| Summary of <i>Salmonella</i> Isolations from Human, 1963-1969 | 7 |

I. INTRODUCTION

This report summarizes the results of the seventh year (January 7, 1969 - January 2, 1970) of the Salmonella Surveillance Program established jointly by the Center for Disease Control (formerly National Communicable Disease Center) and the Association of State and Territorial Epidemiologists and Laboratory Directors. The bulwark of the program is the weekly reporting of isolations of salmonellae submitted by the 50 states, New York City, the District of Columbia, the Salmonella Reference Center-Beth Israel Hospital (New York City), the U.S. Department of Agriculture, National Animal Disease Laboratory (USDA), and the U.S. Food and Drug Administration.

II. MATERIALS AND METHODS

The data analyzed are collected by the Salmonellosis Unit and represent laboratory identifications of salmonellae, without distinction as to whether the isolate came from a clinical case or a carrier. Clinical cases of salmonellosis not confirmed by culture are excluded.

Interpretations are limited by the bias inherent in the data analyzed. For example, geographical prevalence and age of patients may reflect "interest factors." In addition, such factors as the seriousness of the disease and a lack of adequate laboratory facilities in some areas are an influence on the results presented.

Despite these limitations, certain observations are justified, and the data herein provide the basis for comparison with past and future results.

III. SUMMARY

In 1969, 21,413 isolations of salmonellae from humans were reported, representing a 8.5 percent increase from the 19,740 reported for 1968 and a 8.6 percent increase from the 19,723 reported in 1967. Salmonella typhi-murium and S. typhi-murium var. copenhagen, as in previous years, were the most common serotypes, accounting for 27.0 percent of all isolations.

A total of 9,453 recoveries of salmonellae from nonhuman sources were reported during 1969, an increase of 6.5 percent over 1968 and 7.5 percent over 1967.

IV. REPORTS FROM THE STATES

A. HUMAN

Incidence

Since the first full year of operation of the present salmonella surveillance system (1963), the incidence of reported isolations of salmonellae has remained essentially constant (Figure 1).

The seasonal distribution of salmonella isolations from humans from 1965 through 1969 shows a consistent seasonal pattern, with the greatest number of isolations being reported from July through October for each year and the lowest number from January through April (Figure 2).

Serotype Frequency

A total of 165 different salmonella serotypes were reported in 1969, compared with 154 in 1968 (Tables I and II). This number (165) represents approximately 12 percent of the more than 1,400 known salmonella serotypes.

The 10 most frequently reported serotypes appear in the table below. These 10 serotypes accounted for 15,457 (72.2 percent) of the 21,413 isolations reported in 1969. The frequency of isolation of S. thompson showed the greatest increase with a rise of 57 percent over 1968. The same 10 serotypes were most frequently reported in 1968, but with minor differences in rank. This table also demonstrates the close correlation between human and nonhuman sources of salmonellae, with five serotypes appearing on both lists. The similarities demonstrate the importance of the nonhuman reservoirs of salmonellae in the epidemiology of human salmonellosis.

The Ten Most Frequently Isolated Serotypes From Human and Nonhuman Sources - 1969

| HUMAN | | | | NONHUMAN | | |
|--|--------|---------|----------------|--|--------|---------|
| Serotype | Number | Percent | Rank Last Year | Serotype | Number | Percent |

Geographic Patterns

The geographic distribution of salmonella isolations in 1969 showed California reporting the largest number, 2,239. Other states reporting over 1,000 isolations were New York, Massachusetts, Florida, Illinois, and Texas (Figure 3).

The incidence of salmonella infection for the entire country was 10.6 per 100,000 population. As in past years, Hawaii reported the highest incidence, with 57.0 isolations per 100,000. Other areas reporting incidence rates higher than 20 per 100,000 were Alaska, Massachusetts, District of Columbia, and Florida. The high incidence in Alaska can be attributed to a single large outbreak of salmonellosis.

Geographic variations among specific serotypes are seen in Tables I and II. Several serotypes continued to exhibit definite regional patterns which have been remarkably consistent in recent years. For example, Hawaii, which accounted for only 2.1 percent of the national salmonella isolations, reported 93 percent (50 of 54) of all Salmonella weltevreden isolations. Four southern states, Florida, Texas, Georgia, and Louisiana, accounted for 77 percent of the 465 total S. javiana isolations. All 15 S. atlanta isolations were reported from Georgia. Texas reported 13 of the 15 S. lomita isolations, and 13 of the 14 S. saphra isolations. Appropriately, 86 of 106 (81 percent) S. miami isolations were made in Florida.

Outbreaks

In 1969, 19 outbreaks involving 1,023 individuals were reported in the Salmonella Surveillance Reports (see table on page 4). Of nine foodborne outbreaks, seven were traced to a specific contaminated food, including three caused by turkey, one by chicken, one by beef, one by spaghetti and meatballs, and one by muktuk (whale skin and blubber). In two foodborne outbreaks, the specific food could not be identified. Three outbreaks involving 4 individuals were traced to household pets infected with the same serotypes. Although it could not be firmly established in all instances that the pets caused the human illness and not vice versa, the circumstances of these outbreaks favor the former explanation.

Six outbreaks involving 137 individuals occurred in hospitals or nursing homes. Person-to-person contact was the primary mode of spread in one of these outbreaks. The source of infection in the five S. infantis outbreaks could not be determined.

An outbreak of typhoid fever involving four individuals was traced to a S. typhi carrier employed by a restaurant.

Although the etiology of all outbreaks was confirmed bacteriologically, many of the 1,023 ill individuals were never cultured and are not included as reported isolations in the national surveillance data. Thus only a very small fraction of the total of 21,413 isolations of salmonellae in 1969 were from reported outbreaks. This suggests that many outbreaks are never investigated.

Age and Sex Distribution

Of the 15,749 individuals reported by age in 1969, 10,729 (68.1 percent) were less than 20 years of age. This is almost the same proportion as in 1968. The number of isolations per 100,000 population in various age groups in 1969 closely approximates those for the years 1963 through 1968. However, the rates in the age group less than 10 appear to be increasing over the past 6 years. This is particularly true in the less-than-1-year age groups where the rates per 100,000 have been 43, 53, 63, 69, 74, 84, and 97, respectively, for the years 1963 through 1969 (Figure 4 and Table IV).

Salmonella Outbreaks Reported in the Salmonella Surveillance Reports - 1969

TOTALS: Outbreaks 19

Cases 1,023

*Reported in detail in Salmonella Surveillance Report No. 87.

Of the 21,137 individuals for whom sex was reported during 1969, 10,663 (50.4 percent) were males, and 10,474 (49.6 percent) were females (Table IV). Although there was no overall sex predilection, it is interesting to note that for the age groups under 20 years there was a significant preponderance of males and the opposite was true for age groups over 20 years. The same distribution has been seen for the past 6 years and has been noted with certain other bacterial enteric diseases. It is thought to be related to an inherent increased susceptibility of males, especially in infancy, and a higher degree of exposure of adult females because of their more intimate contact with sick children. The following table presents this age-sex distribution of the 15,701 individuals for whom both age and sex were reported in 1969.

| Age (Years) | Male | | Female | | Total |
|--------------|--------------|-------------|--------------|-------------|--------------|
| | Number | Percent | Number | Percent | |
| Less than 20 | 5,786 | 54.1 | 4,904 | 45.9 | 10,690 |
| 20 and over | <u>2,111</u> | <u>42.1</u> | <u>2,900</u> | <u>57.9</u> | <u>5,011</u> |
| TOTAL | 7,897 | 50.3 | 7,804 | 49.7 | 15,701 |

(Unknown and unspecified ages not included)

Mortality

An accurate assessment of the number of deaths related to salmonella infections is not possible. Reporting officials are not always provided information concerning the clinical status of the individual from whom an isolation has been made. Also, since fatal cases of salmonellosis often occur in patients with severe underlying illness, it can be difficult to assess the role of salmonella infection in the final outcome. Finally, cases in which isolates are reported prior to death would not be reported as fatalities. The best available measure of the case fatality ratio of clinical salmonellosis can be obtained by studying investigated outbreaks. Although no deaths occurred in the 19 outbreaks reported in the Salmonella Surveillance Reports in 1969, 53 deaths were reported among 19,138 persons involved in 219 outbreaks in the years 1962 - 1968, giving a case fatality ratio of .28 percent.

Uncommon and Rare Serotypes

One hundred twenty-five serotypes are classified as uncommon or rare (Table II). Eighty-three serotypes, representing 50 percent of the 165 reported serotypes had five or less isolations each, accounting for only 153 (0.7 percent) of the 21,413 isolations reported during 1969.

Typhoid Fever - Cases and Carriers

Of 549 isolations of S. typhi reported in 1969, 92 were from cases of typhoid fever and 158 from asymptomatic carriers; for the remaining 299, the clinical classification was not reported. The sex distribution of typhoid cases showed no significant sex predilection (F:M = 1.04:1); however, for carriers, females predominated (F:M = 3.65:1). Most cases occurred in the younger age groups, with 74.3 percent of cases occurring in persons less than 30 years of age. In contrast, most carriers were in the older age groups, with 85.7 percent 50 years of age or older.

B. NONHUMAN

In 1969, 9,453 salmonella isolations from nonhuman sources were reported (Tables V, VI, VII, and VIII). This represents a 6.5 percent increase over the 8,877 isolations reported in 1968. The number of nonhuman isolations has increased each year since 1963, but this probably reflects increasing surveillance. The sources of these isolations are given in Figure 5 and Tables VI, VII, and VIII. The number and percent of isolations by source demonstrate the importance of poultry and poultry products as vehicles of salmonellosis. Turkey, chicken, eggs and egg products, which together were responsible for 44 percent of the foodborne outbreaks reported in 1969, accounted for 40.0 percent of all nonhuman isolations. Swine and cattle accounted for 21.2 percent of all nonhuman recoveries, and dried milk and other human food for 6.4 percent.

Isolations from animal feedstuffs accounted for 20.7 percent of nonhuman isolations during 1969. This reflects continued interest in the surveillance of animal feeds.

The 10 most common salmonella serotypes isolated from nonhuman sources during 1969 are listed in the table on page 2. These 10 serotypes accounted for 58.4 percent of all nonhuman isolates.

Sources (Table VI)

Domestic Fowl and Their Products

In 1969, there were 3,500 isolations (37.0 percent of nonhuman isolations) from domestic fowl and 279 isolations (3.0 percent) from eggs and egg products. S. typhi-murium including var. copenhagen replaced S. heidelberg as the most common serotype isolated from chickens, with 298 isolations (19.0 percent of the isolations from that source), and was followed by S. heidelberg with 285 (18.2 percent), S. thompson with 159 (10.1 percent), S. infantis with 113 (7.2 percent), and S. blockley with 106 (6.8 percent).

The five most common serotypes isolated from turkeys were S. heidelberg with 495 isolations (25.6 percent), S. saint-paul with 272 (14.1 percent), S. anatum with 169 (8.7 percent), S. san-diego with 128 (6.6 percent), and S. typhi-murium including var. copenhagen with 101 (5.2 percent).

The five most common serotypes isolated from eggs and egg products were S. thompson with 39 isolations (14.0 percent), S. montevideo with 32 (11.5 percent), S. heidelberg with 24 (8.6 percent), S. infantis with 22 (7.9 percent), and S. senftenberg with 21 (7.5 percent). Whole eggs accounted for only 27 (9.7 percent) of the 279 isolations in this category.

Domestic Animals

In 1969, the five most common serotypes isolated from swine were S. cholerae-suis var. kunzendorf with 677 isolations (47.1 percent), S. typhi-murium including var. copenhagen with 227 (15.8 percent), S. derby with 133 (9.2 percent), S. anatum with 62 (4.3 percent), and S. heidelberg with 43 (3.0 percent). The 1,438 total isolations from swine represent an increase of 80.2 percent from the 798 isolations reported in 1968. Most of this increase was probably due to increased laboratory surveillance for S. cholerae-suis var. kunzendorf which requires atypical isolation techniques.

The five most common serotypes isolated from cattle in 1969 were S. typhi-murium including var. copenhagen with 343 isolations (60.6 percent), S. dublin with 121 (21.4 percent), S. newport with 21 (3.7 percent), S. saint-paul with 16 (2.8 percent),

and S. heidelberg with 9 (1.6 percent). S. dublin, a host adapted serotype in cattle, accounted for 4.3 percent of bovine isolations in 1967 and for 14.5 percent of the isolations in 1968.

Reptiles and Their Environment

In 1969, there were 270 salmonella isolations (2.9 percent of nonhuman isolations) from reptiles and their environment. Turtles and turtle water, which accounted for 241 (89.3 percent) of the reptile recoveries, constituted a significant source of infection to children keeping these animals as pets. The most common serotypes isolated from reptiles were S. newport with 35 isolations (13.0 percent), S. urbana with 31 isolations (11.5 percent), S. typhi-murium with 21 isolations (7.8 percent), S. java with 16 isolations (5.9 percent), and S. muenchen and S. saint-paul with 12 isolations each (4.4 percent).

Animal Feed and Feed Ingredients

In 1969, there were 1,953 salmonella isolations (20.7 percent of nonhuman isolations) reported from animal feed and feed ingredients as compared with 2,055 isolations (23.1 percent) during 1968. Of the 1,953 salmonella isolations, only one was obtained from vegetable protein supplements. The most common serotypes isolated from animal feeds were S. anatum with 182 isolations (9.3 percent), S. montevideo with 159 (8.1 percent), S. livingstone with 127 (6.5 percent), S. senftenberg with 98 (5.0 percent), and S. kentucky with 96 (4.9 percent).

V. SPECIAL REPORTS

Summary of Salmonella Isolations from Humans, 1963-1969

During the 7-year period 1963-1969, 276 different salmonella serotypes have been recovered from humans. Sixty-seven of these serotypes were isolated only once during the 7 years. A list of the reported serotypes with the numbers of isolations per year is presented in Table IX.

Several interesting patterns are apparent. S. enteritidis isolations steadily increased in frequency from 801 in 1963 to 1,988 in 1969. The number of S. thompson isolations more than tripled in the same time period. On the other hand, the frequency of S. oranienburg isolations has decreased by 55 percent since 1965. The frequency of S. derby isolations has remained at relatively low levels since reaching a peak of 2,360 in 1964.
