$ ), and hospital discharges ( $62 \%$ ); fewer states obtained data on spinal cord injuries ( $32 \%$ ), ambulatory care ( $23 \%$ ), and Alzheimer disease ( $15 \%$ ).
Reported by: R Brownson, PhD, J Taylor, PhD, F Bright, MS, D Momrow, MPH, R Moon, MPH, G Stoodt, MD, P Remington, MD, S Benn, J Bowie, MPH, S Foerster, MPH, C Laramey, L Larsen, R Schwartz, MSPH, R Spengler, ScD, F Wheeler, PhD, G Wright, MD, A Yerkes, MPH, W Young, Association of State and Territorial Chronic Disease Program Directors. A Chacon, S Madden, J Dimas, MPA, Public Health Foundation. K Marconi, PhD, National Cancer Institute, National Institutes of Health. National Center for Chronic Disease Prevention and Health Promotion, CDC.
Editorial Note: In the United States, six chronic diseases-heart disease, cancer, stroke, diabetes mellitus, chronic obstructive pulmonary disease, and chronic liver disease - are among the major causes of death, disability, and medical expenditures (2). In 1988, these six diseases accounted for $71.5 \%$ of all deaths in the United States (3). Six ( $27 \%$ ) of the 22 priority areas of the year 2000 national health objectives (4) relate directly to control of chronic diseases (i.e., heart disease and stroke, cancer, and diabetes and other chronic disabling conditions) or major chronic disease risk factors (i.e., tobacco use, poor nutrition, and physical inactivity). Four other priority areas address issues indirectly related to chronic disease control (i.e., prevention of alcohol and other drug abuse, educational and community-based programs, clinical preventive services, and surveillance and data systems).

During FY 1989, programs for maternal and child health accounted for $13 \%$ of state public health expenditures; environmental health, $6 \%$; human immunodeficiency

TABLE 2. Percentage of states and territories that have developed or have planned health objectives for selected chronic diseases and chronic disease risk factors United States, 1990*

[^0]virus infection/acquired immunodeficiency syndrome, 3\%; and communicable disease control, 3\% (Public Health Foundation, unpublished data). The proportion of expenditures dedicated to chronic diseases is likely to increase with the implementation of several new programs (e.g., the Breast and Cervical Cancer Screening Initiative from CDC and the American Stop Smoking Intervention Study for Cancer Prevention from the National Cancer Institute and the American Cancer Society [Project ASSIST]).

Although a variety of data sets were available for chronic disease surveillance in most jurisdictions, $85 \%$ of respondents reported that these data were inadequate, reflecting in part the collection and location of data sets outside the chronic disease unit or an insufficient analytic capacity. In addition, lack of adequate data on minority groups was reported as a major deficiency. Therefore, improved chronic disease surveillance systems are needed, particularly to address the needs of high-risk groups and to measure progress toward year 2000 national health objectives.

Based on recent estimates, eliminating a single risk factor for each of nine key chronic diseases could reduce mortality from these causes by $47 \%$, from 427 per 100,000 persons to 224 per 100,000 (5). Preventable risk factors for chronic diseases include cigarette smoking, high blood pressure, high blood cholesterol, overweight, physical inactivity, poor nutrition, heavy alcohol consumption, and failure to use screening tests such as mammography and Papanicolaou smears (2,5). However, the well-established public health approaches to controlling these risk factors are underused (2). Factors that contribute to the success of public health strategies include targeting high-risk populations, addressing multiple risk factors, and intervening through multiple channels (e.g., schools, health-care settings, worksites, and community settings.)

## Effectiveness in Disease and Injury Prevention

## Successful Strategies in Adult Immunization

Safe and effective vaccines are available to prevent pneumococcal disease and influenza and hepatitis B virus (HBV) infections among persons in the United States; however, a substantial number of adults at increased risk for these preventable infections remain unvaccinated. This report describes collaborative public and private efforts to increase the vaccination of adults and highlights National Adult Immunization Awareness Week, October 27-November 2, 1991.

## Medicare Influenza Vaccine Demonstration Project

In October 1988, CDC, in collaboration with the Health Care Financing Administration, awarded demonstration grant funds to nine programs to assess the cost-

## Adult Immunization - Continued

effectiveness of providing influenza vaccine to Medicare part B beneficiaries and measure the impact of Medicare coverage on promoting the vaccine as a routine preventive health measure. The addition of a 10th program in 1990 increased the study population to more than 1.9 million Medicare beneficiaries.

Through a variety of promotional and educational efforts directed at providers and patients, the project substantially improved influenza vaccine delivery during the first 3 years of the 4 -year study period. Vaccine doses administered increased from 481,000 the first full year to 786,000 the third, representing an overall increase in vaccine coverage of Medicare beneficiaries from $30 \%$ to $41 \%$. Descriptions of the programs in Monroe County, New York, and Maricopa County, Arizona, illustrate the approaches that have been used to improve vaccine delivery and coverage.

Monroe County, New York. In 1989, a random sample of private-practice physicians identified all persons $\geqslant 65$ years of age (who should be vaccinated against influenza). In 28 (62\%) of the 45 participating practices, a graph indicating the percentage of such patients in the practice who had been vaccinated was placed on a conspicuous wall in each office and updated weekly during the influenza season. Those practices achieved $30 \%$ higher vaccination levels than did those not using the graph ( $67 \%$ vs. $50 \%$ of patients vaccinated; $p<0.01$ ) (1). In 1990, this target-based system was expanded countywide and included an incentive of bonuses above the usual vaccine administration fees for practices that vaccinated $70 \%$ or more of their target population. Preliminary data indicate that one group of physicians vaccinated $72 \%$ of eligible Medicare patients (range: $44 \%-72 \%$ in the different physician practices).

Maricopa County, Arizona. As part of the Medicare demonstration project in Maricopa County, the county health department arranged for nine private-practice physicians to conduct influenza vaccination clinics for Medicare beneficiaries at shopping malls during October 1990-February 1991. Participating physicians were provided free vaccine and an administration fee for each vaccinee in the program. Billboards, newspaper advertisements, and public service announcements were used to promote the clinics. Of the 101,882 Medicare beneficiaries who were vaccinated through the project, 43,617 ( $43 \%$ ) were vaccinated in nine mall clinics.

## California Influenza/Pneumococcal Vaccination Program

The California Influenza/Pneumococcal Vaccination Program was initiated in 1974 (2). Both influenza and pneumococcal vaccines are state-funded and are administered primarily at local health department clinics, community sites, and nursing homes. Local hospitals, senior citizen groups, and local American Red Cross chapters assist by providing facilities, nurses, and volunteers. Promotional efforts by local health departments include press releases, public service announcements, fliers, posters, and close coordination with senior citizen groups.

In fiscal year (FY) 1982, a total of 341,375 doses of influenza vaccine were administered, compared with 653,877 doses in FY 1991-an increase of $92 \%$. In FY 1991, $16 \%$ of the total population aged $\geqslant 65$ years in the state were vaccinated against influenza. In FY 1987, a total of 23,753 doses of pneumococcal vaccine were administered (2), compared with 45,548 doses in FY 1990-also an increase of $92 \%$.

## Hepatitis B Vaccine in Sexually Transmitted Diseases Clinics

In 1990, CDC initiated a demonstration project to assess the feasibility of offering hepatitis $B$ (HB) vaccination in sexually transmitted diseases (STD) clinics to persons

## Adult Immunization - Continued

at high risk for sexually transmitted HBV infection. New patients who had no history of HBV infection or HB vaccination were offered vaccine. Patients accepting vaccination were tested for HB core antibody (a marker of past HBV infection) and given their first vaccine dose at their initial visit. Those with no evidence of past HBV infection were eligible for subsequent doses and were reminded by mail and telephone to return to complete their primary vaccination series.

During July 1990, in San Francisco, vaccine was offered to 1386 persons, of whom $611(44 \%)$ accepted. Of these, $181(30 \%)$ had prior evidence of HBV infection, and 430 ( $70 \%$ ) were susceptible and eligible for subsequent doses. Of those eligible, 210 ( $49 \%$ ) persons returned for a second vaccine dose, and 135 (31\%) completed a three-dose series.

During a 3-week period in April 1991, in Birmingham, Alabama, vaccine was offered to 1079 persons, of whom 744 ( $69 \%$ ) accepted. Of these, 638 ( $86 \%$ ) were eligible for subsequent doses. Through September 1991, 249 (39\%) of those eligible returned and received a second vaccine dose.

In both San Francisco and Birmingham, among participants having evidence of prior HBV infection, seropositivity was strongly associated with age ( $8 \%$ of persons $<20$ years of age had evidence of past infection, compared with $39 \%$ of persons aged $\geqslant 30$ years).

P Lesniak, J Hartner, MD, Div of Public Health, Maricopa County Dept of Health Svcs, Phoenix, Arizona. M Fleenor, MD, J Hardin, Jefferson County Dept of Health, Birmingham, Alabama. F Taylor, GA Bolan, MD, San Francisco Dept of Public Health; GW Rutherford, III, MD, State Epidemiologist, California Dept of Health Svcs. Office of Research and Demonstrations, Health Care Financing Administration. Div of Viral and Rickettsial Diseases and Div of Bacterial and Mycotic Diseases, National Center for Infectious Diseases; Div of STD/HIV Prevention and Div of Immunization, National Center for Prevention Svcs, CDC.
Editorial Note: A substantial proportion of vaccine-preventable diseases occur among adults (Table 1) despite the availability of safe and effective vaccines. Reasons contributing to low vaccination levels among adults are that 1) no comprehensive vaccine delivery systems are available in the public and private sectors; 2 ) although statutory requirements exist for vaccination of children, no such requirements exist for all adults; 3) vaccination schedules are complicated because of the detailed recommendations that may vary by age, occupation, lifestyle, or health condition; 4) opportunities to vaccinate adults are frequently missed during contacts with health-care providers in offices, outpatient clinics, and hospitals (3); 5) vaccination

*Influenza and pneumococcal disease are not included in the national system of notifiable disease reporting.
programs have not been established in other settings where adults congregate (e.g., the workplace); and 6) patient and provider fears exist concerning adverse events following vaccination.

In the United States, influenza epidemics are often associated with more than 20,000 excess deaths annually, $80 \%-90 \%$ of which occur among persons $\geqslant 65$ years of age. Although influenza vaccine is estimated to be up to $70 \%$ effective in reducing deaths among high-risk elderly persons (3), findings from the 1989 National Health Interview Survey (NHIS) indicate that only $30 \%$ of persons aged $\geqslant 65$ years were vaccinated for influenza during the previous year (4). Disease caused by Streptococcus pneumoniae infection remains a problem in the very young, the elderly, and persons with certain high-risk conditions. Although pneumococcal vaccine is more than $60 \%$ effective in preventing invasive pneumococcal infections, data from the 1989 NHIS indicate that only $14 \%$ of persons aged $\geqslant 65$ years reported ever having received pneumococcal vaccine (4). The Medicare Influenza Vaccine Demonstration Project and the California Influenza/Pneumococcal Vaccination Program both illustrate how efforts to motivate providers and develop collaborative public and private delivery strategies can improve vaccination coverage against influenza and pneumococcal disease.

Each year HBV infection occurs in an estimated 300,000 persons, primarily young adults; $6 \%-10 \%$ of these persons become chronic HBV carriers. Heterosexuals with multiple sex partners are one category of persons at increased risk for HBV infection (5); the proportion of HBV infections in the United States accounted for by persons with only heterosexual activity as a risk factor increased from $14.7 \%$ in 1982 to $26.0 \%$ in 1988 (6). The findings in San Francisco and Birmingham, as well as in other sites (7), indicate that STD clinics may be opportune sites to vaccinate persons in this risk group against HBV infection. However, strategies to improve completion rates are needed: only half of susceptible persons have received at least two doses of vaccine through these programs, even though $70 \%$ or more of those receiving two doses will develop detectable protective antibody (8). Although universal vaccination of infants and adolescents is the optimal long-term strategy to prevent HBV infection, until then the continued targeting of high-risk groups is necessary to reduce disease incidence.

Of the 19 national health objectives for the year 2000 that target vaccination and infectious diseases, 10 are related to vaccination of adults ( 9 ). The objectives include 1) reduction of epidemic-related pneumonia and influenza deaths and provision of influenza and pneumococcal vaccines to at least $60 \%$ of noninstitutionalized high-risk populations and at least $80 \%$ of institutionalized chronically ill or older persons and 2) increasing HB vaccination among high-risk populations to at least $90 \%$. The proportion of primary-care providers and public health departments that provide adult vaccinations for influenza, pneumococcal disease, and HBV should increase to 90\% (9).

Vaccination programs have markedly reduced the incidence of vaccinepreventable diseases among children, but many adults remain susceptible because they are inadequately immunized. Improving vaccine use among adults and reaching the year 2000 national health objectives for immunization (9) require multifaceted strategies involving collaboration of public and private organizations to improve awareness and vaccine delivery, publicly supported delivery mechanisms that remove cost and accessibility constraints, and special surveys to assess current

## Adult Immunization - Continued

programs. The goal of National Adult Immunization Awareness Week is to emphasize the importance of appropriately vaccinating all adults by focusing attention on efforts that promote prevention and control of vaccine-preventable diseases. The National Coalition for Adult Immunization (telephone [301] 656-0003) and CDC offer more information on the week's activities.

## Current Trends

## Update: Influenza Activity - Worldwide, 1990-91, and Influenza Vaccination - United States

During the 1990-91 influenza season, influenza occurred at relatively low levels throughout much of the world. All reporting countries (except Brazil and Papua New Guinea, which reported epidemic levels) indicated either sporadic cases, small local outbreaks, or regional outbreaks. This report summarizes worldwide influenza activity reported from April through September 1991.

Asia. From April through August, sporadic isolations of influenza B were reported from Hong Kong, Japan, Singapore, and Thailand; influenza A(H3N2), from southern China, India, and Singapore; and influenza A(H1N1), from China, Hong Kong, Japan, Singapore, and Taiwan.

Europe. Influenza activity decreased in Europe during April and May, with only sporadic isolations of influenza $B, A(H 3 N 2)$, and $A(H 1 N 1)$ reported in 10 countries.

Canada and the United States. Canada reported continued sporadic isolation of influenza A and influenza B from April through July; most influenza A isolates were subtype $A(H 3 N 2)$. In the United States, influenza A(H3N2) activity increased during late February, was associated with culture-confirmed outbreaks in a military facility and nursing homes from March through May, and continued to be reported sporadically through June.

Influenza - Continued
Central and South America. From June through August, sporadic isolations of influenza B were reported in Argentina, Brazil, Chile, and Uruguay. During May, an outbreak of influenza $A(H 3 N 2)$ was reported in Guayaquil, Ecuador; during July, epidemic levels of influenza $A(H 3 N 2)$ were reported in Brazil. During June, influenza $A(H 1 N 1)$ virus was reported from Brazil.

Oceania. Influenza B outbreaks occurred in Papua New Guinea from May through August and throughout the South Island of New Zealand in May and June. Australia reported sporadic influenza $B$ activity from April through July. From May through June, Papua New Guinea reported epidemic levels of influenza A(H3N2) in one highland region community (estimated attack rate: 45\%). During July, influenza A(H3N2) was isolated sporadically in Australia, and influenza A(H1N1) was isolated sporadically in New Zealand.

South Africa. Influenza B (32 isolates) and influenza A(H3N2) (42 isolates) were identified from May through August.

Characterization of influenza virus isolates. During the 1990-91 worldwide influenza season, 812 isolates were antigenically characterized by the World Health Organization (WHO) Collaborating Center for Surveillance, Epidemiology, and Control of Influenza at CDC; of these, 584 (72\%) were from the United States. Of 450 influenza B viruses characterized, $4 \%$ were B/Victoria/02/87-like and $96 \%$, B/Yamagata/ 16/88-like. Most ( $66 \%$ ) of the B/Yamagata-like viruses were most closely related to B/Panama/45/90, a minor variant of B/Yamagata/16/88. A total of 188 influenza $\mathrm{A}(\mathrm{H} 3 \mathrm{~N} 2)$ viruses were characterized antigenically, and 168 ( $89 \%$ ) of these were A/Beijing/353/89-like; all 145 influenza $A(H 1 N 1)$ viruses analyzed were $A / T a i w a n /$ 1/86-like.
Reported by: National Influenza Centers. Communicable Diseases Div, World Health Organization, Geneva, Switzerland. Epidemiology Activity, and WHO Collaborating Center for Surveillance, Epidemiology, and Control of Influenza, Influenza Br, Div of Viral and Rickettsial Diseases, National Center for Infectious Diseases, CDC.
Editorial Note: Both influenza A and influenza B circulated at low levels worldwide from October 1990 through September 1991. An increase in the proportion of U.S. isolates subtyped as influenza A(H3N2) after March 1991 and the identification of sporadic isolates of influenza $A(H 1 N 1)$ and influenza $A$ (not subtyped) in midSeptember 1991 suggest that influenza A may predominate in the United States during the 1991-92 influenza season.

Morbidity and mortality associated with influenza can be reduced by annual vaccination of persons at increased risk for influenza-related complications and their contacts (1). However, in the United States, only $30 \%$ of persons belonging to groups at high risk for influenza-related complications are vaccinated each year (2). One of the year 2000 national health objectives is to achieve influenza vaccination levels of at least $80 \%$ in institutionalized older or chronically ill persons, and at least $60 \%$ in noninstitutionalized high-risk persons (3). Persons at increased risk for complications from influenza include those $\geqslant 65$ years of age; all residents of nursing homes or chronic-care facilities; persons with chronic pulmonary or cardiovascular disorders (including children with asthma); persons requiring medical follow-up during the past year for chronic metabolic diseases, renal dysfunction, hemoglobinopathies, or immunosuppression; and children and teenagers on long-term aspirin therapy, who are at increased risk for Reye syndrome if infected with influenza. In addition,

Influenza - Continued
vaccination is recommended for all persons who provide care for or live with high-risk persons, including health-care providers and household members.

Antibody titers that are protective against influenza infection are achieved approximately 2 weeks following vaccination and begin to decline after approximately 4-6 months. The 1991-92 trivalent influenza vaccine contains hemagglutinin antigens from A/Beijing/353/89-like(H3N2), A/Taiwan/1/86-like(H1N1), and B/Panama/45/90-like viruses, which closely resemble recently identified strains. Because substantial influenza activity in the United States rarely occurs before December, November is the optimal time for vaccination campaigns. When influenza surveillance indicates the occurrence of regional influenza activity before December, vaccination programs should be initiated as soon as the currently recommended vaccine is available. Age-specific vaccination recommendations for the 1991-92 U.S. influenza season have been published (Table 1) (1).

Amantadine is an adjunct to vaccination for prevention and control of influenza $A$, particularly in institutional settings. Advanced contingency planning (e.g., individualized standing orders for amantadine that can be implemented at the start of an influenza A outbreak) can facilitate rapid implementation of chemoprophylaxis. Amantadine can provide effective prophylaxis for persons who are unvaccinated and, because a full protective response from vaccination requires 2 weeks to develop, for those vaccinated after influenza $A$ is already circulating in the community. Because amantadine is ineffective against influenza $B$, culturing pharyngeal or nasal secretions of persons with an influenza-like illness can be helpful in guiding influenza control measures (i.e., by detecting and identifying specific influenza types/subtypes in the community).

From October through May, surveillance information is updated weekly at CDC and is available by telephone (CDC Voice Information System [influenza update]

TABLE 1. Influenza vaccine* dosage, by patient age - United States, 1991-92 season

| Age group | Product $^{\dagger}$ | Dosage | No. doses | Route $^{5}$ |
| :--- | :--- | :--- | :---: | :---: |
| $6-35 \mathrm{mos}$ | Split virus only | 0.25 mL | 1 or $2^{\top}$ | M |
| $3-8 \mathrm{yrs}$ | Split virus only | 0.50 mL | 1 or $2^{\dagger}$ | IM |
| $9-12 \mathrm{yrs}$ | Split virus only | 0.50 mL | 1 | IM |
| $>12 \mathrm{yrs}^{* *}$ | Whole or split virus | 0.50 mL | 1 | IM |

*Contains $15 \mu \mathrm{~g}$ each of A/Beijing/353/89-like(H3N2), A/Taiwan/1/86-like(H1N1), and B/Panama/ 45/90-like hemagglutinin antigens in each 0.5 mL . Manufacturers include: Connaught Laboratories, Inc. (distributed by E.R. Squibb \& Sons, Inc.) (Fluzone® whole or split); Evans Medical Ltd.-Lederle Laboratories (distributed by Lederle Laboratories) (Flu-Imune® purified surface antigen vaccine); Parke-Davis (Fluogen® split); and Wyeth-Ayerst Laboratories (Influenza Virus Vaccine, Trivalent ${ }^{\circledR}$ split). Further product information is available from Connaught, (800) 822-2463; Lederle, (800) 533-3753; Parke-Davis, (800) 223-0432; and WyethAyerst, (800) 950-5099.
${ }^{\dagger}$ Because of the lower potential for causing febrile reactions, only split-virus vaccines should be used for children. They may be labeled as "split," "subvirion," or "purified-surfaceantigen" vaccine. Immunogenicity and side effects of split- and whole-virus vaccines are similar for adults when vaccines are used at the recommended dosage.
${ }^{5}$ The recommended site of vaccination is the deltoid muscle for adults and older children. The preferred site for infants and young children is the anterolateral aspect of the thigh.
'Two doses are recommended for children $<9$ years of age who are receiving influenza vaccine for the first time.
**Corrected from MMWR Recommendations and Reports published May 24, 1991 (1).

Influenza - Continued
[404] 332-4555) or through the CDC Information Service on the Public Health Network electronic bulletin board. In addition, periodic updates about influenza are published in MMWR. Additional information on local influenza activity is available from state and local health departments.

## Cigarette Smoking Among Youth - United States, 1989

In 1988, an estimated 434,000 persons in the United States died as a result of cigarette smoking (1). About three fourths of adults who have ever been regular cigarette smokers reported trying their first cigarette before their 18th birthday (National Institute on Drug Abuse [NIDA], unpublished data), and about half of them had become regular smokers by that time (2; NIDA, unpublished data). This report, based on the Teenage Attitudes and Practices Survey (TAPS), presents the prevalence of self-reported smoking among U.S. adolescents aged 12-18 years during 1989.

In 1989, the TAPS focused on adolescents' knowledge, attitudes, and practices regarding tobacco use. The sample described in this report includes all youth aged 12-18 years who were living in households. Questionnaires were administered by computer-assisted telephone interviewing and mail (for homes without telephones and for initial nonrespondents). Adolescents were sampled from households that had participated in the second half of the 1988 National Health Interview Survey (NHIS) and the first half of the 1989 NHIS. During this period, the household participation rate was $95 \%$. Data were obtained from 9965 ( $82.4 \%$ ) of 12,097 adolescents in the NHIS households and were adjusted to provide national estimates. Confidence intervals (Cls) were calculated by using the Software for Survey Data Analysis (3). Participants were asked the following questions about cigarette smoking behavior: "Think about the last 30 days. On how many of these days did you smoke?" and "Now, think carefully about the last SEVEN days. Did you smoke cigarettes on any of THOSE days?"

Respondents who were still in school or who had already graduated from high school were classified as "school attenders/high school (HS) graduates." Respondents who were not attending school at the time of the survey and who had not completed the 12th grade were classified as "dropouts." Among youth 17-18 years of age, 2355 ( $80.8 \%$ ) were enrolled in school, 489 (16.8\%) were dropouts, and 69 ( $2.4 \%$ ) had completed high school and were not currently in school.

Overall, $15.7 \%$ of respondents reported smoking on 1 or more days during the month, and $11.5 \%$ reported smoking on 1 or more days during the week before the survey (Table 1). Patterns were similar by gender in all categories, except among persons 18 years of age. The prevalence of smoking was higher among white youth than among black youth. Although the prevalence of smoking in the past month was lower among Hispanic (11.7\%) than among non-Hispanic (16.1\%) youth, the preva-

[^3]Cigarette Smoking - Continued
lence of smoking in the past week was similar in each group ( $9.3 \%$ and $11.8 \%$, respectively). Prevalence of smoking in the past month and in the past week increased directly by age.

Among youth 17-18 years of age, the prevalence of smoking during the previous week was substantially higher among dropouts ( $43.3 \%$ [ $95 \% \mathrm{Cl}= \pm 4.9 \%]$ ) than among school attenders/HS graduates (17.1\% [95\% Cl= $\mathbf{C l} 1.7 \%]$ ). Among school attenders/HS graduates, the prevalence of smoking during the previous week was similar by gender (males: $17.5 \%$ [ $95 \% \mathrm{Cl}= \pm 2.3 \%$ ]; females: $16.7 \%$ [ $95 \% \mathrm{Cl}=$ $\pm 2.3 \%]$ ). However, dropouts who were male ( $51.7 \%$ [ $95 \% \mathrm{Cl}= \pm 6.6 \%]$ ) were more likely to report having smoked during the previous week than were dropouts who were female ( $33.3 \%$ [ $95 \% \mathrm{Cl}= \pm 6.5 \%]$ ). Among school attenders/HS graduates, $19.3 \%$ ( $95 \% \mathrm{Cl}= \pm 1.9 \%$ ) of whites and $5.7 \%$ ( $95 \% \mathrm{Cl}= \pm 2.8 \%$ ) of blacks reported smoking during the previous week. Similarly, dropouts who were white (46.1\% [95\% $\mathrm{Cl}= \pm 5.2 \%]$ ) were more likely to report having smoked during the previous week than were dropouts who were black ( $17.1 \%$ [ $95 \% \mathrm{Cl}= \pm 9.3 \%]$ ).
Reported by: CW Heath, MD, RD Corcoran, EdD, American Cancer Society. SL Mills, MD, DR Shopland, National Cancer Institute; SE Marcus, PhD, National Institute of Dental Research, National Institutes of Health. JP Pierce, PhD, Univ of California at San Diego. Office on Smoking and Health and Div of Adolescent and School Health, National Center for Chronic Disease Prevention and Health Promotion; Div of Health Interview Statistics, National Center for Health Statistics, CDC.
Editorial Note: The findings in this report are consistent with findings from three other recent national surveys that measure smoking by youth: rates of smoking are similar for males and females and higher for whites than blacks (4,5; J.G. Bachman, L.D. Johnston, P.M. O'Malley, University of Michigan, unpublished data, 1990). In addition, the findings from TAPS confirm previous reports of higher smoking rates among dropouts (6) and suggest gender and racial differences in smoking prevalence among dropouts. Differences in overall prevalence estimates between surveys may be explained by the mode of data collection (i.e., household interview vs. school-based, self-administered questionnaire) (7), composition of the samples, varying response rates, and the wording of questions (8).

Cigarette use among U.S. youth appears to have declined sharply in the late 1970s and stabilized in the 1980s $(9,10)$, especially among white youth (2). The findings from TAPS underscore the need for interventions that focus on both in-school and out-of-school youth. The national health objectives for the year 2000 have established four relevant targets for this problem:

- establish tobacco-free environments in all elementary, middle, and secondary schools and include tobacco use prevention programs in school curricula (objective 3.10);
- enact and enforce state laws nationwide prohibiting the sale and distribution of tobacco products to youth aged $<19$ years (objective 3.13);
- implement state plans nationwide to reduce tobacco use, especially among youth (objective 3.14); and
- eliminate or severely restrict all forms of tobacco product advertising and promotion to which youth $\leqslant 18$ years of age are likely to be exposed (objective 3.15) (11).
To help achieve these and other smoking-related objectives, the Public Health Service has developed and implemented several programs. For example, the National Cancer Institute and the American Cancer Society have recently initiated the American Stop

## Cigarette Smoking - Continued

Smoking Intervention Study for Cancer Prevention (Project ASSIST) in 17 states. This demonstration project is designed to disseminate various interventions to prevent and stop tobacco use among adults and youth throughout the nation. CDC provides states with technical assistance to develop and conduct targeted interventions to reduce tobacco consumption among youth. During the 1990s, intensive collaborative efforts will be necessary to reduce tobacco use among U.S. youth.

## Notice to Readers

## Unavailability of Streptomycin and Para-Aminosalicylic Acid in the United States

Streptomycin (SM) and para-aminosalicylic acid (PAS), antimicrobial agents used to treat tuberculosis (TB), are currently unavailable in the United States. Because of problems in the supply of bulk SM, which is produced outside the United States, the U.S. manufacturer has ceased production of the finished product. The U.S. manufacturer of PAS has voluntarily discontinued production on a temporary basis. Although CDC and the Food and Drug Administration are attempting to reestablish production of these drugs, health-care providers should be prepared for an interruption in their supply. For guidance in selecting appropriate alternatives to SM and PAS for the treatment of TB, health-care providers should contact their state or local TB control program.

The Morbidity and Mortality Weekly Report（MMWR）Series is prepared by the Centers for Disease Control and is available on a paid subscription basis from the Superintendent of Documents，U．S． Government Printing Office，Washington，DC 20402；telephone（202）783－3238．

The data in the weekly MMWR are provisional，based on weekly reports to CDC by state health departments．The reporting week concludes at close of business on Friday；compiled data on a national basis are officially released to the public on the succeeding Friday．Inquiries about the MMWR Series，including material to be considered for publication，should be directed to：Editor，MMWR Series，Mailstop C－08， Centers for Disease Control，Atlanta，GA 30333；telephone（404）332－4555．
