Introduction ..... 1
Incidence ..... 2
Cost of Uncontrolled Syphilis ..... 3-4
Mortality and Insanity Due to Syphilis ..... 5-6
Reported Cases of Venereal Diseases: ..... 7-14
United States Summaries:
All Stages of Syphilis and Gonorrhea, Cases and Rates, 1919-1940 ..... (8)
Stages of Disease, Cases and Rates, 1941-1965 ..... (9)
Stages of Disease, Race, Sex, Rates, 1961-1965 ..... (10)
Congenital Syphilis, Age, 1962-1965 ..... (11)
Infectious Syphilis and Gonorrhea, Age, Rates, 1956, 1962-1964 ..... (12-13)
Each State, Selected Stages of Disease, Cases, Rates, 1965 ..... (14)
Health Department Casefinding Activities ..... 15
Treatment of Syphilis ..... 16-17
Treatment of Gonorrhea ..... 17-18
Penicillin Reactions ..... 18

## Introduction

The VD Fact Sheet is intended as a handy source of basic statistics on the venereal diseases in the United States. In this booklet, public health specialists, students, physicians, and other persons interested in medical data will find venereal diseases measured by incidence and prevalence. The general public will find tables showing the costs of uncontrolled venereal disease and the frequency of psychoses and deaths from syphilis. While the results of casefinding are measured in terms of cases reported, the actual amount of casefinding effort is seen in the volume of diagnostic examinations and epidemiologic activity. As there is no agent for immunizing the population, finding and treating cases continues to be the only feasible means of controlling venereal disease.

Facts on these aspects of the venereal disease problem and program are presented in the text and tables which follow. The information is current as of the date of publication, and it supersedes any previously published data. Where no source is cited, the data presented are based on statistics collected by the Venereal Disease Branch of the Communicable Disease Center, or upon estimates made by the Branch. Where data are indicated as being for "fiscal years," the period runs from July 1 of the previous year through June 30 of the year indicated on the table. Rates per 100,000 population shown in this Fact Sheet are based on appropriate population estimates obtained from the Bureau of the Census.

## Incidence

The incidence of syphilis is defined as the number of new cases occurring in a given area within a specified period of time, usually a year.

Since the symptoms of primary and secondary syphilis appear soon after the disease is acquired, the number of primary and secondary cases occurring in the population within a given period of time would be the same as the incidence of syphilis.

Cases of primary and secondary syphilis are reportable by law in all of the 50 States and the District of Columbia. In the fiscal year ending June 30, 1965, there were 23,250 cases reported to health departments by physicians and clinics in the United States. But the number of cases reported understates actual incidence for two reasons:

1. Not all cases are diagnosed, and
2. Not all diagnosed cases are reported.

In July 1962, the American Social Health Association, in cooperation with the American Medical Association, the National Medical Association, and the American Osteopathic Association sent a questionnaire to every private physician in the United States. One of the questions asked was "How many new cases of primary and secondary (infectious) syphilis did you treat between April 1 and June 30, 1962?"

One hundred and thirty-one thousand two hundred and forty-five responding physicians indicated they treated 13,930 cases of infectious syphilis during these three months (an estimate of 55,720 cases for the year 1962). These 55,720 cases plus 13,769 cases of infectious syphilis treated in 1962 by public clinics (not included in the survey) total an estimated 69,489 newly acquired cases of syphilis treated. Actually, 69,489 cases can be considered minimum incidence since it does not include cases treated by physicians who failed to respond to the survey nor cases occurring but not detected during the year. This estimate is presented only to show that the actual incidence of syphilis is much higher than reported new cases. In fact, if one considers that at least half of the cases occurring are not detected until the late or latent stages of disease, then the actual annual incidence of syphilis would be at least twice the estimated 69,489 cases treated in 1962.

## Costs of Uncontrolled Syphilis

The statistics presented in Table 1 indicate the toll imposed by syphilis upon the manpower and economy of the country.

The estimate of man-years of disability for institutionalization of the syphilitic insane is based on the total number of patients in mental institutions and upon the proportion of those diagnosed as having syphilitic psychoses. Patients in state, county, private, and Veterans Administration hospitals for the permanent care of the insane are included.

The cost of maintenance is based upon the number of patients with syphilitic psychoses in tax supported institutions and upon the average per patient maintenance cost. The three percent of patients with syphilitic psychoses maintained in private institutions has not been included.

Disability attributed to cardiovascular syphilis and to locomotor ataxia is based on conservative estimates of the prevalence of these late manifestations of syphilis.

The loss of life expectancy indicates the loss of future years of life for persons dying of syphilis in 1963. It is based on the expected years of life remaining to persons of that age, race and sex. The loss of income indicates the probable earnings of these persons for the productive years of life lost to age 65. It is based on the per capita personal income rate for 1963.

While disabilities and deaths from syphilis have been diminishing in recent years, costs and losses per case have been rising. As a result, total costs and income losses from syphilitic disabilities and deaths remain high compared to previous estimates.

On the basis of findings of research conducted in Macon County, Alabama, it has been estimated that the life expectancy of a Negro male between the ages of 25 and 60 years, infected with syphilis and receiving no appreciable treatment for his infection, is reduced by about 17 percent.*

[^0]
## ESTIMATED ANNUAL COSTS OF UNCONTROLLED SYPHILIS*

MAN-YEARS OF SYPHILIS DISABILITY PER YEAR
Institutionalization for syphilitic insanity (1963) ..... 19,000
Disability from cardiovascular syphilis, including aneurysm (1963) ..... 5,600
Disability from tabes dorsalis (1963) ..... 300
Disability from syphilitic blindness (1963) ..... 11,000
ECONOMIC COSTS OF SYPHILITIC PSYCHOSES AND SYPHILITIC BLINDNESS PER YEAR
Maintenance of patients with syphilitic psychoses (1963) ..... $\$ 49,974,000$
Maintenance of syphilitic blind (1963) ..... \$4,957,000
LOSS OF LIFE EXPECTANCY FROM DEATHS DUE TO SYPHILIS IN MAN-YEARS (1963)
White males ..... 18,164
White females ..... 7,667
Non-white males ..... 9,245
Non-white females ..... 5,227
Total population ..... 40,303
LOSS OF INCOME TO AGE 65 AT 1963 PER CAPITA PERSONAL INCOME RATE ..... \$31,741,000

[^1]
# Reported Mortality and Insanity <br> Due to Syphilis 

Mortality statistics are compiled by the National Vital Statistics Division from duplicates of death certificates filed with State or local registrars. Mortality rates for syphilis are calculated by dividing the number of deaths in a given year by the population for that year and multiplying by 100,000 (rate per 100,000 population). The infant mortality rate for syphilis for a given year is obtained by dividing the deaths due to syphilis among children under one year of age by the number of live births in the year multiplied by 10,000 (rate per 10,000 live births).

Since deaths from syphilis represent casefinding and treatment failures, mortality due to syphilis may be considered an inverse measure of the success of the syphilis control program.

It has been the practice since 1900 to revise the International Lists of Causes of Death about every 10 years to keep abreast of medical progress. These revisions have at times affected the continuity of syphilis mortality statistics. "The Sixth Revision of the International Lists of Causes of Death," which became effective in 1949, reduced reported syphilis deaths by about 26 percent. In "The Seventh Revision of the International Lists of Causes of Death," which was published in 1955 and became effective beginning January 1958, an increase of 3.3 percent for syphilis and its sequelae occurred by reason of a change in interpretation of "aneurysm of the aorta" reported in a sequence involving arteriosclerosis of sites other than the aorta. It should be noted, however, that the interpretation of such sequences reverted in 1959 to that used with the Sixth Revision. Mortality rates given in this FACT SHEET have been adjusted to the basis of the Seventh Revision. No adjustment was made for infant mortality since it was affected very little by changes in the Seventh Revision.

Insanity due to syphilis is measured by the rate of first admissions to mental hospitals because of syphilis. Excluded are admissions to psychopathic hospitals which provide only temporary care, and admissions to Veterans Administration facilities. The number of admissions is obtained from "Patients in Mental Institutions"published by the National Institute of Mental Health. Since only first admissions are included in the rate, the figures over a period of years represent a measure of the trend of incidence of syphilitic insanity.

Data on mortality and insanity due to syphilis are presented in Table 2.

## Reported Cases of Venereal Disease

All states require that syphilis and gonorrhea cases coming to medical attention be reported to the state or local health officer. Other venereal diseases are also reportable in most states. Quarterly, each state submits to the Public Health Service a summary of the cases reported to it. All cases not previously reported, regardless of duration, are to be included in the report. The reported morbidity, as reported cases are sometimes called, indicates the volume of successful casefinding.

The trend of reported cases or case rates of early syphilis over a period of years may be indicative of incidence trends if no significant changes in casefinding effort have occurred. Reported cases of syphilis in the later stages may be considered as an indication of past casefinding failure as well as present success. Trends in reported cases must be interpreted with caution since changes in casefinding effort are reflected in morbidity data just as much as changes in incidence and prevalence. Table 5 shows venereal disease case rates per 100,000 population by race and sex. However, race differences are biased. The reason for this is twofold: 1) Nonwhites have a tendency to seek treatment at public diagnostic facilities where reporting is complete. 2) Whites have a tendency to seek treatment at private diagnostic facilities where reporting is not complete.

Reported cases and case rates of venereal diseases are shown in Table 3 through Table 9. During the years 1955-1958, reported cases of primary and secondary syphilis, the recently acquired infectious stage of the disease, remained fairly level at about 6,500 cases per year. However, in fiscal year 1959, reported cases of infectious syphilis began to increase and continued to increase at an accelerated rate through 1961. Since 1962, the increases were not nearly as great as in preceding years. These increases are believed to be due to a combination of better reporting by private physicians, to better casefinding, and to a real increase in incidence in most areas.

The trend of reported cases of congenital syphilis by age is shown in Table 6.
The trend of age-specific case rates by age-groups by race and sex for primary and secondary syphilis and gonorrhea are shown in Table 7 and Table 8.

[^4]TABLE 6

## REPORTED CASES OF CONGENITAL SYPHILIS, BY AGE* UNITED STATES <br> Fiscal Years 1962-1965

| Age Group | 1962 |  | 1963 |  | 1964 |  | 1965 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Number | Percent | Number | Percent | Number | Percent | Number | Percent |
| 0-1 Year | 330 | 8.1 | 410 | 9.9 | 374 | 10.0 | 373 | 10.6 |
| 1-4 Years | 57 | 1.4 | 58 | 1.4 | 59 | 1.6 | 59 | 1.7 |
| 5-9 Years | 47 | 1.1 | 47 | 1.1 | 24 | 0.6 | 44 | 1.3 |
| 10 Years and Over | 3,651 | 89.4 | 3,625 | 87.6 | 3,280 | 87.8 | 3,029 | 86.4 |
| GRAND TOTAL | 4,085 | 100.0 | 4,140 | 100.0 | 3,737 | 100.0 | 3,505 | 100.0 |

*Cases not reported by age have been prorated according to known ages. In 1962, states failed to report the ages of approximately onethird of congenital cases. Since 1962, approximately $90 \%$ of congenital cases have been reported by age.

## CASES UNDER 1 YEAR OF AGE

Case rates of congenital syphilis under 1 year of age per 10,000 live births:
$\begin{array}{ll}1962 & 0.8 \\ 1963 & 0.9 \\ 1964 & 0.8\end{array}$
$\begin{array}{ll}1964 & 0.8 \\ 1965 & 0.8\end{array}$

## Health Department Casefinding Activities

Table 10 shows the volume of casefinding investigations performed by public clinics. The data on contact investigations indicate the volume of contacts named and the various indices show the success in finding cases of syphilis on a per patient basis.

TABLE 10
HEALTH DEPARTMENT CASEFINDING ACTIVITIES, UNITED STATES
Fiscal Years 1960-1965

| Clinic and Epidemiologic Data | 1960 | 1961 | 1962 | 1963 | 1964 | 1965 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Number of contact investigations completed | 222,052 | 225,541 | 186,784 | 179,715 | 192,580 | 186,386 |
| Number of other suspect investigations completed | 227,523 | 239,835 | 234,305 | 243,257 | 241,016 | 245,715 |
| Contact investigation indices: |  |  |  |  |  |  |
| Approximate number of contacts obtained from each primary and secondary syphilis patient (contact index) | 3.95 | 4.10 | 4.03 | 3.98 | 3.86 | 3.69 |
| Approximate number of syphilis infections identified in the contacts of each primary and secondary patient (epidemiologic index) | 1.07 | 1.22 | 1.24 | 1.17* | 1.13* | 1.11* |
| Approximate number of syphilis infections brought to treatment in the contacts of each primary and secondary patient (brought-to-treatment index) | . 52 | . 55 | . 52 | .47* | .46* | .45* |
| Approximate number of primary and secondary syphilis infections brought to treatment in the contacts of each primary and secondary patient (lesion-to-lesion index) | . 31 | . 33 | . 32 | . 30 | . 31 | . 32 |

## Treatment of Syphilis

## Congenital Syphilis

Recommended treatment for early congenital syphilis (less than 2 years) consists of aqueous procaine penicillin $G$ in total dosage of $100,000 \mu / \mathrm{kg}$. in 10 equally divided daily doses. Late congenital syphilis is treated with the same schedules as for comparable manifestations of acquired syphilis.

The earlier penicillin therapy is instituted for congenital syphilis, the more satisfactory the results.

## Early Syphilis

Benzathine penicillin $G$ and procaine penicillin $\mathbf{G}$ in oil with 2-percent aluminum monostearate (PAM) are the most widely used penicillin preparations for the treatment of early syphilis. Since benzathine penicillin G maintains a detectable blood level for a much longer period of time than PAM, a smaller total dosage is required for satisfactory results. The recommended schedules are $2,400,000$ units of benzathine penicillin $G$ administered in a single session ( $1,200,000$ units in each buttock) or $4,800,000$ units of PAM, $2,400,000$ units at first session, and subsequent injections of $1,200,000$ units given at 2 - or 3 -day intervals. If aqueous procaine penicillin $G$ is used, 600,000 units should be administered daily for 8 days to total $4,800,000$ units.

For the patient who is sensitive to penicillin, erythromycin ( $20-30$ grams) or tetracycline ( $30-40$ grams) is recommended for the treatment of syphilis.

## Epidemiologic Treatment

The treatment of all sex contacts of patients with early infectious syphilis is recommended as the most effective procedure for preventing the spread of syphilis. Although clinically and and serologically negative at time of initial examination, some of these contacts will have incubating syphilis and some, particularly females who may have an inconspicuous or no primary lesion, will already have developed syphilis. It is suggested, therefore, that contacts be treated for syphilis (rather than for incubating syphilis) with a dosage of $2,400,000$ units of benzathine penicillin G.

## Syphilis in Pregnancy

Congenital syphilis is completely preventable. Adequate treatment of the mother during the first 18 weeks of gestation prevents infection of the baby; adequate treatment after the 18th week cures the baby in utero.

In two studies, comprising 528 infants born to treated syphilitic mothers, approximately 98 percent of the children were nonsyphilitic. The percentage varied slightly by stage of mother's syphilis during pregnancy.

In the absence of relapse or reinfection, a woman treated with penicillin for syphilis will not require further treatment in the event of pregnancy.

## Neurosyphilis

A cooperative study conducted by the Public Health Service and leading neurosyphilologists in the United States has demonstrated that penicillin is the most effective treatment yet known for neurosyphilis.

Asymptomatic Neurosyphilis - Among 765 patients with asymptomatic neurosyphilis, approximately 75 percent of whom were treated with a minimum of $4,800,000$ units of penicillin, only one bona fide progression to symptomatic neurosyphilis was observed; 11 other patients exhibited minor neurologic changes. In contrast, among 467 patients treated with metal chemotherapy, 29 progressed to symptomatic neurosyphilis and an additional 15 showed minor neurologic changes.

Paresis - Six hundred and twenty-nine patients were treated for paresis with penicillin only, 60 percent of whom received a minimum of $6,000,000$ units. Paresis was diagnosed severe in 330, moderately severe in 141, and mild in 158. Five years after treatment 42 percent of those with severe psychoses were in remission or showed significant improvement, 45 percent remained unchanged, and only 13 percent had progressed or died from paresis. Progression or death from paresis occurred in 7.0 percent of those with moderately severe psychosis and in less than one percent of those with mild psychosis. Further proof of the effectiveness of penicillin is the fact that among those who survived, one-third of those who had been institutionalized, and two-thirds of those who had been unable to work at time of treatment, were gainfully employed 5 years later.

The total recommended dosage of penicillin for both symptomatic and asymptomatic neurosyphilis is $6,000,000$ to $9,000,000$ units. Any benefit from more than $10,000,000$ units is doubtful and has not been demonstrated. Treatment schedules are as follows:

Benzathine penicillin $G-3,000,000$ units at 7-day intervals.
PAM - $1,200,000$ units at 3 -day intervals.
Aqueous procaine penicillin $G-600,000$ units daily.

## Treatment of Gonorrhea

The treatment of gonorrhea is in a state of uncertainty although penicillin still remains the drug of choice. Some strains of the gonococcus are developing increasing resistance to penicillin, but this resistance is relative and not absolute. As a result it is necessary to recommend on an interim basis short acting penicillin preparations in larger doses. Treatment schedules are presently being evaluated and until results are available the following are recommended:

Uncomplicated gonorrhea in men: Aqueous procaine penicillin G, 2,400,000 units in one IM injection.

Uncomplicated gonorrhea in women: Aqueous procaine penicillin G, 4,800,000 units IM in two injection sites at one visit, or the combination of aqueous procaine penicillin $G$ and procaine penicillin $G$ in oil with 2 percent aluminum monostearate for two separate IM injections of $2,400,000$ units in each site given at one visit.

Prophylactic or epidemiologic treatment for gonorrhea (male and female) is accomplished with the same treatment schedules as for uncomplicated gonorrhea.

Treatment of gonorrhea with severe complications must be individualized using large amounts of short acting penicillin.

Excluding the likelihood of reinfection, retreatment is indicated if the discharge in uncomplicated male gonorrhea persists for three or more days following initial therapy and the smear, F.A., or culture is still positive. In uncomplicated gonorrhea in the female retreatment is indicated if followup cultures or F.A. procedures remain positive for gonococci. Retreatment consists of doubling the original dosage at a single visit or in divided doses on two successive days.

Gonorrhea patients sensitive to penicillin may be treated effectively with tetracycline, erythromycin, or oleandomycin. These may be administered as a single oral dose of 1.5 grams or 0.5 grams given orally every $4-6$ hours until $2-3$ grams have been given.

Gonorrhea patients who are sexual contacts to infectious syphilis should be given full prophylactic therapy for syphilis ( $2,400,000$ units of benzathine penicillin G) as well as recommended therapy for gonorrhea. While long acting forms of penicillin (such as benzathine penicillin) are ideal in syphilotherapy, they are not indicated in routine gonorrhea treatment.

## Penicillin Reactions

Since penicillin is the drug of choice for the treatment of both syphilis and gonorrhea, the Venereal Disease Branch is concerned with the frequency and severity of reactions to penicillin therapy. Through the cooperation of venereal disease clinics three studies at 5 -year intervals (1954, 1959 and 1964) have been conducted to determine their frequency.

The 1959 and 1964 studies were patterned after the 1954 study, the single departure being a request that, if possible, patients be detained in the clinic for a 30 -minute period following treatment. Reactions to penicillin were reported in 5.9/1,000 patients treated in 1954 and in $9.7 / 1,000$ treated in 1959. This increase of 64 percent was attributed mainly to the delay in dismissing patients after treatment. Preliminary tabulations of the 1964 data indicate there has been no increase since 1959.

In each study, urticaria was the most frequent type of reaction, occurring in from 4-6/1,000 patients treated. Moderate to severe anaphylaxis was observed in $0.15-0.35 / 1000$ patients treated.
