## PREFACE

Summarized in this report is information received from State Health Departments, university investigators, virology laboratories and other pertinent sources, domestic and foreign. Much of the information is preliminary. It is intended primarily for the use of those with responsibility for disease control activities. Anyone desiring to quote this report should contact the original investigator for confirmation and interpretation.

Contributions to the Surveillance Report are most welcome. Please address to: Chief, Poliomyelitis Surveillance Unit, Communicable Disease Center, Atlanta, Georgia 30333

Eleven cases of poliomyelitis, 8 paralytic, have been reported to the Communicable Disease Center through the 20 th week of 1965 . This represents one-third the total number of cases reported during the corresponding period of 1964 , the previous record low year. The only areas where more than one case have been reported are Morrill County, Nebraska and Pinal County, Arizona. Summaries of the Nebraska and Arizona outbreaks are presented in Section II.

The final report of 1964 paralytic cases reported to the PSU is presented in Section III. Sixty-day follow-up reports were received on 100 percent of the preliminary PSU forms. For 1964, the "Best Available Paralytic Case Count" was 91 paralytic cases. This total is less than one-third that recorded in 1963, previously the record low year. Of the 91 paralytic cases, only 12.5 percent were considered adequately immunized with inactivated polio vaccine ( 4 or more doses) and only 8.8 percent were fully immunized with oral poliomyelitis vaccine. Nineteen of the 91 paralytic cases occurred within 30 days following administration of oral poliomyelitis vaccine. There was no seasonal rise in incidence during the summer months and no epidemics were noted. There were 51 isolations of poliovirus from the 91 paralytic cases in 1964. Type III accounted for 47 percent of the total and Type I accounted for 41 percent.

An analysis of the poliomyelitis vaccination status in the United States as determined by the national immunization survey conducted annually since 1957 is presented in Section IV. While the percentage of persons receiving 3 or more doses of inactivated poliomyelitis vaccine has remained comparable to previous years, the increased utilization of oral poliomyelitis vaccine since 1962 has accounted for a general increase in the percentage of the population considered adequately immunized.

A review of poliomyelitis in Jamaica, including the epidemic of 1964-65, is presented in Section $V$.

The supplement to this report contains the results of the 1964 national immunization survey conducted by the Bureau of the Census in cooperation with the Communicable Disease Center. These results include the data regarding immunization status of the population against poliomyelitis, diphtheria-pertussis-tetanus, smallpox and influenza.

## I. CURRENT POLIOMYELITIS MORBIDITY TRENDS

Through the 20 th week of 1965 a total of 11 cases of poliomyelitis, 8 of which are paralytic, have been reported. This total compares to the 26 cases reported through the 20 th week of 1964 and is 10 percent of the median number of cases reported for a similar period during the years 1960-64.

If present trends continue and no large outbreaks occur, 1965 may again be a record low year. Thus far, no cases of poliomyelitis have been reported to have occurred within 30 days of either oral or inactivated vaccine.

The only 2 counties which have reported more than a single case in 1965 are Morrill County, Nebraska where 2 paralytic cases have been recorded and Pinal County, Arizona where 4 cases, of which 2 were paralytic, (one with December 1964 onset) were recorded over a 4 month period. Special reports on the Nebraska and Arizona cases are presented in Section II. In addition, during the first 20 weeks of 19653 cases have been reported from 3 different counties in Texas and single cases have been reported from Minnesota, New Mexico, and California.

Arizona
During a 4 month period beginning in December 1964, 4 cases of poliomyelitis including 2 paralytic cases were reported from Pinal County (population 62,673). A line listing of the cases appears below:

| Case | Age | Race | Sex | Onset |  Vacc. Status <br> Para. No. Doses |  |  | Virus <br> Isol. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  | Status | IPV | OPV |  |
| 1 | 2 | W | F | 12/27/64 | P | 0 | 0 | No spec. |
| 2 | $15 / 12$ | W | F | 2/19/65 | P | 0 | 0 | Type I . |
| 3 | $21 / 2$ | W | F | 3/29/65 | NP | 0 | 0 | Neg. |
| 4 | 38 | W | F | 4/1/65 | NP | 0 | 3 | Type I |

The initial case, a 2 year old girl, became ill on December 27, 1964, with fever, anorexia and irritability. She subsequently had paralytic involvement with residual weakness of the right leg. The subsequent cases developed illness between February 19, 1965 and April 1, 1965. One of the 2 non-paralytic cases was in a 38 year old female who was the only one who had received any vaccine. She had received a full course of oral poliomyelitis vaccine in 1962. The other 3 cases were all unimmunized preschool age children. All cases occurred in white females who resided in lower socioeconomic areas. The cases were not geographically clustered within Pinal County.

In 1962 a county wide mass immunization program utilizing monovalent oral poliomyelitis vaccines had been conducted. In addition, inactivated poliomyelitis vaccine was available to the population on a continuing basis through regular poliomyelitis immunization clinics conducted by the County Health Department. A health index survey was conducted by the Communicable Disease Center in the fall of 1964 in Casa Grande (population 8,311), the largest community in Pinal County. Among children from upper socioeconomic areas, 76.3 percent had received either 3 or more doses of inactivated poliomyelitis vaccine or 3 doses of oral poliomyelitis vaccine, or both. Only 22 percent of children in the lower socioeconomic area had achieved the same level of immunization. It was primarily among this group of unimmunized children from the lower socioeconomic areas that the current outbreak occurred.

During the first week in April, a county wide vaccination program utilizing Type I oral poliomyelitis vaccine from the CDC epidemic reserve was administered by the State and County Health Departments. Since the vaccination program, no additional cases have been reported.

## Nebraska

Two cases of paralytic poliomyelitis including one death have occurred in Morrill County, Nebraska. A line listing of the cases appears on the following page:

| Case | Location | Age | Race | Sex | Onset | Para. <br> Status | Vacc. Status <br> No. Doses |  | Virus |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  | IPV | OPV | Isol. |
| 1 | Morrill Co. | 11 | Sp. Am. | F | 5/9/65 | $\begin{aligned} & \text { Died } \\ & 5 / 13 / 65 \end{aligned}$ | 1 | 0 | * |
| 2 | Morrill Co. | 11 mo. | Sp. Am. | M | 5/12/65 | P | 0 | 0 | Type I |

* Poliovirus Type I has been recovered from the stools of 7 of 8 siblings studied.

The first case, an 11 year old girl, became ill on May 9, 1965, 5 days after returning from a visit to El Centro, California. Initial symptoms of fever and nausea were followed by stiff neck and flaccid paralysis of both lower extremities which progressed rapidly to include the upper extremities and respiratory musculature. The patient died on May 13. The second case is an 11 month old male cousin of the first case and had onset of illness on May 12. This patient has weakness of the left arm and left facial nerve. Neither case had been adequately immunized against poliomyelitis.

Stool specimens from 7 of 8 siblings of the first case have yielded Type I poliovirus at the Virology Laboratory, Department of Microbiology, University of Nebraska, and confirmed as Type I at the CDC Kansas City Field Station. Laboratory studies on specimens from the second case are in process.

A mass vaccination program utilizing Type I oral poliomyelitis vaccine from the CDC epidemic reserve, was conducted by the Nebraska Department of Health, in Morrill County (population 7,000) and adjacent Scotts Bluff County (population 34,000) on June 6.
(Reported by Dr. E. A. Rogers, Director of Health, Nebraska Department of Health.)
III. 1964 POLIOMYELITIS REPORTED TO PSU - FINAL REPORT

During 1964, the Poliomyelitis Surveillance Unit received individual surveillance case records on 115 cases of poliomyelitis. Follow-up reports, 60 days or longer after onset of illness, were received on all ll5 of these cases. The diligent and persistent efforts of State and local health officials, particularly the State Epidemiologists, have made this completeness of follow-up possible.

Individual surveillance case records, consisting of a preliminary and 60-day follow-up report have been submitted to the Poliomyelitis Surveillance Unit since 1958. Follow-up reports have been received on over 90 percent of the preliminary forms for the past 5 years as shown in the table below:

Table I

| Year | No. States Participating | Total Poliomyelitis Cases Reported To MMWR | Poliomyelitis Surveillance Unit Case Records |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | 60-Day | \% 60-Day |
|  |  |  | Preliminary | Follow-ups | Follow-ups |
| 1958 | 49 | 5,787 | 6,125 | 4,919 | 80.3 |
| 1959 | 50 | 8,425 | 8,635 | 7,523 | 87.1 |
| 1960 | 51 | 3,190 | 3,304 | 3,095 | 93.7 |
| 1961 | 51 | 1,312 | 1,356 | 1,284 | 94.7 |
| 1962 | 51 | 910 | 914 | 898 | 98.2 |
| 1963 | 51 | 449 | 437 | 425 | 97.3 |
| 1964 | 51 | 121 (Preliminary | ) 115 | 115 | 100.0 |

Since 1958, the best continuing index of paralytic disease due to poliomyelitis has been those cases with residual paralysis at 60 days and cases reported initially as paralytic but with no 60 -day follow-up report. The total thus obtained represents the "Best Available Paralytic Poliomyelitis Count." The 103 cases initially reported to the PSU as paralytic poliomyelitis in 1964 are shown in Table II by final classification. The "Best Available Paralytic Poliomyelitis Count" for 1964 includes the 91 cases with residual paralysis.

Table II
Final Classification of 103 Cases Initially Reported as Paralytic Poliomyelitis, United States, 1964

residual paralysis
91
Paralytic Polio - no residual paralysis

11
Paralytic Disease due to other agent - unspecified

1

TOTAL
103

In 1964, the number of reported cases of paralytic poliomyelitis in the United States reached a record low level. The final case count of 91 paralytic cases for 1964 is less than one-third the total reported in 1963, the previous record low year. No county reported more than 2 cases during any month of 1964. Cases occurring within 30 days of receiving oral poliomyelitis vaccine accounted for 19 of the total of 91 paralytic cases. A line listing of these cases appears on page 8 .

Unlike previous years when an increased incidence occurred during the summer and fall months, the seasonal distribution of the cases was relatively uniform. (See Figure 1) All of the 19 cases occurring within 30 days of oral poliomyelitis vaccine administration became ill during the first 6 months of the year. This coincides with the monthly distribution of monovalent oral poliomyelitis vaccine distribution in the United States as shown in Figure 2.

The 91 paralytic cases are shown by age and inactivated poliomyelitis vaccine status in Table III. There were 38 cases ( 42 percent) in the $0-4$ year age group and 23 ( 25 percent) in the $5-14$ year age group. In the 15 year and older age group there were 30 cases of which 15 occurred within 30 days after the administration of oral poliomyelitis vaccine. As in previous years, the majority of the 91 cases had no previous immunization with inactivated poliomyelitis vaccine. Two-thirds of the total had never received any inactivated poliomyelitis vaccine and only 12.5 percent had received 4 or more doses of inactivated poliomyelitis vaccine.

The 91 paralytic cases are shown by age and oral poliomyelitis vaccine status in Table IV. Excluding those cases which occurred within 30 days following administration of oral poliomyelitis vaccine, a total of 8 cases occurred among individuals who had previously received a full series of oral poliomyelitis vaccine ( 3 doses of monovalent oral poliomyelitis vaccine or 2 doses of trivalent oral poliomyelitis vaccine). A line listing of these cases appears on page 9. The 8 cases were all less than 15 years of age and 6 had received 3 or more doses of inactivated poliomyelitis

vaccine. Several cases showed poor antibody response to the poliomyelitis antigens as measured by complement fixation tests. From the 6 cases in which virus isolation was attempted, 2 poliovirus isolates, both Type I, were recovered.

Because of the small number of total cases, special efforts were made to obtain specimens for virus isolation and serologic study from all cases. Isolates were obtained from 51 of 77 fecal specimens examined for virus isolation. Of these, 24 ( 47 percent) were Type III, 21 ( 41 percent) Type I, and 6 ( 12 percent) Type II (see Table $V$ ). This contrasts with the distribution of isolates obtained during the period 1958 to 1963 during which Type I isolates accounted for 60 to 89 percent of the total each year and Type III varied from 10 to 38 percent. The proportional increase in Type III isolates reflects in part a relative increase in cases associated with the administration of Type III vaccine and an absence of the usual Type I epidemics. The 1964 poliovirus isolates are shown by State in Table VI.

Figure /

Figure 2
MONTHLY DISTRIBUTION OF MONOVALENT ORAL POLIOMYELITIS VACCINE AND PARALYTIC POLIOMYELITIS BY MONTH OF ONSET 1964

As in past years, the results of the annual United States immunization survey are presented as a supplement to the Poliomyelitis Surveillance Report. The immunization status of the population has been studied annually since 1957 by means of a supplemental schedule included each September in the Current Population Survey conducted by the U.S. Bureau of the Census in cooperation with the Communicable Disease Center.* During the years, 1957-1961, information was obtained on inactivated poliomyelitis vaccine (IPV) only. In 1962, coverage was extended to include oral poliomyelitis vaccine (OPV) and diphtheria-pertussis-tetanus immunization. In 1963 and 1964, questions concerning influenza and smallpox vaccines were added to the survey questionnaire. The 1964 survey findings are presented in the supplement to this report.

The poliomyelitis vaccination status of the U.S. population, as indicated in the supplement tables, reflects the widespread use of oral poliomyelitis vaccine since its licensure in the latter part of 1961. The following table shows the increase in the oral poliomyelitis vaccination level in all age groups between the years 1962 , 1963 and 1964. During this same period of time, the proportion of persons reporting 3 or more doses of inactivated poliomyelitis vaccine has remained essentially stable with some decrease in the youngest age groups.

National Immunization Survey Findings<br>September 1962, 1963, and 1964<br>Poliomyelitis Vaccination Status

## \% Years Covered

1955-57: Sirken, M.G. and Brenner, B.: Population characteristics and participation in the poliomyelitis vaccination program. PHS Publication No. 723 (Public Health Monograph No. 61). U.S. Government Printing Office, Washington, D.C., 1960.

1957-1961:1) Sirken, M.G.: National participation trends, 1955-61, in the poliomyelitis vaccination program. Public Health Rep. 77:661-670, August 1962.
2) Morris, L.: Further analysis of national participation in the inactivated poliomyelitis program, 1955-61. Public Health Rep. 79:469-480, June 1964.
1962: Supplement to Poliomyelitis Surveillance Report No. 276, March 29, 1963.
1963: Supplement to Poliomyelitis Surveillance Report No. 284, April 20, 1964.
1964: Supplement to Poliomyelitis Surveillance Report No. 287, June 1, 1965.

With two agents available, an estimate of the population with immunization against poliomyelitis would include not only those receiving a full series of inactivated vaccine but also those who did not receive a full series of inactivated vaccine but did receive 3 doses of oral vaccine. This type of cross-classification is presented in the 1964 survey findings and appears for age groups 1-4 and 5-9 in Section $D$, Table 16 of the supplement.

As shown in Section $A$ of the supplement, 32.2 percent of the population from 1 through 4 years of age have received 4 or more doses of inactivated poliomyelitis vaccine (IPV) and 60.9 percent have received 3 or more doses. The corresponding percentages for the 5 to 9 age group are 57.9 percent and 80.9 percent. Utilizing the findings of the 1964 survey, the proportion of children in these age groups protected by either inactivated or oral vaccine is shown in the following table:

Total Proportion Immunized
With Full Series of IPV or Full Series of OPV Age Groups $1-4$ and 5-9, Sept., 1964

Percent Reporting

| 5-9 years | 80.9 | 9.9 | 90.8 |

## V. FOREIGN REPORT

POLIOMYELITIS IN JAMAICA
This report was prepared by Dr. Donald Luck, Senior Medical Officer, Ministry of Health, Jamaica, and was presented by Dr. Luck at the Tenth Scientific Session of the Standing Advisory Committee for Medical Research for the British Caribbean, March 31, 1965, at Barbados, B.W.I.

## Introduction

Poliomyelitis first appeared in epidemic form in Jamaica in 1954. Prior to that, the virus had been present on the Island, but clinical disease had been rare. The characteristics of succeeding epidemics have been somewhat modified by the effects of immunization against the disease. It is quite probable that prior to 1954 the bulk of the population had been naturally infected with the virus at an early age, thus conferring widespread natural immunity upon the population. After the Second World War, increasing standards of sanitation and hygiene undoubtedly protected many of the people on the Island from having contact with the virus at an early age, and thus a group of susceptibles was built up in the older age groups. Since the widespread use of polio vaccines, much of the population has become artificially immunized against the disease, and presumably natural spread of the virus has greatly decreased. It is interesting
that the most recent epidemic of polio in Jamaica was almost completely limited to children born since the last mass immunization campaign, thus indicating that newly born children may no longer acquire natural immunity by near-universal contact with the virus.

## History of Poliomyelitis in Jamaica

Prior to 1954, notifications of polio in Jamaica were rare. It is important to note, however, that polio was apparently always present. Notifications had ranged between 0 and 13 each year since 1929, and with only one year (1950) having more than 10 cases and only one year (1943) having none. There was no pattern to the notifications, and no tendency to increase up until 1954. Additional evidence that the virus was active and indeed quite prevalent in Jamaica has been obtained by the examination of sera obtained for various reasons before 1954. Examination of such sera has revealed a high percentage of persons with antibodies to all 3 types of poliovirus. Thus, even though clinical polio was rare in Jamaica prior to 1954 , there is evidence of widespread infection by polioviruses.

During the decade prior to 1954, there was a dramatic rise in the living standards in Jamaica. Safe water, sanitary conveniences, medical care, and adequate infant care were rare during the 1930's and early 1940's, but became available to increasingly large percentages of the population during the post-war period. As can be seen in Figure I, the Infant Mortality Rate declined steadily during this period, and the Per Capita Income rose concomitantly. The indices are thought to mirror the types of changes which lead to better hygiene and presumably decreased fecal-oral spread of intestinal viruses such as polio.

In 1954 a severe epidemic of 759 reported cases of poliomyelitis with 94 deaths occurred throughout the Island. Serological evidence on a small number of the cases indicated that Type I polio was the causative agent. The outbreak started in June, reached a peak in September, and had nearly ended by the first of January, 1955. The first cases were reported from Kingston (where sanitation and living conditions had long been superior to those in the rural parishes); however, cases subsequently occurred through the rest of the Island. The attack rates showed somewhat higher rates of disease in Kingston than in the rural parishes, but it is impossible to say whether this difference was due to higher natural immunity in the country areas or poorer notifications of the disease. The most interesting feature of this epidemic is that polio was observed in all age groups, although of course attack rates were somewhat higher in the preschool children than in other age groups. The numbers of cases by age and the agespecific attack rates can be seen in Table I. It should be noted (see Figure III) that 54 percent of the patients reported were in the $0-4$ age group.

In 1957, a second epidemic occurred with 395 cases reported, including ll deaths. The pattern of this somewhat smaller epidemic was similar to the 1954 outbreak, except that the disease became prevalent late in March, reached its peak in June, and had virtually disappeared by October. Once again the highest attack rates were in Kingston, but the disease was reported from all parishes. The age distribution and age-specific attack rates once again showed widespread infection of all age groups (see Table I). Fifty percent of the cases occurred in the $0-4$ age group (see Figure III). Type I poliovirus was isolated from specimens from 9 cases. An attempt was made to modify it with an Island-wide campaign to offer inactivated poliomyelitis vaccine to all children in the 0-4 age group. Almost 82,000 children received at least one dose of vaccine through this program. Interestingly, only 15 cases occurred in this group (giving an attack rate of 18 per 100,000 ) whereas 166 cases occurred in the remaining 144,000 unprotected children (giving an attack rate of 125 per 100,000 ). Immunizations were routinely offered only to the $0-4$ age group, and may have had the effect of lowering the attack rate in that group.

In 1960, a third epidemic occurred with 132 cases and 9 deaths. Type I poliovirus was isolated from patients with clinical illness during this outbreak. The pattern was similar to the 1957 epidemic in that it had started in March, peaked in June, and was essentially over by November. Once again, the illness had been first noted in the Kingston area, but soon spread throughout the Island. Thus it was becoming apparent that poliomyelitis was settling into an every-third-year epidemic pattern. This was perhaps due in part to the failure to routinely immunize the infants born subsequent to the previous epidemic.

Immunization with Oral Poliomyelitis Vaccine 1962-63
In late 1962, the health authorities in Jamaica felt that an epidemic similar to the ones which occurred in 1954, 1957 and 1960 might well occur in 1963. Only a small number of doses of inactivated vaccine had been given since the 1960 campaign. It was decided to conduct a mass feeding of oral vaccine to the $0-4$ age group in late 1962 and early 1963. This decision was reinforced by the slow buildup of numbers of reported cases in the inter-epidemic years, suggesting that the population was becoming quite susceptible to clinical disease associated with infection by poliovirus. Accordingly, a mass vaccination program was held in which at least 432,000 doses of trivalent oral vaccine were administered throughout the Island to the 0-4 age group. Seventyfour percent received at least one dose of vaccine, and as many as 57 percent may have received two doses. The campaign was thus felt to have had considerable success. This feeling was reinforced when in 1963 only 15 cases of poliomyelitis were reported, the lowest total since 1956.

During the year and a half between the end of the mass feeding and August 1964, essentially no vaccine was given out in Jamaica. In the late summer of 1964, an extensive immunization program was initiated in the rural parishes. By the end of 1964, some 146,000 doses of trivalent oral poliomyelitis vaccine was given to children in the $0-4$ age group through this program. The vaccine was not offered within the Kingston and St. Andrew Corporate area because an extensive immunization campaign with DPT antigen had just been completed, and the difficulties in mounting another mass campaign were felt to be too great.

## The 1964 Epidemic

During the late months of 1964, an outbreak of poliomyelitis occurred which was sharply limited to the Kingston-St. Andrew Corporate (KSAC) area, and which was also unlike previous epidemics in that it was confined almost entirely to the 0-4 age group. The epidemic curve is shown in Figure IV. Of the 60 cases and 3 deaths found both through notification and by search of hospital records in the Kingston hospitals, only 4 were from outside of the KSAC area. The failure of the disease to reach epidemic proportions elsewhere on the Island may well be due to the vaccine distributed to preschool age children in the rural parishes during the fall of 1964. The age distribution shown in Table I and Figure III was primarily among preschool age children. Fully 91 percent of the cases occurred in children less than 5 years old, and 43 of the 60 , ( 71 percent) were less than 2 years of age. The vast majority of these cases had received no immunizations against poliomyelitis.

## Discussion

The occurrence of poliomyelitis in epidemic form in infants in Kingston during 1964 raises some grave issues for the future methods of control of this disease. Prior to this outbreak there was no reason to suspect that epidemics would occur unless some 3 years had elapsed during which newly born children remained unimmunized. Also, successful mass immunization campaigns, it was hoped, might abort such epidemics and by breaking up the cycle of naturally occurring infection actually lead to the eradication of polio from large populations. The success of the Jamaican mass oral vaccine feeding in 1962 and 1963 led authorities to feel that there was no great urgency in mounting a continuous follow-up program. Rather, the next epidemic, which might not be expected
until 1965 or 1966, might have been aborted by another mass campaign. There seemed little reason to fear that very small numbers of infants, who presumably have little close contact with each other, would be sufficient to propagate the virus in epidemic proportions. However, the 1964 outbreak makes it apparent that it is not advisable to allow even small numbers of susceptibles to be built up through failure to reach and continuously immunize newly born children. The fact that poliomeylitis became epidemic only in Kingston where no vaccine had been used for some 18 months, while the well immunized rural areas were almost completely spared, emphasizes this concept. Thus, to eradicate poliomyelitis for any more than a brief period of time, continuous vaccination of young infants must be carried out.

Prior to the widespread availability of good sanitary conditions, near-universal natural infection with wild poliovirus "controlled" the disease in the sense that it did not occur in epidemics. It is now apparent that near-universal artifical infection of the very young with live-attenuated vaccine must replace the older situation, or local epidemics such as that in Kingston in 1964 will occur. The implications of this, and the problems it raises for public health practice and administration are obvious, and grave.

## Summary and Conclusion

Poliomyelitis in Jamaica before the days of good sanitation and hygiene was probably a nearly universal infection, but rarely resulted in clinical illness. Subsequent to 1954, epidemics occurred every 3 years, initially affecting all age groups, but progressively concentrating on the very young. Efforts to abort such periodic epidemics with vaccine have been successful over short periods, but there are indications that if vaccination is not vigorously pursued on a routine basis and efforts are not made to reach the very young children with vaccine, even small numbers of susceptible children may be enough to result in epidemics of severe clinical disease.

Dr. Luck acknowledges the assistance of Dr. O. F. Warner, Senior Medical Officer (Health) KSAC, who was responsible for providing the up-to-date data on the cases, Professor Louis Grant, Professor of Microbiology, University of the West Indies, who provided laboratory confirmation, and Dr. Michael Lane, an EIS Officer who assisted in the preparation of the manuscript.

ADDENDUM: Supplement to Poliomyelitis Surveillance Report No. 285 (Sept. 30, 1964) Section II, Table l-Additional information received indicates that during the 1963 mass oral poliomyelitis vaccine program in epidemic areas, 2,986,000 doses of Type I oral polio vaccine were fed in Metropolitan Philadelphia and 102,000 doses were fed in Cumberland and Perry Counties, Pennsylvania. Previous figures were $1,500,000$ doses and 77,000 doses respectively.

POLIOMYELITIS CASES BY WEEK OF ONSET JAMAICA-1964

RESULTS OF THE SEPTEMBER 1964 UNITED STATES IMMUNIZATION SURVEY

Oral Poliovaccine Inactivated Poliovaccine Diphtheria-Pertussis-Tetanus<br>Smallpox<br>Influenza

Prepared by
Ida L. Sherman, Assistant Chief, Statistics Section, and Statistical Assistants, Sara Wingo, Julia Stone, Judy Williams
in cooperation with
Earle Gerson, Bureau of the Census

The tables in this Supplement present the results of the September 1964 survey of the immunization status of the population of the United States conducted by the Bureau of the Census in cooperation with the Communicable Disease Center. Information was obtained on poliovaccine status, both oral and inactivated for ages under 50 years, diphtheria-pertussis-tetanus immunization for children under 15 years, smallpox vaccination for all ages, and recent receipt of influenza vaccine for ages 15 years and over.

The immunization data were collected by means of a special questionnaire included in the schedule for the Current Population Survey, a survey conducted monthly by the Bureau of the Census. The survey sample, with coverage in each of the 50 States and the District of Columbia, includes approximately 110,000 persons in 32,000 interviewed households.

Tables of data are presented in the following Sections:
Section A. Tables 1-5. United States by Age Groups
Section B. Tables 6-9. By Age by Standard Metropolitan Statistical Area Classification

Section C. Tables 10-15. By Age and Race for the United States
Section D. Table 16. Cross-classification, Inactivated Poliovaccine Status by Oral Poliovaccine Status, Ages 1-4, 5-9

Section E. Tables 17-22. Detailed Data for Age Group, 1-4 Years
Section F. Tables 23-25. Age Groups by Geographic Divisions
Section G. Tables 26-27. Standard Error Tables, Computed by the Bureau of the Census

Tables 26-27

Section G. Standard Errors of the Estimated Percentages Computed by the Bureau of the Census

The standard errors presented in Tables 26 and 27 provide an indication of the order of magnitude of the standard errors rather than precise values for any specific item. In order to derive standard errors that would be applicable to the wide variety of items and could be prepared at moderate cost, a number of approximations were required.

Table 26. Standard Error of the Estimated Percentage
(A) Of Persons who Received Oral Poliovaccine
( 68 Chances out of 100 )

| Estimated |  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Percentage | 500 | 1,000 | 2,500 | 5,000 | 10,000 | 25,000 | 50,000 | 100,000 |
| 2 or 98 | 1.1 | .8 | .5 | .3 | .2 | .2 | .1 | .1 |
| 5 or 95 | 1.7 | 1.2 | .8 | .5 | .4 | .2 | .2 | .1 |
| 10 or 90 | 2.3 | 1.6 | 1.0 | .7 | .5 | .3 | .2 | .2 |
| 25 or 75 | 3.3 | 2.4 | 1.5 | 1.1 | .7 | .5 | .3 | .2 |
| 50 | 3.9 | 2.7 | 1.7 | 1.2 | .9 | .5 | .4 | .3 |

(B) Of Persons who Received Inactivated Poliovaccine; and of Persons who Received DPT Immunizations
(68 Chances out of 100)

| Estimated |  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Percentage | 500 | 1,000 | 2,500 | 5,000 | 10,000 | 25,000 | 50,000 | 100,000 |
| 2 or 98 | 1.4 | 1.0 | .6 | .4 | .3 | .2 | .1 | .1 |
| 5 or 95 | 2.1 | 1.5 | 1.0 | .7 | .5 | .3 | .2 | .2 |
| 10 or 90 | 3.0 | 2.1 | 1.3 | .9 | .7 | .4 | .3 | .2 |
| 25 or 75 | 4.3 | 3.0 | 1.9 | 1.4 | 1.0 | .6 | .4 | .3 |
| 50 | 4.9 | 3.5 | 2.2 | 1.6 | 1.1 | .7 | .5 | .3 |

(C) Of Persons who Received both Oral and Inactivated Poliovaccine
(68 Chances out of 100 )

| Estimated |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :---: | :---: | :---: | :---: |
| Percentage | 250 | 500 | 1,000 | 2,500 | 5,000 | 10,000 | 25,000 |
| 2 or 98 | 1.7 | 1.2 | .9 | .6 | .4 | .3 | .2 |
| 5 or 95 | 2.7 | 1.9 | 1.4 | .9 | .6 | .4 | .3 |
| 10 or 90 | 3.7 | 2.6 | 1.9 | 1.2 | .8 | .6 | .4 |
| 25 or 75 | 5.4 | 3.8 | 2.7 | 1.7 | 1.2 | .9 | .5 |
| 50 | 6.2 | 4.4 | 3.1 | 2.0 | 1.4 | 1.0 | .6 |

Table 27. Standard Error of Level of Estimates of the Number of Persons Immunized by Type of Immunization
(68 Chances out of 100)

| Level of <br> Estimate <br> (000) | Standard Error (000) <br> Poliovaccine | Inactivated <br> Poliovaccine; <br> DPT | Inactivated <br> Poliovaccine <br> and oPV | Smallpox <br> Vaccination; <br> Influenza <br> Vaccine |
| :---: | :---: | :---: | :---: | :---: |
| 250 | 27 | 35 | 31 | 29 |
| 500 | 39 | 49 | 44 | 40 |
| 1000 | 54 | 69 | 61 | 57 |
| 2500 | 85 | 109 | 92 | 90 |
| 5000 | 120 | 152 | 120 | 126 |
| 10000 | 245 | 310 |  | 175 |
| 25000 | 305 | 360 |  | 260 |
| 50 |  |  |  | 330 |

## Illustrations for Use of the Tables of Standard Errors (All numbers in thousands)

Table 1 shows that 46.8 percent $(7,759 / 16,590)$ of children in the age group $1-4$ had received 3 doses of OPV. Using Table 26 (A), the standard error of 46.8 percent, based on 16,590 children is found by taking 50 percent (in the first column) as approximately equal to 46.8 percent and interpolating between the standard errors, 0.9 and 0.5 , given in the body of the table under bases of 10,000 and 25,000 respectively. Taking the interpolated value as 0.7 of a percentage point, the chances are 68 out of 100 that a complete census would have shown a result between 46.1 and 47.5 percent of children age $1-4$ with three doses of oral poliovaccine; and 95 chances out of 100 that a census result would have been between 45.4 and 48.2 percent.

The standard error of the number of $1-4$ year old children, 7,759 , who had received 3 doses of oral poliovaccine can be estimated from Table 27. Referring to this table, the number 7,759 falls between 5,000 and 10,000 in the column "Level of Estimate" so that the standard error of the estimate (second column, Oral Poliovaccine) lies between 165 and 120 . By linear interpolation, the standard error of the 7,759 children in the $1-4$ year age group who were reported to have 3 doses of OPV is 145 (thousand). The chances are 68 out of 100 that a complete census would have differed by less than or more than 145 thousands; and 95 out of 100 that the difference would have been plus or minus 290 thousands.

Key to all disease surveillance activities are those in each State who serve the function as State epidemiologists. Responsible for the collection, intrepretation and transmission of data and epidemialogical information from their individual States, the State epidemiologists perform a most vital role. Their major contributions to the evolution of this report are gratefully acknowledged.
