## SP.ECIAL NOTE

This report is intended for the information and administrative use of those involved in the investigation and control of poliomyelitis and polio-like diseases. It presents a summary of provisional information reported to CDC from State Health Departments, Virology Laboratories, Epidemic Intelligence Service Officers, and other pertinent sources. Since much of the information is preliminary in nature, confirmation and final interpretation should be determined in consultation with the original investigators prior to any further use of the material.

SUMMARY
There was a slight decrease in the number of reported cases during the 39 th week of the year. The 67 cases reported are more widely dispersed geographically than the 71 cases reported for the previous week.

Poliomyelitis in New York continues to decline as the outbreak in the Syracuse area has greatly diminished. Preliminary information from Pennsylvania has revealed a cluster of cases in the city of Erie. No other concentrations are noted throughout the United States.

The epidemic of aseptic meningitis in Rhode Island due to Coxsackie B-5 is now over. A report on the character of that outbreak and the nature of the febrile illness which occurred concurrently in the communities involved is presented in Section 5.

1. CURRENT POLIOMYELITIS MORBIDITY TRENDS

A total of 67 cases of poliomyelitis was reported for the week ending September 30, 1961. Of these, 36 were classified as paralytic, 17 as nonparalytic and 14 were unspecified (See Table 1). Although New York State again reported the greatest number of cases, their current week's total was 17 as compared to 24 the previous week. Pennsylvania reported 11 cases, 7 of these from one county. Further comment will be made in Section 2 on these States and Maryland. Ohio, Louisiana and Texas, the only other States reporting more than 3 cases, have noted no concentrations.

Six week totals for the 34 th through 39 th week as shown below reflect the low seasonal incidence. Figure 1 clearly indicates the absence of any upward trend and suggests that the peak week may have already been reached.

Six Week Totals (34th through 39th Week) for Past 5 Years

|  | 1961 | 1960 |  | 1959 | 1958 |
| :--- | ---: | ---: | ---: | ---: | ---: |
|  |  |  |  | 1957 |  |
| Paralytic | 269 | 699 | 1854 | 1025 | 526 |
| Total | 429 | 1066 | 2936 | 2127 | 1647 |

2. REPORTS

## A. New York State

Only two new cases of paralytic poliomyelitis have been reported during the past week from the outbreak in Central New York State. Both cases were from Onondaga County bringing the total number of paralytic cases in the contiguous tri-county area to 74 through October 4. Of the 74 cases, 44 have occurred in Onondaga County (31 in Syracuse), 17 in Madison County, and 13 in Oneida County.

Dr. Robert M. Albrecht, Director, Office of Epidemiology, New York State Department of Health, reports that both of the new cases were adults with onsets on September 19 and 24. They both had received type I oral vaccine during the mass immunization campaign on August 2931. The epidemic curve by county and date of onset in three-day periods showing those cases receiving oral vaccine appeared in last week's P.S.U. Report No. 240.

The paralytic cases are shown below by age group and vaccination history. Over 40 percent have been preschool children and 30 percent have been adults at least 20 years old. Forty percent of the 74 paralytic cases have had three or more doses of inactivated vaccine while 38 percent have been unvaccinated. Fifteen of the 28 cases with onset since the oral vaccine program began on August 29 have received oral vaccine.

| Age <br> Group | Inactivated Vaccine |  |  |  |  | TOTAL | \% | Type I Oral Vaccine* |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | OV | 1V | 2V | 3V | $4+$ |  |  | Yes | No |
| 0-4 | 12 | 2 | 4 | 8 | 5 | 31 | 41.9 | 2 | 3 |
| 5-9 | 1 | 0 | 3 | 4 | 3 | 11 | 14.9 | 1 | 0 |
| 10-19 | 3 | 0 | 4 | 1 | 2 | 10 | 13.5 | 5 | 1 |
| 20-29 | 5 | 3 | 0 | 3 | 2 | 13 | 17.6 | 3 | 6 |
| 30+ | 7 | 0 | 0 | 1 | 1 | 9 | 12.2 | 4 | 3 |
| TOTAL | 28 | 5 | 11 | 17 | 13 | 74 | 100.0 | 15 | 13 |

In addition to the 74 paralytic cases, 23 nonparalytic cases have been recognized in the three counties. The entire outbreak is shown on the following page by week of onset and paralytic status. As in the 1960 Providence epidemic, nonparalytic cases tended to be reported only after the paralytic outbreak had been well established. (1) However, specific laboratory studies on the nonparalytic cases are still in progress. To date, there have been 14 type I poliovirus isolations from this area, 13 from paralytic cases and one from a nonparalytic case.
${ }^{(1)}$ Oren, J. et al: Rhode Island Medical Journal 44:337-342, June 1961.

## B . Pennsylvania

The eleven cases reported this week from Pennsylvania represent a marked increase over previous weeks. Four cases were scattered throughout the State while seven patients unspecified as to paralytic status were reported from Erie County. Preliminary investigations reveal that all were children under ten years of age, with three cases occurring in one family. Five of seven had onset in the latter half of September.

A high incidence of enterovirus disease or aseptic meningitis has not been noted in the area. Laboratory identification of the responsible agent has not been accomplished.

Across the State line, four cases have been reported from adjacent Chautauqua County, New York, by the New York State Department of Health. Although all four cases have occurred in September, there is no geographic localization within the county.

## C. Maryland

Two of the three paralytic cases reported from Maryland for the week ending September 30, were acute fatalities in Washington County. Both cases, three-year old white females, had onset in midSeptember and died within three days. One patient was unvaccinated and the other had received two doses of inactivated vaccine. Two previous paralytic cases have been reported from Washington County earlier this year. Adjacent Frederick County, scene of an August outbreak, has had a total of 13 paralytic cases, the last one having onset on August 31 (See P.S.U. Report No. 235).

In addition, four cases have occurred in adjacent Franklin County, Pennsylvania, two in September.
3. 1961 POLIOMYELITIS REPORTED TO PSU

Through September 30, there have been 647 cases of poliomyelitis with onset in 1961 submitted on individual case forms to the Poliomyclitis Surveillance Unit. Of these 647 cases, 473 ( 73 percent) are paralytic, 153 nonparalytic and 21 unspecified as to paralytic status. These cases are presented below in Table 3 by paralytic status, age group and vaccination history.

Sixty-day follow-up reports on cases occurring earlier in the year are being received daily. of the 473 paralytic cases shown in Table 3, 151 follow-up reports received reveal that 16 have had no residual paralysis at sixty days and another 14 were not poliomyelitis. Thus, the follow-ups received on paralytic cases show 20 percent to not be true paralytic poliomyelitis. This emphasizes the importance of careful and adequate sixtyday follow-up reports.

4. ROUTINE POLIOMYELITIS SURVEILIANCE
A. Cases with Onset Within 30 Days of Vaccination

Two cases of poliomyelitis, one paralytic, within 30 days of receiving inactivated vaccine have been reported to the Poliomyelitis Surveillance Unit during the past week ending September 30. This brings the corrected 1961 total to 13 cases, of which 10 are paralytic (two correlated). The three paralytic cases reported during the last two months are presented in Table II. The under-30-day cases reported previous to August appeared in Table II of PSU Report 232 dated August 4, 1961.
5. ENTEROVIRUS SURVEILLANCE - ASEPTIC MENINGITIS IN RHODE ISLAND

Drs. R.F. McAteer, Assistant Director of Health, and Earl Byrne, EIS Officer, assigned to the Rhode Island State Department of Health report that a total of 64 cases of aseptic meningitis have been hospitalized in the State this summer. There has been a sharp decrease in the number of cases with recent onset.

The large number of cases originating from the northern part of the State (Woonsocket Area) is quite evident from the histogram.

## RHODE ISLAND ASEPTIC MENINGITIS BY WEEK OF ONSET

Number
of Cases

These hospitalized cases assumed the following age distribution:

| Age | Male | Female | TOTAL |
| :---: | ---: | :---: | ---: |
|  |  |  | 3 |
| $5-4$ | 11 | 6 | 8 |
| $10-14$ | 8 | 7 | 17 |
| $15-19$ | 4 | 2 | 15 |
| $20-24$ | 4 | 3 | 6 |
| $25-29$ | 0 | 3 | 7 |
| $30+$ | 2 | 6 | 3 |
|  |  |  | -8 |
| TOTAL | 34 | 30 | 64 |

The aseptic meningitis from Woonsocket was associated with a high incidence of febrile illness in the area. In thirty-two families visited with febrile illness 67 of 158 family members were affected. The following clinical complaints were made by these 67 patients.

| Fever | $100 \%$ | (varying from $100^{\circ}-105^{\circ} \mathrm{F}$ ) |
| :--- | :---: | :--- |
| Headache | 68 |  |
| Nausea and Vomiting | 51 |  |
| Sore Throat | 39 |  |
| Stiff Neck | 30 |  |
| Abdominal Pain | 30 |  |
| Myalgia | 21 |  |
| Pleurisy | 11 |  |
| Diarrhea | 9 |  |

The illness reported in the non-hospitalized cases, and those hospitalized with aseptic meningitis was identical, differing only in degree of severity of symptoms.

Several strains of Coxsackie B-5 have been isolated from hospitalized cases of aseptic meningitis and from the patients with febrile illness. Pericarditis or neonatal myocarditis has not been noted.
(This surveillance report was prepared by the Poliomyelitis and Poliolike Diseases Surveillance Unit, Michael J. Regan, M.D., Chief, James A. Bryan, II, M.D., and Mr. Leo Morris, Statistician, with the assistance of Statistics Section, CDC.)
