## INTRODUCTION

The VD Fact Sheet is intended to serve persons interested in public heal th and venereal disease problems as a handy source of basic statistics on the venereal diseases in the United States. The extent of the problem facing venereal disease control is indicated by incidence and prevalence, while the costs of uncontrolled venereal disease and the frequency of psychoses and deaths from syphilis are indicative of the seriousness of the VD problem. The results of case-finding effort are measured in terms of cases reported while the actual amount of case-finding effort by public facilities is described by the volume of diagnostic examinations and epidemiologic activity. Since there is no agent for immunizing the population, the only feasible means of controlling venereal diseases are the finding and treating of cases. Therefore, facts about the efficacy of various types of treatment are very necessary to an understanding of venereal disease control.

Facts on these various measures of the VD problem and program are presented in the text and tables which follow. The information is current as of the date of publication and supersedes any previously published data. Where no source is cited, the data presented are based on statistics collected by the Venereal Disease Program or upon estimates made by the Program. Where data are indicated as being for "fiscal years", the period runs from July 1 of the previous year to June 30 of the year indicated on the table. Rates per 100,000 population shown in this Fact Sheet are based on appropriate population estimates obtained from the Bureau of the Census.

## INCIDENCE AND PREVALENCE

The incidence of a disease is defined as the number of new cases occurring in a given area within a specified period of time, usually one year. As in many other diseases the true incidence of syphilis in the United States is not known because many cases are not discovered until they have entered the later stages and because some cases may escape detection completely. Furthermore, because of incomplete reporting, some discovered cases do not come to the attention of the health officials. The Venereal Disease Program is presently investigating these problems in order to strengthen its confidence in the estimating procedures which placed the incidence of syphilis for fiscal year 1954 at 86,800 cases. Incidence of gonorrhea is estimated to be approximately one million cases per year.

The prevalence of a disease is defined as the total number of cases existing in a specified area at a point of time. The true prevalence of syphilis has not of course, been established since this would require the examination of every person in the country within a minimal period of time. Estimates of prevalence involve estimates of incidence, which as mentioned above, are being reexamined. Meanwhile, the most recent estimate is $1,921,000$ persons in the United States requiring treatment for syphilis as of December 31, 1954. This figure may be revised as new data become available.

## TABLE 1

## PREVALENCE RATES OF SYPHILIS DETECTED PER 1,000 MALE SELECTEES

 AND VOLUNTEERS EXAMINED November 1940 to August 1941, By Color and AgeFrom time to time prevalence data have been obtained on large groups of persons. One of these groups, Selective Service Registrants examined for military service in World War 11, was not only a large group but a fairly random selection of the young male population. The syphilis prevalence rates per 1,000 examined, by age and race, for the first two million registrants examined are shown below:

| Age Groups | White | Nonwhite | Other and Unknown | Total |
| :---: | :---: | :---: | :---: | :---: |
| 18-20 | 11.1 | 105.8 | 29.7 | 55.1 |
| 21-25 | 10.2 | 191.7 | 25.3 | 30.1 |
| 26-30 | 21.0 | 294.8 | 46.6 | 54.4 |
| 31-35 | 37.9 | 357.8 | 80.6 | 83.5 |
| 36-40 | 44.4 | 375.6 | 103.2 | 101.9 |
| TOTAL | 17.6 | 245.2 | 41.0 | 46.1 |

In 1946, the prevalence of syphilis among examined sexual contacts of persons known to have primary or secondary syphilis was approximately 50 percent for white males, 51 percent for white females, 55 percent for nonwhite males, and 59 percent for nonwhite females. More recent data available for the total of all contacts to primary or secondary syphilis indicate that 31 percent of contacts examined in fiscal 1955 were infected compared to 54 percent in 1946.

## COSTS OF UNCONTROLLED SYPHILIS

The statistics presented in Table 2 indicate the toll imposed by syphilis upon the manpower and economy of the country.

The estimate of man-years of disability for institutionalization for syphilitic insanity has been based on total number of patients in mental institutions and the proportion diagnosed as having syphilitic psychoses in institutions caring for over half the mental patients in the country. Patients in State, county, private, and Veterans Administration hospitals for the permanent care of the insane are included.

The cost of maintenance is based upon the number of patients with syphilitic psychoses in tax supported institutions and average per patient maintenance cost. It represents the cost of syphilitic insanity to the public since the maintenance cost for the three percent of patients with syphilitic psychoses maintained in private institutions has not been included. The loss of income and tax payments reflects the probable earnings and tax payments of male patients had they been self-supporting in 1953. This is based on the average earnings per employed worker and average income tax payments per adult for that year.

Disability attributed to cardiovascular syphilis and to locomotor ataxia is based on conservative estimates of the prevalence of these late manifestations of syphilis.

The loss of life expectancy indicates the loss of future years of life for persons dying of syphilis in 1953 based on the expected years of life remaining to persons of that age, race, and sex. The loss of income indicates the possible earnings of these persons for the productive years of life lost to age 65 at the average 1953 per adult income.

While disability and death from syphilis have been diminishing in recent years, costs and losses per case have been rising. As a result of this, total costs and income losses from syphilitic disability and deaths remain high compared to previtus estimates.

On the basis of findings in a research study conducted in Macon County, Alabama, it has been estimated that the life expectancy of a Negro male between the ages, of 25 and 50 years, infected with syphilis and receiving no appreciable treatment for his infection, is reduced by about 17 percent. a/

[^0]
## TABLE 2

## ESTIMATED ANNUAL COSTS OF UNCONTROLLED SYPHILIS a/

Man-years of Syphilis Disability Per Year
Institutionalization for syphilitic insanity (1953) ..... 36, 000
Disability from cardiovascular syphilis, including aneurysm (1953) ..... 8,900
Disability from locomotor ataxia (1953) ..... 1,200
Disability from syphilitic blindness (1951) ..... 26,000
Economic Costs of Syphilitic Psychoses and Syphilitic Blindness Per Year
Maintenance of patients with syphilitic psychoses (1953) ..... $\$ 43,376,000$
Loss of income by males with syphilitic psychoses (1953) ..... 96,600,000
Loss of State and Federal income tax payments from patients with syphilitic psychoses (1953) ..... 10, 262,000
Maintenance of syphilitic blind (1951) ..... 12,500,000
Loss of Life Expectancy Due to Syphilis in Man-years Per Year (1953)
White Male ..... 38,572
White Female ..... 14,469
Nonwhite Male ..... 23,777
Nonwhite Female ..... 12,599
Total Population ..... 89,417
Loss of Income to Age 65 at 1953 per Adult Income Rate ..... $\$ 100,000,000$
a/ Revised estimates based on most recent available data for years indicated.

## REPORTED MORTALITY AND INSANITY DUE TO SYPHILIS

Mortality statistics are compiled by the National Office of Vital Statistics from duplicates of death certificates filed with State or local registrars. Mortality rates for syphilis are calculated by dividing the number of deaths in a given year by the population for that year and multiplying by 100,000 (rate per 100,000 population). The infant mortality rate for syphilis for a given year is obtained by dividing the deaths due to syphilis among children under one year of age by the number of live births in that year multiplied by 1,000 (rate per 1,000 live births).

Since deaths from syphilis represent case-finding and treatment failures, mortality due to syphilis may be considered an inverse measure of the success of the syphilis control program.

The method of classifying deaths is revised decennially by international agreement. These revisions have at times affected the continuity of syphilis mortality statistics. "The Sixth Revision of the International Lists of Causes of Death" which became effective in 1949 reduced reported syphilis deaths by about 26 percent. (Vital Statistics in the U.S., 1949, P.H.S., and Statistical Letter No. 23, August 1949, V.D. Division.) Mortality rates given in this Fact Sheet have been adjusted to the basis of the Sixth Revision for all years previous to 1949, using provisional comparability ratios. Infant mortality was affected very little by the Sixth Revision, and no adjustment was made.

Insanity due to syphilis is measured by the rate of first admissions to mental hospitals because of syphilis. Excluded are admissions to psychopathic hospitals which provide only temporary care and admissions to Veterans Administration facilities. The number of admissions is obtained from "Patients in Mental Institutions" published by the National Institute of Mental Health. Since only first admissions are included in the rate, the figures over a period of years represent a measure of the trend of incidence of syphilitic insanity.

Data on mortality and insanity due to syphilis are presented in Table 3.

## REPORTED CASES OF VENEREAL DISEASES

All States require that syphilis cases coming to medical attention be reported to the State or local health officer. Gonorrhea is a reportable disease in all States except one, and the other venereal diseases are reportable in most States. Quarterly, each State submits to the Public Health Service a summary of the cases reported to it. All cases not previously reported, regardless of duration, are to be included in the report. The reported morbidity, as reported cases are sometimes called, indicates the volume of successful case finding.

The trend of reported cases of early syphilis (or reported case rates) over a period of years may be indicative of incidence trends if no significant changes in case-finding effort have occurred. Reported cases of syphilis in the later stages may be considered as an indication of past case-finding failure as well as present success. Trends in reported cases must be interpreted with caution since changes in case-finding effort are reflected in morbidity data just as much as changes in incidence and prevalence.

It is believed that the current downward trend in reported morbidity reflects real decreases in incidence and prevalence. With a declining problem, however, case finding becomes increasingly difficult so that there is a distinct possibility that downward trends in incidence and prevalence are not as great as might appear from the study of reported case trends.

Reported cases of venereal diseases are shown in Tables 4 through 8.

## HEALTH DEPARTMENT CASE-FINDING ACTIVITIES

The correct interpretation of case-finding success depends upon a knowledge of the volume of case-finding effort. Table 9 shows the volume of case-finding effort in public clinics and cases of venereal disease found through these efforts. Total activity is indicated by the number of diagnostic examinations performed and investigations completed. The section on contact investigation indices indicates the volume of contacts named and the success in finding cases of syphilis on a per patient basis. It should be noted that at least one infected contact should be identified for each case of primary or secondary syphilis.

TABLE 4
CASES OF SYPHILIS AND GONORRHEA REPORTED TO THE PUBLIC HEALTH SERVICE BY STATE HEALTH DEPARTMENTS, AND RATES PER 100,000 POPULATION All Reporting Areas in Continental U.S. 1919-1955

| Fiscal | SYPHILIS |  | GONORRHEA |  |  |

a/ Indices for 1954 and 1955 computed on a slightly different basis.

## MORBIDITY BY AGE

For a better understanding of the venereal disease problem, a study of reported cases of venereal diseases by age was undertaken for calendar year 1953. A summary of these data are presenteu below:

TABLE 10
REPORTED SYPHILIS AND GONORRHEA RATES PER 100,000 POPULATION BY AGE, CONTINENTAL UNITED STATES, CALENDAR 1953

| Age | Total <br> Syphilis | Primary <br> and <br> Secondary | Early <br> Latent | Gonorrhea |
| :---: | :---: | :---: | :---: | :---: |
| $0-4$ | 3.87 | .04 | .07 | 3.94 |
| $5-9$ | 5.68 | .05 | .28 | 4.33 |

## REPORTED CASES UNDER 1 YEAR OF AGE

Reported case rate of congenital syphilis under 1 year of age per 10,000 live births was 1.7 in the fiscal year 1952, 1.1 in the fiscal year 1953, .7 in the fiscal year 1954, and .7 in the fiscal year 1955.

INFANT MORTALITY DUE TO SYPHILIS - See Table 3.

## PENICILLIN IN THE TREATMENT OF SYPHILIS

## CONGENITAL SYPHILIS

A minimum of 1,500,000 units of procaine penicillin $G$ in oil with 2 percent aluminum monostearate (PAM) is recommended in the treatment of early congenital syphilis (less than 2 years). Late congenital syphilis should be treated with the same schedules as for comparable manifestations of acquired syphilis.

The earlier that penicillin therapy is instituted for congenital syphilis, the more satisfactory the results. Results, 18-21 months after treatment, are shown iņ Table 12 by child's age at time of treatment. All types and amounts of penicillin are included.

TABLE 12

> RESULTS OF PENICILLIN THERAPY FOR EARLY CONGENITAL SYPHILIS, 18-21 MONTHS POSTTREATMENT, BY AGE OF CHILD AT TIME OF TREATMENT

| Age at Time <br> of Treatment | Number |  | Percent |  |  | Failure |  |
| :--- | ---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Treated | Observed | Seronegative | Seropositive | Serologic | Clinical |  |
| Under 3 Months | 107 | 38 | 92.1 | - | 1.7 | 6.2 |  |
| $3-5$ Months | 139 | 52 | 95.1 | 3.8 | 1.1 | - |  |
| $6-11$ Months | 96 | 44 | 80.7 | 17.9 | - | 1.4 |  |
| $12-24$ Months | 130 | 47 | 42.4 | 52.6 | 5.0 | - |  |

## EARLY SYPHILIS

Benzathine penicillin $G$ and procaine penicillin $G$ in oil with 2 percent aluminum monostearate (PAM) are the principal penicillin preparations used for the treatment of early syphilis. Since benzathine penicillin $G$ maintains a detectable blood level for a much longer period of time than PAM, a smaller total dosage is required for satisfactory results. For the treatment of early syphilis the recommended dosages are $2,400,000$ units of benzathine penicillin $G$ or $4,800,000$ units of PAM.

Results of treatment for secondary syphilis with these two preparations are shown in Table 13.

## TABLE 13

## PENICILLIN IN THE TREATMENT OF SECONDARY SYPHILIS <br> Results 2 Years Following Treatment

| Schedule of Treatment | Total Cases | $\frac{\text { Cumulative Percent Retreated }}{\text { Clinical or }}$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Total | Serologic Failure | Reinfection | Percent Seronegative* |

*Or less than 4 Kahn units.

## SYPHILIS IN PREGNANCY

In two studies, comprising 528 infants born to treated syphilitic mothers, approximately 98 percent of the children were nonsyphilitic (Table 14). The percentage varied slightly by stage of mother's syphilis at time of treatment during pregnancy.

## TABLE 14

## CUTCOME OF PREGNANCY BY STAGE OF SYPHILIS AT TIME OF MOTHER'S TREATMENT DURING PREGNANCY

| Stage of Disease at Time of Mother's Treat ment with Penicillin | Total Live Birth |  | Nonsyphilitic |  | Syphilitic |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| total | 528 | 100.0 | $\overline{518}$ | 98.1 | 10 | 1.9 |

In the absence of relapse or reinfection, a woman treated with penicillin for syphilis will not require further treatment in the event of pregnancy. The two syphilitic children reported in Table 15 were born to mothers with an unsatisfactory course following treatment for secondary syphilis - one was reinfected, the other experienced a serologic relapse.

TABLE 15

## OUTCOME OF PREGNANCY IN WOMEN TREATED FOR SYPHILIS PRIOR TO, BUT NOT DURING, PREGNANCY

|  | TotalLive Births |  | Nonsyphilitic |  | Syphilitic |  |

| Series A | 154 | 100.0 | 153 | 99.4 | 1 | 0.6 |
| Series B | 229 | 100.0 | 228 | 99.6 | 1 | 0.4 |
| TOTAL | 383 | 100.0 | 381 | 99.5 | 2 | 0.5 |

## PENICILLIN REACTIONS

Among 19,510 patients treated in venereal disease clinics, only 116 experienced reactions to penicillin therapy, an incidence of 6 per 1,000 treated. Reactions, in order of frequency, were classified as follows:
Urticaria ..... 96
Serum sickness ..... 5
Dermatitis medicamentosa ..... 5
Anaphylaxis ..... 4
Generalized pruritus ..... 2
Dyspnea ..... 2
Erythema multiforme-like bullous lesions ..... 1
Dermatophytid ..... 1
Nausea and vomiting ..... 1

Some of the factors affecting the incidence of reactions are shown in Table 16. Patients treated for syphilis had a reaction rate of 22.4 per 1,000 as compared with a rate of 2.4 per 1,000 treated for gonorrhea. The higher reaction rate among patients treated for syphilis is attributable to the fact that these patients received from $2,400,000$ to $9,600,000$ units, or from 4 to 16 times the generally recommended dosage for gonorrhea. The incidence of reactions was greater in the Caucasian race than in the Negro, greater in females than in males. Patients $10-29$ years of age tolerated penicillin better than patients in the older age groups, but patients 50 years of age and older demonstrated a greater tolerance than patients 30 to 49 years of age. The greatest incidence of reactions ( 99 per 1,000 ) occurred among patients who had previously reacted to penicillin. Among patients who reported no reaction to previous penicillin, only 3.9 per 1,000 showed side effects from subsequent penicillin therapy. In contrast, 9.1 per 1,000 patients who were treated with penicillin the first time reacted to it.

The group of patients studied was comprised principally of those exhibiting the greatest tolerance to penicillin, namely, young Negroes treated on low-dosage schedules who had received previous penicillin without difficulty. The reaction incidence of 6 per 1,000 patients treated is considerably lower, therefore, than the reaction rate which might occur in general practice.

TABLE 16

INCIDENCE OF REACTIONS TO PENICILLIN IN A VENEREAL DISEASE CLINIC POPULATION

| Classification | Total Cases | Cases <br> Number | $\begin{gathered} \hline \text { reacting } \\ \hline \text { Rate per } \\ 1,000 \\ \hline \end{gathered}$ |
| :---: | :---: | :---: | :---: |
|  |  |  |  |
| Grand Total | 19,510 | 116 | 5.95 |
| Epidemiologic treatment | 3,757 | 10 | 2.66 |
| Gonorrhea | 12,026 | 29 | 2.41 |
| Syphilis | 3,442 | 77 | 22.37 |
| PAM | 12,179 | 97 | 7.96 |
| Benzathine penicillin G | 7,109 | 17 | 2.39 |
| White - Male | 965 | 7 | 7.25 |
| - Female | 670 | 7 | 10.45 |
| Negro - Male | 9,548 | 32 | 3.35 |
| Negro - Male - Female | 7,738 | 51 | 6.59 |
|  | 3,908 | 12 | 3.07 |
| 20-29 years of age | 9,512 | 37 | 3.89 |
| $30-39$ | 3,674 | 34 | 9.25 |
| 40-49 | 1,252 | 21 | 16.77 |
| 50 years and over | 1,012 | 11 | 10.87 |
| Previous penicillin - Reacted | 121 | 12 | 99.17 |
| Previous penicillin - Reacted <br> - Did not React | 14,214 | 56 | 3.94 |
| No previous penicillin | 3,750 | 34 | 9.07 |
