

## U.S. DEPARTMENT OF HEALTH, EDUCATION, AND WEEGRE

MEASLES _ ISABELLA COUNTY, MICHIGAN

Beginning December 2, 1965, an increased incidence of measles was reported from Isabella County, Michigan (population 35,348 ). A total of 22 cases was reported in December and 52 additional cases by mid-January. These included two patients hospitalized with measles encephalitis, and one patient with brochopneumonia. A plan was developed to contain the epidemic as a community effort of the physicians of the Central Michigan Community Hospital, the Central Michigan Health District, the United Fund of Isabella County, and numerous civic and student groups.

A survey of absenteeism due to measles in kindergarten through the second grades of the eight schools in

Mt. Pleasant (population 14,875 ) and the 12 county schools revealed an additional 224 cases known to the schools to have occurred from December 1, 1965, to January 14, 1966. Six of the eight city schools had from 16 to 40 cases each, while the other two schools had 1 and 2 cases respectively. Six of the 12 county schools reported measles absences; 3 county schools had 12 cases or more.

MEASLES - ISABELLA COUNTY, MICHIGAN<br>(Continued from front page)

Figure 1 shows the monthly incidence of reported measles from January 1961 through February 1966. The last major measles epidemic began in November 1962, and reached a peak over the 3 -month period of January through March 1963, with increased measles incidence persisting through June. A total of 349 cases was reported during this 8 -month period.

## FIGURE 1 <br> REPORTED CASES OF MEASLES BY MONTH <br> ISABELLA COUNTY, MICHIGAN JANUARY 1961 - FEBRUARY 1966

Five measles immunization centers were established. The clinics were staffed by volunteer physicians, public health nurses from the local and State health departments, volunteer registered and practical nurses, and volunteer clerical personnel. The vaccine was offered free of charge to all children who had not had vaccine or prior measles. A request was made for a contribution of at least $\$ 1.00$. A total of 2,074 children from 1 to 8 years of age received Schwarz strain measles vaccine in the 2 -day campaign.

Table 1 presents the number of children immunized and the population estimates by age group based on the 1960 school census. Nearly 40 percent of the children from 1 to 8 years of age were immunized.

Gamma globulin furnished by the Michigan Department of Public Health was made available to practicing physicians for children known to have had a close exposure
to a case of measles (for example, a household or intimate playmate contact, excluding casual school contacts) A summary of the distribution of gamma globulin by month is as follows: November - 54 cc ; December - 378 cc; January - 442 cc ; February - 114 cc . During the period January 20 to February 15, a total of 54 cases of measles was reported through routine channels. However, all but one of these children became ill in January.

On February 15, 1966, a second school survey for absenteeism due to measles revealed that 89 cases had occurred between January 19 and February 15. Twenty seven of these children had not had vaccine in the cam paign; 62 school children developed measles from 2 to 12 days following vaccination, as shown in Table 2. No school cases occurred among those vaccinated after January 31, 1966. From February 15 to March 1, only three cases of measles have been reported. No gamm ${ }^{8}$ globulin for measles exposure has been requisitioned from the Health Department since mid-February.
(Reported by Dr. George Agate, State Epidemiologist, Michigan Department of Public Health; Dr. E.J. Brenner, Director, Mrs. Louise Eppel, R.N., Mr. Kent L. Gray, Health Educator, Central Michigan District Health Department; Dr. Andrew V. Bedo, Central Michigan Community Hospital, Mt. Pleasant; and an EIS Officer.)

## CURRENT TRENDS - MEASLES

During the 4 -week period ending February 26, 1966, a total of 28,234 cases of measles were reported, an in-
crease of 8,170 cases over the total notified during th preceding 4 -week period. The comparable total for the

Second 4-week period in 1965 was 35,117 , which was 6,883 more than were reported in 1966 (Figure 2). Nine States reported more than 1,000 cases during the last 4 Weeks: Wisconsin $(5,640)$, Illinois $(2,838)$, Texas $(2,392)$, New York $(2,269)$, Michigan ( 1,655 ), Tennessee $(1,644)$, California ( 1,467 ), Kentucky $(1,446)$, and Pennsylvania $(1,138)$.

A total of 32 cases of post-measles encephalitis has veen reported to date in 1966,10 of which occurred during
the first 4 weeks and 22 cases during the second 4 weeks. Illinois has had 10 cases, Kentucky 6, California 5, Michigan 3, Minnesota and Pennsylvania 2 each, and New York, Tennessee, Louisiana and Texas, 1 each. In the comparable periods in 1965 and 1964, there were 14 and 7 cases respectively.
(Reported by the Childhood Virus Disease Unit, CDC.)

FIGURE 2
MEASLES REPORTED BY FOUR-WEEK PERIODS - UNITED STATES EPIDEMIOLOGIC YEARS, 1964-65 AND 1965-66 COMPARED WITH 10-YEAR PERIOD, 1954-1963

## CURRENT TRENDS - INFLUENZA

At the present time, there have been reports of confirmed type $B$ influenza outbreaks in 15 States, primarily in the eastern part of the country, of type A Outbreaks in two states; and of influenza-like illnesses in an additional five States.

Since publication of the summary table of States ${ }^{r}$ eperting laboratory confirmed outbreaks of influenza (MMWr, Vol. 15, No. 8), five States (New York, PennSylvania, Virginia, Michigan, and Oregon) have reported laboratory confirmed type B influenza as the cause of primarily scattered outbreaks. Idaho has reported sero${ }^{l}{ }^{\text {gical }}$ confirmation of type A influenza infection in one part of the State, and Nevada recognizes evidence of influenza-like illness although laboratory confirmation
is not yet available.
Although no associated outbreaks have been reported, influenza viruses have been recovered from individual cases in three States; Illinois - type B, Iowa - type A2, Michigan - type 42.

Pncumonia-influenza mortality reported from 122 United States cities has increased slightly in the last week, influenced primarily by the substantial increase in the number of deaths notified from the Pacific Division.
(Compiled by the Influenza-Respiratory Disease Unit, CDC, from reports provided by State Health Departments and reports received from the WHO International Influenza Center for the Americas, CDC.)

Week No. DEATHS IN 122 UNITED STATES CITIES FOR WEEK ENDED MARCH 5, 1966
(By place of occurrence and week of filing certificate. Excludes fetal deaths)

## INTERNATIONAL NOTES

 smallpox surveillance - CanadaOn November 29, 1965, a mother and her son arrived in Winnipeg, Canada, from London, on an international flight which originated in East Pakistan. As these passengers had come from a declared smallpox "local infected area" in East Pakistan, a surveillance certificate was issued by the Winnipeg International Airport quarantine officer. A copy of this certificate was sent to the Winnipeg City Health Department which, in turn, sent a letter to the new arrivals requesting them to report any illness occurring within 14 days of entry to Canada.

Both travellers had been vaccinated on November 20 and had presented valid international certificates of vaccination against smallpox on arrival. Each of them also had two well defined scars which were shown in evidence of successful vaccinations prior to those performed on November 20.

On December 3, the day after receiving the letter from the City Health Department, the husband telephoned the Department, from a lodging house in which the family was living, to report that both his wife and son were suffering from an itchy rash. The rash had been present before leaving Pakistan but had suddenly become worse the day after arriving in Canada.

Medical examination revealed little constitutional disturbance although each patient had a generalized but discrete pustular rash with some localization on one of the boy's knees and on the palm of the mother's left hand. Other lesions on the anterior surface of the child's wrists and on the mother's toes and hands were suggestive scabies. However, a provisional diagnosis of eczema vaccinatum was made and, in view of the history and nature of the rash, it was clearly necessary to regard the condition as modified smallpox until proved otherwise. Accordingly the two patients and the father were quarantined in special hospital accommodation and all primary contacts in the lodging house were identified, vaccinated, and put under surveillance. The isolation hospital staff and two ambulance drivers were also vaccinated and placed under surveillance.

Preliminary laboratory reports on December 4 indicated that the skin eruption in both patients was due to a pox virus. Examination at the Manitoba Virus Laboratory and the National Laboratory of Hygiene in Ottawa of material obtained from the patients later confirmed that this virus was vaccinia virus.
(Reported by Dr. E. Snell, L.R.C.P., D.P.H., Director, Preventive Medical Services, Department of Health, Province of Manitoba, Winnipeg, Canada; Dr. E.W. R. Best, Chief, Epidemiology Division, Department of National Health and Welfare, Ottawa, Canada and Dr. Peter Constantinidis, Deputy Medical Officer of Health, City of Winnipeg.)
