CENTER FOR DISEASE CONTROL

MNWR

MORBIDITY AND MORTALITY WEEKLY REPORT

ANNUAL SUMMARY 1978

Reported Morbidity & Mortality
in the United States

RECEIVED

NOV 28 1979

CDC LIBRARY
ATLANTA, GA 30333

U.S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE / PUBLIC HEALTH SERVICE

The annual statistical summary is published as the last issue in each volume of the Morbidity and Mortality Weekly Report by the Center for Disease Control, Public Health Service, U.S. Department of Health, Education, and Welfare, Atlanta, Georgia 30333.

SUGGESTED CITATION

Center for Disease Control: Reported Morbidity and Mortality in the United States, 1978. Morbidity Mortality Weekly Rep 27 (54 Annual Suppl), 1979

Center for Disease Control William H. Foege, M.D.,
Director

This report was prepared by:

Bureau of Epidemiology Philip S. Brachman, M.D.,
Director

Editor, Morbidity and
Mortality Weekly Report. Michael B. Gregg, M.D.

Consolidated Surveillance and
Communications Activity Stephen B. Thacker, M.D.,
Chief

Virginia Bales, M.C.H.
Keewhan Choi, Ph.D.

TABLE OF CONTENTS

Preface	iii
Historical Development of National Morbidity Reporting and Surveillance in the United States	v
Sources of Data	vii
SECTION 1 — Summary of Notifiable Diseases in the United States	1
Reported Cases by Year, 1969-1978	3
Reported Case Rates by Year, 1969-1978	4
Reported Deaths by Year, 1968-1977	5
Reported Cases by Month, 1978	6
Reported Cases by Age, 1978	7
Reported Cases by Geographic Division and by State, 1978	8
SECTION 2 — Additional Analysis of Notifiable Diseases in the United States	15
(Statistical tables, graphs, maps, and narratives for each of 36 notifiable conditions are grouped in alphabetical order in this section.)	
SECTION 3 — Conditions of Special Interest	75
Cases Optionally Reported by Certain States, 1978	77
Deaths from Selected Acute Conditions by Year, 1968-1977	79
Abortion	81
Lead Poisoning	84
Pneumonia and Influenza (Deaths in 121 Selected Cities)	88
Reye Syndrome	92
Index	93
State Epidemiologists	Inside Back Cover

HISTORICAL DEVELOPMENT OF MORBIDITY REPORTING AND SURVEILLANCE IN THE UNITED STATES

In 1878 an act of Congress authorized collection of morbidity reports by the Public Health Service for use in connection with quarantine measures against pestilential diseases such as cholera, smallpox, plague, and yellow fever. In 1893 an act provided for the collection of information on a weekly basis from state and municipal authorities throughout the United States, and gradually an increasing number of states began submitting monthly and annual summaries to the Public Health Service. It was not until 1925, however, that all states began to report regularly.

Responsibilities for data collection and analysis were subsequently transferred several times within the Public Health Service. The Communicable Disease Center acquired responsibility for the venereal disease program in 1957, the tuberculosis program in 1960, the collection of data on nationally notifiable diseases in 1961, and the foreign quarantine program in 1967. Changing characteristics of diseases have necessitated modifications in the reporting system and the addition of new diseases. In 1970 the Communicable Disease Center was renamed the Center for Disease Control to reflect a broader mandate in preventive health services. Over the years the surveillance systems maintained by CDC have expanded, and emphasis has shifted as certain diseases have declined in incidence and other diseases have taken on new aspects. In addition, CDC's increasing interest in noncommunicable diseases is reflected in new programs in family planning, childhood lead poisoning prevention, congenital birth defects, and chronic diseases.

In 1978 the Consolidated Surveillance and Communications Activity was established in the Bureau of Epidemiology to provide ongoing examination of surveillance efforts, including MMWR statistics. This activity's primary responsibility is to work with state health departments and bureaus within CDC to propose, coordinate, and evaluate future changes in surveillance activities.

SOURCES OF DATA

Data on the reported incidence of notifiable diseases are routinely published in the *Morbidity and Mortality Weekly Report* (MMWR) and compiled in final form in this summary from annual reports supplied by the state and territorial departments of health. However, totals for the United States do not include data listed for Guam, Puerto Rico, the Virgin Islands, and the Trust Territory of the Pacific Islands.

CDC also maintains national surveillance programs for selected diseases, with the cooperation of state and local health departments, and publishes detailed epidemiologic analyses on a periodic basis. Data appearing in a surveillance report may not agree exactly with reports published by the MMWR because of differences in timing of reports or because of refinements in case definition.

It should be noted that the MMWR and the national surveillance program are separate systems; data from each appear in this *Annual Summary*. These data should be interpreted with caution. Some diseases such as plague and rabies that cause severe clinical illness and are associated with serious consequences are probably reported quite accurately. However, diseases such as salmonellosis and mumps that are clinically mild and infrequently associated with serious consequences are less likely to be reported. Additionally, subclinical cases are seldom detected except in the course of special studies. The degree of completeness of reporting is also influenced by the diagnostic facilities available, the control measures in effect, and the interests and priorities of state and local officials responsible for disease control and surveillance. Finally, factors such as the introduction of new diagnostic tests (e.g., hepatitis B) and the discovery of new disease entities (e.g., infant botulism and Legionnaires' disease) may cause changes in disease reporting independent of the true incidence of disease. Despite these limitations the data in this report have proven to be useful in the analysis of trends.

Mortality data, with the exception of statistics obtained from the 121 participating cities, are from the National Center for Health Statistics, Health Services Administration. Each year these data are also published in *Vital Statistics of the United States*, Vol. II.

The population data for 1978 used in computing rates are from the Bureau of the Census and are provisional estimates of the resident population as of July 1, 1978. The data are in the Bureau's *Current Population Reports* series: state estimates in Series P-25, No. 790; age estimates in P-25, No. 800 and in unpublished data; New York City data in P-26, No. 78-32. Data for U.S. Territories are provisional, unpublished estimates. Population data from those states where diseases were not notifiable or where age-specific data were not available were

excluded from rate calculation. Rates were calculated using resident population with the exception of chancroid, gonorrhoea, granuloma inguinale, lymphogranuloma venereum, and syphilis, for which only civilian resident population data were utilized.

In order not to delay the publication of this document, provisional data from California were included. For further modification of any of those data, contact the California Department of Health Services.

EXPLANATION OF SYMBOLS USED IN TABLES

Data not available	NA
No reported cases	—
Report of disease not required by state health department (not notifiable)	NN
Case imported from outside United States	I

SECTION 2:

**Additional Analysis of
Notifiable Diseases
in the United States**

ANTHRAX – ASEPTIC MENINGITIS

ANTHRAX – Reported Cases in Humans by 5-Year Period, United States, 1920–1978

* 10 CASES 1975 - 1978.

ASEPTIC MENINGITIS – Reported Case Rates by Month, United States, 1976–1978

Since 1976 there has been a pronounced increase in the rate of reported cases of aseptic meningitis. This increase is probably associated with variations in etiologic agents as well as changes in reporting practices.

BOTULISM

The identification of the infant botulism syndrome has necessitated the differentiation among infant, wound, foodborne, and unspecified cases.

BOTULISM (INFANT) – Reported Cases by Month of Onset, United States, 1976–1978

BRUCELLOSIS — Reported Cases by Year, United States, 1950–1978

BRUCELLOSIS — Reported Cases by County, United States, 1978

CHICKENPOX – CHOLERA

CHICKENPOX – Reported Case Rates by Month, United States, 1974–1978

Cholera

In 1978, 12 cases of culture-confirmed cholera occurred in the United States. Eleven of these were sporadic cases which occurred in August and September in Louisiana and were caused by eating crabs caught in Louisiana marshes. One case was the result of a laboratory accident in Michigan.

DIPHTHERIA — Reported Case and Death Rates by Year, United States, 1920–1978

DIPHTHERIA — Reported Case Rates by Age Group, United States, 1978

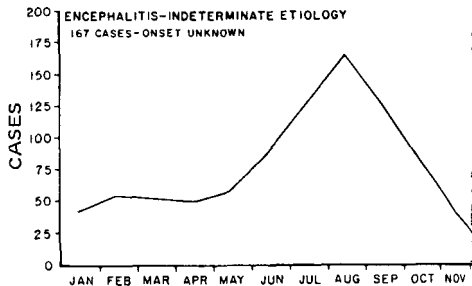

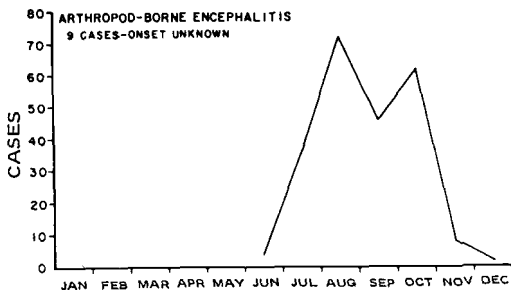

The relatively high rates of diphtheria in persons over the age of 30 represent cases of cutaneous disease. Under the age of 5 diphtheria is primarily found during the first year of life.

ENCEPHALITIS

ENCEPHALITIS — Reported Cases by Month of Onset, United States, 1970–1977

ENCEPHALITIS — Reported Cases by Etiology and Month, United States, 1977

ENCEPHALITIS — Reported Cases by Geographic Division and by State, United States, 1977

This table has been included to update the provisional data published in the 1977 Annual Summary.

GONORRHEA

The sharp increase in the reporting of gonorrhea during the past decade appears to have leveled off. Both an actual increase in the occurrence of disease as well as improved case ascertainment are thought to be reasons for the earlier increase. The recent plateau in reported cases is thought to be due to disease-intervention activities initiated by health departments (e.g., screening high-risk populations for gonorrhea, providing sexual-partner referral services to patients with gonorrhea and providing facts about venereal disease to people at risk to prevent exposure and to influence infected individuals to seek early medical care for themselves and their sexual partners). The geographic clustering may reflect a high incidence of disease as well as a high level of case detection. The impact of the introduction of penicillinase-producing *Neisseria gonorrhoeae* in 1976 has not been determined.

GONORRHEA — Reported Civilian Case Rates by Year, United States, Calendar Years 1941–1978

Viral hepatitis continues to be one of the 5 most frequently reported infectious diseases in the United States. The total number of viral hepatitis cases reported for 1978, however, was the lowest since 1968; the case rate, the lowest reported since 1967. Decreases were found in 1978 in the case rates and in the number of cases of both hepatitis A and hepatitis B. Persons from 15 through 29 years of age continue to be the group most affected by hepatitis.

¹ Cases reported by state of Georgia included in Hepatitis, unspecified.² Cases represent patients tested for HBsAg and found to be positive.

LEGIONNAIRES' DISEASE – LEPROSY

LEGIONNAIRES' DISEASE – Reported Sporadic Cases by Month of Onset, United States, 1978

LEPROSY – Reported Cases by Year, United States, 1942–1978

The increase in leprosy cases is most likely due to an increase in imported cases of disease.

LEPTOSPIROSIS – MALARIA

LEPTOSPIROSIS – Reported Cases by Year, United States, 1950–1978

MALARIA – Reported Cases by Year, United States, 1933–1978

MEASLES

MEASLES (Rubeola) — Reported Case Rates by Year, United States, 1950—1978

The long-term decrease in the reported incidence of measles has resumed following an increase in reported cases in 1975-1977.

MEASLES (Rubeola) — Reported Death Rates by Year, United States, 1950—1977

* NOT AVAILABLE FOR 1978.

MEASLES

MEASLES (Rubeola) -- Reported Case Rates by Age Group*, United States, 1978

*EXCLUDES UNKNOWN AGES.

The relatively large number of cases among adolescents and young adults reflects the recent upward shift in the age distribution of reported cases, attributable to incomplete or inadequate immunization in these populations.

PLAGUE — Reported Cases in Humans by Year, United States, 1950–1978

PLAGUE — Reported Cases and Deaths in Humans by Age Group, United States, 1950–1978

POLIOMYELITIS

POLIOMYELITIS (Paralytic) — Reported Case Rates by Year, United States, 1951–1963

POLIOMYELITIS (Paralytic) — Reported Case Rates by Year, United States, 1963–1978

POLIOMYELITIS

Nine cases of paralytic poliomyelitis were reported for 1978. Six of these were classified epidemiologically as "vaccine-associated," implicating virus from the oral polio vaccine (OPV) as the cause of disease. The attack rate for paralytic poliomyelitis has declined markedly since the 1950s; most of the decline has been attributed to the success of poliovirus vaccines in preventing disease. However, among the small number of recent cases, a larger proportion were classified as vaccine associated between 1969-1978 than during the previous decade. Of the 165 paralytic cases reported to the poliomyelitis surveillance program between 1969-1978, 65 (39%) were classified as vaccine associated. Eliminating the 30 cases occurring during the poliomyelitis epidemics of 1970 and 1972, 48% of cases were attributed etiologically to OPV. Vaccine-associated cases constituted 21%-80% of annual cases reported during the 8 years in which no poliomyelitis outbreak occurred. The majority of vaccine-associated cases (72%) occurred in contacts of vaccinees: 55% in household contacts, 17% in nonhousehold contacts. The remainder (28%) were in OPV recipients.

RABIES — Reported Cases in Wild and Domestic Animals by Year, United States, 1953–1978

Although there has been a relatively stable total number of reported cases of rabies annually in wild and domestic animals over the past 15 years, there have been changes in numbers of specific kinds of animals reported positive. Compared with 15 years ago, less cases of rabies are now reported in dogs, cats, cattle, and horses, whereas more cases are being reported in skunks, bats, and raccoons. The top 3 animals continue to be the wild animals most frequently determined to have laboratory-confirmed rabies.

RABIES — Reported Cases in Humans by Year, United States, 1950–1978

Reported human rabies cases have ranged from 0 to 4 annually for the past 19 years. In 1978 a human-to-human transmission of rabies by corneal transplant was reported.

RUBELLA

RUBELLA (German Measles) — Reported Case Rates by Year, United States, 1966—1978

Reported rubella activity continues to fluctuate at a level that is 70% less than that reported before vaccine licensure in 1969.

RUBELLA (German Measles) — Reported Case Rates by Month, United States, 1976—1978

RUBELLA (German Measles) — Reported Cases by State and by Month, United States, 1978

RUBELLA

RUBELLA (German Measles) — Reported Case Rates by Age Group,* United States, 1978

*EXCLUDES UNKNOWN AGES.

The relatively large number of cases among adolescents and young adults reflects the recent upward shift in the age distribution of reported cases, attributable to inadequate immunization levels in these populations.

SALMONELLOSIS

SALMONELLA — Reported Isolations from Humans by Week,* United States, 1974–1978

*Each point represents the weekly average number of isolates for the month.

The average number of *Salmonella* isolations from humans has shown a slight increase over the past 10 years and continues to show a seasonal increase in the late summer.

TYPHUS FEVER

**TYPHUS FEVER, FLEA-BORNE (Endemic, Murine) —
Reported Cases by Year, United States, 1969–1978**

Typhus Fever, Tick-Borne (Rocky Mountain Spotted Fever)

In 1978, 1,063 cases (0.49 cases/100,000) of Rocky Mountain spotted fever were reported to CDC, a decrease from the 1,153 cases (0.53 cases/100,000) reported in 1977. This was the first drop in case reporting since 1970, interrupting an otherwise steadily increasing trend. Again, the South Atlantic states accounted for the majority of reported cases (53.3%). Most cases continued to occur from May through September, most commonly in children and young adults. Less than 5% of reported cases are fatal. The disease is more serious in those older than 40.

TYPHUS FEVER, TICK-BORNE (Rocky Mountain Spotted Fever) – Reported Case Rates by Year, 1950–1978

TYPHUS FEVER, TICK-BORNE (Rocky Mountain Spotted Fever) – Reported Cases by County, United States, 1978

Trachoma	Calif. 5; N. Mex. 6; Oreg. 1; Utah 1

Conditions included in this table are not officially notifiable to the Center for Disease Control but are reported *optionally* by some states. These data should be used with great caution and should in no way be considered a representative national sample. We have not included a summary of every optionally reported condition because of the limitations of space and infrequency of reports. Unpublished data will be made available to individuals on specific request.

¹ Abortion and resident live birth data from central health agency unless otherwise noted.

² Abortions per 1,000 live births.

³ Estimated by Family Planning Evaluation Division, CDC, based on data from Current Population Reports, Series P-20, No. 334, and Series P-25, No. 794.

⁴ Abortions per 1,000 females aged 15-44.

⁵ Reported from hospitals and/or facilities in state.

⁶ Data from Vital Statistics Division, National Center for Health Statistics.

⁷ Abortion and occurrence-live-birth data from New York City Health Department.

⁸ Occurrence-live-birth data from central health agency.

* Greater than 1,000 abortions per 1,000 live births.

* EXCLUDES UNKNOWN CATEGORY.

LEAD POISONING

In calendar year 1978, 64 community-based programs identified 26,734 children with lead toxicity among 410,211 who were screened. A positive test was defined as an erythrocyte protoporphyrin (EP) $\geq 50 \mu\text{g}/\text{dl}$ in association with a blood lead $\geq 30 \mu\text{g}/\text{dl}$. Using the number of children reported with lead toxicity by these programs as the numerator and the entire U.S. population between 1 and 5 years of age as the denominator, the age-specific prevalence rate of lead toxicity in the United States is 175/100,000. This clearly underestimates the extent of the problem. There is a seasonal fluctuation of lead toxicity, the causes of which are unknown. This fluctuation occurs within all risk categories; however, the children at greatest risk show the least change. The EP test also identifies children with iron deficiency. The increasing use of this test in screening programs for lead toxicity has resulted in a parallel increase in the identification of iron deficiency. Children who are iron deficient tend to absorb more lead. Lead toxicity alone can result in anemia.

Environmental investigations indicate that lead-based paint is the most common high-dose lead source for children identified with lead toxicity.

Pneumonia-Influenza

The predominant influenza strain in the United States during 1978-79 was A/Brazil/78, a variant of the H1N1 prototype A/USSR/77. This strain caused outbreaks in schools, colleges, and military bases, as had been the case with the prototype strain. People over 25 years of age generally were not affected, presumably because of previous infection with antigenically related strains that had circulated throughout the world in the early 1950s. Therefore, the elderly were spared and increased influenza-associated mortality was not observed. Influenza B viruses resembling the B/Hong Kong/72 strain were isolated from a small number of outbreaks in this country. Strains of the subtype H3N2 were not isolated in the United States during 1978-79, but other countries reported the isolation of both H1N1 and H3N2 strains.

During the 1978-79 influenza season, epidemics of influenza A (H1N1) that first occurred in California and in several other western states in December were preceded by virus isolations from sporadic cases or localized outbreaks in Texas and Puerto Rico in October. Reported activity decreased during the Christmas holidays, then spread to other parts of the country in early 1979. A few localized outbreaks of influenza B occurred late in the spring.

PNEUMONIA-INFLUENZA — Reported Deaths in 121* Selected Cities by Week, United States, September 1970—June 1979

*Mortality data in this table are voluntarily reported from 121 cities, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

Totals include delayed reports from 4 Pennsylvania cities—Erie, Philadelphia, Pittsburgh, and Scranton. Also, the increased number of deaths reported by Las Vegas, Nevada, and San Jose, California, reflect changes from city to county jurisdictions.

REYE SYNDROME

REYE SYNDROME — Reported Cases and Percentage of Influenza A Virus Isolates from Respiratory Specimens by Week of Isolation, United States, December 3, 1977–November 18, 1978

In the 1977-78 period, the majority of cases of Reye syndrome occurred between December and March, when epidemic respiratory diseases are usually seen in children. Using data collected through 59 WHO collaborating laboratories as a measure of influenza activity, a temporal association is seen between the occurrence of Reye syndrome and the reporting of both the H3N2 and H1N1 influenza viruses. However, this association is not clear-cut; Reye syndrome cases dropped in frequency before a decrease in isolations of influenza A, and clusters of Reye syndrome cases were not reported in association with local outbreaks of influenza A. This is in contrast to the patterns in 1973-74 and 1976-77, when the epidemic curve for Reye syndrome cases more closely paralleled reported isolations of influenza B nationally, and outbreaks which were temporally and geographically associated with influenza B were reported in several states.

INDEX

A

- Abortions, legal 79, 81, 82, 83
- Actinomycosis 78, 79
- Amebiasis 3, 4, 5, 6, 8
- Anthrax 3, 4, 5, 6, 8, 17
- Arboviruses (see Encephalitis)
- Aseptic meningitis 3, 4, 6, 8, 17, 18, 19
