# Partner Services Annual Report 2014

Program Evaluation Branch

---

## **Acknowledgements**

The report was prepared by Michele Rorie, Wei Song, Sam Dooley, Janet Heitgerd, John Gilford, Mesfin Mulatu, Shubha Rao and Hui Zhang.

Publication of this report would not have been possible without the hard work and dedication of all the states, territorial and local health departments that collected and submitted the National HIV Prevention Monitoring and Evaluation Partner Services data. We would also like to acknowledge the contributions of Erica Dunbar and Renee Freeman from the Prevention Program Branch as well as Renee Stein, Dale Stratford Tanjina Shabu (Northrop Grumman), Nadia Duffy, Jarvis Carter (Northrop Grumman) and Lisa Belcher from the Program Evaluation Branch for their contribution toward monitoring and strengthening of HIV prevention efforts.

## Introduction

Each year, an estimated 45,000 people in the United States become newly infected with HIV<sup>6</sup>. More than 90% of these new infections are thought to originate with people who are infected with HIV but not receiving medical care for their infection. Some of these people have not yet been diagnosed, others have been diagnosed but were never

### **Highlights of the Report\***

- 35,692 index patients were identified across all HIV Partner Services programs.
- Of the 30,648 index patients who were eligible<sup>1</sup>, located and with a reported enrollment status, 92% were interviewed for HIV Partner Services.
- 28,432 partners were named by index patients across all HIV Partner Services programs and 75% were initiated<sup>2</sup> for HIV Partner Services.
- Of the 17,544 notifiable<sup>3</sup> partners with valid data, 99% were notified of their potential HIV exposure.
- Of the 12,426 notified partners with HIV test information, 80% were tested for HIV.
- Of the 7,981 partners tested with a documented HIV test result, 36% were newly identified<sup>4</sup> as HIV-positive.
- Of the 598 newly identified HIV positive partners with follow-up information, 87% were linked to HIV medical care<sup>5</sup>.

\*Reported percentages were calculated based on individuals with valid data on the outcome and excludes those reported as pending, lost to follow-up, don't know, or missing.

<sup>1</sup> An index patient is eligible for partner services if he or she is not deceased, or out of jurisdiction at the time of report.

<sup>2</sup> Partners named, for whom a record was created in the NHM&E client-level partner services database in EvaluationWeb®. It includes partners determined to be out of jurisdiction, deceased, not notifiable due to assessed risk for potential violence on the part of the index patient or the partner, or previously diagnosed with HIV infection.

<sup>3</sup> Partners that are not known to be HIV-positive, out of jurisdiction, deceased, or potentially violent.

<sup>4</sup> Partners who test positive for HIV infection after having no evidence of previous HIV diagnosis from cross-check with the health department surveillance system; review of laboratory reports, medical records, or other available data sources (e.g., partner services database, evidence of previous treatment for HIV); or patient self-report.

<sup>5</sup> The referring agency has confirmed that the client accessed the HIV medical care to which he or she was referred.

linked to medical care, and still others were linked to medical care but were subsequently lost to medical follow-up. The most critical challenge for HIV prevention is to identify people with HIV infection who are not in care; help them access care, where they can receive treatment with antiretroviral therapy (ART); and help them remain in care.

Partner services is a key strategy for identifying people with HIV infection – those with undiagnosed infection and those with previously diagnosed infection who are not receiving medical care – and helping them access care and treatment. All persons with newly diagnosed HIV infection should receive partner services to help them identify sex and drug-injection partners who may also be infected, or may be at very high risk for becoming infected. The partners can then be notified of their potential exposure and offered HIV testing. Those who test positive for HIV can then be linked to HIV medical care and other services.

Partner services can also help persons living with HIV and their partners address other needs, such as reducing behavioral risk for transmitting or acquiring HIV; accessing treatment for mental health issues and substance abuse; and obtaining social services to address housing, transportation, and employment issues.

This report summarizes 2014 client-level partner services data submitted by CDC-funded jurisdictions in the United States and dependent areas (Puerto Rico and U.S. Virgin Islands).

## Methods

Health departments collect standardized, client-level, National HIV Prevention Program Monitoring &

<sup>6</sup> HIV in the United States: *At A Glance*. <http://www.cdc.gov/hiv/statistics/basics/ataglance.html>

Evaluation (NHM&E) data from their partner services programs and report them to CDC twice yearly for monitoring at the national level. Data are reported through EvaluationWeb<sup>®</sup>, a web-based software tool made available to grantees by CDC. The data undergo a quality assurance process and are then used to calculate program indicators at the national and jurisdictional levels to assess each step of the partner services process. Indicators are stratified by age, gender, race/ethnicity, target population<sup>1</sup>, and geographic region as defined by the U.S. Census Bureau<sup>2</sup>. Risk data used to define target population is only required and reported for individuals diagnosed as HIV-positive.

This report includes all partner services cases opened during the period of January 1 – December 31, 2014. The following partner services program indicators are reported:

1. Interview of index patients (partner elicitation)
  - Percentage of located index patients who were interviewed for partner services
2. Partner notification
  - Percentage of notifiable partners who were notified
3. Partner testing
  - Percentage of notified partners who were tested
  - Percentage of tested partners who had newly diagnosed HIV infection
4. Linkage to HIV medical care
  - Percentage of partners with newly diagnosed HIV infection who were linked to HIV medical care

Indicators were calculated and reported for those records with complete and valid data.

## Findings

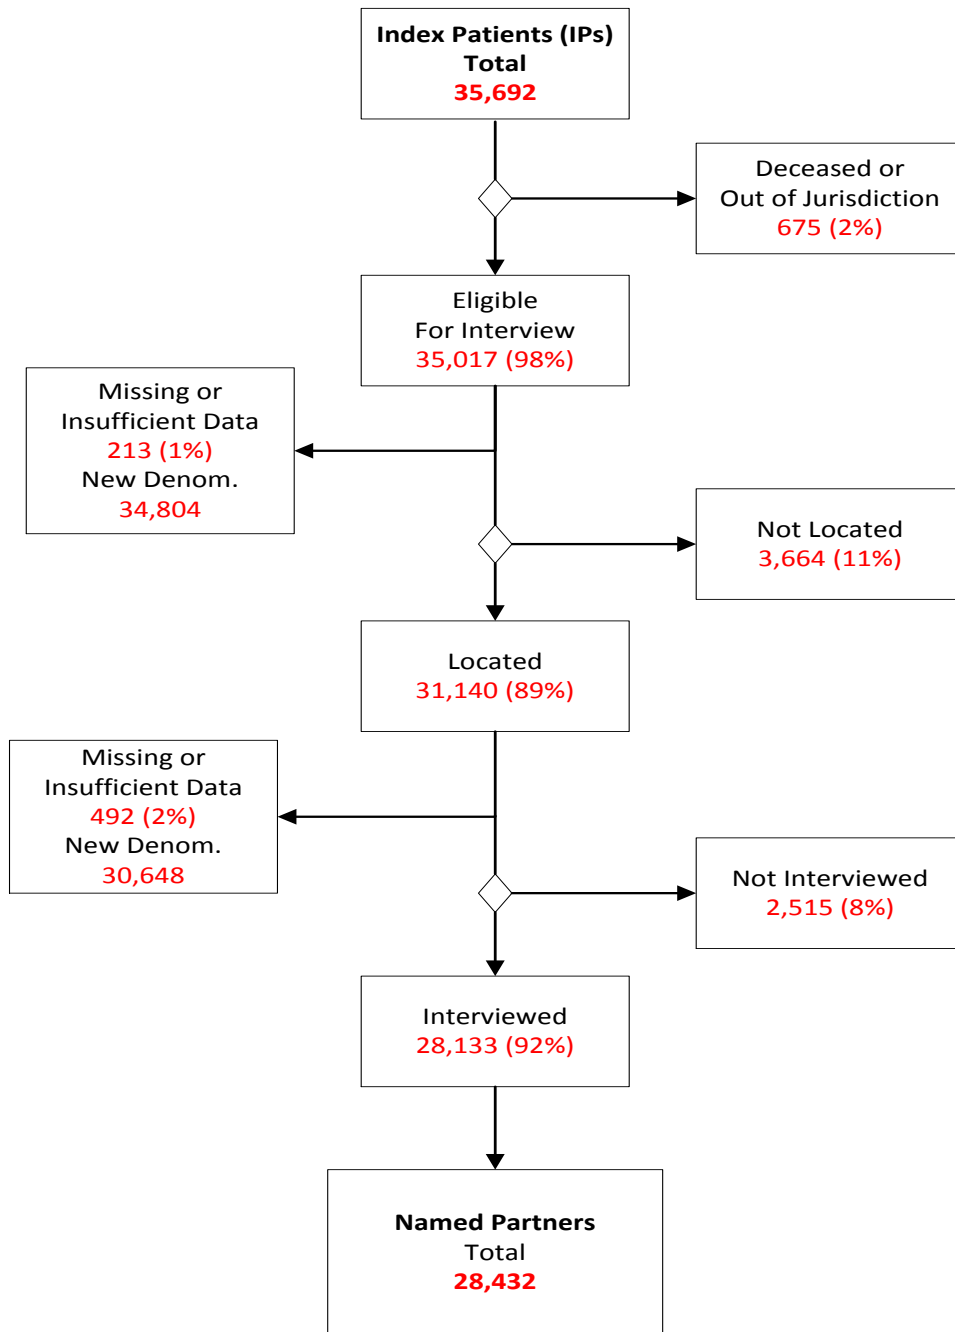

This report summarizes 2014 client-level partner services data from 57 of the 61 CDC funded jurisdictions in the United States and dependent areas (Puerto Rico and U.S. Virgin Islands). Data from four jurisdictions (Houston, Kansas, Texas and Wyoming) are not included in this report because data files were not received by the July 1, 2015 EvaluationWeb<sup>®</sup> data transfer to CDC. The following flowchart represents the calculated index patient indicators used to answer key partner services program evaluation questions.

---

<sup>1</sup> Target populations are categorized as follows: Men who have sex with men and report injection drug use; Men who have sex with men; Transgender persons who report injection drug use; Transgender persons; Persons who inject drugs; Heterosexual males; Heterosexual females

<sup>2</sup> U.S. geographic regions include the following **Northeast**: Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island and Vermont; **Midwest**: Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota and Wisconsin; **South**: Alabama, Arkansas, Delaware, District of Columbia, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia and West Virginia; **West**: Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming. U.S. Dependent Areas: Puerto Rico and the U.S. Virgin Islands

**Figure 1. Flowchart of the 2014 Partner Services Index Patient Indicators**

Data Source: NHM&E Partner Services data (January 1, 2014- December 31, 2014) as of July 1, 2015

### ***Index Patients***

In 2014, a total of 35,692 index patients were identified by partner services programs after testing HIV-positive. Of them, 35,017 (98%) were eligible for HIV partner services.

- **Age:** The largest percentage of index patients were in the age group 20-29 years (32%) followed by 30-39 (25%). Only 3% of index patients were younger than 19 years (Table 2).
- **Gender:** The majority of index patients were males (81%), with females and transgender persons accounting for 17% and 1% respectively (Table 2).
- **Race/Ethnicity:** A large percentage of index patients were black/African American (45%), followed by white (29%), and Hispanic/Latino (18%) (Table 2).
- **U.S. Geographic Region:** Almost half (49%) of the index patients lived in the South (Table 2).
- **Target Population:** Men who have sex with men (MSM) accounted for 38% of index patients in 2014. However, there was a large percentage (40%) of no risk/missing/invalid data reported (Table 2).

### **How Effective Are Partner Services Programs At Identifying And Interviewing Index Patients With HIV Infection?**

#### ➤ ***Indicator: Percentage of located index patients who were interviewed for partner services***

A total of 31,140 (90%) index patients were located and of those 30,648 with a reported partner services enrollment status, 28,133 (92%) were interviewed to elicit partner names and identify risk behavior.

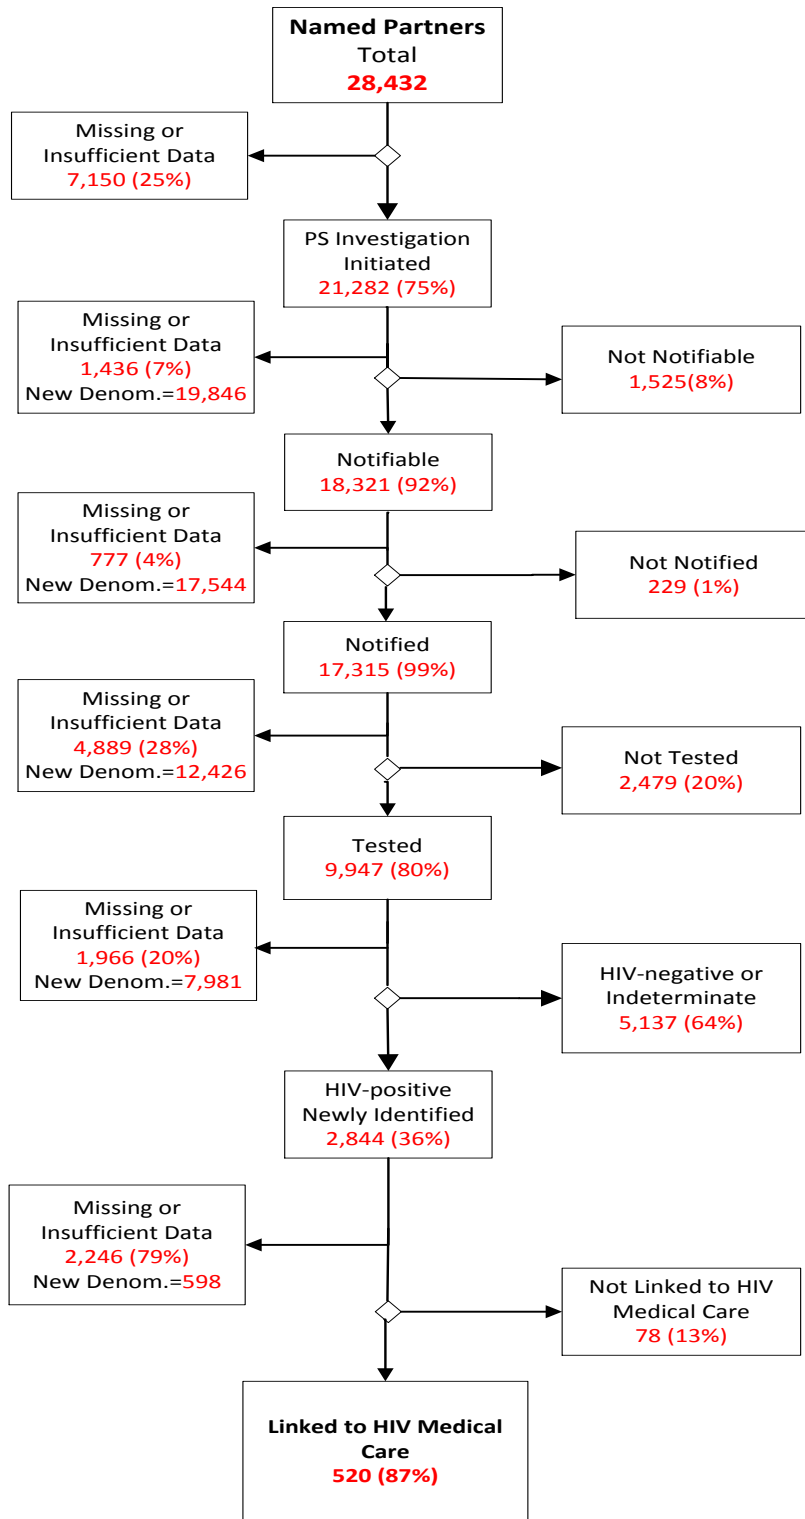

- **Age:** Index patients aged 13-19 were most often located and interviewed (95%), while those in the <13 age group had the lowest percentages located and interviewed (69% and 71%, respectively) (Table 2).
- **Gender:** Females (90%) were located at approximately the same rate as males (89%), but females were interviewed more often (96%) than males (91%) (Table 2).
- **Race/Ethnicity:** Blacks/African Americans were located and interviewed for partner services more frequently (92% and 95%, respectively) than whites (88% and 89%) and Hispanics/Latinos at 89% for both located and interviewed for partner services (Table 2).
- **U.S. Geographic Region:** Ninety-four percent of index patients residing in the South were located for partner services, with the lowest rate reported in the Midwest (76%). The U.S. Dependent Areas had the highest percentage of partner services interviews conducted, 100%; while the West had the lowest, 73% (Table 2).
- **Target Population:** Almost all MSM (96%), heterosexual men and heterosexual women were located for partner services (97%). However, MSM index patients were interviewed (90%) less frequently than heterosexual men and heterosexual women (96% and 97%, respectively) (Table 2).

### ***Partners***

A total of 28,432 partners were named by index patients in 57 partner services programs. The following flowchart represents the calculated partner indicators used to answer key partner services program evaluation questions.

**Figure 2. Flowchart of the 2014 Partner Services Partner Indicators**

Data Source: NHM&E Partner Services data (January 1, 2014-December 31, 2014) as of July 1, 2015

## How Effective Are Partner Services Programs at Notifying Partners Of Their Potential HIV Exposure?

### ➤ **Indicator: Percentage of notifiable partners who were notified**

Of the 28,432 partners that were named, 21,282 (75%) were initiated for partner services. Of the partners that were initiated for partner services 1,525 (8%) were excluded because they were either previously known to be HIV-positive, out of jurisdiction, deceased, or potentially violent. Another 1,436 records (7%) contained insufficient or invalid data. The remaining 18,321 (92%) were considered notifiable. Of the 17,544 notifiable partners with valid data, a total of 17,315 (99%) partners were notified of their potential HIV exposure.

- **Age:** The majority of partners initiated for partner services were in the age groups 20-29 and 30-39 (34% and 24%, respectively). Although partners from all age groups were notified at a rate greater than 98%, those aged younger than 13 were notified 100% of the time (Table 4).
- **Gender:** More males were initiated for partner services (78%) than females (16%). Male, female and transgender partners were notified at the rate of 98% or higher (Table 4).
- **Race/Ethnicity:** Although more Blacks/African Americans were initiated for partner services (46%) than whites (26%) and Hispanics/Latinos (16%), the groups were all notified (99%) at the same rate (Table 4).
- **U.S. Geographic Region:** The majority of partners initiated for partner services lived in the South (51%) compared to the Northeast (21%), West (17%) and Midwest (10%) (Table 4).
- **Target Population:** Risk data are only required for those partners who test positive. Of those with a complete risk profile, 19% of the named partners initiated for partner services were MSM (Table 4).

## How Effective Are Partner Services Programs In Testing Notified Partners And Identifying HIV Infections?

### ➤ **Indicator 1: Percentage of notified partners who were tested**

### ➤ **Indicator 2: Percentage of tested partners who had newly diagnosed HIV infection**

Of the 12,426 notified partners with valid testing data, 9,947 (80%) were tested for HIV (Table 3). Of the 7,981 partners tested with a documented HIV test result, 2,844 (36%) were newly identified as HIV-positive (Table 5).

- **Age:** The percentage of notified partners tested for HIV was about 80% for all age groups except for those aged <13 where the rate was 57% (Table 4). Partners in the age group 40-49 had the highest percentage newly identified as HIV-positive (41%) (Table 6).
- **Gender:** The percentage of male and female partners tested for HIV were equal (82%), while the rate of testing for transgender partners was lower (30%) (Table 4). The percentage newly identified as HIV-positive was higher for male partners (39%) than female partners (25%) (Table 6).
- **Race/Ethnicity:** The rate at which black/African American partners (79%) were tested for HIV was slightly lower than that for whites (81%) and Hispanics/Latinos (82%). American Indians or Alaska Natives had the highest rate at 89% (Table 4). The percentage newly identified as HIV-positive was highest for black/African American partners (42%) (Table 6).

- **U.S. Geographic Region:** The U.S. Dependent Areas had the highest percentage of notified partners tested for HIV (94%) and the Northeast had the lowest (57%) (Table 4). When excluding the U.S. Dependent Areas, the South had the highest percentage of partners newly identified as HIV-positive (41%) and the Northeast had the lowest (13%) (Table 6).
- **Target Population:** Risk data were only required and reported for partners newly diagnosed as HIV-positive. Of these data, 39% of MSM tested were newly identified as HIV-positive (Table 6).

### How Effective Are Partner Services Programs In Linking HIV-Positive Partners To HIV Medical Care Services?

- **Indicator: Percentage of partners with newly diagnosed HIV infection who were linked to HIV medical care**

Partners who test positive for HIV should be linked as soon as possible to HIV medical care. In 2014, a total of 2,844 partners were newly identified as HIV-positive from all partner services programs. Of the 598 newly identified HIV-positive partners with follow-up information to verify that services were accessed, 520 (87%) were linked to HIV medical care (Table 5).

- **Age:** HIV-positive partners aged 40-49 had the highest linkage to HIV medical care at 90%. Partners aged 20-29 and 30-39 were linked to HIV medical care at a rate of 87% (Table 6).
- **Gender:** Male and female HIV-positive partners had the same linkage to HIV medical care at 88%, however, only 40% of transgender partners were linked to HIV medical care (Table 6).
- **Race/Ethnicity:** Black/African American HIV-positive partners (91%) were linked to HIV medical care at a higher rate than white (85%), Hispanic/Latino (78%) and multi-race (75%) partners (Table 6).
- **U.S. Geographic Region:** Partners who lived in the South (94%) were linked more than those in the Northeast (87%), the Midwest (77%) and the West (65%) (Table 6).
- **Target Populations:** Among the newly identified HIV-positive partners who could be categorized as one of the listed target populations, all MSM/IDU (3) and Transgender/IDU (1) partners were linked to medical care. Heterosexual women (83%) were linked to medical care more often than MSM (78%) and heterosexual men (75%) (Table 6).

### Limitations

While partner services data reporting and quality are continuously improving, the interpretation of findings contained in this report has to be informed by the level of missing data on key variables and the factors that contributed to missing data.

In the 2014 partner services data, several key variables used to calculate program performance indicators had missing data ranging between 2% and 79% of the total records.

- Enrollment Status for Index Patients 2%
- Partner Notifiability 7%
- HIV Test Performed for Partners 28%
- Test Results for Partners 20%
- Linkage to HIV Medical Care 79%

This report focuses on “reported” percentages calculated by excluding missing data, thus possibly overestimating the true values for the indicators.

In addition, other important variables that are required to describe the indicators by demographic and other population groups (particularly behavioral risk) had significant levels of missing data. There are at least two factors that contributed to missing data. The first is related to the varied data collection systems used by grantees. Although the NHM&E required variables are standardized, health departments use different systems for collecting and reporting partner services data. Sixty-one percent of grantees use their own locally developed or adapted systems (e.g., PRISM, Maven, PartnerServicesWeb®) and 22% use some version of STD\*MIS, a CDC-supported data collection tool. Versions prior to the most recent installment of STD\*MIS did not capture 14 of the key variables needed to calculate partner services program performance indicators and several grantees are still using these earlier versions. Other data systems were missing key identifying variables, such as case number that is needed for linking index patients to partners. HIV testing and referral to HIV medical care variables for newly identified HIV-positive partners were also missing in some systems.

Secondly, tracking partners’ past and current HIV test results and their linkage to care and other services is a complex time and labor intensive activity. At a minimum, it requires data sharing between various providers and data systems that are continuously updated. While many health departments report linking 100% of their newly identified partners to HIV medical care, their partner services data submitted to CDC do not reflect this for a variety of reasons. For example, it is very likely that the high levels of missing data on linkage to HIV medical care is due to the lack of formal systems to confirm if a person has indeed attended their first HIV medical appointment; or lack of a method to collect information (no designated place to enter the data in the systems). This appears to be a recurring problem within partner services programs.

\*Reported denominator is the number of partners with valid data on the outcome and excludes missing/invalid data.

^ Reported percentage was calculated based on individuals with valid data on the outcome and excludes missing/invalid data.

^ Data reflect a partial submission.

**Table 6. Demographic and Risk Behavior Characteristics of Newly-Identified HIV+ Partners Linked to HIV Medical Care, 57 Health Departments, 2014**

<sup>#</sup>Reported denominator is the number of partners with valid data on the outcome and excludes missing/invalid data.

<sup>\*</sup>Reported percentage was calculated based on individuals with valid data on the outcome and excludes missing/invalid data.

<sup>^</sup>Determined by comparing “birth gender” and “current gender”.

<sup>§</sup>As reported in the risk profile.
