## Introduction

The VD Fact Sheet is intended as a handy source of basic statistics on the venereal diseases in the United States. In this booklet, public health specialists, students, physicians, and other persons interested in medical data will find venereal diseases measured by incidence and prevalence. The general public will find tables showing the costs of uncontrolled venereal disease and the frequency of psychoses and deaths from syphilis. While the results of casefinding are measured in terms of cases reported, the actual amount of casefinding effort is seen in the volume of diagnostic examinations and epidemiologic activity. As there is no agent for immunizing the population, finding and treating cases continues to be the only feasible means of controlling venereal disease.

Facts on these aspects of the venereal disease problem and program are presented in the text and tables which follow. The information is current as of the date of publication, and it supersedes any previously published data. Where no source is cited, the data presented are based on the statistics collected by the Venereal Disease Program of the National Communicable Disease Center, or upon estimates made by the Program. Where data are indicated as being for "fiscal years," the period runs from July 1 of the previous year through June 30 of the year indicated on the table. Rates per 100,000 population shown in this Fact Sheet are based on appropriate population estimates obtained from the Bureau of the Census.

## Incidence and Prevalence

The incidence of syphilis is defined as the number of new cases occurring in a given area within a specified period of time, usually a year.

Since the symptoms of primary and secondary syphilis appear soon after the disease is acquired, the number of primary and secondary cases occurring in the population within a given period of time would be the same as the incidence of syphilis.

Cases of primary and secondary syphilis are reportable by law in all of the 50 States and the District of Columbia. In the fiscal year ending June 30, 1967, physicians and clinics in the United States reported 21,090 cases to State or local departments of health. But the number of cases reported understates actual incidence for two reasons:

1. Not all cases are diagnosed, and
2. Not all diagnosed cases are reported.

The Venereal Disease Program currently estimates that the actual occurrence of syphilis was about 80,000 cases in Fiscal Year 1967 of which 21,090 were diagnosed and reported to health departments.

Cases of syphilis which occur but go untreated cumulate to form a large reservoir of cases needing treatment. This reservoir of cases needing treatment (prevalence), most of which are in the latent stage of disease and are detectable only by means of bloodtests, is currently estimated to number about 639,000.

Gonorrhea is underreported for the same reasons given above for the underreporting of syphilis but the problem of underdiagnosis is more acute in females than males due to the frequent asymptomatic nature of disease in the female. The Venereal Disease Program estimates that at least $1,200,000$ cases of gonorrhea occurred in the United States in Fiscal Year 1967, of which 376,000 were diagnosed and reported to health departments.

## Costs of Uncontrolled Syphilis

The statistics presented in Table 1 (next page) indicate the toll imposed by syphilis upon the manpower and economy of the country.

The estimate of man-years of disability for institutionalization of the syphilitic insane is based on the total number of patients in mental institutions and upon the proportion of those diagnosed as having syphilitic psychoses. Patients in State, county, and Veterans Administration hospitals for the permanent care of the insane are included.

The cost of maintenance is based upon the number of patients with syphilitic psychoses in tax supported institutions and upon the average per patient maintenance cost. Approximately three percent of patients with syphilitic psychoses are maintained in private institutions and these have not been included in this report.

Disability attributed to cardiovascular syphilis and to locomotor ataxia is based on conservative estimates of the prevalence of these late manifestations of syphilis.

The loss of life expectancy indicates the loss of future years of life for persons dying of syphilis in 1965. The loss of life expectancy is based on the expected years of life remaining to persons of that age, color and sex. The loss of income is based on projected earnings of these persons for the productive years of life lost to age 65. The estimated earnings are based on the median total money income rate for adults for 1965.

While disabilities and deaths from syphilis have been diminishing in recent years, costs and losses per case have been rising. As a result, total costs and income losses from syphilitic disabilities and deaths remain high compared to previous estimates.

On the basis of findings of research conducted in Macon County, Alabama, it has been estimated that the life expectancy of a Negro male between the ages of 25 and 60 years, infected with syphilis and receiving no appreciable treatment for his infection, is reduced by about 17 percent.*

[^0]MAN-YEARS OF SYPHILIS DISABILITY PER YEAR
Institutionalization for syphilitic insanity ..... 15,505
Disability from cardiovascular syphilis including aneurysm ..... 7,600
Disability from syphilitic blindness ..... 6,000
ECONOMIC COSTS OF SYPHILITIC PSYCHOSES AND SYPHILITIC BLINDNESS PER YEAR
Maintenance of patients with syphilitic psychoses ..... $\$ 45,184,000$
Compensation to syphilitic blind ..... \$ 6,624,000
LOSS OF LIFE EXPECTANCY FROM DEATHS DUE TO SYPHILIS IN MAN-YEARS
White males ..... 17,489
White females ..... 7,946
Non-white males ..... 7,592
Non-white females ..... 4,278
Total population ..... 37,305
LOSS OF INCOME TO AGE 65 AT 1965 MEDIAN TOTAL MONEY INCOME RATE ..... $\$ 36,187,000$

[^1]
# Reported Mortality and Insanity Due to Syphilis 

Mortality statistics are processed and tabulated in the National Center for Health Statistics (NCHS) from microfilm copies of the original certificates filed with State or local registrars. Mortality rates for syphilis are calculated by dividing the number of deaths in a given year by the population for that year and multiplying by 100,000 (rate per 100,000 population).

The infant mortality rate for syphilis for a given year is obtained by dividing the number of deaths due to syphilis among children under one year of age by the number of live births in the year multiplied by 10,000 (rate per 10,000 live births).

Since deaths from syphilis represent casefinding and treatment failures, mortality due to syphilis may be considered an inverse measure of the success of the syphilis control program.

It has been the practice since 1900 to revise the International Lists of Diseases and Causes of Death about every 10 years to keep abreast of medical progress. These revisions have at times affected the continuity of syphilis mortality statistics. "The Sixth Revision of the International Lists of Causes of Death," which became effective in 1949, reduced reported syphilis deaths by about 26 percent. In "The Seventh Revision of the International Lists of Causes of Death," which was published in 1955 and became effective beginning January 1958, an increase of 3.3 percent for syphilis and its sequelae occurred by reason of a change in interpretation of "aneurysm of the aorta"' reported in a sequence involving arteriosclerosis of sites other than the aorta. It should be noted, however, that the interpretation of such sequences reverted in 1959 to that used with the Sixth Revision. Mortality rates given in this FACT SHEET have been adjusted to the basis of the Seventh Revision. No adjustment was made for infant mortality since it was affected very little by changes in the Seventh Revision.

Insanity due to syphilis is measured by the rate of first admissions to mental hospitals because of syphilis. Excluded are first admissions to psychopathic hospitals which provide only temporary care, and admissions to Veterans Administration facilities. The number of admissions is obtained from "Patients in Mental Institutions" published by the National Institute of Mental Health. Since only first admissions are included in the rate, the figures over a period of years represent a measure of the trend of incidence of syphilitic insanity.

Data on mortality and insanity due to syphilis are presented in Table 2 (next page).

TABLE 2

## Reported Cases of Venereal Disease

All States require that each case of syph1lis and gonorrhea which comes to medical attention must be reported to the State or local health officer. The other venereal diseases are also reportable in most States. Every three months, each State submits to the Public Health Service a statistical summary of cases reported during the quarter. All cases not previously reported in the State, regardless of duration of infection or treatment status, are to be counted in the statistical report of cases. Reported morbidity, as reported cases are sometimes called, indicates the volume of successful casefinding.

The trend of reported cases or case rates of early syphilis over a period of years may be indicative of incidence trends if no significant changes in casefinding efforts or completeness of case reporting have occurred. Similarly, the trend of reported cases of syphilis in all stages of disease can be interpreted as indicative of prevalence trends subject to the limitations imposed by changes in casefinding efforts and completeness of case reporting. For these reasons, trends in reported cases and rates must be interpreted with caution since changes in casefinding efforts and completeness of case reporting are reflected in morbidity data just as much as changes in disease incidence and prevalence.

Reported venereal disease cases and rates are shown in Tables 3 through 9. Of particular recent interest are the decreases in primary and secondary syphilis cases which occurred in Fiscal Years 1966 and 1967 after eight successive years of increases, the increases measuring as much as 50 percent per year in the years 1960 and 1961. Reported cases of gonorrhea have increased in nine of the last ten years. During the last decade, gonorrhea cases increased by 74 percent while cases per capita increased 49 percent.

The differences in reported cases and rates between color groups as shown in Table 5 may be biased because nonwhites tend to utilize public diagnostic and treatment facilities where reporting is complete and whites tend to seek treatment at private diagnostic facilities where reporting is not complete.

The trend of reported cases of congenital syphilis by age is shown in Table 6, and Tables 7 and 8 show age specific cases and rates by color and sex for primary and secondary syphilis and for gonorrhea.

CASES OF SYPHILIS AND GONORRHEA REPORTED TO THE PUBLIC HEALTH SERVICE BY STATE HEALTH DEPARTMENTS, AND RATES PER 100,000 POPULATION A11 Reporting Areas in United States Fiscal Years 1919-1940

| Fiscal Year | ALL STAGES OF SYPHILIS |  | GONORRHEA |  |

## Health Department Casefinding Activities

Casefinding investigations fall into two categories: (1) the investigation of sex contacts of patients with recently acquired and infectious disease, and (2) the investigation of persons other than sex contacts who are suspected of having venereal disease. Most of the latter group of suspects are persons with reactive tests for syphilis which are generated by the estimated $38,000,000$ serologic tests performed annually in the United States, and are referred to in Table 10 as positive diagnostics. Thousands of the investigations of positive diagnostics and sex contacts carry health department casefinding workers into the offices of private physicians who make the medical determination of whether or not the suspects have syphilis.

For many years, the proficiency of the interviewing-contact investigation process in ferreting out the foci of syphilis infections in the community has been measured by a series of epidemiologic indices. The indices presented in Table 10 are based only on infectious cases diagnosed in health department clinics and do not include cases diagnosed and reported by private physicians. These indices are defined as follows:

The Contact Index is the average number of sex contacts elicited per infectious (primary and secondary) syphilis case interviewed.

The Epidemiologic Index is the average number of cases of syphilis identified per infectious case interviewed. A number of these identified cases will already have been diagnosed and treated.

The Brought-to-Treatment Index is the average number of previously not diagnosed cases of syphilis brought to treatment per infectious case interviewed.

The Lesion-to-Lesion Index is the average number of infectious (lesion or primary or secondary) cases brought to treatment per infectious case interviewed.

## Treatment of Syphilis

## Congenital Syphilis

For the treatment of very small infants with congenital syphilis, aqueous procaine penicillin $G$ is the preferred form of penicillin, the schedule consisting of $100,000 \mathrm{u} / \mathrm{kg}$. of body weight in 10 equally divided daily doses. Benzathine penicillin $G$ in a single injection of 50,000 $\mathrm{u} / \mathrm{kg}$. is recommended for all other children under 12 years of age or under 70 pounds in welght. Older or heavier children are generally treated with schedules recommended for adults in comparable stages of syphilis.

The earlier penicillin therapy is instituted for congenital syphilis, the more satisfactory the results.

## Early Syphilis

Benzathine penicillin $G$ and procaine penicillin $G$ in oil with 2-percent aluminum monostearate (PAM) are the most widely used penicillin preparations for the treatment of early syphilis. Since benzathine penicillin $G$ maintains a detectable blood level for a much longer period of time than PAM, a smaller total dosage is required for satisfactory results. The recommended schedules are $2,400,000$ units of benzathine penicillin $G$ administered in a single session ( $1,200,000$ units in each buttock) or $4,800,000$ units of PAM, $2,400,000$ units at first session, and subsequent injections of $1,200,000$ units given at 2 - or 3 -day intervals. If aqueous procaine penicillin $G$ is used, 600,000 units should be administered daily for 8 days to total $4,800,000$ units.

For the patient who is sensitive to penicillin, erythromycin or tetracycline in a total dosage of $30-40$ grams administered over a $10-15$ day period is recommended for the treatment of syphilis.

## Epidemiologic Treatment

The treatment of all sex contacts of patients with early infectious syphilis is recommended as the mosteffective procedure for preventing the spread of syphilis. Although clinically and serologically negative at time of initial examination, some of these contacts will have incubating syphilis and some, particularly females who may have an inconspicuous or no primary lesion, will already have developed syphilis. It is suggested, therefore, that contacts be treated for syphilis (rather than for incubating syphilis) with a dosage of $2,400,000$ units of benzathine penicillin G.

## Syphilis in Pregnancy

Congenital syphilis is completely preventable. Adequate treatment of the mother during the first 18 weeks of gestation prevents infection of the baby; adequate treatment after the 18 th week cures the baby in utero.

In two studies, comprising 528 infants born to treated syphilitic mothers, approximately 98 percent of the children were nonsyphilitic. The percentage varied slightly by stage of mother's syphilis during pregnancy.

In the absence of relapse or reinfection, a woman treated with penicillin for syphilis will not require further treatment in the event of pregnancy.

## Neurosyphilis

A cooperative study conducted by the Public Health Service and leading neurosyphilologists in the United States has demonstrated that penicillin is the most effective treatment yet known for neurosyphilis.

Asymptomatic Neurosyphilis - Among 765 patients with asymptomatic neurosyphilis, approximately 75 percent of whom were treated with a minimum of $4,800,000$ units of penicillin, only one bona fide progression to symptomatic neurosyphilis was observed; 11 other patients exhibited minor neurologic changes. In contrast, among 467 patients treated with metal chemotherapy, 29 progressed to symptomatic neurosyphilis and an additional 15 showed minor neurologic changes.

Paresis - Six hundred and twenty-nine patients were treated for paresis with penicillin only, 60 percent of whom received a minimum of $6,000,000$ units. Paresis was diagnosed severe in 330 , moderately severe in 141, and mild in 158. Five years after treatment 42 percent of those with severe psychoses were in remission or showed significant improvement, 45 percent remained unchanged, and only 13 percent had progressed or died from paresis. Progression or death from paresis occurred in 7.0 percent of those with moderately severe psychosis and in less than one percent of those with mild psychosis. Further proof of the effectiveness of penicillin is the fact that among those who survived, one-third of those who had been institutionalized, and two-thirds of those who had been unable to work at time of treatment were gainfully employed 5 years later.

The total recommended dosage of penicillin for both symptomatic and asymptomatic neurosyphilis is $6,000,000$ to $9,000,000$ units. Any benefit from more than $10,000,000$ units is doubtful and has not been demonstrated. Treatment schedules are as follows:

Benzathine penicillin $G-3,000,000$ units at 7 -day intervals. PAM - $1,200,000$ units at 3 -day intervals. Aqueous procaine penicillin G - 600,000 units dally.

## Treatment of Gonorrhea

The treatment of gonorrhea is in a state of uncertainty although penicillin still remains the drug of choice. Some strains of the gonococcus are developing increasing resistance to penicillin, but this resistance is relative and not absolute. Treatment schedules presently recommended are as follows:

Uncomplicated gonorrhea in men: Aqueous procaine penicillin G, $2,400,000$ units in one IM injection.

Uncomplicated gonorrhea in women: Aqueous procaine penicillin G, 4,800,000 units IM in two injection sites at one visit, or the combination of aqueous procaine penicillin $G$ and procaine penicillin G in oil with 2 percent aluminum monostearate for two separate IM injections of $2,400,000$ units in each site given at one visit.

Prophylactic or epidemiologic treatment for gonorrhea (male and female) is accomplished with the same treatment schedules as for uncomplicated gonorrhea.

Treatment of gonorrhea with severe complications must be individualized using large amounts of short acting penicillin.

Excluding the likelihood of reinfection, retreatment is indicated if the discharge in uncomplicated male gonorrhea persists for three or more days following initial therapy and the smear, F.A., or culture is still positive. In uncomplicated gonorrhea in the female retreatment is indicated if followup cultures or F.A. procedures remain positive for gonococci. Retreatment consists of doubling the original dosage at a single visit or in divided doses on two successive days.

Gonorrhea patients sensitive to penicillin may be treated effectively with tetracycline, erythromycin, or oleandomycin. These may be administered as a single oral dose of 1.5 grams or 0.5 gram given orally every 4-6 hours untll 2-3 grams have been given.

Gonorrhea patients who are sexual contacts to infectious syphilis should be given full prophylactic therapy for syphilis ( $2,400,000$ units of benzathine penicillin $G$ ) as well as recommended therapy for gonorrhea. While long acting forms of penicillin (such as benzathine penicillin) are ideal in syphilotherapy, they are not indicated in routine gonorrhea treatment.

## Penicillin Reactions

Since penicillin is the drug of choice for the treatment of both syphilis and gonorrhea, the Venereal Disease Program is concerned with the frequency and severity of reactions to penicillin therapy. Through the cooperation of venereal disease clinics three studies at 5 -year intervals (1954, 1959 and 1964) have been conducted to determine their frequency.

The 1959 and 1964 studies were patterned after the 1954 study, the single departure being a request that, if possible, patients be detained in the clinic for a 30 -minute period following treatment. Reactions to penicillin were reported in $5.9 / 1,000$ patients treated in 1954, in $9.7 / 1,000$ treated in 1959, and in 8.0/1,000 treated in 1964. The increase over 1954 is attributed mainly to the delay in dismissing patients after treatment.

In each study, urticaria was the most frequent type of reaction, occurring in from $4-6 / 1,000$ patients treated. Moderate to severe anaphylaxis was observed in 0.21 to $0.35 / 1,000$ patients. The only death reported during a study period occurred in 1964.
