Vol. 13, No. 28

PROVISIONAL INFORMATION ON SELECTED NOTIFIABLE DISEASES IN THE UNITED STATES AND ON DEATHS IN SELECTED CITIES FOR WEEK ENDED JULY 11, 1964

BRUCELLOSIS

A total of 12 cases of brucellosis was reported for the weekended July 11. This brings to 213 the cumulative total of cases reported thus far in 1964. For the comparable period of 1963, 189 cases were reported. A table of reported brucellosis cases through the 28th week and the annual totals for the past 5 years is shown in the accompanying table.

Of the cases reported to date in 1964, the 7 States comprising the West North Central area have reported 99 (47 percent) of the U.S. total. Iowa accounts for 58 of the 99 cases. Cases have been reported from each geographic subdivision, and from 32 States and New York City this year.

TICK-BORNE TYPHUS OF THE EASTERN HEMISPHERE (KENYA TICK TYPHUS) - Maryland

Maryland reported a case of tick-borne typhus of the Eastern Hemisphere (Kenya tick typhus-fievre bouton-neuse), diagnosed clinically in Baltimore in a 55-year-old white American male who had returned from extended residence in Kenya.

The patient, a State Department Official, hunted in Kenya on several occasions during the prior 18 months. On his last two safaris, March 27 to 29 and April 3 and 4, he skinned the animals shot. He frequently removed ticks from the hunting dog as well as those ticks attached to his skin.

On the day he left Kenya, April 8, the patient noted, but disregarded, a non-tender lesion in the right axilla. While enroute to Greece the following day, he experienced insomnia, a symptom attributed to the stress of travel. On the day after arrival in the United States (April 10), he felt chilly and noted fever of 101.5° F. On April 13, his temperature was 102.4° F. Because of mild headache, nausea, malaise, fever and the persistence of the lesion on his axilla, he entered the U.S. Public Health Service Hospital in Baltimore for a medical check-up. On physical examination, his conjunctivae were noted to be injected bilaterally. The axillary lesion, non-tender, was described as "indurated like a button" with a black center, 1 cm. in diameter with surrounding erythema (tache noire) and with three or four satellite lymph nodes. There was no generalized lymphadenopathy. Lungs were clear. Numerous insect bites were roted on both legs. His white blood count was 4,700 (27 neutrophils, 33 bands, 29 lymphocytes, and 11 monocytes).

On the following day, the fourth day of his illness, the patient demonstrated a maculopapular rash over his abdomen and buttocks for the first time. The rash became more pronounced 24 hours later, extending to the soles. No rash was present on his hands. His temperature rose to a high of 103° F. The blood leukocyte count was 11,000.

The diagnosis of a rickettsial disease, tick-borne typhus of the Eastern Hemisphere (Kenya tick typhus) was considered as the most likely diagnosis. The patient was treated with chloramphenicol. Within 24 hours his temperature dropped to 100° F. and within 48 hours his rash disappeared. The antibiotic was stopped after 5 days of therapy; within the 48 hours thereafter, his temperature rose to 103.8° F., his symptoms of malaise, headache, and backache, and the conjunctival injection returned. Antibiotic therapy was reinstituted and his symptoms disappeared. The antibiotic was stopped at discharge April 28. The patient was asymptomatic when examined for follow-up evaluation on May 25.

The patient's serum showed a rise in agglutinins to Proteus OX-2, but not to OX-19:

	0 X -2	0 X - 1 9
April 15	Neg.	1:40
April 20	1:320	1:40

Further laboratory studies, including complement fixation tests are being performed. Attempts to isolate rickettsiae from the patient's blood were negative. Specimens of the eschar and skin lesion obtained by biopsy showed a vascular reaction considered typical of a rickettsial infection. Ticks obtained from the dog with which the patient had contact are under evaluation for the presence of rickettsiae.

(Reported by George F. Ellinger, M.D., Chief of Medicine, USPHS Hospital, Baltimore, Md., T. E. Woodward, M.D., Professor of Medicine and Head, Department of Medicine, University of Maryland School of Medicine, and John H. Janney, M.D., M.P.H., Acting Chief, Bureau of Preventive Medicine, Division of Epidemiology, Maryland State Department of Health.)

Editor's Note: Kenya Tick Fever is caused by Rickettsia conorii. The disease is widely distributed geographically, occurring throughout the African continent, the Mediterranean, Black and Caspian Sea areas, and in India. It is transmitted by the bite of the brown dog tick and other ixodid ticks from dog and wild rodent hosts. This case is an excellent example of the lack of geographical boundaries in the occurrence of exotic diseases in this era of jet air travel.

ENCEPHALITIS IN HORSES - Florida

A total of 51 cases of encephalitis-like illness in horses has been observed in Florida to date in 1964. Cases were first reported in March but most occurred in May and June; there is evidence of continuing infection among horses. The cases for the most part concentrated in counties of the central and north central part of the State. No known human cases have occurred to date, although one suspect human case is being investigated at present.

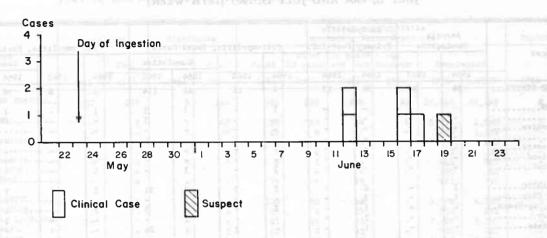

Virologic study of brain specimens from 12 of the horse cases submitted to 3 State laboratories has resulted in isolation of Western Equine Encephalitis virus from the brain of one horse and Eastern Equine Encephalitis virus from the brains of 3 other horses. Viral agents have been recovered from brain tissue of 4 others, but as yet these remain to be identified.

Group A arboviruses have also been recovered from pools of mosquitoes collected in areas where horse cases have occurred. Both Western Equine Encephalitis virus and Eastern Equine Encephalitis virus have been identified in pools of *Culiseta melanura*.

Serologic evidence of previous infection with Group A arboviruses have been detected in a few wild birds and mammals and in sentinel chickens in the areas of horse cases. In the tri-county Tampa Bay area, 150 humans with suspected central nervous system disorders during 1964

TRICHINOSIS OUTBREAK - NEW BRIGHTON VILLAGE, MINNESOTA, 1964

TRICHINOSIS - Minnesota

From 20 to 27 days after a private outdoor barbecue in New Brighton Village, Minnesota, May 23, 6 of 8 individuals who ate rare hamburger developed clinical or suspect cases of trichinosis. (See graph above).

The symptoms varied with each individual and included fever, malaise, periorbital edema, muscle pains, headache, and abdominal discomfort. All but Case 6 had periorbital edema. Only Case 4 experienced diarrhea. A line listing appears below.

Two patients required hospitalization; electrocardiograms of both patients were interpreted as normal. Acute sera were submitted to CDC; Bentonite-flocculation tests for trichinosis were negative. Convalescent samples will be studied. Muscle biopsies were not performed.

Two packages of hamburger, purchased from different supermarkets, were used. One was purchased the day of consumption as "ground round," the other had been purchased earlier and stored in the freezer of the home refrigerator until the day of the barbecue. Four patties were made from the frozen meat, the remainder from the fresh meat; they were not mixed. There was no known con-

sumption of sausage, ham or pork by the patients. No hamburger remained for analysis.

The namburger was traced to 2 supermarkets, but no evidence of substituted or infected meat was found. No meat grinder, common to both pork and beef was used in either supermarket.

No other cases have been reported.

(Reported by D. S. Fleming, M.D., M.P.H., Director, Division of Disease Prevention and Control, Minnesota Department of Health)

Editor's Note: It is not known which batch of hamburger the ill patients ate. The fact that illness developed in at least 5 individuals, and that only 4 patties were made from frozen meat (from which the chance of infection would be less), would make the fresh meat more suspect. Were this the case, then the consumption of the 4 frozen patties could be accounted for by the 2 guests who remained well and by Cases 3 and 4, who each ate an additional hamburger.

^{*}Estimate - based on average percent of divisional total. Totals for previous weeks include reported corrections.

NOTE: All deaths by place of occurrence.

SUMMARY OF DEATHS AMONG PERSONS 65 YEARS AND OVER IN 108 U.S. CITIES

The weekly average number of deaths among persons 65 years and over in 108 cities for the four-week period ending July 11 was 6,365 as compared with an expected weekly average of 6,237.

37.11	200	Week !	Ending		4 Week	Weekly		
2	6/20	6/27	7/4	7/11	Total	Average		
Observed	6,082	6,563	5,975	6,839	25,459	6,365		
Expected	6,302	6,256	6,214	6,176	24,948	6,237		
Excess	_ 220	307	- 239	663	511	128		

(See Table, page 247)

were investigated serologically and none showed evidence of recent arbovirus infection.

(Reported by C.M. Sharp, M.D., Acting Director, Bureau of Preventable Diseases, Florida State Board of Health, and James O. Bond, M.D., Director, Encephalitis Research Center, Florida State Board of Health, Tampa, Florida.)

Editor's Note: The recovery of Western Equine Encephalitis from horses is unusual in the eastern third of the U.S.A., although it is occasionally isolated in this area from mosquitoes. The isolation of the agent from a horse in Florida appears to be the first such isolation in that State.
